Set the frequency band switch to the broadcast position. Rotate the gang condenser until the dial pointer indicates the 1500 kc. calibration point, and adjust the test oscillator to this frequency. The "B" band trimmers are located underneath the chassis. (See Fig. 2.) Adjust the broadcast oscillator trimmer for maximum output. This trimmer is the one nearest the volume control. When the oscillator has been peaked, adjust the antenna trimmer for maximum output. Here again, as pointed out previously, it is necessary to maintain a small R. F. input from the test oscillator to avoid erratic action of the output indicator due to automatic volume control action.

Now set the test oscillator at 580 kc. and tune the receiver to that frequency. Slowly, rocking the tuning condenser back and forth through the signal, adjust the 580-kc. padding capacitor for maximum output. When this has been done, return to 1500 kc. on the receiver and test oscillator and recheck the alignment at that frequency for maximum output. The broadcast band should now be in alignment.

DESCRIPTION OF ELECTRICAL CIRCUIT

Models E-81 and E-86 employ eight metal envelope tubes in a superheterodyne circuit, giving the excellent sensitivity and selectivity inherent in this type circuit. The radio frequency section of this eight-tube chassis utilizes a novel type of construction known as the "Junior Sentry Box." This type construction permits using extremely short connecting leads and isolates each radio frequency circuit in its own particular shielded section. Separate groups of coils are used for each band in the oscillator section. The antenna and R. F. sections are composed of two coils, a separate coil for the "D" band and a composite coil for the "B" band and "C" band. Operation on the "C" band is obtained by shorting out a section of the antenna and R. F. "B" band coils.

The signal from the antenna is applied to the control grid of the 6K7 R. F. amplifier tube through the antenna coil, the secondary of which is tuned to the incoming signal by the rear section of the main tuning condenser. The antenna coil, for bands "B" and "C," contains two primary coils connected for operation on the "B" band; however, when the band switch is turned to the "C" band position, the lower primary coil, L-5, is shorted out. The high frequency trimming adjustment, for the "B" band antenna and R. F. stages, is accomplished by two adjustable trimmers connected from the "C" band tap on each coil to ground. The capacity coupling coil, L-3, acts only on the "C" band and its function is similar to that of a fixed antenna stage trimmer for that band.

The amplified radio frequency signal is impressed upon the signal control grid of the 6A8 converter tube through the R. F. coil, the secondary of which is tuned to the signal frequency by the center section of the main tuning condenser. In the 6A8 tube, the incoming signal is combined with the local oscillator signal which is 465 kc. different in frequency. The local signal is generated by the oscillator elements of this tube and the proper frequency difference is maintained throughout the tuning range by the front section of the main tuning condenser in conjunction with the oscillator coils and padding capacitors.

The combination of the signal frequency with the local oscillator frequency in the 6A8 converter tube produces the intermediate frequency of 465 kilocycles. This particular intermediate frequency is chosen to reduce image response and improve short-wave performance.

The intermediate frequency amplifier consists of a two-stage cascade section composed of three I. F. transformers and two 6K7 amplifier tubes. Each I. F. transformer has two tuned circuits. The first I. F. amplifier 6K7 is operated on both self bias and on AVC for the broadcast band, since its grid return connects to the AVC bus. On the two short-wave bands the self bias resistor is shorted out by one of the band switch sections and this tube receives only AVC bias. The second I.F. amplifier 6K7 tube operates on self bias for all bands. This enables the second I.F. tube to provide maximum power to the 6H6 diode rectifier.

The output of the I.F. amplifier is applied to one plate of the 6H6 diode rectifier, which is a combined second detector, initial bias and automatic volume control tube. The direct current component of the rectified signal, through one diode of this tube, produces a voltage drop across resistor R-10 This voltage drop provides automatic bias for the R. F. amplifier, converter and the first I.F. amplifier, and thus gives automatic volume control action. The other diode of the 6H6 provides an initial bias for the tubes on the AVC circuit under conditions of little or no signal. This initial bias diode, under conditions of small signal, draws current which flows through resistors R-9 and R-10. The resulting voltage is the required minimum operating bias for the tubes on the AVC circuit. Upon receiving signals above the level of the initial bias, the initial bias diode stops drawing current and the automatic volume control diode takes over the controlling bias.

The audio frequency present across R-10 is impressed upon the volume control R-15 through capacitor C-34. The movable arm on the volume control selects the amount of audio signal applied to the control grid of the 6F5 audio amplifier tube and thus regulates the output of the receiver. Across the volume control, R-15, is placed a compensating network of capacitors and a resistor. The music speech switch is found in this circuit, and when closed places capacitor C-38 in shunt with C-39, which results in the accentuation of the low audio frequencies. The output of the 6F5 audio tube is resistance coupled to the grid of the 6L6 beam power tetrode. The plate circuit of the 6L6 is suitably matched to the electro-dynamic loudspeaker by means of a step-down output transformer.

The tone control is found in the plate circuit of the 6F5 first audio tube and consists of capacitor C-43 in series with a variable resistor R-18 across the 6F5 plate resistor R-17. Cutting out resistance in R-18 lessens the treble response of the receiver. Between the plate of the 6F5 first audio tube and the grid of the 6L6 tetrode output tube are found two capacitors in series, C-41 and C-42. The smaller capacitor, C-42, is shorted out by the wave band switch for operation on the broadcast band. On the two short-wave bands it is left in the circuit to attenuate the low frequency response and thereby lessen the tendency toward microphonic howl.

Plate and grid voltages for all tubes are supplied by the power supply system employing a 5Z4 full-wave rectifier tube; which, together with a suitable network of resistors and capacitors, supplies the required voltages and filtering action.

ALIGNMENT PROCEDURE

The receiver should first be allowed to run for fifteen minutes to reach its approximate normal operating temperature. Before making any adjustments, it is wise to determine the correctness of the existing alignment. This may be done by supplying a signal from the test oscillator to the receiver and inserting a "Tuning Wand" into the coil involved. The tuning wand consists of a rod of insulating material having a ring of nonmagnetic metal attached to one end, and a small core of finely divided iron compacted into the opposite end. By inserting the metal ring end into the center of a particular coil the inductance of the coil is lowered, increasing its resonant frequency. Inserting the iron-filled end into the coil raises its inductance, lowering its resonant frequency. If the circuits are in exact alignment, inserting either end of the tuning wand in any coil will result in a decrease in output. When an increase in signal is obtained with the iron-filled end of the wand, a decrease in resonant frequency of that circuit by increasing its trimmer capacity is indicated. When an increase in signal is obtained with the metal ring, a decrease in trimmer capacity is indicated.

Changes Indicated by Wand

Wand	Signal	Timmer adjustment required
Metal ring Iron filings	Decrease Decrease	None
Metal ring Iron filings	Increase Decrease	Decrease capacity
Metal ring Iron filings	Decrease Increase	Increase capacity

Alignment Frequencies

I.F.	Band "B"	"Band "C"	Band "D"
465 kc.	580 kc. 1500 kc.	5220 kc.	18,000 kc.

In order to align this receiver properly, it is necessary to have available the following test equipment:

1. A modulated test oscillator with frequencies available of 465, 580, 1500, 5220, and 18,000 kc.
2. An output indicator, such as a high resistance a-c. voltmeter with a maximum scale reading of 3 to 5 volts, or a neon lamp indicator.
3. An alignment tool consisting of an insulating shaft with a small screwdriver blade.
4. A tuning wand.

The location of all trimmer capacitors is shown in Fig. 3.

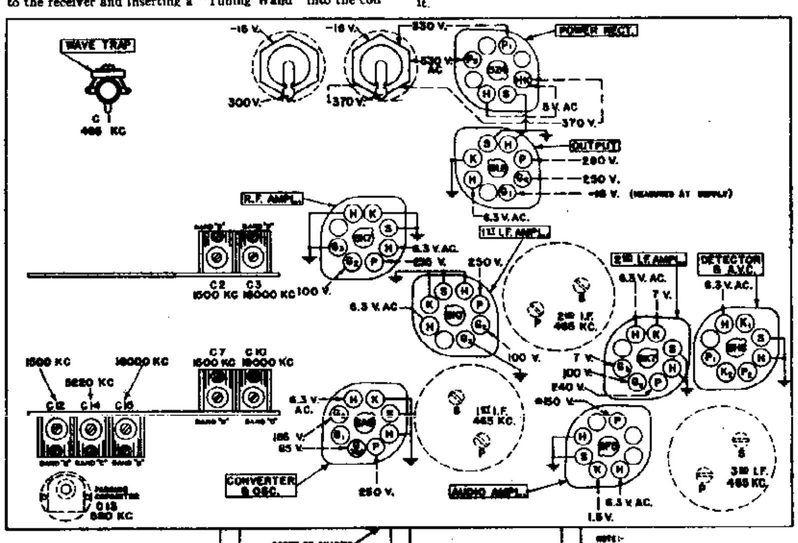
1. I. F. Alignment

Set the frequency band switch of the receiver to Band "D," short circuit the antenna and ground terminals and tune the receiver to some point near maximum tuning condenser capacity where no signal is heard. Set the volume control at its maximum position and ground the chassis.

The I. F. amplifier is tuned to 465 kc.; set the test oscillator so as to produce a signal at this frequency. Connect the test oscillator output between the top grid terminal of the 6K7 2nd I. F. tube and the chassis using a .05-mfd. capacitor (RC-072) in series with the oscillator output lead to the top grid connection. First remove the grid lead connecting to the same point from the 2nd I. F. transformer. Provide a path for grid bias by connecting a 10,000-ohm resistor (RQ-083) between grid cap and top grid terminal of tube.

Connect the output meter across the voice coil of the speaker and adjust the test oscillator output control so that, with the receiver volume control at maximum, a small deflection is observed in the output meter. During both I. F. and R. F. alignment, the test oscillator signal should be maintained at the lowest level that will give a good readable output indication.

Adjust the secondary trimmer of the third I. F. transformer until a maximum output reading is obtained. Maintain a small deflection on the output meter throughout alignment by adjusting the test oscillator output. Next, adjust the primary trimmer of the third I. F. transformer for maximum output. This transformer is then adjusted and should not require readjustment when aligning transformers ahead of it.



VIEWED FROM UNDERSIDE OF CHASSIS

Fig. 3. Trimmer Location and Socket Voltages

MODELS E-81, E-86
Alignment, Parts
Voltage, Dial Data

GENERAL ELECTRIC CO.

RBS-24 Radio Receivers, Models E-81 and E-86

Transfer the test oscillator connections to the top grid terminal of the 6K7 1st I. F. tube, replace the grid lead on 2nd I. F. tube and reduce the output of the test oscillator as low as possible consistent with obtaining an easily readable indication on the output meter. Adjust secondary and primary trimmers respectively on the 2nd I. F. transformer until maximum deflection of the output meter is obtained.

Transfer the test oscillator connections to the top grid terminal of the 6A8 converter tube and replace the grid cap connection on the 6K7 1st I. F. tube. It will probably be found desirable to set the tone control for minimum high response and to reduce the volume control setting to lessen noise reproduced due to the extremely high sensitivity of this receiver. Again adjust the test oscillator output to as low a value as will allow accurate adjustment. Adjust secondary and primary trimmers respectively on the 1st I.F. transformer until maximum deflection on the output meter is obtained.

I. F. alignment is now complete.

2. *I. F. Wave Trap Alignment*

Set the band switch to Band "B" and tune receiver to about 1000 kc. With the test oscillator still set at 465 kc. remove the shorting connections between antenna and ground terminals and apply this signal to the antenna terminal through a dummy antenna consisting of a 400-ohm resistor and 250-mmfd. capacitor in series. With the 465 kc. signal applied to the antenna terminal, adjust the I. F. Wave Trap Trimmer for minimum output indication.

3. *R. F. Alignment*

First check the position of the dial pointer by rotating the tuning condenser to maximum capacity position, i.e., plates fully meshed. At this position, the pointer should coincide with the end mark at the left-hand end of the scale. If it does not, it may be set by loosening the dial drum set screws and rotating the drum on the tuning condenser shaft. Hold the tuning condenser rotor while doing this, to prevent its rotating. Tighten the two set screws after the pointer is correctly set.

Band "B" (540-1600 Kc.)

Set the test oscillator for operation at 1500 kc. and connect its output to the antenna terminal of the receiver through the dummy antenna described under I. F. Wave Trap Alignment. Tune the receiver until the pointer is at 1500 on the scale. Set the tone control for minimum high response and reduce the volume control setting so as to avoid excessive noise response. Adjust the Band "B" oscillator, R. F., and antenna trimmers respectively (C-12, C-7, and C-2, Fig. 3) to give maximum deflection on the output meter. Maintain the test oscillator output at the lowest level which will give an easily readable output indication.

Now set the test oscillator at 580 kc., and tune the receiver to resonance with this signal. Adjust the 580 kc. padding capacitor, C-13, rocking the tuning condenser back and forth through resonance as the padding capacitor is adjusted and note the deflection of the tuning meter each time the receiver is tuned through resonance. Leave the padding capacitor at the setting which gives greatest deflection.

Retune the receiver to 1500 kc., and set the test oscillator for this frequency. Check the alignment by again adjusting the Band "B" oscillator, R. F. and antenna trimmers for maximum deflection on the tuning meter.

Band "C" (1680-6000 Kc.)

No trimmers are provided for alignment of the R. F. and antenna transformers in Band "C" of these receivers. Correct tracking between R. F. and antenna transformers is obtained by the action of the capacity coil, L-3, and between oscillator and the other tuned circuits by means of the adjustable oscillator trimmer C-14 and the fixed padding capacitor, C-34.

Turn the band switch to Band "C." Set the test oscillator at 5550 kc. and tune the receiver to resonance at this frequency. Adjust the Band "C" oscillator trimmer, C-14, for maximum output indication on the tuning meter, rocking the tuning condenser back and forth through resonance while making this adjustment.

Band "D" (6.0-18.0 Mc.)

Turn the band switch to Band "D." Set the test oscillator at 18,000 kc. (18.0 mc.) and tune the receiver until the pointer coincides with the 18.0 mc. mark. Adjust the Band "D" oscillator trimmer, C-15, to give maximum output indication. It will probably be found that there will be two settings of the oscillator trimmer that will give an output response. The lower capacity setting of the trimmer is the one that should be used. To be sure that correct adjustment has been obtained, tune for the image signal at 17.07 mc. with the test oscillator set at 18.0 mc. It may be necessary to increase the test oscillator output to obtain response at this point.

Retune the receiver to 18.0 mc. and adjust Band "D" antenna and R. F. trimmers, respectively (C-3 and C-10), for maximum output indication. When adjusting the R. F. trimmer, C-10, rock the tuning condenser back and forth through resonance as in the 580-kc. padding capacitor adjustment.

Alignment of the receiver is now complete.

VISUAL ALIGNMENT OF I.F.

In order to realize to full advantage the performance built into these receivers at the factory, circuit alignment using cathode ray oscilloscope equipment is much to be preferred. The oscilloscopic method is particularly advantageous in aligning the I.F. tuned circuits.

For visual alignment it is necessary to vary the frequency of an unmodulated test oscillator signal over a range extending on both sides of the peak frequency. This variation must take place in synchronism with the horizontal traverse of the cathode ray beam on its screen. The frequency modulator must, therefore, provide means for synchronizing the periodic test frequency variation with the cathode ray horizontal deflection circuit. The test oscillator may advantageously have facilities for audio frequency amplitude modulation of a fixed radio frequency test signal, as well as for frequency modulation, but audio modulation is not required for visual I. F. alignment.

Instead of an output meter across the speaker voice coil, the vertical plates of the cathode ray tube are connected across the load resistor of the diode rectifier. With the frequency modulator in operation, in conjunction with the test oscillator, the resonance curve of the circuit under test will be then shown on the screen.

Preliminary Procedure

For visual alignment, adjust the receiver controls and connect the test oscillator as outlined in the section entitled "I. F. Alignment" under "ALIGNMENT PROCEDURE." Connect the vertical deflecting plates of the cathode ray tube across the diode rectifier load resistor, R-10. The location of this resistor is clearly shown in Fig. 2.

Place the oscilloscope in operation as an output indicator and proceed as outlined in the section entitled, "I. F. Alignment."

Alignment Adjustments

Adjust the oscilloscope so that the luminescent spot on the cathode ray screen traces a horizontal line across the screen. Now place the frequency modulator and test oscillator in operation to give an unmodulated radio frequency signal varying from one side to the other of 465 kc. Adjust the oscilloscope and test oscillator controls to show a single overall resonance curve of the signal I.F. channel on the cathode ray tube screen. Do not change the test oscillator setting thereafter.

To align the I.F. transformers, follow in sequence the same procedure outlined in the sections under "ALIGNMENT PROCEDURE" describing this operation. Instead of aligning for maximum output on an output indicator, the object should be to make the curve symmetrical. If the sweep circuit is so arranged that two symmetrically reversed curves appear on the screen, the curves should be made to coincide by adjusting the I.F. trimmer capacitors.

Visual R.F. alignment may be carried out in the same general manner as above by applying a suitable frequency-modulated signal between the antenna and ground terminals of the receiver and connecting the cathode ray vertical deflecting plates across the diode rectifier load resistor.

ADJ[illegible] DIAL MECHANISM

To Rep[illegible]

Remove the drive cable to be replaced. Referring to Fig. 4, rotate drive wheel (14) counterclockwise until condenser plates are open. Place the end of the cable having an eyelet in slot [A]. Thread cable as shown making sure cable passes over pin [B], and runs along the correct grooves, the looped end hooking over spring (16). Check the position of the drive wheel on the condenser shaft making sure that the cable coming off the right-hand idler pulley lines up with the grooves in the drive pulley. Also, as the condenser plates become fully closed, the drive wheel (14) should just touch the bushing [D] of the tuning shaft (39). With the drive wheel in this position place the pointer on rail [E] and, with the tip of the pointer on the extreme left-hand scale division, crimp pointer tab onto the drive cable.

To Adjust Pointer for Scale Calibration

Three positions of the dial pointer cable are provided to adjust the pointer up or down scale. The position shown on Fig. 4, with the cable over pin [B] is the medium position. By changing the cable to the position between pins [B] and [C] the pointer may be moved down scale. The cable position below pin [C] moves the pointer up scale from the medium position.

To Replace Dial Scale

Remove the band change cable (12). Then remove the end support (8) held by a single self-tapping screw and withdraw the scale assembly from the housing. Replace the end caps on the new scale and re-assemble. Before attaching band change cable (12) to the gear (41), the spring (7) should be given two full turns to give the proper tension to the cable.

To Adjust Rotation of Scale

Bend tab [F] up or down to give the correct position of the scale divisions with respect to the pointer tip. The pointer should slightly overlap the divisions.

DESCRIPTION OF ELECTRICAL CIRCUIT

Models A-83 and A-85 employ eight metal envelope tubes to perform the above functions in a superheterodyne circuit, giving the excellent selectivity and sensitivity inherent in this type circuit. Separate groups of coils are used for each frequency band. Ample undistorted power output is obtained through use of diode detection and a push-pull power amplifier final audio stage.

The signal from the antenna is applied to the control grid of the 6K7 R. F. amplifier tube through the antenna coil, the secondary of which is tuned to the incoming signal by the rear section of the main tuning condenser. The secondary of the coil for the band next lower in frequency to the one in use is short-circuited by the band switch to prevent absorption of energy at its resonant frequency which falls in the next higher band.

The amplified radio frequency signal is impressed on the control grid of the 6A8 converter and oscillator tube through the R. F. coil, the secondary of which is tuned to the signal frequency by the center section of the main tuning condenser. In the 6A8 tube the incoming signal is combined with the local oscillator signal which is 465 kc higher in frequency. The local signal is generated by the oscillator elements of this tube and the proper frequency difference is maintained throughout the tuning range by the front section of the main tuning condenser in conjunction with the oscillator coil and padding capacitors.

The combination of the signal frequency with the local oscillator frequency in the converter tube produces the intermediate frequency of 465 kilocycles. This particular intermediate frequency is chosen to reduce image response and improve short-wave performance. The intermediate frequency amplifier consists of a 6K7 tube and two transformers, each with two tuned circuits.

The output of the I. F. amplifier is applied to the 6H6 diode rectifier, which is a combined detector and automatic volume control tube. The direct current component of the rectified signal produces a voltage drop across R-6 and R-8. This voltage drop provides automatic bias for the R. F. and I. F. amplifier and converter tubes and so gives automatic volume control action. Full automatic bias voltage is applied to the R. F. amplifier tube, while half this voltage is applied to the converter tube and I. F. amplifier, which handle a somewhat larger signal voltage than the R. F. amplifier.

Condenser C-29 couples the audio signal to the volume control (R-12) and to the speech clarifier network (C-30, C-31, R-11). When switch S7 is open the frequency response is correct for music, while closing this switch raises the level of certain frequencies and renders speech extremely understandable. The amount of signal impressed on the control grid of the 6F5 audio amplifier tube is selected by the variable arm on the volume control, this in turn determining the output of the receiver.

The output of the 6F5 tube is capacitively coupled to the coupling reactor (L23) which gives a balanced excitation to the 6F6 push-pull power amplifier. The tone control consisting of R-16 and C-36 is connected across the 6F5 plate resistor. Cutting out resistance in R-16 lessens the treble response of the receiver.

The 6F6 tubes are connected in pentode and their plate circuit is suitably matched to the dynamic speaker by a step-down transformer T1.

Plate and grid voltages for all tubes are supplied by the power supply system employing a 5Z4 full-wave rectifier tube which, together with a suitable network of resistors and capacitors, supplies the required voltages and filtering action.

ALIGNMENT PROCEDURE

The receiver should first be allowed to run for fifteen minutes in order to reach its approximate normal operating temperature. Before making any adjustments, it is wise to determine the correctness of the existing alignment. This may be done by supplying a signal at the alignment frequency from the test oscillator to the receiver and inserting a "Tuning Wand" into the coil involved. The "Tuning Wand" consists of a bakelite rod having a brass cylinder attached to one end, and a small core of finely divided iron compacted into the opposite end. By inserting the brass cylinder end into the center of a particular coil, through the opening provided in the top of the shield, the inductance of the coil is lowered, increasing its resonant frequency. Inserting the iron-filled end into the coil raises its inductance, lowering its resonant frequency. If the circuits are in exact alignment, inserting either end of the tuning wand in any coil will result in a decrease in output. When an increase in signal is obtained with the iron-filled end of the wand, a decrease in resonant frequency of that circuit by increasing its trimmer capacity is indicated. When an increase in signal is obtained with the brass cylinder, a decrease in trimmer capacity is indicated.

Changes Indicated by Wand

Wand	Signal	Trimmer Adjustment Required
Brass cylinder	Decrease	None
Iron filings	Decrease	
Brass cylinder	Increase	Decrease capacity
Iron filings	Decrease	
Brass cylinder	Decrease	Increase capacity
Iron filings	Increase	

Fig. 3 shows the location of the antenna, R. F., and oscillator coils for each of the three frequency bands of Model A-83 and A-85 receivers.

ALIGNMENT FREQUENCIES

I. F.	Band "B"	Band "C"	Band "D"
465 kc	580 kc 1500 kc	5220 kc	18,000 kc

In order to align these receivers properly, it is necessary to have available the following test equipment:

1. A modulated test oscillator with frequencies available of 465, 580, 1500, 5220 and 18,000 kc.
2. An output indicator, such as a high resistance a-c voltmeter with a maximum scale reading of 3 to 5 volts, or a neon lamp output indicator.
3. An alignment tool consisting of an insulating shaft with a small screw-driver blade.
4. A tuning wand.

The location of all trimmer capacitors, as well as socket voltages to chassis, is shown in Fig. 4.

1. I. F. Alignment

In order to maintain proper bias voltage during I. F. alignment, the test oscillator should be connected to the 6A8 converter tube control grid through a .01-mfd. (or larger) capacitor. The normal grid cap connection should be removed and a 25,000-ohm to 50,000-ohm resistor connected between it and the 6A8 control grid. The ground side of the test oscillator may then be connected directly to the chassis.

Set the frequency band switch of the receiver to Band "B", short-circuit the antenna and ground terminals and tune the receiver at some point above 1500 kc so that no signal is heard. Set the volume control at its maximum position and ground the chassis.

The I. F. amplifier is tuned to 465 kc; set the test oscillator dial at this frequency. Connect the output meter across the cone coil of the speaker and adjust the test oscillator output control so that, with the receiver volume control at maximum, a small deflection is observed in the output meter. During both I. F. and R. F. alignment, the test oscillator signal should be maintained at the lowest level that will give a good readable output indication.

Adjust the secondary trimmer of the second I. F. transformer until a maximum output reading is obtained. Maintain a small deflection on the output meter throughout alignment by adjusting the test oscillator output. Next, adjust the primary trimmer of the second I. F. transformer for maximum output. Continue this procedure, adjusting the secondary trimmer of the first I. F. transformer and lastly the primary trimmer of the first I. F. transformer. After completing this procedure, repeat it a second time for final alignment. The I. F. alignment will then be complete.

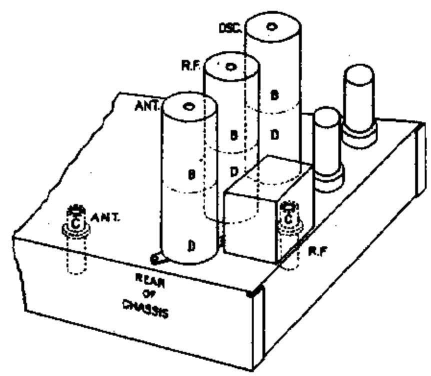

Fig. 3. Coil Locations

2. R. F. Alignment

Band "B" requires four trimmer adjustments, while Band "C" and Band "D" each require three adjustments. Care should be taken to adjust only the trimmers of the band under test. Check the position of the dial pointer as outlined in the section on adjustment of the dial mechanism. Make sure the antenna and ground terminals of the receiver are not short-circuited and connect to them the output from the test oscillator, preferably using a dummy antenna of 250 mmfd. in series with 200 ohms between the test oscillator and receiver antenna terminal. Connect the output indicator across the speaker cone coil.

Band "B"—540-1720 kc

Set the frequency band switch to the position where the dial indicates the above range. Tune the test oscillator to 1500 kc and set the dial pointer on the receiver to this frequency. Adjust the Band "B" oscillator trimmer for maximum output, keeping the receiver volume control at its extreme clockwise position and adjusting the test oscillator output to maintain a small reading on the output indicator. When optimum adjustment on the Band "B" oscillator trimmer is obtained, adjust the Band "B" R. F. and antenna trimmers for maximum output.

Now tune the test oscillator to 580 kc and set the receiver to that frequency. Slowly rocking the tuning condenser back and forth through the signal, adjust the 580 kc padding capacitor for maximum output. When this has been done, return to 1500 kc on the receiver and test oscillator and recheck the alignment for maximum output. Band "B" should now be in alignment.

Band "C"—1.72–5.8 mc (1720–5800 kc)

Set the band switch to the position where the dial indicates the above range. Tune the test oscillator to 5220 kc and set the dial pointer on the receiver to this frequency. Adjust the Band "C" oscillator trimmer for maximum output, using the first peak obtained when increasing the capacitance from minimum to maximum.

Check for the image signal which should be received at about 4290 kc on the receiver dial. It should be necessary to increase input to the receiver from the test oscillator for this check. Retune the receiver to the correct scale reading (5220 kc) and reduce the test oscillator output to its previous value. Then adjust the Band "C" R. F. and antenna trimmers for maximum output.

Band "D"—5.8–18.0 mc (5800–18,000 kc)

Set the band switch to the position where the dial indicates the above range. Tune the test oscillator to 18,000 kc and set the dial pointer on the receiver to this frequency. Adjust the Band "D" oscillator trimmer for maximum output, using the first peak obtained when increasing the capacitance from minimum to maximum.

Check for the image signal which should be received at about 17070 on the receiver dial. It may be necessary to increase input to the receiver from the test oscillator for this check. Retune the receiver to the correct scale reading (18,000 kc) and reduce the test oscillator output to its previous value.

Reduce the capacitance of the R. F. trimmer to a minimum. While slowly rocking the tuning condenser through the 18,000 kc point, increase the Band "D" R. F. trimmer capacitance until a maximum response point is obtained. The Band "D" antenna trimmer should next be peaked. It is not necessary to rock the tuning condenser while making this last adjustment.

DIAL MECHANISM ADJUSTMENTS

The dial mechanism is rigidly mounted to the chassis. The tuning condenser is mounted by means of rubber cushions and bushings at points of support. The dial pointer, station selector knob, and tuning condenser drive drum are interconnected by means of the drive cord and drive cable; the frequency band switch, the cylindrical dial scale and switch knob, by gear and toggle assemblies.

1. Position of Drum on Condenser Shaft

With set screws (19) loosened and tuning condenser plates fully engaged, place the drum in the position as shown in Fig. 5 so that drum spring (12) is approximately horizontal, and the top rim of the drum is $\frac{1}{16}$ in. away from the mounting plate. Guide (48) should stop at equal distances from each end of the mounting plate slot.

2. Removing and Replacing Scale

Pry out fastener (39), and remove the scale by lowering that end below the ear and taking the scale out of cap assembly (24), holding parts (24), (11), and (7) in place. Replace, locating tabs of caps (24) and (25) in slots of scale. Replace fastener (39).

3. Locating Scale

Loosen the two gear set screws (16). Rotate the scale upward until there is slight tension on spring (11) with the pointer indicating on the Band "D" scale. With the frequency band switch in the Band "D" position, place gear (7) in mesh with the gear on part (6) and tighten the two set screws (16)

4. Replacing Drive Cord

The position of the dial scale pointer with respect to the tuning condenser drum is held fixed by means of a special metal braid cable connecting the drum with the guide (48). Tension is maintained on the cable through the drum spring (12) and drive cord. To replace either the drive cable or the drive cord, remove the dial scale for convenient access to guide (48). Unhook spring (12) from tab (46) to release tension. Unhook the cable or cord from guide (48) and unwind from the pulleys and drum. To replace the cable, rethread to agree with Fig. 5 and rehook drum spring (12) as shown.

5. Replacing Reduction Drive

To replace the reduction drive, unhook spring (12), loosening the drive cord. Unscrew palnut (44) and remove drive. Replace with new drive and rehook drive cord.

6. Replacing Toggle Assembly

Loosen the two set screws holding the toggle mechanism on the band change switch and on shaft (6). Replace with new assembly, setting lower lever arm $\frac{1}{16}$ in. away from the condenser drive drum as shown in Fig. 5 and tighten set screw on frequency band switch shaft. Rotate shaft (6) clockwise until there is slight tension on spring (11) with the scale in the Band "D" position. Place upper lever arm in shaft and tighten set screw.

7. Setting Scale Pointer

The scale pointer is soldered to the slider. To set the pointer mechanically, turn the tuning condenser rotor so that the plates are fully engaged, and solder the pointer to indicate the extreme left-hand line on the Band "D" scale as shown in Fig. 5.

8. Replacing Dial Lamp

Take hold of terminals of lamp bracket and push up until lamps protrude above the opening in reflector (18). Lamps may then be replaced in socket clips. After replacing lamps, slide the socket mounting bracket back into the mounting clip.

DESCRIPTION OF ELECTRICAL CIRCUIT

Models E-91 and E-95 employ nine metal envelope tubes in a superheterodyne circuit, giving the excellent sensitivity and selectivity inherent in this type circuit. The radio frequency section of this nine-tube chassis utilizes a novel type of construction known as the "Junior Sentry Box." This construction permits the use of extremely short connecting leads and isolates each radio frequency circuit in its own particular shielded section. Separate groups of coils are used for each band in the oscillator section. The antenna and R. F. sections are composed of two coils, a separate coil for the "D" band and a composite coil for the "B" band and "C" band. Operation on the "C" band is obtained by shorting out a section of the antenna and R. F. "B" band coils.

The signal from the antenna is applied to the control grid of the 6K7 R. F. amplifier tube through the antenna coil, the secondary of which is tuned to the incoming signal by the rear section of the main tuning condenser. The antenna coil, for bands "B" and "C," contains two primary coils both connected for operation on the "B" band; however, when the band switch is turned to the "C" band position, the lower primary coil, L-6, is shorted out. The high frequency trimming adjustment for the "B" band antenna and R. F. stage is accomplished by two adjustable trimmers connected from the "C" band tap on each coil to ground. The capacity coupling coil L-3 acts only on the "C" band and its function is similar to that of a fixed antenna stage trimmer for that band.

The amplified radio frequency signal is impressed upon the control grid of the 6A8 converter tube through the R. F. coil, the secondary of which is tuned to the signal frequency by the center section of the main tuning condenser. In the 6A8 tube, the incoming signal is combined with the local oscillator signal which is 465 KC different in frequency. The local signal is generated by the oscillator elements of this tube and the proper frequency difference is maintained throughout the tuning range by the front section of the main tuning condenser in conjunction with the oscillator coils and padding capacitors.

The combination of the signal frequency with the local oscillator frequency in the 6A8 converter tube produces the intermediate frequency of 465 kilocycles. This particular intermediate frequency is chosen to reduce image response and improve short-wave performance.

The intermediate frequency amplifier consists of a two-stage cascade section composed of three I. F. transformers and two 6K7 amplifier tubes. Each I. F. transformer has two tuned circuits. Initial bias for the 6K7 R. F. amplifier, the 6A8 converter, and the 6K7 first I. F. amplifier is supplied by returning the diode rectifier load resistor to a negative voltage supply of approximately 3 volts on the main bleeder resistor. The second I. F. amplifier 6K7 tube operates on self bias for all bands. This enables the second I. F. tube to provide maximum power to the 6H6 diode rectifier.

The output of the I. F. amplifier is applied to one plate of the 6H6 diode rectifier, which is a combined second detector and automatic volume control tube. The direct current component of the rectified signal, through one diode of this tube, produces a voltage drop across resistors R-10 and R-12. This voltage drop provides automatic bias for the R. F. amplifier, converter and the first I. F. amplifier, and thus gives automatic volume control action. Full automatic bias voltage is applied to the R. F. amplifier tube, while a portion of this voltage, from the junction of resistors R-10 and R-12, is applied to the converter and 1st I. F. amplifier which handle a somewhat larger signal voltage than the R. F. amplifier.

This same automatic bias voltage is used to control the Colorama tuning tube. Switch S-4 makes it possible to apply either full or partial voltage to the tube, thereby allowing control of the color indication in accordance with prevailing receiving conditions. A complete description of Colorama tuning is given in a later paragraph.

The audio frequency present across R-10 and R-12 is impressed upon the volume control R-15 through capacitor C-34. The movable arm on the volume control selects the amount of audio signal applied to the control grid of the 6F5 audio amplifier tube and thus regulates the output of the receiver. Across the volume control R-15 is placed a compensating network of capacitors and a resistor. The music-speech switch is found in this circuit, and when closed places capacitor C-38 in shunt with C-39, which removes the bass compensation. The output of the 6F5 audio tube is resistance coupled to the grid of the 6L6 beam power tetrode. The plate circuit of the 6L6 is suitably matched to the electro-dynamic loud-speaker by means of a step-down output transformer.

The tone control is found in the plate circuit of the 6F5 first audio tube and consists of capacitor C-43 in series with a variable resistor R-18 across the 6F5 plate resistor R-17. Cutting out resistance in R-18 lessens the treble response of the receiver. Between the plate of the 6F5 first audio tube and the grid of the 6L6 tetrode output tube are found two capacitors in series, C-41 and C-42. The smaller capacitor, C-42, is shorted out by the wave band switch for operation on the broadcast band. On the two short-wave bands it is left in the circuit to attenuate the low frequency response and thereby lessen the tendency toward microphonic howl.

Plate and grid voltages for all tubes are supplied by the power supply system employing a *5Z4* full-wave rectifier tube which, together with a suitable network of resistors and capacitors, supplies the required voltages and filtering action.

COLORAMA TUNING

These receivers are equipped with Color Tuning, a novel method which indicates approach to resonance by means of a change of color of the light illuminating the tuning scale.

The colored light is produced by a group of four red-stained pilot bulbs and a group of three green stained bulbs behind the scale. At zero signal strength the red group is at full brilliance and the green invisibly dim. As the signal increases from zero, the red gets dimmer and the green brighter over a broad range until at extreme signal strength the green is fully bright and the red below visibility through the dial. Hence, as a station is tuned-in the color changes smoothly, and the maximum change in the green direction is an indication of resonance.

Weak stations will produce a small color change and strong stations a larger change. The difference in signal strength, between the weakest and the strongest station likely to be listened to, has been found to be so great in different localities that the receivers have been equipped with a two-position sensitivity range switch for "sensitive" and "insensitive" settings of the color tuning. The switch is located near the power transformer on the chassis and may be reached from the rear of the cabinet. In the sensitive position, the weakest station to which the user can listen comfortably, above the general noise level, will shift the color to neutral white at resonance. Stronger stations give resonant points at bright greens. In localities near a relatively large group of high-powered stations and having a high noise level, such as Chicago and New York, the range switch must be thrown to the insensitive position when standard outdoor antennas are used, or else the color will be fixed green over so wide a band that resonance cannot be accurately found. The difference in sensitivity is about twenty to one. On short wave bands the band switch connects the color tuning to the sensitive setting and the switch on the chassis is inoperative. This is because practically all the short-wave signals are relatively weak. The insensitive setting is used only on the 540-1680 KC band.

There is a group of four red and a group of three green pilot bulbs behind the scale. These are controlled by a Saturable Reactor in a circuit which is shown in the schematic diagram, Fig. 1. The saturable reactor is controlled by a D. C. coil which decreases its reactance smoothly from a high-value at no D. C. to a very low value at maximum D. C. The saturable reactor acts very much like a dimming rheostat except that it is controlled by the D. C. plate current of a 6C5 tube used solely for that purpose. This tube receives for its bias a portion of the A.V.C. voltage of the set so that at no signal the bias is nearly zero. At this point, the plate current is at maximum; therefore, the red is brightest and the green invisibly dim.

SOME THINGS WHICH MAY AFFECT THE OPERATION OF COLOR TUNING ARE AS FOLLOWS:

Seven colored bulbs are used to give good diffusion of color over the scale; but if one of the seven fails it unbalances the whole group and should be replaced immediately. The lamp socket assembly may be removed by reaching into the rear of the cabinet, pulling the lamp socket assembly up on its guides and drawing it partly out. A shipping screw, which should be removed when the set is unpacked, may need to be removed the first time. There is enough slack in connecting wires to allow the assembly to be drawn forward. When the socket assembly has been drawn far enough out for unscrewing the bulbs turn on the power switch and replace the bulbs which do not glow. All will not be bad as each group is in series (green) or series parallel (red). Take care the wires do not foul the tuning mechanism when the assembly is replaced. The colored lamps used for replacement *MUST ALL BE 6.3 VOLTS, 0.15 AMPERE LAMPS.* No other size will work.

If the red is unusually dim on no signal and the colored bulbs are all good, try removing the antenna. Next try replacing the 6C5 Colorama tube or replace the rectifier. Sometimes the antenna noise level is so high that it dims the red like a signal. If the tubes in the set become weak, or the set is out of alignment, or for any other reason loses its sensitivity, the color tuning will appear insensitive.

ALIGNMENT PROCEDURE

The receiver should first be allowed to run for fifteen minutes in order to reach its approximate normal operating temperature. Before making any adjustments, it is wise to determine the correctness of the existing alignment. This may be done by supplying a signal from the test oscillator to the receiver and inserting a "Tuning Wand" into the coil involved. The "Tuning Wand" consists of a rod of insulating material having a ring of nonmagnetic metal attached to one end, and a small core of finely divided iron compacted into the opposite end. By inserting the metal ring end into the center of a particular coil, the inductance of the coil is lowered, increasing its resonant frequency. Inserting the iron-filled end into the coil raises its inductance, lowering its resonant frequency. If the circuits are in exact alignment, inserting either end of the tuning wand in any coil will result in a decrease in output. When an increase in signal is obtained with the iron-filled end of the wand, a decrease in resonant frequency of that circuit by increasing its trimmer capacity is indicated. When an increase in signal is obtained with the metal ring, a decrease in trimmer capacity is indicated.

Changes Indicated by Wand

Wand	Signal	Trimmer adjustment required
Metal Ring	Decrease	None
Iron filings	Decrease	
Metal Ring	Increase	Decrease capacity
Iron filings	Decrease	
Metal Ring	Decrease	Increase capacity
Iron filings	Increase	

Alignment Frequencies

I. F.	Band "B"	Band "C"	Band "D"	Wave Trap
465 kc	580 kc 1500 kc	5220 kc	18,000 kc	465 kc

In order to align this receiver properly, it is necessary to have available the following test equipment:

1. A modulated test oscillator with frequencies available of 465, 580, 1500, 5220 and 18,000 Kc.
2. An output indicator, such as a high resistance a-c voltmeter with a maximum scale reading of 3 to 5 volts, or a neon lamp indicator.
3. An alignment tool consisting of an insulating shaft with a small screwdriver blade.
4. A tuning wand.

The location of all trimmer capacitors, as well as socket voltages to chassis, is shown in Fig. 3.

1. *I. F. Alignment*

Set the frequency band switch of the receiver to Band "D", short circuit the antenna and ground terminals and tune the receiver to some point near maximum tuning condenser capacity where no signal is heard. Set the volume control at its maximum position and ground the chassis.

The I. F. amplifier is tuned to 465 Kc; set the test oscillator so as to produce a signal at this frequency. Connect the test oscillator output between the top grid terminal of the 6K7 2nd I. F. tube and the chassis using a .05 mfd. Capacitor (RC-072) in series with the oscillator output lead to the top grid connection, after first removing the grid lead connecting to the same point from the 2nd I. F. transformer. Provide a path for grid bias by connecting a 10,000 ohm resistor (RQ-083) between grid cap and top grid terminal of tube.

Connect the output meter across the voice coil of the speaker and adjust the test oscillator output control so that, with the receiver volume control at maximum, a small deflection is observed on the output meter. During both I. F. and R. F. alignment, the test oscillator signal should be maintained at the lowest level that will give a good readable output indication.

Adjust the secondary trimmer of the third I. F. transformer until a maximum output reading is obtained. Maintain a small deflection on the output meter throughout alignment by adjusting the test oscillator output. Next, adjust the primary trimmer of the third I. F. transformer for maximum output. This transformer is then adjusted and should not require readjustment when aligning transformers ahead of it.

Transfer the test oscillator connections to the top grid terminal of the 6K7 1st I. F. tube, replace the grid lead on 2nd I. F. tube, and reduce the output of the test oscillator as low as possible consistent with obtaining an easily readable indication on the output meter. Adjust secondary and primary trimmers respectively on the 2nd I. F. transformer until a maximum deflection on the output meter is obtained.

Transfer the test oscillator connections to the top grid terminal of the 6A8 converter tube and replace the grid cap connection on the 6K7 1st I. F. tube. It will probably be found desirable to set the tone control for minimum high response, and to reduce the volume control setting, to lessen the noise reproduced due to the extremely high sensitivity of this receiver. Again adjust the test oscillator output to as low a value as will allow accurate adjustment. Adjust secondary and primary trimmers respectively on the 1st I. F. transformer until maximum deflection on the output meter is obtained.

The I. F. alignment is now complete.

2. *I. F. Wave Trap Alignment*

Set the band switch to Band "B" and tune the receiver to about 1000 Kc. With the test oscillator still set at 465 Kc., remove the shorting connections between antenna and ground terminals and apply this signal to the antenna terminal through a dummy antenna consisting of a 400 ohm resistor and 250 mmfd. capacitor in series. With the 465 Kc. signal applied to the antenna terminal, adjust the I. F. Wave Trap Trimmer for *minimum* output indication.

3. *R. F. Alignment*

First check the position of the dial pointer by rotating the tuning condenser to maximum capacity position, i.e., plates fully meshed. At this position, the pointer should coincide with the end mark at the left-hand end of the scale. If it does not, it may be set by loosening the dial drum set screws and rotating the drum on the tuning condenser shaft. Hold the tuning condenser rotor while doing this, to prevent its rotating. Tighten the two set screws after the pointer is correctly set.

Band "B" (540-1680 Kc.)

Set the test oscillator for operation at 1500 Kc. and connect its output to the antenna terminal of the receiver through the dummy antenna described under I. F. Wave Trap Alignment. Tune the receiver until the pointer is at 1500 on the scale. Set the tone control for minimum high response and reduce the volume control setting so as to avoid excessive noise response. Adjust the Band "B" oscillator, R. F., and antenna trimmers respectively (C-12, C-7 and C-2, Fig. 3) to give maximum deflection on the output meter. Maintain the test oscillator output at the lowest level which will give an easily readable output indication.

Now set the test oscillator to 580 Kc. and tune the receiver to resonance with this signal. Adjust the 580 Kc. padding capacitor, C-13, rocking the tuning condenser back and forth through resonance as the padding capacitor is adjusted and note the deflection of the tuning meter each time the receiver is tuned through resonance. Leave the padding capacitor at the setting which gives greatest deflection.

Retune the receiver to 1500 Kc. and reset the test oscillator for this frequency. Check the alignment by again adjusting the Band "B" oscillator, R. F. and antenna trimmers for maximum deflection on the tuning meter.

Band "C" (1680-6000 Kc.)

No trimmers are provided for alignment of the R. F. and antenna transformers in Band "C" of these receivers. Correct tracking between R. F. and antenna transformers is obtained by the action of the capacity coil, L-3, and between oscillator and the other tuned circuits by means of the adjustable oscillator trimmer C-14 and the fixed padding capacitor, C-54.

Turn the band switch to Band "C". Set the test oscillator at 5220 Kc. and tune the receiver to resonance at this frequency. Adjust the Band "C" oscillator trimmer, C-14, for maximum output indication on the tuning meter, rocking the tuning condenser back and forth through resonance while making the adjustment.

Band "D" (6.0-18.0 Mc.)

Turn the band switch to Band "D". Set the test oscillator at 18,000 Kc. (18.0 Mc.) and tune the receiver until the pointer coincides with the 18.0 mark. Adjust the Band "D" oscillator trimmer, C-15, to give maximum output indication. It will probably be found that there will be two settings of the oscillator trimmer that will give an output response. The lower capacity setting of the trimmer is the one that should be used. To be sure that correct adjustment has been obtained, tune for the image signal at 17.07 Mc. with the test oscillator set at 18.0 Mc. It may be necessary to increase the test oscillator output to obtain response at this point.

Retune the receiver to 18.0 Mc. and adjust Band "D" antenna and R. F. trimmers, respectively (C-3 and C-10) for maximum output indication. When adjusting the R. F. trimmer, C-10, rock the tuning condenser back and forth through resonance as in the 580 Kc. padding capacitor adjustment.

Alignment of the receiver is now complete.

VISUAL ALIGNMENT OF I.F.

In order to realize to full advantage the performance built into these receivers at the factory, circuit alignment using cathode ray oscilloscope equipment is much to be preferred. The oscilloscopic method is particularly advantageous in aligning the I. F. tuned circuits.

For visual alignment it is necessary to vary the frequency of an unmodulated test oscillator signal over a range extending on both sides of the peak frequency. This variation must take place in synchronism with the horizontal traverse of the cathode ray beam on its screen. The frequency modulator must, therefore, provide means for synchronizing the periodic test frequency variation with the cathode ray horizontal deflection circuit. The test oscillator may advantageously have facilities for audio frequency amplitude modulation of a fixed radio frequency test signal, as well as for frequency modulation, but audio modulation is not required for visual I. F. alignment.

Instead of an output meter across the speaker voice coil, the vertical plates of the cathode ray tube are connected across the load resistor of the diode rectifier. With the frequency modulator in operation in conjunction with the test oscillator, the resonance curve of the circuit under test will be then shown on the screen.

Preliminary Procedure

For visual alignment, adjust the receiver controls and connect the test oscillator as outlined in the section entitled "I. F. Alignment" under "ALIGNMENT PROCEDURE." Connect the vertical deflecting plates of the cathode ray tube across the diode rectifier load resistor, which in these receivers consists of R-10 and R-12 in series. The location of these resistors is clearly shown in Fig. 3.

Place the oscilloscope in operation as an output indicator and proceed as outlined in the section entitled, "I. F. Alignment."

Alignment Adjustments

Adjust the oscilloscope so that the luminescent spot on the cathode ray screen traces a horizontal line across the screen. Now place the frequency modulator and test oscillator in operation to give an unmodulated radio frequency signal varying from one side to the other of 465 Kc. Adjust the oscilloscope and test oscillator controls to show a single overall resonance curve of the I. F. channel on the cathode ray tube screen. Do not change the test oscillator setting thereafter.

To align the I. F. transformers, follow in sequence the same procedure outlined in the sections under "ALIGNMENT PROCEDURE" describing this operation. Instead of aligning for maximum output on an output indicator, the object should be to make the curve symmetrical. If the sweep circuit is so arranged that two symmetrically reversed curves appear on the screen, the curves should be made to coincide by adjusting the I. F. trimmer capacitors.

Visual R. F. alignment may be carried out in the same general manner as above by applying a suitable frequency-modulated signal between the antenna and ground terminals of the receiver and connecting the cathode ray vertical deflecting plates across the diode rectifier load resistors.

ADJUSTMENT OF DIAL MECHANISM

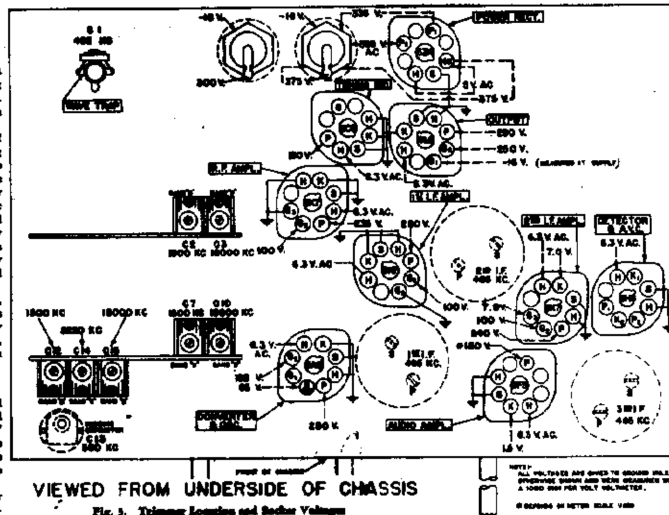
The dial mechanism (Fig. 4) is rigidly mounted to the chassis by means of two brackets and four self-tapping screws. The dial pointer is operated by means of an "automatic vernier" reduction drive unit, mounted on the gang condenser, and connected to the gang rotor by a set of anti-backlash gears. Motion imparted to the gang condenser rotor is transmitted through a series of pulleys and an interconnecting cable to the dial pointer slider which is supported on a rail above the dial scale.

To Mount Escutcheon

Care should be taken to use a well ground screw driver of proper size to fasten the screws in the escutcheon plate. Holes have been jigged in the cabinet front panel to insure the proper location of the escutcheon with respect to the scale housing.

To Replace Drive Cable

Remove the defective drive cable to be replaced. Rotate the drive wheel (14) counter-clockwise until the gang condenser plates are fully open. Place the end of the cable having an eyelet in slot [A]. Thread the cable as shown in Fig. 4, making certain that the cable passes *over* the pin [B] and runs along the correct grooves, the looped end hooking over the tension spring (15). Check the position of the drive wheel (14) on the condenser shaft to make sure that the cable coming off the right hand idler pulley lines up with the groove in the drive pulley. Also, as the condenser plates become fully meshed, the drive wheel (14) should just meet the bushing [D] of the reduction drive unit (30). With the drive wheel in this position, place the pointer on the rail [E] and, with the tip of the pointer (11) on the extreme left hand dial scale division, crimp the pointer tab on the drive cable.



VIEWED FROM UNDERSIDE OF CHASSIS

Fig. 3. Trimmer Location and Socket Voltages

To Adjust Pointer for Scale Calibration

Three positions of the dial pointer cable are provided on the drive wheel (14) to adjust the dial pointer up or down scale. The position shown in Fig. 4 with the cable over pin [B] is the medium position. Changing the cable to the position between pins [B] and [C] moves the pointer down scale. The position below the pin [C] moves the pointer up scale from the medium position.

To Replace Scale

Remove the band change cable (12) by unhooking it from the fork [F] on gear (41). Remove the end support bracket (8) held by a single self-tapping screw and withdraw the scale assembly from its housing. Replace the end caps (37) and (38) on the new scale and reassemble. Before reattaching the band change cable to the fork [F] the tension spring (7) should be given two full turns to provide proper tension for the cable.

To Adjust Rotation of Scale

The forked tab [F] may be bent up or down to give the correct position of the scale divisions with respect to the dial pointer. The pointer tip should slightly overlap the scale divisions.

To Change Dial Lamps

Make certain that the shipping screw [G] has been removed before attempting to remove the dial lamp bracket. Lift up the lamp bracket from the tabs under which it is clipped. Care should be taken that the lamp leads do not put an undue strain upon the drive cable. With the lamp bracket laid back horizontally, the lamps may be replaced. When the lamp bracket is reinserted, care should be exercised to avoid having the lamp leads foul the gang mechanism.

DESCRIPTION OF ELECTRICAL CIRCUIT

Models E-101, E-105 and E-106 employ ten metal envelope tubes in a superheterodyne circuit, giving the excellent sensitivity and selectivity inherent in this type circuit. The radio frequency section of this ten-tube chassis utilizes a novel type of construction known as the "Junior Sentry Box." This type construction permits using extremely short connecting leads and isolates each radio frequency circuit in its own particular shielded section. Separate groups of coils are used for each band in the oscillator section. The antenna and R. F. sections are composed of two coils, a separate coil for the "D" band and a composite coil for the "B" band and "C" band. Operation on the "C" band is obtained by shorting out a section of the antenna and R. F. "B" band coil.

The signal from the antenna is applied to the control grid of the 6K7 R. F. amplifier tube through the antenna coil, the secondary of which is tuned to the incoming signal by the rear section of the main tuning condenser. The antenna coil, for bands "B" and "C," contains two primary coils connected for operation on the "B" band; however, when the band switch is turned to the "C" band position, the lower primary coil, L-5, is shorted out. The high frequency trimming adjustment for the "B" band antenna and R. F. stage is accomplished by two adjustable trimmers connected from the "C" band tap on each coil to ground. The capacity coupling coil, L-3, acts only on the "C" band and its function is similar to that of a fixed antenna stage trimmer for that band.

The amplified radio frequency signal is impressed upon the signal control grid of the 6A8 converter tube through the R. F. Coil, the secondary of which is tuned to the signal frequency by the center section of the main tuning condenser. In the 6A8 tube, the incoming signal is combined with the local oscillator signal which is 465 kc. different in frequency. The local signal is generated by the oscillator elements of this tube and the proper frequency difference is maintained throughout the tuning range by the front section of the main tuning condenser in conjunction with the oscillator coils and padding capacitors.

The combination of the signal frequency with the local oscillator frequency in the 6A8 converter tube produces the intermediate frequency of 465 kilocycles. This particular intermediate frequency is chosen to reduce image response and improve short-wave performance.

The intermediate frequency amplifier consists of a two-stage cascade section composed of three I. F. transformers and two 6K7 amplifier tubes. Both primary and secondary windings of the I. F. transformers are tuned, and are made resonant at a frequency of 465 kilocycles. The second I. F. amplifier 6K7 tube is operated on self bias for all bands. This enables the second I. F. tube to deliver maximum power to the 6H6 diode rectifier.

The output of the I. F. amplifier is applied to the 6H6 diode rectifier, which is a combined second detector, automatic volume control, and automatic frequency control bias supply tube. The secondary of the third I. F. transformer is center-tapped providing the push-pull connection to the 6H6 diode plates necessary to secure the variable grid bias for the 6J7 automatic frequency control tube. This automatic frequency control feature is completely described in a following paragraph. One diode of the 6H6 twin-diode tube is used to detect the modulated signal furnished by the I. F. amplifier. The audio frequency developed by this action is transferred to the audio frequency system for amplification and reproduction. The D.C. voltage resulting from detection is used for automatic volume control action and for the operation of the colorama tuning tube. The diode load resistor consists of R-24, R-31 and R-32 in series. The D.C. voltage developed across R-32 is applied as automatic control grid bias to the R. F. converter and first I. F. amplifier tubes. Initial bias for these tubes is supplied by returning the diode load resistor to a negative voltage supply of approximately 3 volts on the main bleeder resistor.

Automatic bias voltage developed across R-31 and R-32 is used to control the Colorama Tuning tube. Switch S-4 makes it possible to apply full or partial voltage to the tube, thereby allowing control of the color indication in accordance with prevailing receiving conditions. A complete description of Colorama Tuning is given in a later paragraph.

The audio frequency present across R-31 and R-32 is impressed upon the volume control, R-15, through capacitor C-34. The movable arm on the volume control selects the amount of audio signal applied to the control grid of the 6F5 audio amplifier tube and thus regulates the output of the receiver. Across the volume control, R-15, is placed a network of capacitors and a resistor. The music-speech switch is found in this circuit, and when closed removes the bass compensation. The output of the 6F5 audio tube is resistance coupled to the grid of the 6L6 beam power tetrode. The plate circuit of the 6L6 is suitably matched to the electro-dynamic loud-speaker by means of a step-down output transformer.

The tone control is found in the plate circuit of the 6F5 first audio tube and consists of capacitor C-43 in series with a variable resistor R-18 across the 6F5 plate resistor R-17. Cutting out resistance in R-18 lessens the treble response of the receiver. Between the plate of the 6F5 first audio tube and the grid of the 6L6 tetrode output tube are found two capacitors in series, C-41 and C-42. The smaller capacitor, C-42, is shorted out by the wave band switch for operation on the broadcast band. On the two short-wave bands it is left in the circuit to attenuate the low frequency response and thereby lessen the tendency toward microphonic howl.

Plate and grid voltages for all tubes are supplied by the power supply system employing a 5Z4 full-wave rectifier tube which, together with a suitable network of resistors and capacitors, supplies the required voltages and filtering action.

Automatic Frequency Control

These receivers employ automatic frequency control (AFC) which is a device for automatically controlling the oscillator frequency in such a way that, although the receiver is not exactly tuned to the signal being received, the correct intermediate frequency will still be produced. This control of the oscillator frequency is secured by means of the 6J7 AFC tube, so connected to the oscillator that it draws a lagging current from the tank circuit and thus gives the effect of a shunt inductance. Variation of the D.C. grid bias on the 6J7 control tube will affect the mutual conductance of the tube, thereby changing the amount of lagging current drawn from the oscillator tank with a consequent effect of variation of the amount of shunt inductance connected across the oscillator coil. This alters the total inductance in the oscillator tuned circuit and changes its resonant frequency.

Grid bias for the 6J7 control tube, which will vary in accordance with the amount of detuning of the receiver, is obtained from the 6H6 diode rectifier operating in conjunction with its special I. F. transformer. This control voltage is the difference between the drop across resistor R-24, the load resistance for one diode section of the 6H6 diode rectifier, and the drop across resistors R-31 and R-32, which constitute the load resistance for the other diode section. When the receiver is correctly tuned to the incoming signal, the intermediate frequency produced will be 465 kc. which is the resonant frequency of the tuned circuit feeding the 6H6 diode rectifier. Under this condition each diode plate receives equal signal voltage and the D.C. voltage drops across the load resistors will be equal, giving no change in grid bias on the 6J7 control tube. If the receiver is so tuned that the intermediate frequency produced is above 465 kc., the signal voltage applied to diode plate No. 2 will exceed that applied to diode plate No. 1. In this case, the D.C. voltage drop across load resistor R-31 and R-32 will be larger than that across load resistor R-24 and a resultant voltage will be produced which will increase the 6J7 AFC tube grid bias, lowering the mutual conductance of the tube and causing it to draw less lagging current from the oscillator tank. This is the same effect as would be produced by increasing the amount of shunt inductance across the oscillator coil and the oscillator frequency is thereby lowered by the amount necessary to compensate for the detuning. The opposite takes place when the receiver is tuned so as to produce an intermediate frequency below 465 kc. Diode plate No. 1 then receives more signal voltage than diode plate No. 2 and the resultant voltage developed across the load resistance is such as to decrease the grid bias on the 6J7 AFC tube. This causes a larger current to be drawn from the oscillator tank circuit, which in effect is the same as a decrease in shunt inductance with its consequent increase in oscillator frequency to overcome the detuning.

ALIGNMENT PROCEDURE

The receiver should first be allowed to run for fifteen minutes in order to reach its approximate normal operating temperature. Before making any adjustments, it is wise to determine the correctness of the existing alignment. This may be done by supplying a signal to the receiver from the test oscillator at the alignment frequency and inserting a "Tuning Wand" into the coil involved. The tuning wand consists of a rod of insulating material having a ring of non-magnetic metal attached to one end, and a small core of finely divided iron compacted into the opposite end. By inserting the metal ring end into the center of the R. F. coil, the inductance of this coil is lowered, increasing its resonant frequency. Inserting the iron-filled end into the coil raises its inductance, lowering its resonant frequency. If the R. F. circuits are in exact alignment, inserting either end of the tuning wand into the coil will result in a decrease in output. When an increase of signal is obtained with the iron-filled end of the wand, a decrease in resonant frequency of that circuit by increasing its trimmer capacity is indicated. When an increase of signal is obtained with the metal ring, a decrease in trimmer capacity is indicated.

Changes Indicated by Wand

Wand	Signal	Trimmer Adjustment Required
Metal Ring Iron Filings	Decrease Decrease	None
Metal Ring Iron Filings	Increase Decrease	Decrease capacity
Metal Ring Iron Filings	Decrease Increase	Increase capacity

ALIGNMENT FREQUENCIES

I.F.	Band "B"	Band "C"	Band "D"	Wave Trap
465 kc.	580 kc. 1500 kc.	5330 kc.	18,000 kc.	465 kc.

In order to align these receivers properly it is necessary to have available:

1. A modulated test oscillator capable of producing the above alignment frequencies.
2. An output indicator, such as a high resistance a-c voltmeter with a maximum scale reading of 3 to 5 volts, or a neon lamp indicator.
3. An alignment tool consisting of a fiber shaft screwdriver.
4. A tuning wand

To realize the full advantage of the performance built into these receivers at the factory, circuit alignment using cathode ray oscilloscope equipment is much to be *preferred*. The oscilloscopic method is particularly advantageous in aligning the I. F. tuned circuits.

The location of all alignment trimmer capacitors, as well as socket voltages, is shown in Fig. 8.

1. *Visual Alignment of I. F.*

For visual alignment it is necessary to vary the frequency of an unmodulated test oscillator signal over a range extending on both sides of the peak frequency. This variation must take place in synchronism with the horizontal traverse of the cathode ray beam on its screen. The frequency modulator must, therefore, provide means for synchronizing the periodic test frequency variation with the cathode ray horizontal deflection circuit. The test oscillator may advantageously have facilities for audio frequency amplitude modulation of a fixed radio frequency test signal, as well as for frequency modulation, but audio modulation is not required for visual I. F. alignment.

Instead of an output meter across the speaker voice coil, the vertical plates of the cathode ray tube are connected across the load resistor of the diode rectifier. With the frequency modulator in operation in conjunction with the test oscillator, the resonance curve of the circuit under test will be then shown on the screen.

Set the tuning dial indicator at the low end of the broadcast band to some point where no signal is received since an extraneous signal might interfere with the aligning process. The volume control should be in an "off," or nearly "off" position. Apply a frequency modulated signal to the grid of the 1st I. F. amplifier tube through a .05-mfd. (RC-072) capacitor leaving the grid cap in place. Connect the vertical plates of the oscilloscope between ground and the junction point between R-24 and R-31, which are the diode load resistors, and with the AFC switch in the "off" position proceed to align the primary and secondary of the 2nd I. F. and the AFC I. F. transformers.

The object should be to make the two curves coincide with each other at the top and throughout their length with the maximum amplitude obtainable. This will require that all four I. F. trimmers be adjusted in the usual manner *excepting the AFC secondary (hexagonal nut) trimmer which must be adjusted for minimum amplitude* before the curves will coincide properly. Fig. 4 gives the appearance of the curve when the alignment adjustments have been completed satisfactorily thus far. Apply the same frequency modulated input to the grid of the converter (6A8) tube through a .05-mfd. capacitor as before. Adjust the primary and secondary of the 1st I. F. transformer until the curves coincide as before and have the appearance of Fig. 4.

A further adjustment of the AFC secondary (hexagonal nut) trimmer is necessary in order to complete the I. F. alignment satisfactorily. Apply the same signal to the grid of the second I. F. amplifier tube. Unsolder the ground end of C-31 and connect the vertical deflecting plates of the oscilloscope between ground and the 6H6 cathode prong No. 8. Since the cathode prong is inaccessible this connection can be made at the AFC switch contact marked "Plate B" on the parts layout, Fig. 8.

Carefully adjust the AFC secondary trimmer until a curve is obtained which is similar to that shown in Fig. 5. Correct adjustment is made when the two sides of the curve are symmetrical and intersect exactly at the axis. No adjustment of the other I. F. trimmers should be made at this time.

2. *I. F. Wave Trap Alignment*

Set the band switch to Band "B" and tune receiver to about 1000 kc.

With the test oscillator still set at 465 kc. apply this signal to the antenna terminal through a dummy antenna consisting of a 400-ohm resistor and 250-mmfd. capacitor in series. With the 465 kc. signal applied to the antenna terminal, adjust the I. F. Wave Trap Trimmer for *minimum* output indication.

3. *R. F. Alignment*

First check the position of the dial pointer by rotating the tuning condenser to maximum capacity position, i.e., plates fully meshed. At this position, the pointer should coincide with the end mark at the left-hand end of the scale. If it does not, it may be set by loosening the dial drum set screws and rotating the drum on the tuning condenser shaft. Hold the tuning condenser rotor while doing this, to prevent its rotating. Tighten the two set screws after the pointer is correctly set. During R. F. alignment the AFC switch must be set in its "Off" (counterclockwise) position.

Band "B" (540-1680 Kc.)

Set the test oscillator for operation at 1500 kc. and connect its output to the antenna terminal of the receiver through the dummy antenna described under I. F. Wave Trap Alignment. Tune the receiver until the pointer is at 1500 on the scale. Set the tone control for minimum high response and reduce the volume control setting so as to avoid excessive noise response. Adjust the Band "B" oscillator, R. F., and antenna trimmers respectively (C-12, C-7, and C-2, Fig. 8) to give maximum deflection on the output meter. Maintain the test oscillator output at the lowest level which will give an easily readable output indication.

Now set the test oscillator at 580 kc. and tune the receiver to resonance with this signal. Adjust the 580 kc. padding capacitor, C-13, rocking the tuning condenser back and forth through resonance as the padding capacitor is adjusted and note the deflection of the tuning meter each time the receiver is tuned through resonance. Leave the padding capacitor at the setting which gives greatest deflection.

Retune the receiver to 1500 kc. and set the test oscillator for this frequency. Check the alignment by again adjusting the Band "B" oscillator, R. F. and antenna trimmers for maximum deflection on the tuning meter.

Band "C" (1680-6000 Kc.)

No trimmers are provided for alignment of the R. F. and antenna transformers in Band "C" of these receivers. Correct tracking between R. F. and antenna transformers is obtained by the action of the capacity coil, L-3, and between oscillator and the other tuned circuits by means of the adjustable oscillator trimmer, C-14, and the fixed padding capacitor, C-54.

Turn the band switch to Band "C." Set the test oscillator at 5330 kc., and tune the receiver to resonance at this frequency. Adjust the Band "C" oscillator trimmer, C-14, for maximum output indication on the tuning meter, rocking the tuning condenser back and forth through resonance while making this adjustment.

Band "D" (6.0-18.0 Mc.)

Turn the band switch to Band "D." Set the test oscillator at 18,000 kc. (18.0 mc.) and tune the receiver until the pointer coincides with the 18.0 mark. Adjust the Band "D" oscillator trimmer, C-15, to give maximum output indication. It will probably be found that there will be two settings of the oscillator trimmer that will give an output response. The lower capacity setting of the trimmer is the one that should be used. To be sure that correct adjustment has been obtained, tune for the image signal at 17.07 mc. with the Test Oscillator set at 18.0 mc. It may be necessary to increase the test oscillator output to obtain response at this point.

Retune the receiver to 18.0 mc. and adjust Band "D" antenna and R. F. trimmers, respectively (C-8 and C-10) for maximum output indication. When adjusting the R. F. trimmer, C-10, rock the tuning condenser back and forth through resonance as in the 580 kc. padding capacitor adjustment.

4. *I. F. Alignment with Output Meter*

Although the use of the cathode-ray oscillograph for alignment purposes is to be preferred, it is possible to make the I. F. adjustments with reasonable accuracy using a 465 kc. signal generator and output meter.

Place a modulated signal of 465 kc. on the grid of the last I. F. (6K7) tube with the volume control set at maximum and the AFC switch turned off. Place a low range A.C. voltmeter or other output indicator across the voice coil of the loud-speaker. Adjust the output of the signal generator so that an indication of not more than two or three volts is obtained on the output meter.

Adjust and readjust the primary trimmer for maximum output and *the secondary for minimum output.* This latter adjustment will be very broad. Apply the signal input to the grid of the 1st I. F. (6K7) tube and adjust both primary and secondary trimmers for maximum output, reducing the input as necessary to obtain approximately the same output indication as before. Apply the signal input to the grid of the converter (6A8) tube and adjust both primary and secondary trimmers for maximum output indication in the same manner as before.

It is now necessary to make a fine adjustment of the secondary trimmer of the last I. F. (AFC) transformer, which is as follows: Without changing the frequency of the signal generator, place the input lead on the rubber insulation of the converter (6A8) grid lead. This will provide a small signal input through the capacity between the leads. Increase the attenuator setting if necessary to make the output audible. If the signal generator is provided with a means of removing the modulation, this should be done. However, the adjustment may be carried out satisfactorily even with a modulated generator signal.

Now tune in any broadcast signal in the usual manner and tune carefully for zero beat between this carrier and the 465 kc. signal generator. It may be necessary to use a short antenna or to remove it entirely if the station is a strong local. Throw the AFC on and adjust the last I. F. secondary (AFC) trimmer by ear for zero beat. This adjustment is very critical and must be made with great care. When the adjustment is properly made, there will be no appreciable change from zero beat as the AFC switch is thrown off and on. This completes the alignment of the I. F. and AFC circuits.

The alignment of the oscillator and R. F. circuits may be carried out in the usual manner. However, the AFC switch must remain in the off position.

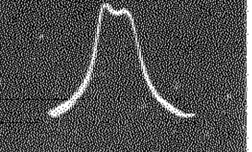

Fig. 4. Overall I. F. Curve

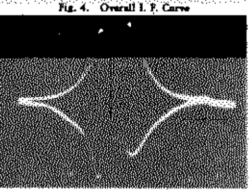

Fig. 5. AFC Adjustment Curve

ADJUSTMENT OF DIAL MECHANISM

The dial mechanism (Fig. 6) is rigidly mounted to the chassis by means of two brackets and four self-tapping screws. The dial pointer is operated by means of an "automatic vernier" reduction drive unit, mounted on the gang condenser, and connected to the gang rotor by a set of anti-backlash gears. Motion imparted to the gang condenser rotor is transmitted through a series of pulleys and an interconnecting cable to the dial pointer slider which is supported on a rail above the dial scale.

To Mount Escutcheon

Care should be taken to use a well-ground screw driver of proper size to fasten the screws in the escutcheon plate. Holes have been jigged in the cabinet front panel to insure the proper location of the escutcheon with respect to the scale housing.

To Replace Pointer and Drive Cable

Remove the defective pointer or drive cable to be replaced. Rotate the drive wheel (14) counterclockwise until the gang condenser plates are fully open. Place the end of the cable having an eyelet in slot [A]. Thread the cable as shown in Fig. 6, making certain that the cable passes over the pin [B] and runs along the *correct* grooves, the looped end hooking over the tension spring (16). Check the position of the drive wheel (14) on the condenser shaft to make sure that the cable coming off the right-hand idler pulley lines up with the grooves in the drive pulley. Also, as the condenser plates become fully meshed, the drive wheel (14) should just meet the bushing [D] of the reduction drive unit (30). With the drive wheel in this position, place the pointer on the rail [E] and, with the tip of the pointer (11) on the extreme left-hand dial scale division, crimp the pointer tab on the drive cable.

To Insert "Personalizer Strip"

The "Personalizer Strip" designed for use in these receivers is marked E-10. To install the strip, remove the holder from its mounting clips and slide the paper slip and metallic frame out of the celluloid cover. Replace the paper slip with a "Personalizer Strip" suitable for the locality in which the receiver will be operated and reassemble. Care should be taken to avoid scratching the back of the "Personalizer Strip" when sliding the strip and metallic frame back into the celluloid cover.

Colorama Tuning

These receivers are equipped with Color Tuning, a novel method which indicates the approach to resonance by means of a change in the color of the light illuminating the tuning scale.

The colored light is produced by a group of four red-stained pilot bulbs and a group of three green-stained bulbs behind the scale. At zero signal strength the red group is at full brilliance and the green invisibly dim. As the signal increases from zero, the red gets dimmer and the green brighter over a broad range until at extreme signal strength the green is fully bright and the red below visibility through the dial. Hence, as a station is tuned in the color changes smoothly, and the maximum change in the green direction is an indication of resonance.

Weak stations will produce a small color change and strong stations a larger change. The difference in signal strength between the weakest and the strongest station likely to be listened to, has been found to be so great in different localities that the receivers have been equipped with a two-position sensitivity range switch for "sensitive" and "insensitive" settings of the color tuning. The switch is located on the chassis near the power transformer and may be reached from the rear of the cabinet. In the sensitive position, the weakest station to which the user can listen comfortably above the general noise level, will shift the color to neutral white at resonance. Stronger stations give resonant points at bright green. In localities near a relatively large group of high-powered stations and having a high noise level, such as Chicago and New York, the range switch must be thrown to the insensitive position when standard out-door antennas are used, or else the color will be a fixed green over so wide a band that resonance cannot be accurately found. The difference in sensitivity is about twenty to one. On short-wave bands the band switch connects the color tuning to the sensitive setting and the switch on the chassis is inoperative. This is because practically all the short-wave signals are relatively weak. The insensitive setting is used only on the 540-1500 kc. band.

There is a group of four red and a group of three green pilot bulbs behind the scale. These are controlled by a Saturable Reactor, L-27 and L-28, in a circuit which is shown in the schematic diagram, Fig. 1. The saturable reactor is controlled by a D.C. coil which decreases its reactance smoothly from a high value at no D.C. to a very low value at maximum D.C. The saturable reactor acts very much like a dimming rheostat except that it is controlled by the D.C. plate current of a 6C5 tube used solely for that purpose. This tube receives for its bias a portion of the AVC voltage of the set so that at no signal the bias is nearly zero. At this point, the plate current is at maximum; therefore, the red is brightest and the green invisibly dim.

Some things which may affect the operation of color tuning are as follows:

Seven colored bulbs are used to give good diffusion of color over the scale; but if one of the seven fails it unbalances the whole group and should be replaced immediately. The lamp socket assembly may be removed by reaching into the rear of the cabinet, pulling the lamp socket assembly up on its guides and drawing it partly out. A shipping screw, which should be removed when the set is unpacked, may need to be removed the first time. There is enough slack in connecting wires to allow the assembly to be drawn forward. When the socket assembly has been drawn far enough out for unscrewing the bulbs, turn on the power switch and replace the bulbs which do not glow. All will not be bad as each group is in series (green) or series parallel (red). Take care the wires do not foul the tuning mechanism when the assembly is replaced.

The colored lamps used for replacement must all be 6.3 volts 0.15 ampere lamps. No other size will work.

If the red is unusually dim on no signal and the colored bulbs are all good, try removing the antenna. Next try replacing the 6C5 colorama tube, or replace the rectifier. Sometimes the antenna noise level is so high that it dims the red color like a signal. If the tubes in the set become weak, or the set is out of alignment, or the set for any other reason loses sensitivity the color tuning will appear insensitive.

DESCRIPTION OF ELECTRICAL CIRCUIT

Model A-125 employs twelve metal envelope tubes in a superheterodyne circuit, giving the excellent sensitivity and selectivity inherent in this type circuit. Separate groups of coils are used for each frequency band, all radio frequency coils being housed in the "Sentry Box" unit, together with their associated band switches, capacitors, resistors, and tube sockets. This type of construction permits using extremely short connecting leads and isolates each radio frequency circuit in its own shielded compartment. Permanence of alignment adjustments is assured through use of the new sealed, air-dielectric "Permaliner" trimmer capacitors in all tuned circuits. Sturdy chassis construction, including a removable base shield, insures rigidity of parts and freedom from microphonic vibration.

The signal from the antenna is applied to the control grid of the 6K7 R.F. amplifier tube through the antenna coil, the secondary of which is tuned to the incoming signal by the rear section of the main tuning condenser. The secondaries of the antenna, R.F. and oscillator coils for the band next lower in frequency to the one in use are short-circuited by the band switch to prevent absorption of energy at their resonant frequencies, which fall in the next higher band. The primaries of all antenna and R.F. coils not in use are short-circuited by the band switch.

The amplified radio frequency signal is impressed upon the signal control grid of the 6L7 hexode converter tube through the R.F. coil, the secondary of which is tuned to the signal frequency by the center section of the main tuning condenser. The 6L7 hexode is a new type tube designed for improved superheterodyne conversion efficiency in conjunction with a separate oscillator tube. In the 6L7, two separate control grids are shielded from each other and each acts independently upon the electron stream. Coupling effects between the signal and oscillator control grids are very small, making possible high gain and stable oscillator outputs at high frequencies and effectively reducing interaction between tuned circuits in the receiver.

The superheterodyne oscillator signal is generated by the 6C5 oscillator tube, its frequency being maintained 465 kc above the incoming signal frequency by the front section of the main tuning condenser in conjunction with the oscillator coil and padding capacitors. The oscillator section of the main tuning condenser, although of the same capacity as the other two sections, is larger physically to permit wider spacing of the plates, thereby reducing the possibility of microphonic feedback howl. The oscillator output is coupled to the oscillator grid of the 6L7 tube, where it is combined with the signal frequency to produce the intermediate frequency of 465 kilocycles. This particular intermediate frequency is chosen to reduce image response and improve short-wave performance.

The converter I.F. (intermediate frequency) transformer, consisting of two tuned circuits, transfers the I.F. output from the converter tube to the control grids of the 6K7 signal I.F. amplifier tube and the 6K7 AVC (automatic volume control) I.F. amplifier tube. Separate I.F. channels are used for signal amplification and automatic volume control. The sensitivity of the receiver is controlled by a variable resistor in the cathode circuit of the 6K7 signal I.F. amplifier which varies the amplification in that circuit upon manipulation of the sensitivity control. By controlling sensitivity in the I.F. circuit, better signal-to-noise ratio is obtained at reduced sensitivity, and changing the setting of the sensitivity control does not affect the tuning meter, which is in the R.F. amplifier plate circuit.

The output from the signal I.F. amplifier tube is coupled to the 6H6 diode detector through the signal I.F. transformer. Both primary and secondary coils of this transformer are tuned and each coil is tapped for connection to its respective tube to reduce the load imposed on the tuned circuit and thereby improve selectivity and sensitivity.

In the 6H6 tube the signal is rectified, the audio frequency component producing a corresponding voltage drop across the R-42 section of the manual volume control. This is a dual control, the second or lo-note compensation section (R-21) acting with capacitors C-53 and C-82 and resistors R-40, R-44 and R-45 to preserve proper balance between high and low audio frequencies as the volume is changed. The manual volume control selects the amount of audio signal applied through coupling capacitor C-52 to the grid of the 6F5 first audio amplifier tube and thus controls the output of the receiver. The treble tone control, consisting of variable resistor R-23 in series with capacitor C-57, is connected from the 6F5 plate to chassis ground. Load resistor R-25 and blocking capacitor C-55 couple the 6F5 plate to the grid of the 6F6 second audio amplifier tube, the plate and screen grid of which are connected together externally for triode operation. The bass tone control circuit, consisting of variable resistor R-22, capacitor C-56, and reactor L-37, is connected between the second audio grid and chassis ground.

The second audio amplifier is coupled to the grids of the 6F6 push-pull output pentodes through a special resistance-capacity network utilizing the bridge principle to reduce residual hum to a minimum, and working into the primary of the push-pull audio input transformer. This transformer has a step-down ratio from primary to each half of the secondary, giving good regulation on signal peaks when power is delivered to the push-pull output pentode grids. The plate circuits of the output pentodes are suitably matched to the loud-speaker by means of a step-down push-pull output transformer.

Signal for automatic volume control is amplified by the 6K7 AVC I.F. amplifier tube, the plate circuit of which is connected to a tap on the primary coil of the AVC I.F. transformer. Both primary and secondary of this transformer are tuned, the 6H6 AVC rectifier being connected across the entire secondary. The selectivity of the AVC I.F. channel is slightly less than that of the signal I.F. channel. This is desirable to avoid distortion and overloading as stations are being tuned in. An initial negative voltage of about 11 volts, obtained from the cathode bias resistor of the second audio amplifier, is maintained on the plates of the AVC rectifier tube. This gives delayed AVC action, which prevents attenuation of weak signals and gives a flat AVC characteristic on strong signals. Through the use of dual-channel, delayed AVC, the output of the receiver will not vary more than a few per cent over variations in signal input of 100,000 to 1. The d-c drop across R-35 and R-36 due to the rectified signal supplies full automatic bias to the R.F. amplifier and converter tubes, while partial automatic bias, from R-36 only, is applied to the signal I.F. amplifier. The tuning meter is in the plate circuit of the R.F. amplifier tube and indicates the plate current of this tube, which reaches a minimum as a signal is tuned in when the automatic bias applied to the tube is maximum.

Plate and grid voltages for all tubes are supplied by the power supply system employing a 5Z4 full-wave rectifier, which with a suitable network of resistors and capacitors, supplies the required voltages and filtering action.

ALIGNMENT PROCEDURE

Alignment Frequencies

I.F.	Band "A"	Band "B"	Band "C"	Band "D"	Band "E
465 kc	400 kc	1500 kc	5220 kc	15,000 kc	36,000 kc
	145 kc	580 kc			

In order to align this receiver properly, it is necessary to have available the following test equipment:

1. A modulated test oscillator with the above alignment frequencies available. In case 36,000 kc (36 mc) is not directly available, the second harmonic of 18,000 kc usually will be found strong enough for alignment purposes. The test oscillator calibration points for all alignment frequencies should be checked at the time of using. A reliable check by the zero beat method may be obtained against known controlled frequencies such as broadcast station frequencies and their harmonics.
2. An output indicator, such as a high resistance a-c voltmeter with a maximum scale reading of 3 to 5 volts, or a neon lamp indicator.
3. An alignment tool consisting of an insulating shaft with a small screw-driver blade.
4. A tuning wand.

The location of all trimmer capacitors is shown in Fig. 5. *It should be noted that on "Permaliner" trimmer capacitors, used throughout this receiver, clockwise rotation of the adjusting screw decreases capacity, while counterclockwise rotation increases capacity.*

1. *I.F. Alignment Adjustments*

First, turn on the test oscillator and let it run at approximately 465 kc for a short time in order to reach a state of equilibrium and to reduce frequency drift to a minimum. The I.F. alignment adjustment is not easily made without oscillograph equipment. Moreover, the AVC channel alignment requires removal of the chassis from the cabinet and removal of the base shield. (Removal of the base shield does not, however, affect any of the circuits.) There is also the danger that the frequency of the test oscillator will be much farther from 465 kc than the receiver's I.F. peak, even after long service. Unless the test oscillator frequency can be given a precision check at the time of using, it is better not to shift the I.F. peak frequency of the receiver at all, unless bad alignment is definitely indicated.

Each of the three I.F. transformers has two air-dielectric "Permaliner" trimmer capacitors. The secondary of the converter I.F. transformer delivers signal to two separate I.F. channels, the signal channel and the AVC channel, which must be aligned independently.

Signal I.F. Channel

Set the frequency band switch of the receiver to Band "B." Short-circuit the antenna and ground terminals, tune the receiver to some point above 1500 kc so that no signal is heard, and ground the chassis.

Connect the test oscillator output between the connected grid clip of the 6L7 converter tube and the receiver chassis. Connect the output indicator across the cone coil of the loud-speaker. Turn on the receiver and set the volume and sensitivity controls to maximum (extreme clockwise position). Place the test oscillator in operation and adjust the test oscillator dial near 465 kc to give a response. Reduce the input from the test oscillator until only a slight output registers on the output indicator across the speaker cone coil. The input should be kept at such a low level that temporary removal of the 6H6 AVC rectifier tube makes no appreciable difference in output.

MODEL A-125
Alignment, Part 2
"Sentry Box"
Coil Locations

GENERAL ELECTRIC CO.

Before touching the receiver trimmers, adjust the *test oscillator* for maximum response. Then after an interval of a few minutes, check for oscillator drift and be sure of equilibrium. Note the exact final setting of the test oscillator dial so it may be duplicated if necessary. This setting is likely to be very close to 455 kc and should be used without touching the oscillator dial again for the I.F. adjustment following, unless bad misalignment is definitely evident; in this case the most accurate known test oscillator setting may be used.

Alignment adjustments should be made in the following sequence:

1. Signal I.F. Transformer.

Remove the test oscillator connection from the grid of the 6L7 tube and attach it to the connected grid clip of the 6K7 signal I.F. amplifier tube. Adjust each of the two signal I.F. trimmers in turn. There is some interaction between two trimmers of the same transformer, so that these alternate adjustments should be repeated several times until a maximum output is obtained. Do not touch these trimmers again.

2. AVC I.F. Transformer.

After alignment of the signal I.F. transformer is finished, remove the 6H6 detector tube, thereby rendering the signal channel inoperative. The AVC channel may temporarily be substituted for alignment purposes in the following way:

Remove the base pan shield. With a .02 mfd capacitor (Stock No. RC-046), connect the yellow wire from the AVC I.F. transformer to the corresponding signal I.F. transformer terminal from which a shielded lead goes to the volume control, where connection is most readily made. The AVC rectifier tube has delay bias voltage which should be temporarily removed by connecting its cathode to ground. Then adjust each of the two AVC I.F. trimmers alternately several times until a maximum output is obtained, which should be somewhat greater than that of the signal channel. The peak, however, being rather broad when properly trimmed, may be somewhat difficult to obtain. Do not touch the AVC I.F. trimmers again.

3. Converter I.F. Transformer.

After alignment of the signal I.F. transformer *and* the AVC I.F. transformer is finished, restore the test oscillator connection to the grid clip of the 6L7 converter tube and replace the 6H6 detector tube. Adjust each of the two converter I.F. trimmers alternately several times until a maximum output is obtained. Do not touch these trimmers again.

Restore all original connections and replace the base pan shield; this complete the I.F. alignment.

2. *R.F. "Sentry Box" Alignment Adjustments*

Bands "A" and "B" each require four trimmer adjustments, while Bands "C," "D," and "E" each require only three. Take care to adjust only the trimmers under test. Connect the test oscillator to the antenna and ground terminals and place the receiver in operation with the output indicator across the speaker cone coil. A standard "dummy antenna," for connection between the test oscillator and the receiver antenna terminal, is a capacitor of 250 mmfd. (Stock No. RC-258) in series with a resistor of 200 ohms; a condenser at least *must* be used, having some such small value of capacitance. Before any alignment the position of the pointer should be checked. This position should just be to the left of the extreme left-hand scale mark on the Band "B" scale for maximum capacitance position of the main tuning condenser (plates fully engaged). In cases where the pointer is seriously off calibration at 1000 kc after alignment, the pointer should be reset with a soldering iron to be accurate at that point. The entire "Sentry Box" alignment procedure should then be repeated.

The Oscillator, Converter Input, and Antenna Compartments of the Sentry Box are conveniently referred to as "OSC," "R.F." and "ANT," respectively, thereafter. Fig. 6 shows Sentry Box Coil Locations and Compartment Assemblies. Before making any adjustments, it is wise to determine the correctness of the existing alignment. This may be done by supplying a signal from the test oscillator to the receiver, *at the alignment frequencies only*, and inserting a "Tuning Wand" into the coil involved. The "Tuning Wand" consists of a rod of insulating material having a ring of non-magnetic metal attached to one end, and a small core of finely divided iron compacted into the opposite end. By inserting the metal ring into the center of a particular coil through the openings provided in the "Sentry Box" compartment shields, the inductance of that coil is lowered, increasing its resonant frequency. If the circuits are in exact alignment, inserting either end of the tuning wand in any coil will result in a decrease in output. When an increase in signal is obtained with the iron-filled end of the wand, a decrease in resonant frequency of that circuit by increasing its trimmer capacity is indicated. When an increase in signal is obtained with the metal ring, a decrease in trimmer capacity is indicated.

Changes Indicated by Wand

Wand	Signal	Trimmer adjustment required
Metal Ring	Decrease	None
Iron Filings	Decrease	
Metal Ring	Increase	Decrease Capacity
Iron Filings	Decrease	
Metal Ring	Decrease	Increase Capacity
Iron Filings	Increase	

Band "A" (140-410 KC)

Set the band change switch to the position where the scale indicates the above range. This will be at the extreme counter-clockwise position of the band change switch knob.

Tune the test oscillator to 400 kc, set the pointer at 400 kc on the receiver, and adjust the Band "A" OSC, R.F. and ANT trimmers for maximum output. If necessary, reduce input from the test oscillator so that the signal reaching the speaker is kept at a low or moderate level.

Next tune the oscillator to 145 kc. Keep slowly rocking the tuning knob through the point of resonance, at the same time adjusting the 145-kc padding trimmer, until the highest peak of output is secured.

"Noise" alignment may be substituted when the preceding adjustment is nearly finished, in cases where there is a steady output of very loud pickup noise at the lower end of the scale. With the pointer at 145 kc on the receiver and the test oscillator removed, simply adjust the 145-kc padding trimmer only until a peak in the noise output is obtained. This should result in the same trimmer setting as in the preceding paragraph.

The interaction between the trimmer adjustments at each end of the scale makes it necessary to repeat the adjustments alternately until both are correct. This may require two or three adjustments each. *The last adjustment* must always be made at the high frequency end of the scale. This completes the adjustment of this Band; do not touch these trimmers again.

Band "B" (540-1740 KC)

Set the band change switch to the position where the scale indicates the above range.

Tune the test oscillator to 1500 kc, set the pointer at 1500 kc on the receiver, and adjust the Band "B" OSC, R.F. and ANT trimmers for maximum output, reducing input to maintain a low or moderate signal.

Next tune the oscillator to 580 kc. Keep slowly rocking the tuning knob through the point of resonance, at the same time adjusting the Band "B" padding trimmer, until the highest peak of output is secured.

The interaction between the trimmer adjustments at each end of the scale makes it necessary to repeat the adjustments alternately until both are correct. This may require two or three adjustments each. *The last adjustments must always be made at the high frequency end of the scale.* This completes the adjustment of this Band: do not touch these trimmers again.

Band "C" (1.74-5.6 MC)

Set the band change switch to the position where the scale indicates the above range.

Tune the test oscillator to 5.22 mc, set the pointer at 5.22 mc on the receiver, and adjust the Band "C" OSC trimmer for maximum output, reducing input to maintain a low or moderate signal.

Check for the image signal which should be received at about 4.3 mc on the receiver dial. It may be necessary to increase the input to the receiver from the test oscillator for this check.

Retune the receiver to the correct scale reading (5.22 mc) to secure the previous response. Adjust the RF and ANT trimmers now also for maximum output. This completes the alignment of Band "C"; do not touch these trimmers again.

Band "D" (5.6-18 MC)

Set the band change switch to the position where the scale indicates the above range. This position should occasionally be readjusted during subsequent trimmer adjustment, since it is possible to get some signals through on the higher frequencies when the switch is not exactly in position.

Tune the test oscillator to 15 mc, set the pointer at 15 mc on the receiver, and adjust the OSC trimmer for maximum output, leaving it at the *first* peak obtained when increasing it from minimum capacitance by counterclockwise rotation.

Check for the image signal which should be received at about 14.1 mc on the receiver dial. It may be necessary to increase the input to the receiver from the test oscillator for this check.

Reduce the capacitance of the RF trimmer to minimum. Reset the main tuning knob to secure the previous response at 15 mc and, while slowly rocking the knob through this resonance point, increase the R.F. trimmer capacitance until a maximum response is obtained.

Carefully holding the main tuning knob on the peak of resonance at 15 mc, adjust the ANT trimmer for maximum output. This completes the alignment of Band "D"; do not touch these trimmers again.

Band "E" (18-40 MC)

Set the band change switch to the position where the scale indicates the above range. This position should occasionally be readjusted during subsequent trimmer adjustment, since it is possible to get some signals through on the higher frequencies when the switch is not exactly in position.

Tune the test oscillator to 36 mc, set the pointer at 36 mc on the receiver, and adjust the OSC trimmer for maximum output, leaving it at the *first* peak obtained when increasing it from minimum capacitance by counterclockwise rotation.

Check for the image signal which should be received at about 35.1 mc on the receiver dial. It may be necessary to increase the input to the receiver from the test oscillator for this check.

Reduce the capacitance of the R.F. trimmer to minimum. Reset the main tuning knob to secure the previous response at 36 mc and while slowly rocking the knob through this resonance point, increase the R.F. trimmer capacitance until a maximum response is obtained.

Carefully holding the main tuning knob on the peak of resonance at 36 mc, adjust the ANT trimmer for maximum output. This completes the alignment of Band "E"; do not touch these trimmers again.

GENERAL ELECTRIC CO.

VISUAL ALIGNMENT OF I.F.

In order to realize to full advantage the performance built into a receiver of this class at the factory, circuit alignment using cathode ray oscilloscope equipment is much to be preferred. The oscilloscopic method is particularly advantageous in aligning the I.F. tuned circuits.

For visual alignment it is necessary to vary the frequency of an unmodulated test oscillator signal over a range extending on both sides of the peak frequency. This variation must take place in synchronism with the horizontal traverse of the cathode ray beam on its screen. The frequency modulator must, therefore, provide means for synchronising the periodic test frequency variation with the cathode ray horizontal deflection circuit. The test oscillator may advantageously have facilities for audio frequency amplitude modulation of a fixed radio frequency test signal, as well as for frequency modulation, but audio modulation is not required for visual I.F. alignment.

Instead of an output meter across the speaker cone coil, the vertical plates of the cathode ray tube are connected across the load resistor of one of the diode rectifiers of the receiver. With the frequency modulator in operation in conjunction with the test oscillator, the resonance curve of the circuit under test will then be shown on the screen.

Preliminary Procedure

For visual alignment, adjust the receiver controls and connect the test oscillator as outlined in the section entitled "I.F. Alignment Adjustments" under "ALIGNMENT PROCEDURE." Connect the vertical deflecting plates of the cathode ray tube across the volume control (R-42) of the receiver. Place the oscilloscope in operation as an output indicator and proceed as outlined in the section entitled, "Signal I.F. Channel."

Alignment Adjustments

Adjust the oscilloscope so that the luminescent spot on the cathode ray screen traces a horizontal line across the screen. Now place the frequency modulator and test oscillator in operation to give an unmodulated radio frequency signal varying from one side to the other of 465 kc. Adjust the oscilloscope and test oscillator controls to show a single overall resonance curve of the signal I.F. channel on the cathode ray tube screen (Fig. 7A). Do not change the test oscillator setting thereafter.

To align the signal I.F. transformer, follow in sequence the same procedure outlined in the sections under "ALIGNMENT PROCEDURE" describing this operation. Instead of aligning for maximum output on an output indicator, the object should be to make the curve symmetrical. If the sweep circuit is so arranged that two symmetrically reversed curves appear on the screen, the curves should be made to coincide by adjusting the I.F. trimmer capacitors.

After alignment of the signal I.F. transformer is completed, remove the base pan shield. Remove the delay voltage temporarily from the AVC rectifier tube by connecting its cathode to ground. Disconnect the cathode ray vertical deflection plates from R-42 and connect between ground and the terminal to which the yellow lead from the AVC I.F. transformer is connected. Adjust each of the two AVC I.F. trimmers until a symmetrical, flat-topped curve similar to Fig. 7C is obtained.

Restore delay bias to the AVC rectifier by removing the connection from its cathode to ground, and again connect the cathode ray vertical deflection plates across R-42. Connect the test oscillator to the grid clip of the 6L7 converter tube. Adjust the converter I.F. trimmers for symmetrical, overlying curves as shown in Fig. 7A, with maximum height (sensitivity), and minimum width (selectivity). This completes the I.F. alignment.

Visual R.F. alignment may be carried out in the same general manner as above by applying a suitable frequency-modulated signal between the antenna and ground terminals of the receiver and connecting the cathode ray vertical deflecting plates across the receiver volume control.

ADJUSTMENT OF DIAL MECHANISM

The dial mechanism is rigidly mounted at one end to the tuning condenser frame by two removable screws, and anchored to the chassis deck at the other end by a rubber-cushioned nut. The dial pointer, station selector knob, and tuning condenser drive drum are interconnected by means of the drive cord and drive cable; the frequency band switch and cylindrical scale by the switch shaft and the scale gears. The precision tuning indicator assembly is mounted independently by two screws to the tuning condenser frame. The tuning meter is fastened to the dial mechanism mounting plate with two other screws.

1. *Position of Drum on Condenser Shaft*

With set screws (5) loosened and tuning condenser plates fully engaged, place the drum in the position shown in Fig. 8. The drum should be located on the tuning condenser shaft so as to be in line with the drive cord pulleys (1/16 in. from the dial mechanism mounting bracket) and so that, with condenser plates fully engaged, guide (50) occupies the position shown in Fig. 8.

2. *Removing and Replacing Scale*

Pry out fastener (40) and remove the scale by lowering the fastener end below the mounting ear. Take the scale out of cap assembly (29). Replace by placing tabs of caps (29) and (30) in slots of scale. Replace fastener (40).

3. *Removing and Replacing Band Switch Shaft*

To remove the band switch shaft with the "Sentry Box" assembled in place, the dial scale cap and gear must be removed. This is done by removing the cylindrical scale as in paragraph 2. Then loosen set screws (9) and remove cap (29), spring (7), and gear (8).

When replacing the switch shaft, note that the shaft will fit the switch gang slots in only one position; turn the shaft before inserting so that the locating button will pass through the keyed side of the slots. Note also that the brass bearing just behind the switch shaft gear determines the forward position of the gear. Insert the bushing just far enough into the index plate hub so that the shaft gear meshes snugly with the scale gear, then tighten the set screw.

4. *Locating Scale*

Loosen the two gear set screws (9). Rotate the scale backward until there is slight tension on spring (7) with the pointer indicating on the Band "A" scale. With the frequency band switch in the Band "A" position, place gear (8) in mesh with the gear on part (6) and tighten the two set screws (9).

5. *Replacing Drive Cord and Drive Cable*

The position of the dial scale pointer with respect to the tuning condenser drum is held fixed by a special metal braid cable (12) connecting the drum with guide (50). Tension is maintained on the cable through the drum spring (13) and drive cord (11). To replace either the drive cable or the drive cord, remove the dial scale for convenient access to guide (50). Unhook spring (13) from its drum tab to release tension. Unhook the cable or cord from guide (50) and unwind from the pulleys and drum. To replace the cable or cord, rethread to agree with Fig. 8, and rehook drum spring (13) as shown.

6. *Replacing Reduction Drive*

To replace the reduction drive, unhook spring (18), loosening the drive cord. Unscrew nut (47) and remove drive. Replace with new drive and rehook drive cord.

7. *Setting Scale Pointer*

The scale pointer is soldered to the slider (50). To set the pointer mechanically, turn the tuning condenser rotor so that the plates are fully engaged, and solder the pointer to indicate a point 3/32 in. to the left of the extreme left-hand mark on the Band "B" scale.

8. *Replacing Dial Lamps*

The dial lamp sockets are easily accessible by lifting them clear of the dial mechanism. Lamps may then be replaced in their sockets. After replacing lamps, slide the socket clip back onto the mounting bracket. Be sure the sockets are quite clear of other metal parts. The tuning meter lamp is easily replaced by merely unscrewing it from its socket at the rear of the meter.

9. *Replacing Tuning Meter*

In case of damage to or defect within the tuning meter (24), the meter should be replaced rather than an attempt made to repair it. The meter is replaceable as a unit by removing its two mounting screws and unsoldering the meter leads and meter lamp leads.

10. *Precision Tuning Indicator*

The precision tuning indicator dial and gear assembly is illustrated at the left of Fig. 8. This assembly is removable as a unit by removing the two mounting screws which fasten its bracket (14) to the tuning condenser frame. The dial and pinion assembly (20) is held on its shaft by a small horseshoe spring washer which should be pried off to replace this assembly. The drive gear (17) and backlash gear (36) may be removed by loosening the set screws on collars (44) and (45), which hold them in place.

When replacing the complete precision tuning assembly, the tuning condenser plates should be fully disengaged. Refasten the assembly to the tuning condenser frame, but before tightening the mounting screws, and before meshing the drum gear sector with the precision dial drive gear, place an initial tension on the backlash spring (16) by rotating the precision dial about two revolutions clockwise from the position in which the spring holds it when unwound. Maintaining this tension on the backlash spring, mesh the gears and tighten the mounting bolts with the precision dial indicating zero when the horizontal dial pointer indicates the extreme right-hand scale mark on the Band "D" scale.

11. *Electrical Connection of Tuning Mechanism to Chassis*

This is effected by a short length of tinned copper braid with two washer connection lugs. These should be securely screwed down.

METHOD OF SERVICE PROCEDURE—SENTRY BOX

The "Sentry Box" assembly includes the tuning condenser and dial mechanism as well as the coil and switch compartments. The complete unit may be dismounted from the chassis by removing the side-fastening bolts, unscrewing the dial mechanism anchoring nut and unsoldering the leads to the chassis from the terminal strips.

In order to remove the compartment shield cans it is necessary to take out the frequency band switch shaft. With the "Sentry Box" dismounted from the chassis the dial gears may be disengaged and the switch shaft removed merely by lifting the reduction drive end of the dial assembly, allowing the switch shaft gear to pass the dial scale cap shaft. With the "Sentry Box" mounted in place, removal of the switch shaft requires removing the dial scale gear and cap shaft as outlined in the section covering "Adjustment of Dial Mechanism."

Each compartment shield can houses a bracket assembly comprising the coils, band switch and other component parts associated with that particular circuit. With the band switch shaft out, any shield may be easily removed by unscrewing the two mounting stud nuts ("Y", Fig. 6).

In most cases, coils or Permaliner trimmer capacitors may be replaced merely by removing their particular shield can. It is an easy matter, however, to remove each complete bracket assembly by taking out the mounting screws ("X", Fig. 6) and unsoldering the bus or braid connections to the tuning condenser. In the case of the R.F. or oscillator units it will also be necessary to unsolder the external leads to the respective terminal boards of these units.

Permaliner trimmers are replaced by unsoldering the bus lead from the trimmer terminal, and then unsoldering the Permaliner case from its mounting cup. The latter operation may require the use of two soldering irons.

Coils are replaceable by merely unsoldering the coil lugs from the switch lugs. If it is necessary to replace a section of the band switch, however, it will be found expedient to remove the complete bracket and coil assembly for easy access to the switch lugs.

GENERAL ELECTRIC CO.

"Double-Doublet" Antenna System (No. 9500-A) for "All-Wave" Radio Receivers

Description of System

With the advent of "all-wave" radio receivers, the antenna installation became a fundamental rather than incidental problem. Short waves are used primarily because of their ability to travel great distances with relatively low transmitting power. Upon reaching the receiver, therefore, these waves are in general far weaker and fade much more severely than those from stations in the standard broadcast band (540 to 1500 kilocycles). Obviously, the antenna must perform very efficiently in the short-wave spectrum; it must be able to transfer signals to the receiver with negligible loss or *reliable* results will be practically impossible.

Short-wave broadcasting covers a very wide frequency range, being segregated by international agreement into four principal narrow bands located approximately at 19, 25, 31 and 49 meters. For any given length, an antenna will favor certain frequencies and tend to reject others. Antennas of the conventional single-wire type, therefore, are quite unsatisfactory for there is no one length which would operate with any degree of uniformity over the required range. The *double-doublet* antenna system, however, serves the purpose admirably.

As its name implies, this system incorporates two distinct *doublet-type* antennas. The doublets are of different lengths, being tuned to opposite ends of the short-wave broadcast range, and cross-connected so that each compensates for weak points of the other at various intervening frequencies. Signals intercepted by the doublets are fed to the receiver through a balanced, twisted-pair lead-in (hereinafter called the transmission line) and a specially-constructed receiver-coupling transformer. The length of the transmission line and coupling ratio of the transformer are correct to afford proper *electrical matching* for greatest energy transfer.

While natural static is almost negligible in the short-wave spectrum, "man-made" interference is often very severe. Such interference usually is of local origin radiated by the house-wiring or by external electrical apparatus including even the ignition systems of passing automobiles. It is "picked up" mainly by the antenna lead-in and so little or nothing can be done with ordinary types of antennas to prevent annoyance from that source. Doublet antennas, however, are particularly advantageous from a standpoint of noise reduction since the transmission line does not form an active part of the system but serves merely to transfer signals from the doublets to the receiver. In this *double-doublet* system, complete rejection of signals "picked up" along that length is achieved by means of a special shield in the receiver-coupling transformer.

There is yet another consideration involved. With an all-wave receiver, the antenna must not sacrifice performance in the standard broadcast and other low-frequency bands in order to obtain good short-wave reception. At frequencies below 6000 kilocycles, therefore, this antenna system is converted from its *double-doublet* form to one approximating the conventional "T-type" arrangement so that the transmission line acts as part of the effective length. This change-over is performed automatically by an electrical filter circuit built integral with the receiver-coupling transformer.

Installation

Although the design of this *double-doublet* antenna system may appear complicated, the installation is actually very simple. As shown by the main illustration (Figure 1), two fundamental arrangements are possible—that is, either horizontal or vertical suspension. The former is most common and perhaps preferable in that when so arranged, the system exhibits a better signal-to-noise ratio and is highly directional to local pickup. Because of this directional property, the doublets will intercept less and less interference as they are rotated toward a position where the span points toward the source of that interference. The vertical arrangement exhibits no directional effect, but often is advantageous when installation space is restricted.

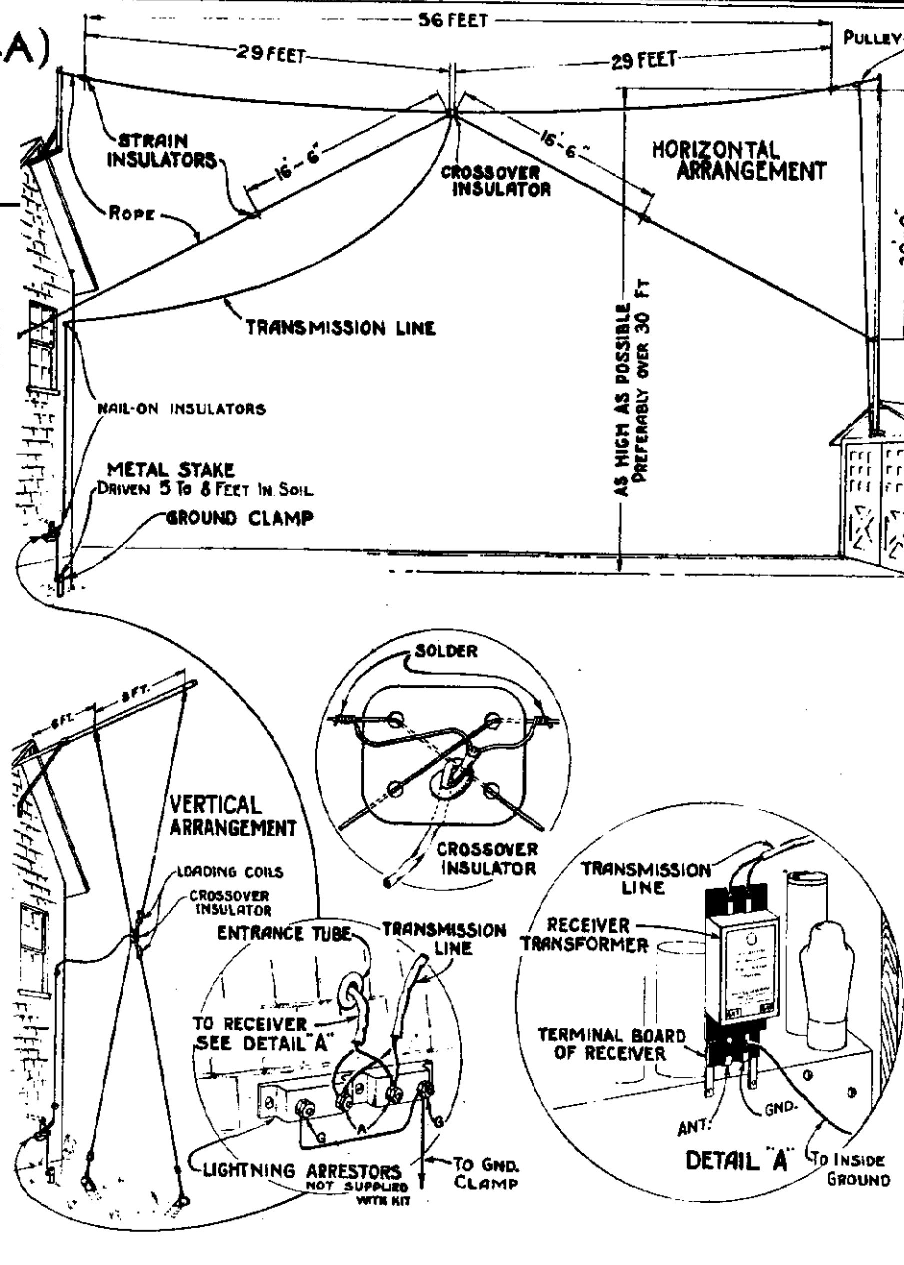

Figure 1—Plan of Installation

MODEL 9500A
Installation Notes
Parts List

GENERAL ELECTRIC CO.

Space Requirements

In its horizontal arrangement, the entire antenna system preferably should lie in one vertical plane as illustrated. This of course requires a straightaway span of approximately 56 feet since the halves of that doublet suspended between the uppermost points of support are each 29 feet long. If sufficient ground space for this purpose is not available, the overall span can be shortened to approximately 30 feet through the use of *loading coils*, as shown in Figure 2. By inserting one coil in each half of the higher doublet, its lengths can be made equal to those of the angular doublet (16½ feet), but the original tuning characteristics of the system will be retained. Loading coils are standard accessories procurable through your dealer.

Obviously, ground space also can be conserved by erecting the antenna so that the halves constitute the sides of a "V." Although this arrangement may eliminate the use of loading coils, it is not as satisfactory in performance and necessitates a third support for the system—that is, at the center. With loading coils, the system suffers a slight loss in efficiency only in the region of 31 meters, whereas the "V"-arrangement exhibits a uniform loss throughout the entire short-wave spectrum. This loss becomes larger as the internal angle of the "V" is decreased, reaching approximately 30 per cent at an angle of 90 degrees. An angle of less than 90 degrees should be avoided.

If ground space is very limited, the vertical form of suspension may be desirable. From a practical standpoint, it is improbable that the full antenna span of 56 feet could be employed except in rare cases. By using loading coils, however, the installation should be fairly simple.

Interference Considerations

Short-wave reception is believed by many to be inherently noisy. This assumption is incorrect since static from natural or atmospheric disturbances is much less severe on the short waves than in the standard broadcast band. Noise on these wavelengths is practically always of local origin and can be eliminated or at least greatly reduced with this *double-doublet* antenna system. To obtain the most benefit from its noise-reducing properties, however, the system should be installed with some forethought. Interference "picked up" by the transmission line cannot affect the receiver. The doublets, therefore, should be erected well remote from sources of interference such as automobile highways, street-railway lines or motor-driven electrical appliances. In some cases, it may be necessary to locate the antenna proper as much as 500 feet distant from the receiver, adding one or more lengths of transmission line as required to the original length. To maintain the correct *electrical matching*, any excess length of transmission line should not be removed unless two or more full lengths have been added. If the required length is less than one or two full lengths, the excess amount should be coiled up neatly at the end nearest the receiver. As this line has a definite known impedance, do not use any random twisted-pair lamp cord for additional length; use only the genuine transmission line sold by your dealer.

Advantage also should be taken of the directional effect of the horizontal arrangement wherever possible. Least interference will be intercepted by the doublets when the span points toward the source of disturbance. This resource will be particularly helpful when the antenna cannot be removed from the field of influence, as in cases where a radio transmitter (such as an amateur station) is operating in the neighborhood.

Set-Up Procedure

Before attempting to set up this *double-doublet* antenna system, the intended plan of assembly should be well understood. First, examine the contents of the kit, referring to the following tabulation and to Figure 1.

Equipment—The following parts are supplied with the kit:

2 Rolls stranded antenna wire (each 46½ feet long).
1 Roll transmission line (80 feet long).
1 Receiver-coupling transformer.
2 Links (for coupling transformer).
1 Crossover insulator.
4 Strain insulators.
2 Nail-on insulators.
1 Entrance-tube insulator.
1 Ground clamp.

Assembly—The two doublet antennas which comprise this system are formed by the two rolls of stranded antenna wire. At the central (crossover) insulator, these wires are crossed to obtain four sections, two for one doublet each 29 feet long and two for the other doublet each 16½ feet long. An extra length of six inches is allowed at each end of the continuous wires for connection to the strain insulator, both (as noted in the preceding paragraph) being 46½ feet long. In threading these wires through the crossover insulator, be careful to have the cross occur on opposite sides of the insulator.

The transmission line is connected to the antenna wires at the junctions of the 29-foot and 16½-foot sections as shown by the enlarged view of the crossover insulator in Figure 1. A tinned spot has been placed on each roll of wire to denote the intended points of connection. When loading coils are employed, connect those coils and the transmission line in accordance with Figure 2. Use only rosin core solder for joints. Finally, attach the strain insulators and suspension ropes, then hang the system as a unit between the masts or intended points of support.

In the horizontal arrangement, it is important to avoid excessive tension in the wires of the higher doublet as breakage may occur. These wires *must not be stretched tightly* but should be allowed to sag so that the crossover insulator is from six to seven feet below the level of the strain insulators. The amount of sag obviously will be governed by the horizontal distance between the strain insulators and will be correct when the latter distance is adjusted to approximately 56 feet (30 feet if loading coils are employed). As an additional safeguard, some slack also should be left in the wires of the lower or angular doublet.

Connection to Receiver—The opposite end of the transmission line is brought to the receiver, using the nail-on insulators and entrance-tube insulator at points best suited to the installation. If lightning arrestors are desirable or required by local ordinance, two (low-capacity) units should be installed as shown in Figure 1. Simply remove a small strip of insulation from the transmission line conductors at the lightning arrestors, connect the bared portions one to each "antenna" terminal and continue on without cutting the transmission line. The ground terminals of the lightning arrestors are made common and connected (by means of the ground clamp furnished) to a metal stake or pipe driven five to eight feet into the soil.

Fasten the receiver-coupling transformer to the "ANT-GND" terminal board on the receiver chassis, using the two links supplied with the kit. Make certain to install the transformer correctly; the links should be attached to those terminals identified as "ANT" and "GND" at bottom of label on metal cover and the label should face outward from rear of receiver. Connect the end of the transmission line to the two terminals at top of transformer, leaving any additional length coiled up behind receiver. Finally, attach a wire from the "GND" link to a water-pipe in the basement or to the external metal stake if employed. The latter connection should be as short as possible and preferably made with No. 14 or larger, rubber-covered, stranded copper wire.

In receivers having no "ANT-GND" terminal board, fasten the coupling transformer to the cabinet as near as possible to the chassis. To insure most noise elimination, the connection from the "GND" terminal of the transformer should be made directly to the chassis metal with a wire no longer than one inch. The connection from the "ANT" terminal to the radio-frequency input circuit of the receiver also should be no longer than necessary, but it is more important to avoid close proximity of this wire to dome (grid) clips of the radio tubes.

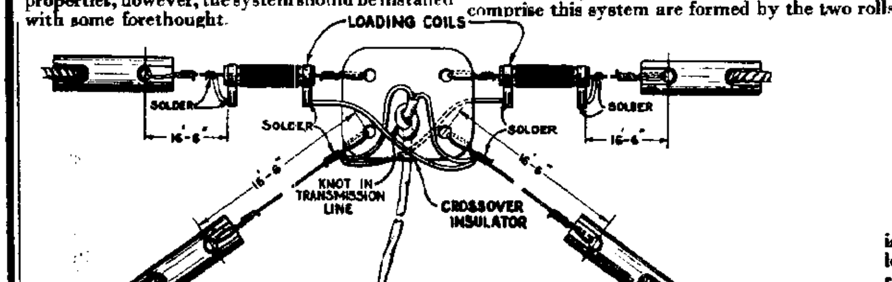

Figure 2—Loading Coil Connections

Replacement Parts

Stock No.	DESCRIPTION	List Price	Stock No.	DESCRIPTION	List Price
4326	Wire (antenna wire consisting of two rolls, each roll 46½ feet long)	$1.16	4759	Transmission line (special lead-in cable—240 feet long)	$10.44
4327	Insulator (antenna crossover insulator)—For replacement purposes only; item to be replaced must be returned with order	.10	4743	Transformer (receiver-coupling transformer)—For replacement purposes only; item to be replaced must be returned with order	2.95
4738	Transmission line (special lead-in cable—80 feet long)	3.48	4753	Link—Connection link—Connects receiver coupling transformer to "Ant-Gnd" terminal board on receiver chassis—Package of 10	.10
4744	Transmission line (special lead-in cable—160 feet long)	6.94	6958	Coils—Doublet loading coils—One pair	.60

Installation Service

Although this *double-doublet* antenna system is not difficult to install, many persons nevertheless prefer to have it erected by an experienced radio serviceman. Such a procedure often is necessary because of physical infirmities, lack of time and various other reasons. Upon request, your dealer or service engineer will make the complete installation at a nominal charge.

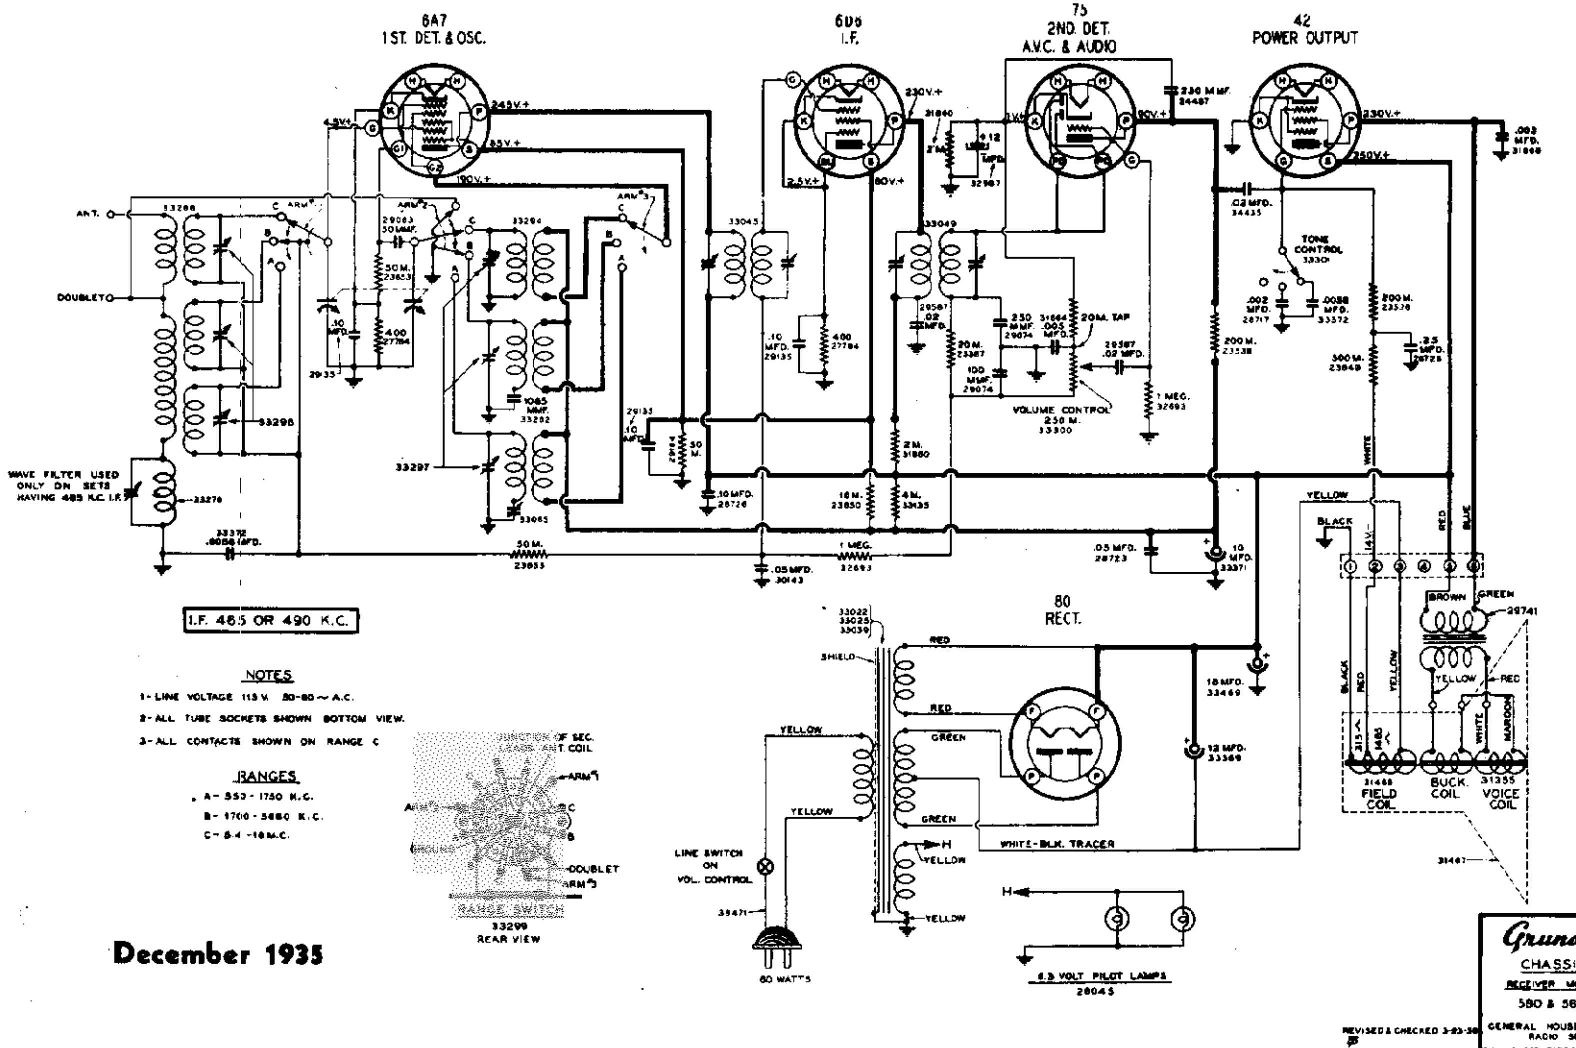
Notes

The GRUNOW 5G Chassis is a Five tube, 115 V-50-60 cycle A.C., three band receiver with A.V.C., Tone Control and a "Band Spread" dial. The tubes used are: 6A7 1st Detector and Oscillator, 6D6 I.F. Amplifier, 75 2nd Detector, A.V.C., and 1st Audio Amplifier, 42 Power Output tube and an 80 Rectifier tube.

The frequency range is divided into three bands or divisions, one covering the band of 550 to 1750 K.C. (A), one the band from 1700 to 5680 K.C. (B), and the other from 5.4 to 18 megacycles (C)



I.F. 465 OR 490 K.C.

SERVICE DATA

CONTINUITY AND VOLTAGE

Continuity and voltage readings should be taken from the underside of the chassis. The values given on the schematic diagram are average and allow the service man to make a quick chect of the chassis constants. The socket layouts given on the schematic diagram show each socket from the underside.

THE RANGE SWITCH

The Range switch is a simple four pole triple throw switch with its contacts in a convenient position over the coil forms allowing operation with very short wire leads.

The 6HB Chassis uses a 4 unit "C" Bias cell in the grid lead of the 30 Audio Driver tube, and a single unit Bias cell in the grid of the 32 A.F. Amplifier tube.

These cells will, in time, have to be replaced, and in so doing, be sure that the carbon (+) side of the cell is connected to the ground side of the cell terminal clip.

An indication of a faulty cell will be distorted tone quality and the quickest check is a substitution of the old cells with new ones. For testing purposes a "C" battery may be used — using a 1½ volt battery in place of the single cell, and a 4½ volt battery in place of the 4 unit cell.

The bias cell has a voltage of about 1.2 volts, but due to their low current output they cannot be measured by any ordinary volt meter.

CIRCUIT ALIGNMENT PROCEDURE

Do not attempt to align the 6HB Chassis without proper equipment. Alignment condensers are shown in the accompanying illustrations, and are numbered in order of procedure.

1. EQUIPMENT:

(A) Test Oscillator.
A modulated Oscillator capable of producing signals at the I.F., Broadcast and Short-Wave frequencies is necessary for alignment of the 6HB Chassis.

(B) Insulated Screw Driver—(All bakelite or fibre) about 6" long.

(C) Output Meter.
This may be any of the standard Output Meters, but should be sufficiently sensitive to provide a good deflection at low signal strength.

(D) Coupling Means.
Coupling Condensers of 200 mmf., .25 mfd., and a 400 Ohm resistor should be used when coupling oscillator to receiver during alignment as specified in the procedure.

(E) The receiver should be aligned in a location free from local interference (interference caused by motors, flashers, automobile ignition, etc.) as high frequency disturbances will cause difficulties when the short wave section is being adjusted. (A screen room is to be recommended.)

2. DIAL SETTING:

Turn dial knob until condensers are fully meshed. The dial pointer (Hour Hand) should be on the horizontal line of the dial, pointing to 9 and 3 o'clock. The minute hand should be at 12 o'clock or in a vertical position.

3. I. F. ALIGNMENT:

(A) Connect signal lead of test oscillator to grid of 1C6 (1st Detector tube) through .25 mfd., condenser. Connect the ground lead to the chassis.

(B) Set Dial Pointer to 1400 K.C. and range switch on position "A".

(C) Place test Oscillator in operation at 465 K.C. Turn receiver volume control and tone control to maximum.

(D) Attenuate test Oscillator output to lowest value, consistent with obtaining a readable indication on output meter.

(E) Adjust four I.F. Trimmers, A1, A2, A3, A4 located on the I. F. Transformers on top of Chassis, Fig. (1), until maximum output is obtained. During alignment, maintain as low a value of signals as will allow obtaining of accurate adjustment.

4. 1400 K.C. ALIGNMENT:

(A) Connect signal lead of test oscillator through 200 mmf., condenser to Antenna binding post.

(B) Connect the test oscillator ground lead to the ground connection of chassis.

(C) Place test oscillator in operation at 1400 K.C.

(D) Turn dial pointer to 1400 K.C.

(E) Turn range switch to range "A".

(F) Adjust broadcast oscillator trimmer A5, Fig. (1), to maximum output.

(G) Adjust 1st Det. Trimmer (A6), Fig. (1), to maximum output.

5. 600 K.C. ALIGNMENT:

(A) Place test oscillator in operation at 600 K.C.

(B) Tune in signal to maximum (this point does not have to be exactly at 600 K.C. dial setting).

(C) Adjust the 600 K.C. Padding Condenser (A7), Fig. (1), (which is on top of Chassis to the rear of variable condenser) in direction of signal increases. At same time rock the tuning condenser back and forth through resonance while adjusting padding condenser until maximum output is obtained.

6. RECHECK 1400 K.C. ALIGNMENT.

7. 5000 K.C. ALIGNMENT:

(A) Set range switch at "B".

(B) Place test Oscillators in operation at 5000 K.C.

(C) Turn Dial Pointer to 5000 K.C.

(D) Adjust Set Oscillator Trimmer (A8), Fig. (1), to maximum output.

(E) Adjust Detector Trimmer (A9) Fig. (1) to maximum output.

8. 18 M.C. ALIGNMENT:

(A) Connect signal lead of test oscillator through 400 Ohm resistor to Antenna binding post of Chassis.

(B) Connect the ground lead to ground connection of Chassis.

(C) Set range switch to range "C" and turn dial pointer to 18 M.C.

(D) Place test oscillator in operation at 18 M.C.

(E) Adjust set Oscillator Trimmer (A10), Fig. (1), to maximum output.

(F) Adjust Detector Trimmer (A11), Fig. (1), to maximum output.

(G) On the 18 M.C. Oscillator Alignment it will be noted that there are two settings at which the signal will be received. Use the lower of the images for aligement point, that is, the setting giving most capacity or the point at which the trimmer screw is farthest in.

GENERAL HOUSEHOLD UTILITIES CO.

MODELS 640,641
Chassis 6J,Revised
Schematic,Voltage

The GRUNOW 6J Chassis is a six tube, 115 V-50-60 cycle A.C., three band receiver with A.V.C., Tone Control and a "Band Spread" dial. The tubes used are: 6A7 1st Detector and Oscillator, 6D6 1st I.F. Amplifier, 6D6 2nd I.F. Amplifier, 75 2nd Detector, A.V.C., and 1st Audio Amplifier, 42 Power Output tube and an 80 Rectifier tube.

The frequency range is divided into three bands or divisions, one covering the band of 550 to 1750 K.C. (A), one the band from 1700 to 5680 K.C. (B), and the other from 5.4 to 18 megacycles (C).

TOP VIEW
FIG. 2

CHASSIS 6J
OCT. 1935
RAS 96

NOTE:—

Due to interference caused by commercial code stations in some locations, it has been necessary to use two different I. F. Frequencies on this Receiver, one of 490 K.C. where code interference is in the neighborhood of 455 K.C. and the other where the interfering stations are operating in the 500 K.C. band, on I. F. of 465 K.C. is used.

The I. F. Frequencies of the Receiver is stamped on the rear of the Chassis, and if there is any doubt as to I. F. peaking, it is only necessary to apply a variable I. F. signal to the I. F. Amplifier, and maximum output will indicate resonance or frequency at which the I. F.'s are peaked.

To further overcome this form of interference, sets peaked at 465, also incorporate a wave filter in the Antenna circuit. This filter should be tuned to the same frequency as the I. F. Transformers. Tuning is accomplished after the set has been completely aligned by applying the I. F. Frequency signal through a 200 mmf. condenser to the Antenna binding post of the Receiver, and tuning the wave-filter condenser, (A14) Fig. 1 (located on the right hand side of the Chassis) so that the incoming signal is at MINIMUM output.

In other words, apply a strong 465 K.C. signal to the Receiver Antenna Post through the 200 mmf. Condenser, and tune wave filter so that the output meter indicates minimum.

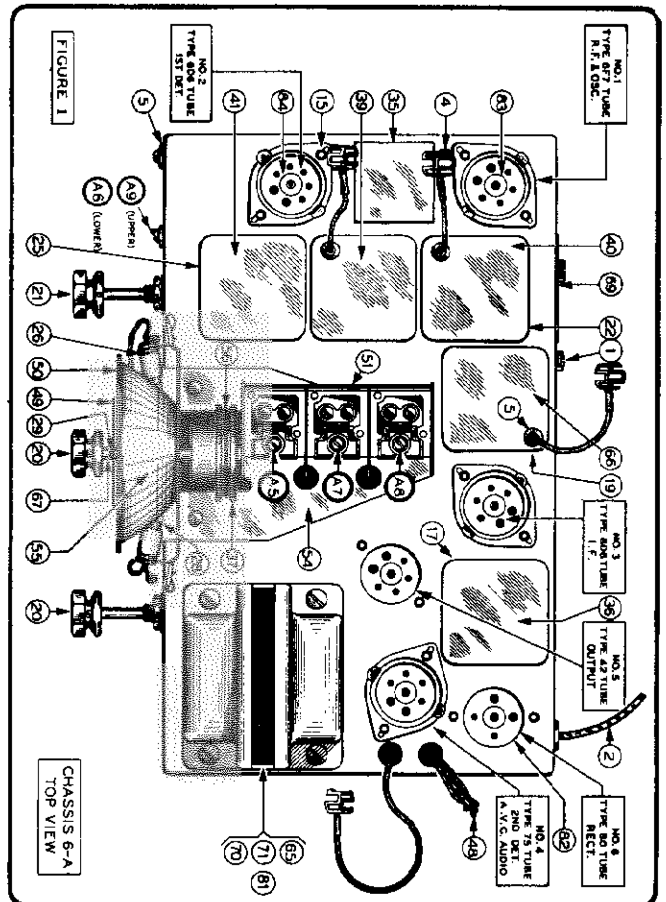

FIGURE 1

CHASSIS 6-A TOP VIEW

The following characteristics apply to the GRUNOW Radio—Chassis 6A:

This model is a 6 tube Super-Hetrodyne Dual Wave (540 to 1500 KC and 1500 to 4200 KC) Receiver using 1-6F7 tube as on R.F. Amplifier and Oscillator, 1-6D6 tube as a 1st Detector, 1-6D6 tube as an I.F. Amplifier, 1-75 tube as a Diode Detector, delayed Automatic Volume Control (AVC) and high gain audio Amplifier. The 42 output tube is a power amplifier pentode and is capable of producing large power output with a relatively small signal input. This tube receives its bias through the voltage drop produced in the tapped speaker field. The rectifier tube is an 80, the output of which is well filtered through the action of the speaker field and the 8 and 18 mfd. electrolytic condensers.

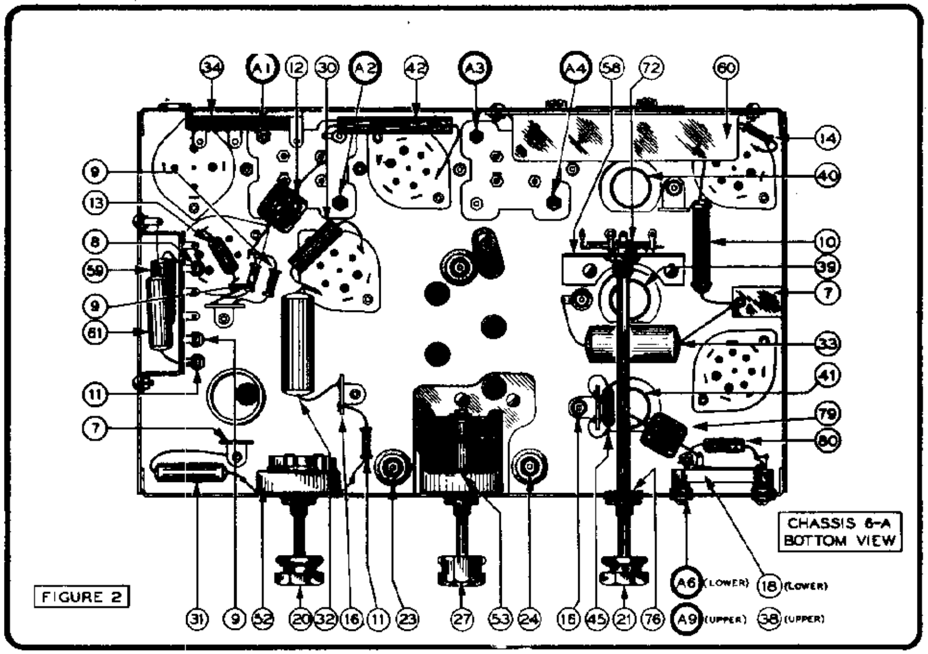

FIGURE 2

CHASSIS 6-A BOTTOM VIEW

ALIGNMENT PROCEDURE

Do not attempt to align the 6A Chassis without the proper equipment. Alignment condensers are shown in the accompanying illustrations and are numbered in order of procedure.

1. EQUIPMENT.

a. Test Oscillator.
A modulated oscillator capable of producing signals at 262 K.C.—600 K.C.—1400 K.C., and 3700 K.C. is necessary for alignment of the 6A Chassis.

b. Output Meter.
This may be any of the standard output meters on the market, but should be sufficiently sensitive to provide a good deflection at low signal strength, and should also incorporate an adjustable shunt so that extremely strong signals may be read.

c. Coupling Means.
Coupling condensers of 200 Mmf., and .25 Mfd. should be used when coupling oscillator to receiver during alignment as specified in the following paragraphs.

2. DIAL SETTING.
Turn dial knob until condensers are fully meshed. The dial pointer should be on the horizontal line of the dial.

3. I. F. ALIGNMENT.

a. Connect signal lead of test oscillator to grid of the 6D6 (First detector tube) through a .25 Mfd. condenser. Connect the ground lead to the Chassis.

b. Set dial pointer to 1400 K.C. and range switch on counter-clockwise (broadcast) position.

c. Place test oscillator in operation at 262 K.C. Turn receiver volume control and tone control to maximum.

d. Attenuate test oscillator output to lowest value consistent with obtaining a readable indication on output meter.

e. Adjust the four I. F. trimmers, (A1-A2-A3-A4) Fig. 2, located on the underside of chassis, until maximum output is obtained. During alignment maintain as low a value of signal as will allow obtaining of accurate adjustment.

4. 3700 K.C. ALIGNMENT.

a. Connect signal lead of test oscillator through 200 mmf. condenser to antenna binding post of chassis.

b. Connect the ground lead to ground terminal of chassis.

c. Set range switch to S.W. range (clockwise position).

d. Place test oscillator in operation at 3700 K.C. and set dial pointer on 3700 K.C.

e. Adjust oscillator trimmer (A5) (front trimmer located on top of variable condenser).

5. 1400 K.C. ALIGNMENT.

a. Turn range switch counter-clockwise to broadcast position.

b. Place test oscillator in operation at 1400 K.C. and set dial pointer at 1400 K.C.

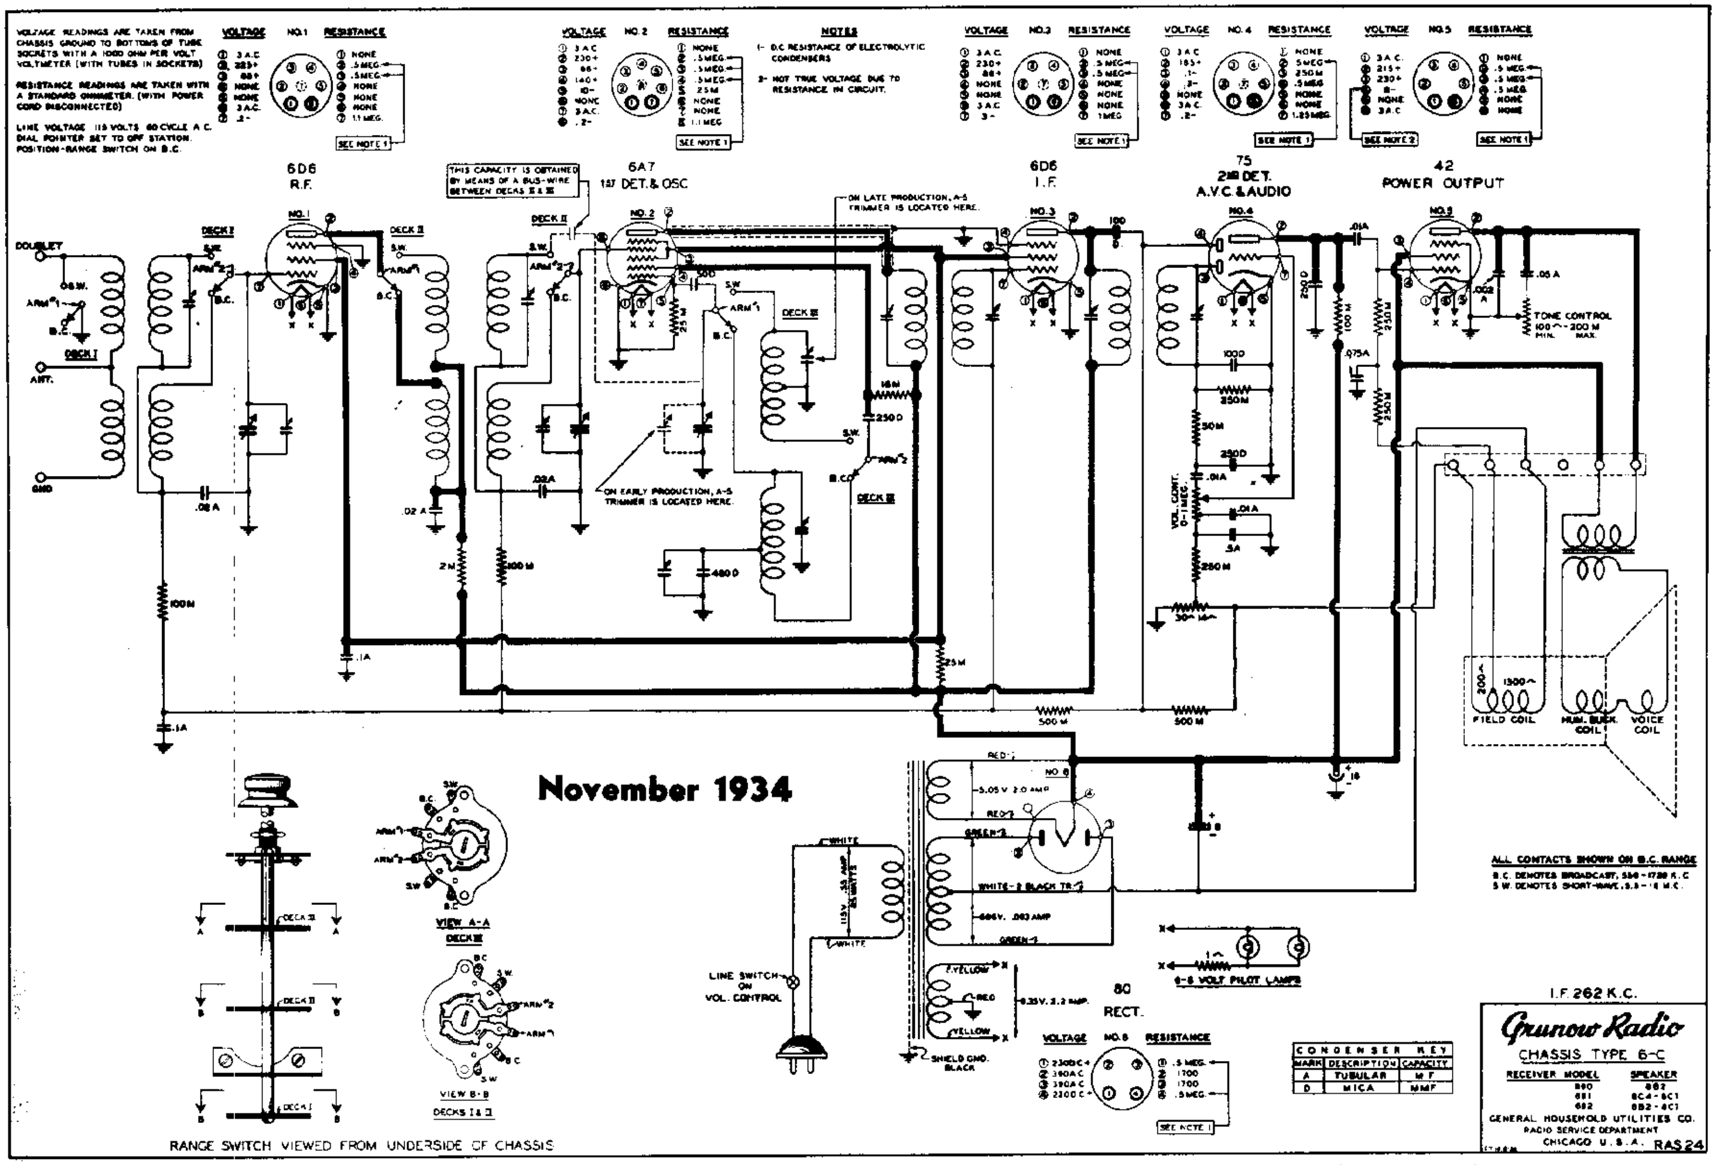
c. Adjust the 1400 K.C. trimmer (A6) located on the front left face of the chassis, the lower of the two at this location.

d. Adjust the second and third trimmers (A7 and A8) on the top of the variable condenser.

e. Repeat the 1400 K.C. alignment at least twice.

GENERAL HOUSEHOLD UTILITIES CO.

MODELS 660, 661, 662
Chassis 6C, Revised
Schematic, Voltage
Resistance, Notes



This model is a 6 tube Super Hetrodyne Short Wave (550 to 1740 K.C. and 5.5 to 16.0 M.C.) Receiver using 1-6D6 (Triple-Grid super-control) tube as an R.F. Amplifier, 1-6A7 (Pentagrid converter) tube as a 1st Detector and Oscillator. 1-6D6 (Triple-grid super-control) tube as an I. F. Amplifier. 1-75 (Duplex-diode high mu triode) tube is used as a Diode Detector or Signal Rectifier, delayed Automatic Volume Control (AVC) and high gain audio amplifier. The 42 output tube is a power amplifier pentode and is capable of producing large power output with a relatively small signal input. This tube receives its bias through the voltage drop produced in the tapped speaker field. The rectifier tube is an 80, the output of which is well filtered through the action of the speaker field and the 8 and 18 mfd. electrolytic condensers.

NOTE:—

Due to interference caused by commercial code stations in some locations, it has been necessary to use two different I. F. Frequencies on this Receiver, one of 490 K.C. where code interference is in the neighborhood of 465 K.C. and the other where the interfering stations are operating in the 500 K.C. band, an I. F. of 465 K.C. is used.

Prices subject to change without notice.

The following is substituted for the 18-mc. alignment in early models.

16 M.C. ALIGNMENT:

(A) Connect signal lead of test oscillator through 400 Ohm resistor to Antenna binding post of Chassis.

(B) Connect the ground lead to ground terminal of Chassis.

(C) Set range switch to range "C" and turn dial pointer to 16 M.C.

(D) Place test oscillator in operation at 16 M.C.

(E) Adjust set Oscillator Trimmer (A10), Fig. (1), to maximum output.

(F) Adjust Detector Trimmer (A11), Fig. (1), to maximum output.

(G) On the 16 M.C. Oscillator Alignment it will be noted that there are two settings at which the signal will be received. Use the lower of the images for alignment point, that is, the setting giving most capacity or the point at which the trimmer screw is farthest in.

SERVICE DATA

CONTINUITY AND VOLTAGE

Continuity and voltage readings should be taken from the underside of the chassis. The values given on the schematic diagram are average and allow the service man to make a quick check of the chassis constants. The socket layouts given on the schematic diagram show each socket from the underside.

THE RANGE SWITCH

The Range switch is a simple four pole triple throw switch with its contacts in a convenient position over the coil forms allowing operation with very short wire leads.

CIRCUIT ALIGNMENT PROCEDURE

Do not attempt to align the 7DB Chassis without proper equipment. Alignment condensers are shown in the accompanying illustrations, and are numbered in order of procedure.

1. EQUIPMENT:

(A) Test Oscillator.
A modulated Oscillator capable of producing signals at the I.F., Broadcast and Short-Wave frequencies is necessary for alignment of the 7DB Chassis.

(B) Insulated Screw Driver—(All bakelite or fibre) about 6" long.

(C) Output Meter.
This may be any of the standard Output Meters, but should be sufficiently sensitive to provide a good deflection at low signal strength.

(D) Coupling Means.
Couplings Condensers of 200 mmf., .25 mfd., and a 400 Ohm resistor should be used when coupling oscillator to receiver during alignment as specified in the procedure.

(E) The receiver should be aligned in a location free from local interference (interference caused by motors, flashers, automobile ignition, etc.) as high frequency disturbances will cause difficulties when the short wave section is being adjusted. (A screen room is to be recommended.)

2. DIAL SETTING:

Turn dial knob until condensers are fully meshed. The dial pointer (Hour Hand) should be on the horizontal line of the dial, pointing to 9 and 3 o'clock. The minute hand should be at 12 o'clock or in a vertical position.

3. I. F. ALIGNMENT:

(A) Connect signal lead of test oscillator to grid of 1C6 (1st Detector tube) through .25 mfd., condenser. Connect the ground lead to the chassis.

(B) Set Dial Pointer to 1400 K.C. and range switch on position "A".

(C) Place test Oscillator in operation at 465 K.C. Turn receiver voleme control and tone control to maximum.

(D) Attenuate test Oscillator output to lowest value, consistent with obtaining a readable indication on output meter.

(E) Adjust four I.F. Trimmers, A1, A2, A3, A4 located on the I. F. Transformers on top of Chassis. Fig. (1), until maximum output is obtained. During alignment, maintain as low a value of signals as will allow obtaining of accurate adjustment.

4. 1400 K.C. ALIGNMENT:

(A) Connect signal lead of test oscillator through 200 mmf., condenser to Antenna Connection.

(B) Connect the test oscillator ground lead to the ground connection of chassis.

(C) Place test oscillator in operation at 1400 K.C.

(D) Turn dial pointer to 1400 K.C.

(E) Turn range switch to range "A".

(F) Adjust broadcast oscillator trimmer A5, Fig. (1), to maximum output.

(G) Adjust 1st Det. Trimmer (A6), Fig. (1), to maximum output.

5. 600 K.C. ALIGNMENT.

(A) Place test oscillator in operation at 600 K.C.

(B) Tune in signal to maximum (this point does not have to be exactly at 600 K.C. dial setting).

(C) Adjust the 600 K.C. Padding Condenser (A7), Fig. (1), (which is on top of Chassis to the rear of variable condenser) in direction of signal increases. At same time rock the tuning condenser back and forth through resonance while adjusting padding condenser until maximum output is obtained.

6. RECHECK 1400 K.C. ALIGNMENT.

7. 5000 K.C. ALIGNMENT:

(A) Set range switch at "B".

(B) Place test Oscillators in operation at 5000 K.C.

(C) Turn Dial Pointer to 5000 K.C.

(D) Adjust Set Oscillator Trimmer (A8), Fig. (1), to maximum output.

(E) Adjust Detector Trimmer (A9) Fig. (1) to maximum output.

8. 18 M.C. ALIGNMENT:

(A) Connect signal lead of test oscillator through 400 Ohm resistor to Antenna connection of Chassis.

(B) Connect the ground lead to ground terminal of Chassis.

(C) Set range switch to range "C" and turn dial pointer to 18 M.C.

(D) Place test oscillator in operation at 18 M.C.

(E) Adjust set Oscillator Trimmer (A10), Fig. (1), to maximum output.

(F) Adjust Detector Trimmer (A11), Fig. (1), to maximum output.

(G) On the 18 M.C. Oscillator Alignment it will be noted that there are two settings at which the signal will be received. Use the lower of the images for alignment point, that is, the setting giving most capacity or the point at which the trimmer screw is farthest in.

SERVICE DATA

CONTINUITY AND VOLTAGE

Continuity and voltage readings should be taken from the underside of the chassis. The values given on the schematic diagram are average and allow the service man to make a quick check of the chassis constants. The socket layouts given on the schematic diagram show each socket from the underside.

THE RANGE SWITCH

The Range Switch is a simple three deck multiple pole, positive acting switch, used to connect the various coils into their proper circuits, and is designed in such a way that the coils being used are isolated from coils of the two succeeding bands of a lower frequency. In the case of the detector circuit both the higher and lower frequency bands, above and below the circuit selected, are shorted out. This switching arrangement not only selects the proper coils for each band, but grounds the unused section, allowing the receiver to work at maximum sensitivity and selectivity on all four ranges.

The Range Switch and Coil Assembly is shown schematically in figure (3) and it will be noted that deck I (Antenna) is the one toward the front of the chassis, deck II (Detector) in the center position and deck III (Oscillator) toward the rear of the chassis. The diagram shows the exact position of the coil and switch lugs, and little difficulty should be experienced in making any necessary repairs or inspection

CIRCUIT ALIGNMENT PROCEDURE

Do not attempt to align the 7C Chassis without proper equipment. Alignment condensers are shown in the accompanying illustrations, and are numbered in order of procedure — I.F. Condensers on top and side of the I.F. Transformers.

1. EQUIPMENT:

(A) Test Oscillator.

A modulated Oscillator capable of producing signals at the I.F., Broadcast, Short-Wave, and weather Band frequencies is necessary for alignment of the 7C Chassis.

(B) Insulated Screw Driver — (all bakelite or fibre) about 6" long.

(C) Output Meter.

This may be any of the standard Output Meters, but should be sufficiently sensitive to provide a good deflection at low signal strength.

(D) Coupling Means.

Coupling Condensers of 200 mmf., .25 mfd., and a 400 Ohm resistor should be used when coupling oscillator to receiver during alignment as specified in the procedure.

(E) The receiver should be aligned in a location free from local interference (interference caused by motors — flashers — automobile ignition, etc.) as high frequency disturbances will cause difficulties when the short wave section is being adjusted. (A screen room is to be recommended.)

2. DIAL SETTING:

Turn dial knob until condensers are fully meshed. The dial pointer (Hour hand) should be on the horizontal line of the dial, pointing to 9 and 3 o'clock.

The minute hand should be at 12 o'clock or in a vertical position.

3. I.F. ALIGNMENT:

(A) Connect signal lead of test oscillator to grid of 6A8 (1st detector tube) through .25 mfd. condenser. Connect the ground lead to the chassis.

(B) Before any adjustment of circuit constants is attempted, allow the chassis to "heat up" to normal operating temperature. This heating period should take from 20 to 30 minutes and is necessary to allow all coils and condensers to reach their normal temperatures so that when alignment is completed, there will be no inductance or capacity changes due to thermal expansion or contraction.

It is good to remember this heating condition when logging station — that is, do not attempt to log or tune in a station previously logged on a "cold" chassis, as the station being tuned in would "drift" and the calibration on the previously logged station would be incorrect.

(C) Set Dial pointer to 1400 K.C. and range switch on "Green" (No. 2) position.

(D) Place test Oscillator in operation at 455 K.C. Turn receiver volume control and tone control to maximum.

(E) Attenuate test Oscillator output to lowest value, consistent with obtaining a readable indication on output meter.

(F) Adjust the five I.F. Trimmers, A1, A2, A3, A4, A5, located on the I.F. Transformers on top of chassis Fig. (1), until maximum output is obtained. During alignment, maintain as low a value of signal as will allow obtaining of accurate adjustment.

4. 175 K.C. ALIGNMENT:

(A) Connect signal lead of test oscillator through 200 mmf. Condenser to Antenna binding post on Chassis.

(B) Connect the test oscillator ground lead to the ground post of chassis.

(C) Place test oscillator in operation at 175 K.C.

(D) Tune in signal to maximum (this point does not have to be exactly at 175 K.C. dial setting) range switch on "Red" (No. 1) position.

(E) Adjust the 175 K.C. Padding Condenser (A6) Fig. 2 (which is on rear of Chassis) in direction of signal increase. At the same time rock the tuning condenser back and forth through resonance while adjusting padding condenser, until maximum output is obtained.

5. 350 K.C. ALIGNMENT:

(A) Place test oscillator in operation at 350 K.C.

(B) Turn dial pointer to 350 K.C.

(C) Turn range switch to "Red" (No. 1) position.

(D) Adjust "weather Band" oscillator trimmer (A7) Fig. 2, to maximum output.

(E) Adjust Detector Trimmer (A8) Fig. 2, to maximum output.

(F) Adjust Antenna Trimmer (A9) Fig. 2, to maximum output.

6. RECHECK 175 K.C. PADDER CONDENSER — See 4 — above.

7. 1400 K.C. ALIGNMENT:

(A) Place test oscillator in operation at 1400 K.C.

(B) Turn dial pointer to 1400 K.C.

(C) Turn range switch to range "Green" (No. 2) position.

(D) Adjust broadcast oscillator trimmer (A10) Fig. 2, to maximum output.

(E) Adjust 1st Det. Trimmer (A11) Fig. 2, to maximum output.

(F) Adjust Antenna Trimmer (A12) Fig. 2, to maximum output.

8. 600 K.C. ALIGNMENT:

(A) Place test Oscillator in operation at 600 K.C.

(B) Tune in signal to maximum (this point does not have to be exactly at 600 K.C. dial setting.)

(C) Adjust the 600 K.C. Padding Condenser (A13), Fig. 2, which is on rear of Chassis, in direction of signal increases. At same time rock the tuning condenser back and forth through resonance while adjusting padding condenser until maximum output is obtained.

9. RECHECK 1400 K.C. ALIGNMENT: See 7 above.

10. 5000 K.C. ALIGNMENT:

(A) Set range switch to "Orange" (No. 3) position.

(B) Place test Oscillators in operation at 5000 K.C.

(C) Turn dial pointer to 5000 K.C.

(D) Adjust Set Oscillator Trimmer (A14), Fig. 2, to maximum output.

(E) Adjust Detector Trimmer (A15) Fig. 2, to maximum output.

(F) Adjust Antenna Trimmer (A16), Fig. 2, to maximum output.

11. 18 M. C. ALIGNMENT:

(A) Connect signal lead of test oscillator through 400 Ohm resistor to Antenna binding post of Chassis.

(B) Connect the ground lead to ground terminal of Chassis.

(C) Set Range Switch to "Amber" (No. 4) position and turn dial pointer to 18 M.C.

(D) Place Test Oscillator in operation at 18 M.C.

(E) Adjust set oscillator Trimmer (A17) Fig. 2, to maximum output.

(F) Adjust Detector Trimmer (A18) Fig. 2, to maximum output.

(G) Adjust Antenna Trimmer (A19) Fig. 2, to maximum output.

(H) On the 18 M.C. Oscillator Alignment it will be noted that there are two settings at which the signal will be received. Use the lower of the images for alignment point, that is, the setting giving most capacity or the point at which the trimmer screw is farthest in.

SERVICE DATA

CONTINUITY AND VOLTAGE

Continuity and voltage readings should be taken from the underside of the chassis. The values given on the schematic diagram are average and allow the service man to make a quick check of the chassis constants. The socket layouts given on the schematic diagram show each socket from the underside.

THE RANGE SWITCH

The Range Switch is a simple three deck multiple pole, positive acting switch, used to connect the various coils into their proper circuits and is designed in such a way that the coils being used are isolated from coils of the two succeeding bands of a lower frequency. In the case of the detector circuit both the higher and lower frequency bands, above and below the circuit selected, are shorted out. This switching arrangement not only selects the proper coils for each band, but grounds the unused section, allowing the receiver to work at maximum sensitivity and selectivity on all four ranges.

The Range Switch and Coil Assembly is shown schematically in figure (3) and it will be noted that deck I (Antenna) is the one toward the front of the chassis, deck II (Detector) in the center position and deck III (Oscillator) toward the rear of the chassis. The diagram shows the exact position of the coil and switch lugs and little difficulty should be experienced in making any necessary repairs or inspection.

CIRCUIT ALIGNMENT PROCEDURE

Do not attempt to align the 8-E Chassis without proper equipment. Alignment condensers are shown in the accompanying illustration, and are numbered in order of procedure — I.F. Condensers on top and side of the I.F. Transformers.

1. EQUIPMENT:

(A) Test Oscillator.

A modulated Oscillator capable of producing signals at the I.F., Broadcast, Short-Wave, and weather Band frequencies is necessary for alignment of the 8-E Chassis.

(B) Insulated Screw Driver — (all bakelite or fibre) about 6" long.

(C) Output Meter.

This may be any of the standard Output Meters, but should be sufficiently sensitive to provide a good deflection at low signal strength.

(D) Coupling Means.

Coupling Condensers of 200 mmf., .25 mfd., and a 400 Ohm resistor should be used when coupling oscillator to receiver during alignment as specified in the procedure.

(E) The receiver should be aligned in a location free from local interference (interference caused by motors — flashers — automobile ignition, etc.) as high frequency disturbances will cause difficulties when the short wave section is being adjusted. (A screen room is to be recommended.)

2. DIAL SETTING:

Turn knob until condensers are fully meshed. The dial pointer (Hour hand) should be on the horizontal line of the dial, pointing to 9 and 3 o'clock.

The minute hand should be at 12 o'clock or in a vertical position.

3. I.F. ALIGNMENT:

(A) Connect signal lead of test oscillator to grid of 6A8 (1st detector tube) through .25 mfd. condenser. Connect the ground lead to the chassis.

(B) Before any adjustment of circuit constants is attempted, allow the chassis to "heat up" to normal operating temperature. This heating period should take from 20 to 30 minutes and is necessary to allow all coils and condensers to reach their normal temperatures so that when alignment is completed, there will be no inductance or capacity changes due to thermal expansion or contraction.

It is good to remember this heating condition when logging station — that is, do not attempt to log or tune in a station previously logged on a "cold" chassis, as the station being tuned in would "drift" and the calibration on the previously logged station would be incorrect.

(C) Set Dial pointer to 1400 K.C. and range switch on "Green" (No. 2) position.

(D) Place test Oscillator in operation at 455 K.C. Turn receiver volume control and tone control to maximum.

(E) Attenuate test Oscillator output to lowest value, consistent with obtaining a readable indication on output meter.

(F) Adjust the five I.F. Trimmers, A1, A2, A3, A4, A5, located on the I.F. Transformers on top of chassis Fig. (1), until maximum output is obtained. During alignment, maintain as low a value of signal as will allow obtaining of accurate adjustment.

4. 175 K.C. ALIGNMENT:

(A) Connect signal lead of test oscillator through 200 mmf. Condenser to Antenna binding post on Chassis.

(B) Connect the test oscillator ground lead to the ground part of chassis.

(C) Place test oscillator in operation at 175 K.C.

(D) Tune in signal to maximum (this point does not have to be exactly at 175 K.C. dial setting) range switch on "Red" (No. 1) position.

(E) Adjust the 175 K.C. Padding Condenser (A6) Fig. 2 (which is on rear of Chassis) in direction of signal increase. At the same time rock the tuning condenser back and forth through resonance while adjusting padding condenser, until maximum output is obtained.

5. 350 K.C. ALIGNMENT:

(A) Place test oscillator in operation at 350 K.C.

(B) Turn dial pointer to 350 K.C.

(C) Turn range switch to "Red" (No. 1) position.

(D) Adjust "weather Band" oscillator trimmer (A7) Fig. 2, to maximum output.

(E) Adjust Detector Trimmer (A8) Fig. 2, to maximum output.

(F) Adjust Antenna Trimmer (A9) Fig. 2, to maximum output.

6. RECHECK 175 K.C. PADDER CONDENSER — See 4 — above.

7. 1400 K.C. ALIGNMENT:

(A) Place test oscillator in operation at 1400 K.C.

(B) Turn dial pointer to 1400 K.C.

(C) Turn range switch to range "Green" (No. 2) position.

(D) Adjust broadcast oscillator trimmer (A10) Fig. 2, to maximum output.

(E) Adjust 1st Det. Trimmer (A11) Fig. 2, to maximum output.

(F) Adjust Antenna Trimmer (A12) Fig. 2, to maximum output.

8. 600 K.C. ALIGNMENT:

(A) Place test Oscillator in operation at 600 K.C.

(B) Tune in signal to maximum (this point does not have to be exactly at 600 K.C. dial setting.)

(C) Adjust the 600 K.C. Padding Condenser (A13), Fig. 2, which is on rear of Chassis, in direction of signal increases. At same time rock the tuning condenser back and forth through resonance while adjusting padding condenser until maximum output is obtained.

9. RECHECK 1400 K.C. ALIGNMENT: See 7 above.

10. 5000 K.C. ALIGNMENT:

(A) Set range switch to "Orange" (No. 3) position.

(B) Place test Oscillators in operation at 5000 K.C.

(C) Turn dial pointer to 5000 K.C.

(D) Adjust Set Oscillator Trimmer (A14), Fig. 2, to maximum output.

(E) Adjust Detector Trimmer (A15) Fig. 2, to maximum output.

(F) Adjust Antenna Trimmer (A16), Fig. 2, to maximum output.

11. 18 M. C. ALIGNMENT:

(A) Contact signal lead of test oscillator through 400 Ohm resistor to Antenna binding post of Chassis.

(B) Connect the ground lead to ground terminal of Chassis.

(C) Set Range Switch to "Amber" (No. 4) position and turn dial pointer to 18 M.C.

(D) Place Test Oscillator in operation at 18 M.C.

(E) Adjust set oscillator Trimmer (A17) Fig. 2, to maximum output.

(F) Adjust Detector Trimmer (A18) Fig. 2, to maximum output.

(G) Adjust Antenna Trimmer (A19) Fig. 2, to maximum output.

(H) On the 18 M.C. Oscillator Alignment it will be noted that there are two settings at which the signal will be received. Use the lower of the images for alignment point, that is, the setting giving most capacity or the point at which the trimmer is farthest in.

DIRECTIONS FOR MECHANICAL ALIGNMENT OF I.F. TRANSFORMERS

FLATS (A) ON THE VERTICAL SHAFTS SHOULD BE MADE PARALLEL WITH EACH OTHER BY ADJUSTING CONNECTING ARM AT (B). TURN THE HIGH-FIDELITY SWITCH CLOCK-WISE AS FAR AS IT WILL GO, (NO. 6 POSITION). IF THE SWITCH DOES NOT TURN TO NO. 6 POSITION, LOOSEN SET SCREW (C) AND TURN SWITCH WITH GEAR LOOSE. WITH SWITCH IN THIS POSITION, MOVE THE LEVER ARMS SO THAT THE FLATS (A) ARE PARALLEL TO THE BACK OF THE CHASSIS BY ADJUSTING LEVER AT (D). TIGHTEN ALL SCREWS AND BE SURE THE SWITCH COVERS ALL SIX POSITIONS EASILY WITHOUT BINDING. NOW PROCEED WITH ELECTRICAL ALIGNMENT.

GENERAL HOUSEHOLD UTILITIES CO.

CIRCUIT ALIGNMENT PROCEDURE

Do not attempt to align the 11C Chassis without the proper equipment. Alignment condensers are shown in the accompanying illustrations and are numbered in order of procedure—I.F. Condensers on top of the I.F. Transformers.

1. EQUIPMENT:

(A) Test Oscillator.

A modulated Oscillator capable of producing signals at the I.F. Broadcast, Short-Wave, and Weather Band frequencies is necessary for alignment of the 11C Chassis.

(B) Insulated Screw Driver—(all bakelite or fibre) about 6" long.

(C) Output Meter.

This may be any of the standard Output Meters, but should be sufficiently sensitive to provide a good deflection at low signal strength.

(D) Coupling Means.

Coupling Condensers of 200 mmf., .25 mfd., and a 400 Ohm resistor should be used when coupling oscillator to receiver during alignment as specified in the procedure.

(E) The Receiver should be aligned in a location free from local interference (interference caused by motors—flashers—automobile ignition, etc.) as high frequency disturbances will cause difficulties when the short wave section is being adjusted. (A screen room is to be recommended.)

2. DIAL SETTING:

Turn dial knob until condensers are fully meshed. The dial pointer (Hour Hand) should be on the horizontal line of the dial, pointing to 9 and 3 o'clock. The minute hand should be at 12 o'clock or in a vertical position.

3. I.F. ALIGNMENT:

EXPLANATION

The GRUNOW High-Fidelity system is incorporated in this Chassis and the following procedure must be strictly adhered to:

The I.F. circuit of this chassis is known as an "expanded I.F. system." In order to reproduce programs of a "High-Fidelity nature" it is not only necessary to build an audio system capable of reproducing all the notes of the audio-spectrum at a mean output level, but it is also necessary to build a radio-frequency system that will pass signals without cutting off the sidebands. In other words, the selectivity of the receiver must be broad enough to pass all high-fidelity signals when desired—and be so designed that the selectivity may be increased at will, so that nearby powerful transmitting stations will not interfere with other local or distant stations. This variable selectivity is accomplished by changing the mutual inductance in two of the I.F. Transformers—the coupling being changed by means of a control knob on the front of the receiver, which also acts as a tone control.

This control varies the transformer coupling, giving maximum selectivity on position No. 1, and broadest selectivity and highest fidelity on position No. 6.

When aligning the I.F. transformers see that the control is in position (No. 1) of greatest selectivity.

Fig. No. 1 shows a graphical picture of the results obtained, first with the control on No. 1 position, or maximum selectivity, second, on No. 6 position, showing the selectivity of the receiver broadened to its greatest extent, permitting the higher frequency sidebands to be passed through the selective circuit with the result that tone quality is greatly improved.

It will be noted that both peaks (No. 6) are practically the same height, and that both slopes are symmetrical.

The third curve represents a condition wherein the I.F. transformers are NOT properly peaked, and it will be noted that one peak is proportionately too high and the other has been practically lost. This illustration is shown merely as an example of what to expect when the receiver is not properly aligned.

Before any adjustment of circuit constants is attempted, allow the Chassis to "heat up" to normal operating temperature. This heating period should take from 20 to 30 minutes and is necessary to allow all coils and condensers to reach their normal temperatures so that when alignment is completed, there will be no inductance or capacity changes due to thermal expansion or contraction.

It is good to remember this heating condition when logging stations—that is, do not attempt to log or tune in a station previously logged on a "cold" chassis, as the station being tuned in would "drift" and the calibration on the previously logged station would be incorrect.

(A) Connect signal lead of test oscillator to grid of 6A8 (1st detector tube) through .25 mfd., condenser. Connect the ground lead to the chassis.

(B) Set dial pointer to 1400 K.C. and range switch on "Green" (No. 2) position.

(C) Place test Oscillator in operation at 455 K.C. Turn receiver volume control to maximum and HI-FIDELITY CONTROL to POSITION No. 1, which is the maximum selectivity position.

(D) Attenuate test Oscillator output to lowest value, consistent with obtaining a readable indication on output meter.

(E) Adjust six I.F. Trimmers, A1, A2, A3, A4, A5, A6, located on the I.F. Transformers on top of Chassis, Fig. (5) until maximum output is obtained. During alignment, maintain as low a value of signal as will allow obtaining of accurate adjustment.

(F) Turn the on and off switch clockwise to the Signal Beacon position.

(G) Adjust Signal Beacon trimmer (A7) Fig. 5, which is located on side of I.F. transformer (near dial) to Zero beat with the 455 K.C. incoming signal.

4. 175 K.C. ALIGNMENT:

(A) Connect signal lead of test Oscillator through 200 mmf. Condenser to Antenna binding post on Chassis.

(B) Connect the test Oscillator ground lead to the ground post of Chassis.

(C) Place test Oscillator in operation at 175 K.C.

(D) PLACE HI-FIDELITY CONTROL IN POSITION NO. 2.

(E) Turn range switch to "Red" (No. 1) position.

(F) Tune in signal to maximum (this point does not have to be exactly at 175 K.C. dial setting.)

(G) Adjust the 175 K.C. Padding Condenser (A8) Fig. 6 (which is on rear of Chassis) in direction of signal increase. At same time rock the tuning condenser back and forth through resonance while adjusting padding condenser until maximum output is obtained.

5. 350 K.C. ALIGNMENT:

(A) Place test Oscillator in operation at 350 K.C.

(B) Turn dial pointer to 350 K.C.

(C) Turn range switch to "Red" (No. 1) position.

(D) Place Hi-Fidelity Control in position No. 2.

(E) Adjust "weather band" oscillator trimmer (A9), Fig. 6, to maximum output.

(F) Adjust Detector Trimmer (A10) Fig. 6 to maximum output.

(G) Adjust Antenna Trimmer (A11), Fig. 6 to maximum output.

6. RECHECK 175 K.C. PADDER CONDENSER—See 4—Above.

7. 1400 K.C. ALIGNMENT:

(A) Place test oscillator in operation at 1400 K.C.

(B) Turn dial pointer to 1400 K.C.

(C) Turn range-switch to range "Green" (No. 2) position.

(D) Hi-Fidelity Control remains in No. 2 position.

(E) Adjust broadcast oscillator trimmer (A12) Fig. 6 to maximum output.

(F) Adjust 1st Det. Trimmer (A13) Fig. 6 to maximum output.

(G) Adjust Antenna Trimmer (A14) Fig. 6 to maximum output.

8. 600 K.C. ALIGNMENT:

(A) Place test oscillator in operation at 600 K.C.

(B) Tune in signal to maximum (this point does not have to be exactly at 600 K.C. dial setting).

(C) Adjust the 600 K.C. Padding Condenser (A15), Fig. 6, which is on rear of Chassis, in direction of signal increase. At same time rock the tuning condenser back and forth through resonance while adjusting padding condenser until maximum output is obtained.

9. RECHECK 1400 K.C. ALIGNMENT—See 7—Above.

10. 5000 K.C. ALIGNMENT:

(A) Set Range Switch to "Orange" (No. 3) position.

(B) Place test Oscillators in operation at 5000 K.C.

(C) Turn Dial Pointer to 5000 K.C.

(D) Adjust Set Oscillator Trimmer (A16) Fig. 6 to maximum output.

(E) Adjust Detector Trimmer (A17) Fig. 6 to maximum output.

(F) Adjust Antenna Trimmer (A18) Fig. 6 to maximum output.

11. 18 M.C. ALIGNMENT:

(A) Connect signal lead of test oscillator through 400 Ohm Resistor to Antenna binding post of Chassis.

(B) Connect the ground lead to ground terminal of Chassis.

(C) Set Range Switch to "Amber" (No. 4) position and turn dial pointer to 18 M.C.

(D) Place test Oscillator in operation at 18 M.C.

(E) Adjust set oscillator Trimmer (A19) Fig. 6 to maximum output.

(F) Adjust Detector Trimmer (A20) Fig. 6 to maximum output.

(G) Adjust Antenna Trimmer (A21) Fig. 6 to maximum output.

(H) On the 18 M.C. Oscillator Alignment it will be noted that there are two settings at which the signal will be received. Use the lower of the images for alignment point, that is, the setting giving most capacity or the point at which the trimmer screw is farthest in.

12. ALIGNMENT OF "I.F. REJECTOR FILTER" CIRCUIT:

Due to interference caused by commercial code stations operating on wave lengths near the frequency at which the I.F. amplifiers of this receiver are aligned, an I.F. filter has been incorporated in the antenna circuit to act as a rejector system, thereby lessening the possibility of this form of interference entering the receiver.

The filter should be tuned to the same frequency as the I.F. Transformers, and this operation should be performed after the set has been completely aligned.

(A) Connect signal lead of test oscillator to antenna binding post through a 200 mmf. condenser.

(B) Connect ground lead to ground terminal of chassis.

(C) Set dial pointer to 1400 K.C. and range switch on Green (No. 2) position.

(D) Place test oscillator in operation at 455 K.C.—turn receiver volume control to maximum and Hi-Fidelity control to No. 2 position.

(E) Attenuate test oscillator output so that a fairly strong signal is applied, and tune filter condenser (A22) Fig. (6) so that the output meter indicates a minimum reading.

13. TUNING ACOUSTIC FILTER:

The I.F. system of a Hi-Fidelity receiver is expanded or broadened so that audio frequencies of the higher musical range will be passed through the selective circuits. It is desirous to pass audio frequencies only up to a value of 10,000 cycles, so that the entire musical range may be reproduced, at the same time frequencies above this value must be cut off—so that station noises and atmospheric disturbances are not admitted to the speaker system.

An acoustic filter is incorporated in this chassis, that may be tuned so that frequencies above 10,000 cycles are excluded. This filter is tuned as follows:

(A) After all other adjustments are completed, apply a 10,000 cycle note, produced by an audio oscillator or phonograph frequency record, connecting one of the signal leads to the grids of the 6F8 (1st A.F. tube) and the ground lead to the chassis.

(B) Set Hi-Fidelity control to maximum (No. 6) position.

(C) Attenuate audio signal so as to obtain a good reading on the output meter.

(D) Tune acoustic filter condenser (A23) Fig. (5) until a MINIMUM output is indicated on the output meter.

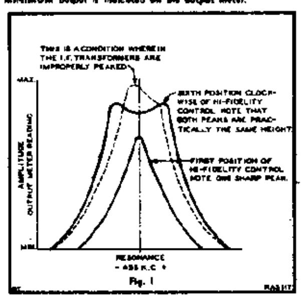

Fig. 1

THE RANGE SWITCH

The Range Switch is a simple three deck multiple pole, positive acting switch, used to connect the various coils into their proper circuits, and is designed in such a way that the coils being used are isolated from coils of the two succeeding bands of a lower frequency. In the case of the detector circuit both the higher and lower frequency bands, above and below the circuit selected, are shorted out. This switching arrangement not only selects the proper coils for each band, but grounds the unused section, allowing the receiver to work at maximum sensitivity and selectivity on all four ranges.

The Range Switch and Coil Assembly is shown schematically in figure (3) and it will be noted that deck I (Antenna) is the one toward the front of the chassis, deck II (Detector) in the center position and deck III (Oscillator) toward the rear of the chassis. The diagram shows the exact position of the coil and switch legs, and little difficulty should be experienced in making any necessary repairs or inspection.

PARTS AND PRICE LIST

Alignment, Notes
Parts List

CIRCUIT ALIGNMENT PROCEDURE

Do not attempt to align the 12A Chassis without the proper equipment. Alignment condensers are shown in the accompanying illustrations and are numbered in order of procedure—I.F. Condensers on top of the I.F. Transformers.

1. EQUIPMENT:

(A) Test Oscillator.

A modulated Oscillator capable of producing signals at the I.F. Broadcast, Short-Wave, and Weather Band frequencies is necessary for alignment of the 12A Chassis.

(B) Insulated Screw Driver—(all bakelite or fibre) about 6" long.

(C) Output Meter.

This may be any of the standard Output Meters, but should be sufficiently sensitive to provide a good deflection at low signal strength.

(D) Coupling Means.

Coupling Condensers of 200 mmf., .25 mfd., and a 400 Ohm resistor should be used when coupling oscillator to receiver during alignment as specified in the procedure.

(E) The Receiver should be aligned in a location free from local interference (interference caused by motors—flashers—automobile ignition, etc.) as high frequency disturbances will cause difficulties when the short wave section is being adjusted. (A screen room is to be recommended.)

2. DIAL SETTING:

Turn dial knob until condensers are fully meshed. The dial pointer (Hour Hand) should be on the horizontal line of the dial, pointing to 9 and 3 o'clock. The minute hand should be at 12 o'clock or in a vertical position.

3. I.F. ALIGNMENT:

EXPLANATION

The GRUNOW High-Fidelity system is incorporated in this Chassis and the following procedure must be strictly adhered to.

The I.F. circuit of this chassis is known as an "expanded I.F. system." In order to reproduce programs of a "High-Fidelity nature" it is not only necessary to build an audio system capable of reproducing all the notes of the audio-spectrum at a mean output level, but it is also necessary to build a radio-frequency system that will pass signals without cutting off the sidebands. In other words, the selectivity of the receiver must be broad enough to pass all high-fidelity signals when desired—and so designed that the selectivity may be increased at will, so that nearby powerful transmitting stations will not interfere with other local or distant stations. This variable selectivity is accomplished by changing the mutual inductance in two of the I.F. Transformers—the coupling being changed by means of a control knob on the front of the cabinet, which also acts as a tone control.

This control varies the transformer coupling, giving maximum selectivity on position No. 1, and broadest selectivity and highest fidelity on position No. 6.

When aligning the I.F. transformers see that the control is in position (No. 1) of greatest selectivity.

Fig. No. 1 shows a graphical picture of the results obtained, first with the control on No. 1 position, or maximum selectivity, second, on No. 6 position, showing the selectivity of the receiver broadened to its greatest extent, permitting the higher frequency sidebands to be passed through the selective circuit with the result that tone quality is greatly improved.

It will be noted that both peaks (Fig. 1) are practically the same height, and that both slopes are symmetrical.

The third graph represents a condition wherein the I.F. transformers are NOT properly peaked, and it will be noted that one peak is proportionately too high and the other has been practically lost. This illustration is shown mainly as an example of what to expect when the receiver is not properly aligned.

Before any adjustment of circuit constants is attempted, allow the Chassis to "heat up" to normal operating temperature. This heating period should take from 20 to 30 minutes and is necessary to allow all coils and condensers to reach their normal temperature so that when alignment is completed, there will be no inductance or capacity changes due to thermal expansion or contraction.

It is good to remember this heating condition when logging stations—that is, do not attempt to log or mark a station previously logged on a "cold" chassis as the station being tuned in would "drift" and the calibration on the previously logged station would be incorrect.

(A) Connect signal lead of test oscillator to grid of 6A8 (1st Detector tube) through .25 mfd. condenser. Connect the ground lead to the chassis.

(B) Set dial pointer to 1400 K.C. and range switch on "Green" (No. 2) position.

(C) Place test Oscillator in operation at 465 K.C. Turn receiver volume control to maximum and HI-FIDELITY CONTROL to POSITION No. 1, which is the maximum selectivity position.

(D) Attenuate test Oscillator output to lowest value consistent with obtaining a readable indication on output meter.

(E) Adjust six I.F. Trimmers, A1, A2, A3, A4, A5, A6, located on the I.F. Transformers on top of Chassis, Fig. (4) until maximum output is obtained. During alignment, maintain as low a value of signal as will allow obtaining of accurate adjustment.

(F) Turn the on and off switch clockwise to the Signal Beacon position.

(G) Adjust Signal Beacon trimmer (A7) Fig. 4, which is located on side of I.F. transformer (near dial) to zero beat with the 465 K.C. incoming signal.

4. 175 K.C. ALIGNMENT:

(A) Connect signal lead of test Oscillator through 200 mmf. Condenser to Antenna binding post on Chassis.

(B) Connect the test Oscillator ground lead to the ground post of Chassis.

(C) Place test Oscillator in operation at 175 K.C.

(D) PLACE HI-FIDELITY CONTROL IN POSITION No. 1.

(E) Turn range switch to "Red" (No. 1) position.

(F) Tune in signal to maximum (this point does not have to be exactly at 175 K.C. dial setting.)

(G) Adjust the 175 K.C. Padding Condenser (A8) Fig. 5 (which is on rear of Chassis) in direction of signal increase. At same time rock the tuning condenser back and forth through resonance while adjusting padding condenser until maximum output is obtained.

5. 350 K.C. ALIGNMENT:

(A) Place test Oscillator in operation at 350 K.C.
(B) Turn dial pointer to 350 K.C.
(C) Turn range switch to "Red" (No. 1) position.
(D) Place Hi-Fidelity Control in position No. 2.
(E) Adjust "weather band" oscillator trimmer (A9), Fig. 5, to maximum output.

(F) Adjust Detector Trimmer (A10) Fig. 5 to maximum output.

(G) Adjust Antenna Trimmer (A11), Fig. 5 to maximum output.

6. RECHECK 175 K.C. PADDER CONDENSER—See 4—Above.

7. 1400 K.C. ALIGNMENT:

(A) Place test oscillator in operation at 1400 K.C.
(B) Turn dial pointer to 1400 K.C.
(C) Turn range switch to range "Green" (No. 2) position.

(D) Hi-Fidelity Control remains in No. 2 position.
(E) Adjust broadcast oscillator trimmer (A12) Fig. 5 to maximum output.

(F) Adjust 1st Det. Trimmer (A13) Fig. 5 to maximum output.

(G) Adjust Antenna Trimmer (A14) Fig. 5 to maximum output.

8. 600 K.C. ALIGNMENT:

(A) Place test oscillator in operation at 600 K.C.
(B) Tune in signal to maximum (this point does not have to be exactly at 600 K.C. dial setting).

(C) Adjust the 600 K.C. Padding Condenser (A15), Fig. 5, which is on rear of Chassis, in direction of signal increase. At same time rock the tuning condenser back and forth through resonance while adjusting padding condenser until maximum output is obtained.

9. RECHECK 1400 K.C. ALIGNMENT—See 7—Above.

10. 5000 ALIGNMENT:

(A) Set Range Switch to "Orange" (No. 3) position.
(B) Place test Oscillators in operation at 5000 K.C.
(C) Turn Dial Pointer to 5000 K.C.
(D) Adjust Set Oscillator Trimmer (A16) Fig. 5 to maximum output.

(E) Adjust Detector Trimmer (A17) Fig. 5 to maximum output.

(F) Adjust Antenna Trimmer (A18) Fig. 5 to maximum output.

11. 18 M.C. ALIGNMENT

(A) Connect signal lead of test oscillator through 400 Ohm Resistor to Antenna binding post of Chassis.

(B) Connect the ground lead to ground terminal of Chassis.

(C) Set Range Switch to "Amber" (No. 4) position and turn dial pointer to 18 M.C.

(D) Place test Oscillator in operation at 18 M.C.

(E) Adjust set oscillator Trimmer (A19) Fig. 5 to maximum output.

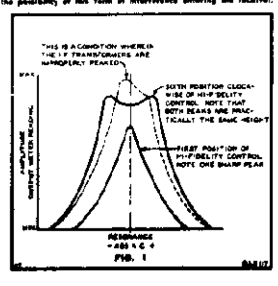
(F) Adjust Detector Trimmer (A20) Fig. 5 to maximum output.

(G) Adjust Antenna Trimmer (A21) Fig. 5 to maximum output.

(H) On the 18 M.C. Oscillator Alignment will be noted that there are two settings at which the signal will be received. Use the lower of the images for alignment point, that is, the setting giving most capacity or the point at which the trimmer screw is farthest in.

12. ALIGNMENT OF "I.F. REJECTOR FILTER" CIRCUIT:

Due to interference caused by commercial code stations operating on wave lengths near the frequency at which the I.F. amplifiers of this receiver are aligned, an I.F. filter has been incorporated in the antenna circuit to act as a rejector system, thereby lessening the possibility of this form of interference entering the receiver.



The filter should be tuned to the same frequency as the I.F. Transformers, and this operation should be performed after the set has been completely aligned.

(A) Connect signal lead of test oscillator to antenna binding post through a 200 mmf. condenser.

(B) Connect ground lead to ground terminal of chassis.

(C) Set dial pointer to 1400 K.C. and range switch on Green (No. 2) position.

(D) Place test oscillator in operation at 465 K.C.—turn receiver volume control to maximum and Hi-Fidelity control to No. 2 position.

(E) Attenuate test oscillator output so that a fairly strong signal is applied, and tune filter condenser (A22) Fig. (4) so that the output meter indicates a minimum reading.

13. TUNING ACOUSTIC FILTER:

The I.F. system of a Hi-Fidelity receiver is expanded or broadened so that audio frequencies of the higher musical range will be passed through the selective circuits. It is desirous to pass audio frequencies only up to a value of 10,000 cycles, so that the entire musical range may be reproduced, at the same time frequencies above this value must be cut off—so that station noises and atmospheric disturbances are not admitted to the speaker system.

An acoustic filter is incorporated in this chassis, that may be tuned so that frequencies above 10,000 cycles are excluded. This filter is tuned as follows:

(A) After all other adjustments are completed, apply a 10,000 cycle note, produced by an audio oscillator or phonograph frequency record, connecting one of the signal leads to the grid of the 6F5 (1st A.F. tube) and the ground lead to the chassis.

(B) Set Hi-Fidelity control to maximum (No. 6) position.

(C) Attenuate audio signal so as to obtain a good reading on the output meter.

(D) Tune acoustic filter condenser (A23) Fig. (4) until a MINIMUM output is indicated on the output meter.

SPEAKER SYSTEM

The 12A Chassis is designed to work into the Grunow triple speaker system. This complete system consists of a dual audio arrangement wherein a two channel audio amplifier is used—one channel comprising a 6F6 tube coupled to two small speakers reproduces the high notes of the musical range and the other channel comprising two types 6F6 tubes in push-pull coupled to a large speaker reproduces the low and middle register of the musical range. If it becomes necessary to replace or change any part of the speaker system, care should be taken to see that the polarity of all transformers, voice coils and tube connections remain as originally connected, otherwise there is a possibility of the speakers working out of "phase," causing one of the speakers to cancel out certain frequency responses of the other.

To determine whether the speakers are in phase—short out the voice coil on the large speaker and reverse the voice coil leads on one of the small speakers, connecting the lead on the small speaker in the position of strongest and best response. Then with the large speaker working with the two small speakers, change the polarity of the large speaker voice coil, connecting it in the position of strongest and best response.

When making this test it is a good idea to have the receiver tuned to a good musical broadcast program.

CONTINUITY AND VOLTAGE

Continuity and voltage readings should be taken from the underside of the chassis. The values given on the schematic diagram are average and allow the service man to make a quick check of the chassis constants. The socket layouts given on the schematic diagram show each socket from the underside.

THE RANGE SWITCH

The Range Switch is a simple three deck multiple pole, positive acting switch, used to connect the various coils into their proper circuits, and is designed in such a way that the coils being used are isolated from coils of the two succeeding bands of a lower frequency. In the case of the detector circuit both the higher and lower frequency bands, above and below the circuit selected, are shorted out. This switching arrangement not only selects the proper coils for each band, but grounds the unused section, allowing the receiver to work at maximum sensitivity and selectivity on all four ranges.

The Range Switch and Coil Assembly is shown schematically in figure (3) of Model 1171, Chassis 11-C and it will be noted that deck I (Antenna) is the one toward the front of the chassis, deck II (Detector) is the center position and deck III (Oscillator) toward the rear of the chassis. The diagram shows the exact position of the coil and switch lugs, and little difficulty should be experienced in making any necessary repairs or inspection.

GRUNOW RADIO

Model 1291--1297

Chassis 12B--12W

Chassis 12-B and 12W are Teledial Receivers and are identical in mechanical and electrical construction except for the audio system. The 12B has two 6F6 tubes in the output and 12W- 2 6L6 tubes. (See note on schematic diagram) Standard practice should be followed for alignment, Trimmer Condenser locations are covered on the diagram and are numbered in order of their procedure.

Alignment

The same standard equipment required in the alignment of other Grunow short wave receivers should be used with these Chassis, in addition to a Galvanometer, such as the the Weston type 699 with a 200 ohm variable wire wound shunt (200 ohm rheostat) to be used in balancing the discriminator circuit.

1. I. F. Alignment - Set signal generator at 465 K. C., connect signal lead to grid of 6A8 oscillator tube thru .05 mfd. condenser. Connect ground lead to chassis. Align I. F. Trimmers, (A1-A2-A3-A4-A5-A6) to maximum output.

NOTE: When adjusting I. F. Trimmers A5-A6 (Discriminator Transformer) very little response will be indicated on output meter, due to the broad tuning of this transformer.

2. Discriminator Alignment - (A) With signal generator connected as above, connect the 30-0-30 (60-0-60 micro amp.) Galvanometer to the two Cathodes of the 6H6 Discriminator tube. (one side of the meter may go to the chassis ground and the other side to the unground cathode.) (B) Turn Power switch to "Dial" position. (C) Attenuate signal Generator to maximum output being sure the frequency remains at exactly 465 K. C. (D) With an insulated screw driver (no metal) back off trimmer screw of Discriminator Secondary (A5 or A6) (see note) until trimmer is wide open.

NOTE: The Primary and Secondary of the discriminator Transformer may be in the reverse to that shown on the drawing - check this polarity by touching the trimmer screws with a metal screw driver - when the metal comes in contact with the screw on the secondary trimmer the Galvanometer pointer will fluctuate. Use only a NON-METALLIC screw driver for alignment.

(E) Adjust Discriminator primary (A5 or A6) to maximum swing of Galvanometer (either positive or negative) (F) Re-align secondary trimmer to position of zero current. Be sure that signal generator has not changed frequency. Do not readjust Primary trimmer unless the entire operation as above is repeated. (G) Vary the I. F. Frequency (Signal Generator) and make sure that discriminator current falls to zero at exact I. F. resonance. Also check to determine the maximum current either side of resonance, that is, one side of resonance will read maximum positive current and the other side will read maximum negative current. Both sides of resonance should read about the same.

3. 1500 K. C. Alignment - (A) Connect signal lead of signal Generator to thru .002 mfd. condenser to the Antenna Binding post. (B) Place Generator signal at 1500 K. C. (C) Turn Dial pointer to 1500 K. C. (D) Range switch to Broadcast position. (E) Adjust B. C. Oscillator trimmer (A7) to maximum output. (F) Adjust B. C. Interstage Trimmer (A8) to maximum output. (G) Adjust B. C. Antenna Trimmer (A9) to maximum output.

4. 600 K. C. Alignment - (A) Place Generator signal to 600 K. C. (B) Dial pointer to 600 K. C. (C) Adjust Padding Condenser (A10) in direction of signal increase and at same time rock tuning condenser thru resonance to maximum output. Dial setting does not have to be exactly 600 K. C.

5. Recheck 1500 K. C. Alignment. See (3) above.

6. 5000 K. C. Alignment - (A) Connect signal lead to Antenna Binding post thru 400 ohm resistor. (B) Set range switch to Police-Amateur position. (C) Place signal in operation at 5000 K. C. (D) Turn dial pointer to 5000 K. C. (E) Adjust Oscillator trimmer (A11) to maximum output. (F) Adjust Interstage Trimmer (A12) to maximum output. (G) Adjust Antenna Trimmer (A13) to maximum output.

7. 18 Megacycle Alignment - (A) Connect signal lead to Antenna Binding post thru 400 ohm resistor. (B) Set range switch to Foreign Short Wave position. (C) Place signal Generator in operation at 18 M. C. (D) Adjust Oscillator Trimmer (A14) to maximum output. (E) Adjust Interstage Trimmer (A15) to maximum output, while rocking tuning condenser thru resonance. (F) Adjust Antenna Trimmer (A16) to maximum output. On the 18 M. C. Oscillator adjustment, use the lower image for alignment, that is the point where the trimmer screw is farthest in.

Chassis 15W
Alignment, Part 1

INTRODUCTION

The Grunow 15-W Chassis is a fifteen Metal tube, 115 Volt, 50-60 cycle A. C., four band receiver with Automatic Volume Control, Variable I. F. system, of Hi-fidelity control, Tone Control, "Band Spread" dial and Automatic Frequency Control with the Teledial. The tubes and their functions are as follows: 1-6K7 R. F. Amplifier, 1-6L7 1st. Detector, 1-6J7 Oscillator, 1-6K7 1st. I. F. Amplifier, 1-6K7 2nd. I. F. Amplifier, 1-6R7 2nd. Detector, A.V.C. and 1st. A. F. Amplifier, 1-6C5 Driver Stage, 1-6F6 H. F. Audio Output, 2-6F6 L. F. Power Output, 1-6K7 Automatic Frequency Control Amplifier, 1-6H6 A. F. C. Discriminator, 1-6J7 A. F. C. Control and 2-5Z4 Rectifiers.

The frequency range is divided into four bands or divisions, one covering the "Standard Broadcast" Band (Green) 550 to 1720 K.C., one the "Police-Amateur" Band (Amber) 1720 to 5500 K.C., one the "Foreign Broadcast" Band (Yellow) 5.5 to 18.20 Megocycles and one the Ultra Short Wave Band (Blue) 17.6 to 72.0 Megocycles.

Continuity and Voltage.

Continuity and voltage readings should be taken from the underside of the chassis. The values given on the schematic diagram are average and allow the service man to make a quick check of the chassis constants. The socket layouts given on the schematic diagram show each socket from the underside.

SERVICE DATE

Speaker System

The 15-W Chassis is designed to work into the Grunow triple speaker system. This complete system consists of a dual audio arrangement wherein a two channel audio amplifier is used- one channel comprising a 6F6 tube coupled to two small speakers reproduces the high notes of the musical range and the other channel comprising two types 6F6 tubes in push-pull coupled to a large speaker reproduces the low and middle register of the musical range. If it becomes necessary to replace or change any part of the speaker system, care should be taken to see that the polarity of all transformers, voice coils and tube connections remain as originally connected, otherwise there is a possibility of the speakers working out of "phase" causing one of the speakers to cancel out certain frequency responses of the other.

To determine whether the speakers are in phase- short out the voice coil on the large speaker and reverse the voice coil leads on one of the small speakers, connecting the lead on the small speaker in the position of strongest and best response. Then with the large speaker working with the two small speakers, change the polarity of the large speaker voice coil, connecting it in the position of strongest and best response.

When making this test it is a good idea to have the receiver tuned to a good musical broadcast program.

CIRCUIT ALIGNMENT PROCEDURE

Do not attempt to align the 15-W Chassis without the proper equipment. Alignment condensers are shown in the accompanying illustrations and are numbered in order of procedure- I. F. Condensers on top of the I. F. Transformers.

1. EQUIPMENT

(A) Test Oscillator.

A modulated Oscillator capable of producing signals at the I.F., Broadcast and Short-Wave Band frequencies is necessary for alignment of the 15-W.

(B) Insulated Screw Driver-(all bakelite of fibre) about 6" long.

(C) Output Meter.

This may be any of the standard Output Meters, but should be sufficiently sensitive to provide a good deflection at low signal strength.

(D) Coupling Means.

Coupling Condensers of 200 mmf., .05 mfd., and a 400 Ohm resistor should be used when coupling oscillator to receiver during alignment as specified in the procedure.

(E) Discriminator meter.

This may be any Galvanometer with sufficient sensitivity to read the current swing of the Discriminator Circuit. A Type #699 Weston Galvanometer or equivalent is recommended. It is further suggested that a variable shunt of approximately 200 ohms (Wire Wound rheostat) be connected across the Galvanometer until approximate balance is reached. The shunt will also act as a safety device and a "keeper" when the meter is not in actual use.

(F) The Receiver should be aligned in a location free from local interference (interference caused by motors-flashers-automobile ignition, etc.) as high frequency disturbances will cause difficulties when the short wave section is being adjusted. (A screen room is to be recommended.)

2. DIAL SETTING

Turn dial knob until condensers are fully meshed. The dial pointer (Hour Hand) should be on the horizontal line of the dial, pointing to 9 and 3 o'clock. The minute hand should be at 12 o'clock or in a vertical position.

3. I. F. ALIGNMENT:

Explanation

The GRUNOW High-Fidelity system is incorporated in this Chassis and the following procedure must be strictly adhered to:

The I. F. circuit of this chassis is known as an "expanded I. F. system". In order to reproduce programs of a "High-Fidelity nature" it is not only necessary to build an audio system capable of reproducing all the notes of the audio-spectrum at a mean output level, but it is also necessary to build a radio-frequency system that will pass signals without cutting off the sidebands. In other words, the selectivity of the receiver must be broad enough to pass all high-fidelity signals when desired- and be so designed that the selectivity may be increased at will, so that nearby powerful transmitting stations will not interfere with other local or distant stations. This variable selectivity is accomplished electrically in the 15-W chassis by a switch in the I. F. transformer circuit, coupling in two of the I. F. Transformers - the coupling being changed by means of a control knob on the front of the receiver which also acts as a tone control. When aligning the I. F. transformers see that the control is in position (No. 3) of greatest selectivity. Fig. No. 3 shows a graphical picture of the results obtained, first with the control on No. 2 position, or maximum selectivity, second on No. 5 position, showing the selectivity of the receiver broadened to its greatest extent, permitting the higher frequency sidebands to be passed through the selective circuit with the result that tone quality is greatly improved. It will be noted that both peaks (No. 5) are practically the same height and that both slopes are symmetrical. The third graph represents a condition wherein the I. F. transformers are NOT properly peaked, and it will be noted that one peak is proportionately too high and the other has been practically lost. This illustration is shown merely as an example of what to expect when receiver is not properly aligned. Before any adjustment of circuit constants is attempted, allow the Chassis to "heat up" to normal operating temperature. This heating period should take from 20 to thirty minutes and is necessary to allow all coils and condensers to reach their normal temperatures so that when alignment is completed, there will be no inductance or capacity changes due to thermal expansion or contraction. It is good to remember this heating condition when logging station- that is, do not attempt to log or tune in a station previously logged on a "Cold" chassis as the station being tuned in would "drift" and the calibration on the previously logged station would be incorrect.

(A) Connect signal lead of test oscillator to grid of 6L7 (1st Detector tube) through .05 mfd., condenser. Connect the ground lead to the chassis.

(B) See that both loud speaker plugs are firmly in their sockets. Turn Power Switch to "STD." (No. 5) position.

(C) Set dial pointer to 1500 K. C. and range switch on Broadcast position.

(D) Place test Oscillator in operation at 455 K. C. Turn receiver volume control to maximum and HI-FIDELITY CONTROL to POSITION No. 3 which is maximum selectivity position.

(E) Attenuate test Oscillator output to lowest value, consistent with obtaining a readable indication on output meter.

(F) Adjust six I. F. Trimmers, A1, A2, A3, A4, A5, A6, located on the I. F. Transformers on top of Chassis until maximum output is obtained. During alignment, maintain as low a value of signal as will allow obtaining of accurate adjustment.

4. Discriminator Alignment

(A) With the Test Oscillator connected as above connect the 30-0-30 (60-0-60 Micro-Amp.) Galvanometer to the two Cathodes of the 6H6 Discriminator Tube. (one side of the meter may go to the chassis ground and the other side to the Cathode marked K2 on the schematic drawing.)

(B) Turn Power switch to Dial (No. 2) position.

(C) Attenuate Test Oscillator to maximum output being sure that the frequency remains at exactly 455 K. C.

(D) With an insulated screw driver (No Metal) back off trimmer screw of Discriminator Secondary (A7) until trimmer is wide open.

(E) Adjust trimmer (A8)-Discriminator primary to maximum swing of Galvanometer (either positive or negative).

(F) Re-align secondary trimmer (A7) to position of no current (0). Be sure that test oscillator has not been changed and that signal is 455 K. C. Do not readjust Primary trimmer (A8) unless the entire operation as outlined above is repeated.

(G) Vary the I. F. frequency (Test Oscillator) and make sure that discriminator current falls to "0" at exact I. F. resonance. Also check to determine the maximum current either side of resonance, that is, one side of resonance will read maximum positive current and the other side will read maximum negative current. Both sides of resonance should read about the same.

Note - The Primary and secondary of the Discriminator Transformer may be in the reverse to that shown on the drawing - check this polarity by touching the trimmer screws with a metal screw driver. When the metal comes in contact with the

MODEL 1541
Chassis 15W
Alignment, Part 2

GENERAL HOUSEHOLD UTILITIES CO.

The Range Switch

The Range Switch is a simple four deck multiple pole, positive acting switch, used to connect the various coils into their proper circuits, and is designed in such a way that the coils being used are isolated from coils of the two succeeding bands of a lower frequency. In the case of the detector circuit both the higher and lower frequency bands, above and below the circuit selected, are shorted out. This switching arrangement not only selects the proper coils for each band, but grounds the unused section, allowing the receiver to work at maximum sensitivity and selectivity on all four ranges. The Range Switch and Coil Assembly is shown schematically in fig. (2) and it will be noted that deck I (Lights) is the one toward the front of the chassis Deck II (Antenna) is the second position, Deck III (Detector) in the center and followed by Deck IV (Oscellator). The diagram shows the exact position of the coil and switch lugs, and little difficulty should be experienced in making any necessary repairs or inspection.

screw on the secondary trimmer the Galvanometer pointer will fluctuate. (use only a non-metallic screw driver for alignment.)

5. 1500 K. C. Alignment:

(A) Connect signal lead of test Oscillator through 200 Mmf. Condenser to antenna binding post of chassis, and ground lead to chassis ground.
(B) Place test oscillator in operation at 1500 K. C.
(C) Turn dial pointer to 1500 K. C.
(D) Turn range switch to Broadcast position.
(E) Turn Hi-Fidelity Control to No. 3 position.
(F) Adjust Broadcast oscillator trimmer (A9) to maximum output.
(G) Adjust Detector Trimmer (A10) to maximum output.
(H) Adjust antenna Trimmer (A11) to maximum output.

6. 600 K. C. Alignment:

(A) Place test oscillator in operation at 600 K. C.
(B) Tune in signal to maximum (this point does not have to be exactly at 600 K. C. dial setting).
(C) Adjust the 600 K. C. Padding Condenser (A12) which is on rear of Chassis, in direction of signal increases. At same time rock the tuning condenser back and forth through resonance while adjusting padding condenser until maximum output is obtained.

7. Recheck 1500 K. C. Alignment - see 5 - Above

8. 5000 K. C. Alignment:

(A) Set Range Switch to Police - Amateur position.
(B) Place test Oscillator in operation at 5000 K. C.
(C) Turn Dial Pointer to 5000 K. C.
(D) Adjust Set Oscillator Trimmer (A13) to maximum output.
(E) Adjust Detector Trimmer (A14) to maximum output.
(F) Adjust Antenna Trimmer (A15) to maximum output.

9. 18 M. C. Alignment:

(A) Connect signal lead of test oscillator through 400 Ohm Resistor to Antenna binding post of Chassis.
(B) Connect the ground lead to ground terminal of Chassis.
(C) Set Range Switch to "Foreign Broadcast" position and turn dial pointer to 18 M. C.
(D) Place test Oscillator in operation at 18 M. C.
(E) Adjust set oscillator Trimmer (A16) to maximum output.
(F) Adjust Detector Trimmer (A17) to maximum output.
(G) Adjust Antenna Trimmer (A18) to maximum output.
(H) On the 18 M. C. Oscillator Alignment will be noted that there are two settings at which the signal will be received. Use the lower of the images for alignment point that is, the setting giving most capacity or the point at which the trimmer screw is farthest in.

10. Ultra Short Wave Alignment:

(A) With the Test Oscillator connected as above apply a 30 megocycle signal to the receiver. If Test Oscillator will not reach 30 megocycles use harmonic of 15 megocycles.
(B) Turn dial pointer to 30 M. C.
(C) Turn Range switch to Ultra short Wave position.
(D) The U. S. W. oscillator coil is adjusted by moving the length of the coil winding, sticking thru the lug on the range switch. (See Note Fig. 2, Deck IV, OSC.)
(E) The U. S. W. Detector coil is adjusted by moving the turns of wire in and out on the coil form and at the same time rocking the tuning condenser back and forth until maximum output is obtained. The Ultra Short Wave Band should never be adjusted unless tubes are changed or other constants in the circuit have been changed.

11. Alignment of "I.F. Rejector Filter" Circuit:

Due to interference caused by commercial code stations operating on wave lengths near the frequency at which the I. F. amplifiers of this receiver are aligned an I. F. filter has been incorporated in the antenna circuit to act as a rejector system thereby lessening the possibility of this form of interference entering the receiver. The filter should be turned to the same frequency as the I. F. Transformers, and this operation should be performed after the set has been completely aligned.

(A) Connect signal lead of test oscillator to antenna binding post thru a 200 mmf. condenser.
(B) Connect ground lead to ground terminal of chassis.
(C) Set dial pointer to 1500 K. C. and range switch on "Broadcast" position.
(D) Place test oscillator in operation at 455 K. C. - turn receiver volume control to maximum and Hi-Fidelity control to No. 3 position.
(E) Attenuate test oscillator output so that a fairly strong signal is applied, and tune filter condenser (A19) so that the output meter indicates a minimum reading.

12. Tuning Acoustic Filter:

The I. F. system of a Hi-Fidelity receiver is expanded or broadened so that audio frequencies of the higher musical range will be passed through the selective circuits. It is desirous to pass audio frequencies only up to a value of 10,000 cycles, so that the entire musical range may be reproduced at the same time frequencies above this value must be cut off - so that that station noises and atmospheric disturbances are not admitted to the speaker system.

An accoustic filter is incorporated in this chassis, that may be tuned so that frequencies above 10,000 cycles are excluded. This filter is tuned as follows:

(A) After all other adjustments are completed apply a 10,000 cycle note, produced by an audio oscillator or phonograph frequency record, connecting one of the signal leads to the grid of the 6R7 (1st. A.F. tube) and the ground lead to the chassis.
(B) Set Hi-Fidelity control to maximum (No. 5) position.
(C) Attenuate audio signal so as to obtain a good reading on the output meter.
(D) Tune accoustic filter condenser (A20) until a MINIMUM-output is indicated on the output meter.

GOODYEAR SERVICE

NOTE: IN SERIES B THE TYPE 75 WAS REPLACED BY TYPE 6B7, DUPLEX DIODE PENTODE AS A SECOND DETECTOR, A.V.C. AND AUDIO.

Series A and B chassis are serially numbered on the back flange of the chassis, series A beginning with number "5B104021A" and up, series B chassis beginning with number "5D114175B" and up. Series A and B may be identified by the letter "A" and "B" at the end of the serial numbers.

Transformers are available and chassis are sometimes equipped with universal transformers for operation on 40 and 60 cycles and with primary taps for 108, 125, 150, 220 and 250 volts (see instructions) and also sometimes equipped with 25 cycle transformers with 105-115 volt or 220 volt primaries, not universals.

SERVICE NOTES

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt. These voltages are clearly indicated on the circuit diagrams of series A and B.

IN ORDER TO PREVENT SIGNAL FROM ACTING UPON AVC AND AFFECTING ACCURACY OF VOLTAGE MEASUREMENTS, AERIAL AND GROUND LEADS SHOULD BE SHORT CIRCUITED WHILE MAKING MEASUREMENTS.

All voltages are to be measured with 119 volts on the primary of the power transformer.

ALIGNING INSTRUCTIONS

Dummy Antennas

The following dummy antennas are used in aligning both series A and B and are referred to in the following alignment instructions as "Dummy 1", "Dummy 2", and "Dummy 3"

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.

Dummy 2: (Broadcast)—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Intermediate and Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

Resonance Indicator:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer, or by means of an adapter between the plate and screen terminals of the type 42 output tube. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used.

ALIGNMENT PROCEDURE SERIES A ONLY

The following adjustments to be made after the I.F.'s have been aligned as explained above.

BROADCAST BAND ALIGNMENT:

1. With wave changing switch in the broadcast position, extreme left of its rotation, and with external oscillator set at 550 kilocycles and connected in series with "Dummy 2" to the tan antenna and black ground lead, make the following adjustments:
   (a) Adjust broadcast series pad to resonance with oscillator. Keep set in tune with oscillator by slowly rocking to and fro the variable condenser until maximum output is obtained. Note: This adjustment is accessible from the top of the chassis and is located between the variable condenser and the electrolytic condenser. See top view.
   (b) Re-set external oscillator to 1500 K.C., move dial pointer to 1500 K.C. and adjust oscillator (adjustment number 3), R.F. (adjustment number 2) and antenna (adjustment number 1) to resonance. See bottom view for location of these adjustments.
   (c) Repeat adjustments "a" and "b" until sensitivity is at its maximum.

NOTE: IT IS EXTREMELY NECESSARY IN MAKING ALL OF THESE ADJUSTMENTS THAT THE FUNDAMENTAL OSCILLATOR SIGNAL BE TUNED IN AND NOT THE IMAGE FREQUENCY WHICH WILL FALL BELOW THE FUNDAMENTAL.

SHORT WAVE BAND ALIGNMENT:

1. With wave changing switch in the short wave position, extreme right of its rotation, and with external oscillator set at 17 megacycles and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:
   (a) Move dial pointer to 17 megacycles and adjust short wave oscillator (adjustment number 8), short wave R.F. (adjustment number 7) and short wave antenna (adjustment number 6) to resonance.
   (b) Re-set external oscillator to 6 megacycles and pick up signal by rotating variable condenser and check for sensitivity.

INTERMEDIATE BAND ALIGNMENT:

1. With wave changing switch in the intermediate position center of its rotation, and with external oscillator set at 5 megacycles and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:
   (a) Move dial pointer to 5 megacycles and adjust intermediate wave oscillator (adjustment number 9), intermediate wave R.F. (adjustment number 5) and intermediate antenna (adjustment number 4) to resonance.
   (b) Re-set external oscillator to 1800 K.C. and pick up signal by rotating variable condenser and check for sensitivity.
   (c) Re-check broadcast sensitivity as outlined under "Broadcast Band Alignment".

Series "A" chassis have no intermediate band series oscillator pad adjustment.

ALIGNMENT PROCEDURE SERIES B ONLY

The following adjustments to be made after the I.F.'s have been aligned as explained above.

BROADCAST BAND ALIGNMENT:

1. With wave changing switch in the broadcast position, extreme left of its rotation, and with external oscillator set at 600 kilocycles and connected in series with "Dummy 2" to the tan antenna and black ground lead, make the following adjustments:
   (a) Adjust broadcast series pad to resonance with oscillator. Keep set in tune with oscillator by slowly rocking to and fro the variable condenser until maximum output is obtained. Note: This adjustment is accessible from the top of the chassis and is located between the variable condenser and the electrolytic condenser. See top view.
   (b) Re-set external oscillator to 1400 K.C., move dial pointer to 1400 K.C. and adjust oscillator (adjustment number 3), R.F. (adjustment number 2) and antenna (adjustment number 1) to resonance. See bottom view for location of these adjustments.
   (c) Repeat adjustments "a" and "b" until sensitivity is at its maximum.

NOTE: IT IS EXTREMELY NECESSARY IN MAKING ALL OF THESE ADJUSTMENTS THAT THE FUNDAMENTAL OSCILLATOR SIGNAL BE TUNED IN AND NOT THE IMAGE FREQUENCY WHICH WILL FALL BELOW THE FUNDAMENTAL.

SHORT WAVE BAND ALIGNMENT:

1. With wave changing switch in the short wave position, extreme right of its rotation, and with external oscillator set at 17 megacycles and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:
   (a) Move dial pointer to 17 megacycles and adjust short wave oscillator (adjustment number 8), short wave R.F. (adjustment number 7) and short wave antenna (adjustment number 6) to resonance.
   (b) Re-set external oscillator to 6 megacycles and pick up signal by rotating variable condenser and check for sensitivity.

INTERMEDIATE BAND ALIGNMENT:

1. With wave changing switch in the intermediate wave position, center of its rotation, and with external oscillator set at 1800 K.C. and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:
   (a) Rotate variable condenser to approximately 1800 K.C., tune in oscillator signal and adjust M.W. series pad (see top view) to resonance. Slowly rock condenser to and fro while making this adjustment to be sure maximum output is obtained.
   (b) Set external oscillator at 5 M.C., rotate condenser, pick up signal and adjust intermediate wave R.F. (adjustment number 5), intermediate wave antenna (adjustment number 4) and intermediate wave oscillator (adjustment number 9) to resonance.
   (c) Re-check broadcast alignment and if it is found necessary to re-adjust either R.F. or antenna trimmers, repeat the 17 M.C. short wave and 5 M.C. intermediate wave adjustments.

ALIGNING I.F. TRANSFORMERS (465 K.C.)

Series A and B.

Series A—Part No. 108-35 Output I.F. Transformer
Series A—Part No. 108-36 Input I.F. Transformer
Series B—Part No. 108-35 Output I.F. Transformer
Series B—Part No. 108-36 Input I.F. Transformer

These I.F. transformers have two adjustments, both of which are accessible from the underside of chassis (see bottom view).

1. With volume control full on, the extreme right of its rotation, and with wave changing switch in the broadcast position, extreme left of its rotation, and with variable condenser set to approximately 1400 kilocycles, make the following adjustments:
   (a) Connect external oscillator set at 465 kilocycles, in series with "Dummy 1", to the control grid cap of the type 6D6 tube, located between the two I.F. transformers, and adjust the output I.F. transformer to resonance.
   (b) With "Dummy 1" still connected, move oscillator output clip from grid of 6D6 to grid cap to 6C6 and adjust input I.F. transformer to resonance.
   (c) With oscillator still connected to 6C6, re-adjust output I.F. transformer.

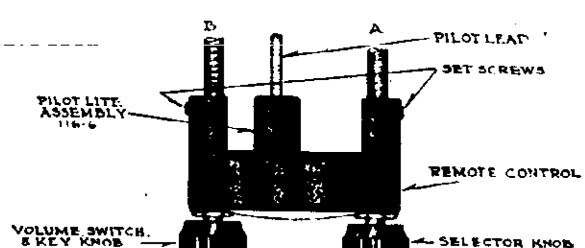
146-12	Steering Column Strap	.15
146-25	Dash Mounting Bracket	.15
147-3	Selector Control Bushing for 112-39 shaft	.10
147-4	Volume Control Bushing for 112-43-112-85 shaft	.10
149-18	Flexible Volume Control Cable—18"	1.25
149-24	Flexible Volume Control Cable—24"	1.50
150-18	Flexible Selector Cable—18"	1.25
150-24	Flexible Selector Cable—24"	1.50
151-7	Remote Control Head, less flexible shafts, with pilot assemblies and with knobs and mounting hardware	4.90

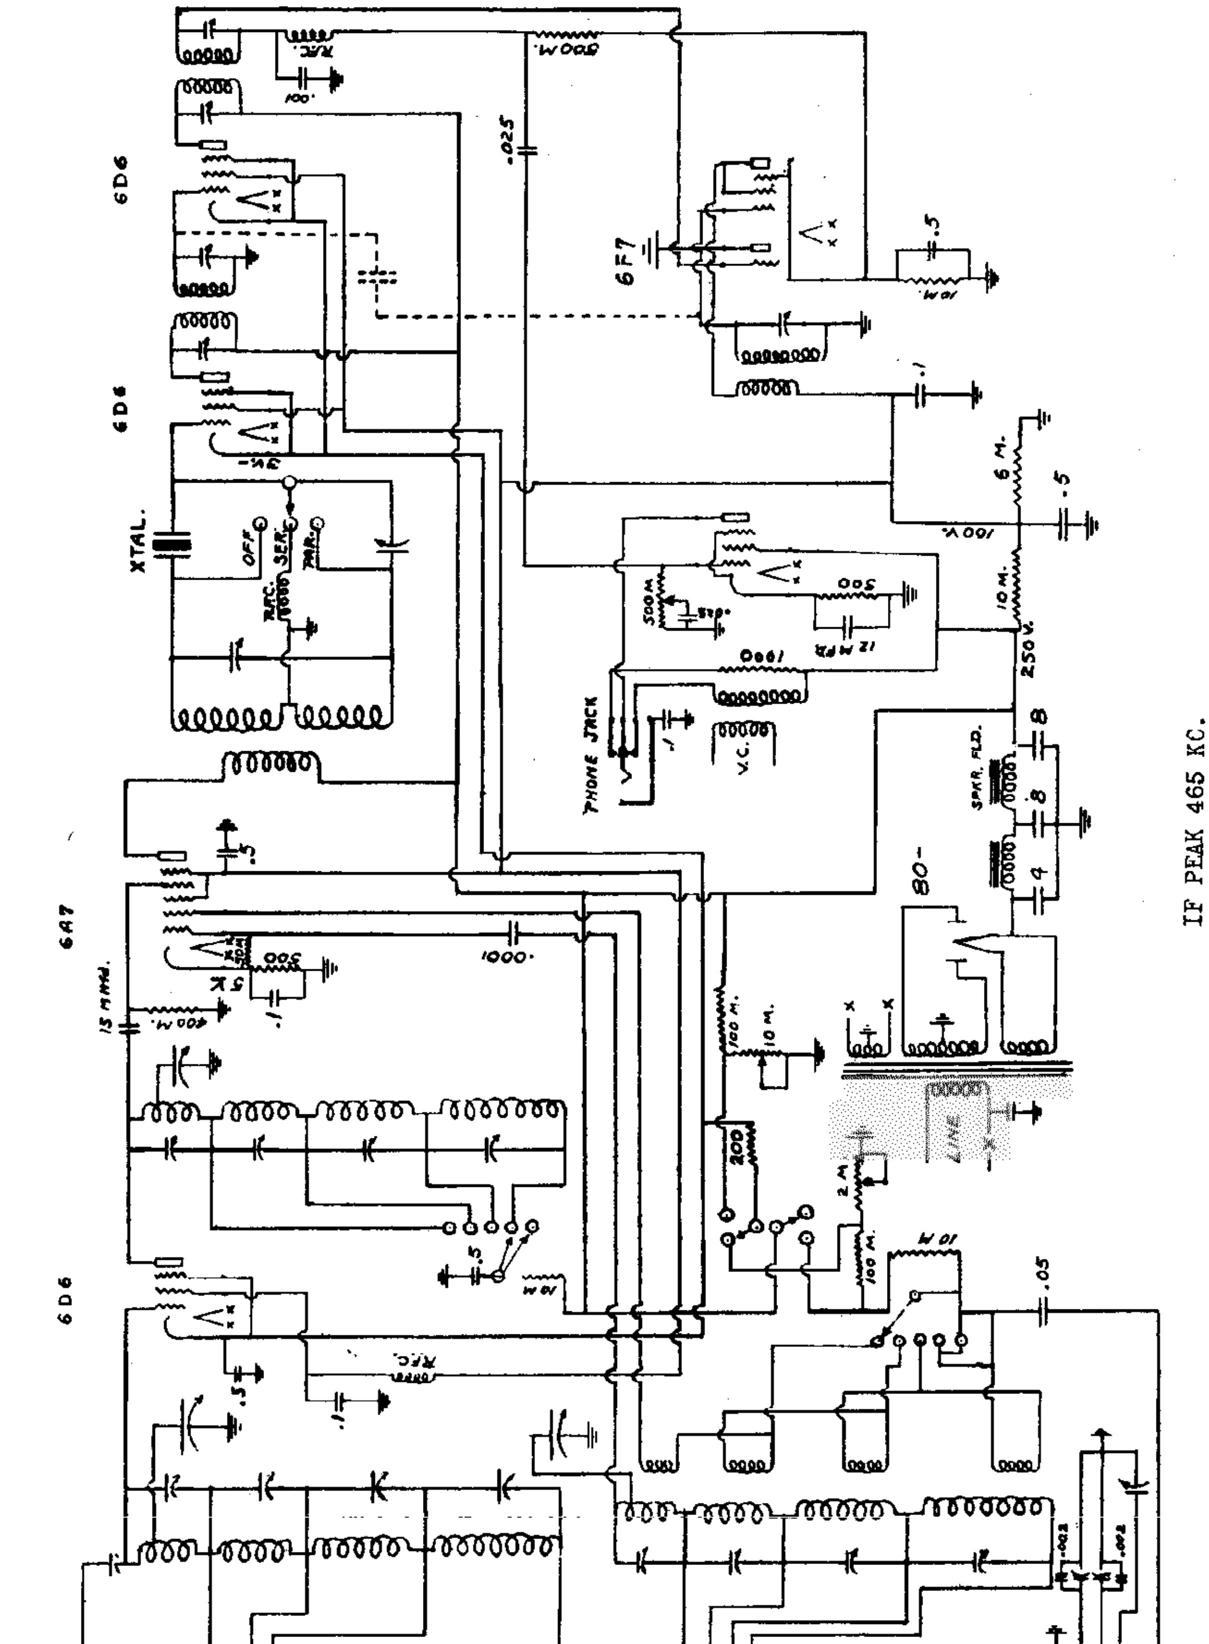
PILOT LIGHT:

Pilot light assembly, part number 116-9, plugs into the set and to the rear of the remote control unit (see illustrations).



HALLICRAFTERS, INC.

MODEL Super Skyrider
Schematic



IF PEAK 465 KC.

MODEL Super Skyrider
Alignment, Socket
Trimmers

HALLICRAFTERS, INC.

ALIGNMENT OF THE SUPER SKYRIDER

Alignment instructions on the Super SKYRIDER are as follows:-

Peak the intermediate frequency transformer at 465 k.c. If a crystal filter is to be used with the receiver, that will have to be aligned with the crystal used to insure maximum results from the filter unit, for although our crystals are held to a very close tolerance, 2 k.c. variation will make considerable difference in the efficiency of the receiver. THEREFORE, THE INTERMEDIATES MUST BE ALIGNED WITH THE CRYSTAL TO BE USED.

This will necessitate a crystal oscillator on the indicating device in the diode circuit of the second detector, preferably a 200 micro ampre meter, so the input I.F. signal can be held as low as possible, to insure the I.F.'s being peaked exactly at resonance. If a 200 micro ampre is not available, a 0 to 1 mil meter can be used with a somewhat higher input signal.

After the I.F.'s have been aligned and rechecked, connect the antenna and ground to the output of the good test oscillator. Set the oscillator for 18 megacycles, then turn the wave band switch to the No. 1 position. Align the oscillator and RF circuit to this point to maximum output. Reset test oscillator and tuning condenser to 12 megacycles and if the receiver does not peak at 12, increase or decrease the length of lead from the low end to the high frequency oscillator coil. This lead is on the last switch head toward the rear of the chassis.

Follow the above instructions for the other three bands, with this exception. Adjust the oscillator pad to the low frequency end of each range to maximum response, rather than to the length of lead. The frequency used in these bands are:

No. 2 range 1100 k.c. to 6000 k.c.
No. 3 range 6000 k.c. to 13,000 k.c.
No. 4 range 2750 k.c. to 1400 k.c.

The alignment procedure will have to follow in this sequence to insure maximum results, that is range No. 1 first, No. 2 second and so forth, since due to the shortening action of the switch, the small trimmer condensers across each coil are cut into the circuit in the rotation.

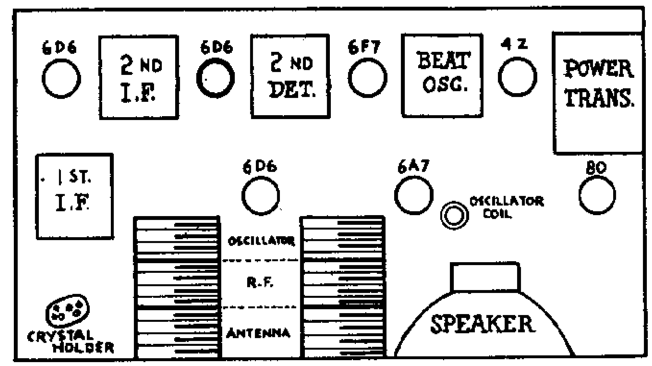
After the receiver has been aligned for maximum results on all ranges, the next step is to adjust the crystal filter circuit, still using a test oscillator to tune in the signal around 3500 k.c. with the crystal filter switch still in the "off" position.

If the test oscillator is modulated, switch the modulation off or place near the carrier signal being received. Turn on the C.W. beat oscillator switch, which is located on the front panel, just below the main tuning condenser. Adjust the trimmer in the rear of the receiver, mounted on the beat oscillator can to the zero beat. Then signal the beat signal to about a 1000 cycle pitch, by tuning the beat oscillator control to the right.

Now, set the crystal filter switch to the center position, which is the series circuit, that is the one used for maximum selectivity and single signal reception. Retune the receiver, preferably using the band spread control through both peaks. One should be strong and the other somewhat lower in volume. On the weaker side, which should be the one to the left of the dial, adjust the crystal phasing condenser, which is mounted above the switch, until the signal disappears, or if a very strong signal is being used, adjust to minimum. Returning to the opposite side, you will find this hasn't been effected at all. By now you can only receive the one side of the signal. Then tune to the maximum point, which should be very sharp and probably a little hard to set, until one has become accustomed to tuning to the crystal notch, which can only come with some practice. Then switch to the series to "off" position. If the crystal has been properly aligned there will be no decrease in sensitivity between these two positions. If there is, recheck your alignment procedure, to make certain that all adjustments have been made properly.

CONNECT TO 110 V 60 CYCLE - UNLESS OTHERWISE SPECIFIED

TUBE AND PARTS PLACEMENT



If by any chance there is a difference in sensitivity between the "off" and series position, adjust the beat oscillator, tuning control slightly until you can find one side which seems to be considerably better in volume than any other. This is the ideal place to set this control.

After all these adjustments have been made, the Super SKYRIDER should be completely aligned and ready to put into operation.

THIS RECEIVER IS SOLD WITH OR LESS CRYSTAL. Since all receivers are sold with the Crystal filter circuit complete with the exception of the crystal, it is a comparatively simple process for any one to incorporate a crystal in the receiver anytime he so desires.

Of course if the crystal is added later the intermediate frequency transformers of the receiver must be aligned to the frequency of the crystal used. This is quite important for maximum results on the series crystal position. The intermediate frequency used is 465 K.C. The receiver may be returned to the factory and we will make the proper adjustments at a nominal cost.

Tubes used are:-

6D6 - PRE SELECTOR
6A7 - 1st DETECTOR - OSC
6D6 - IF
6D6 - IF
6F7 - 2nd DETECTOR - BEAT OSC.
42 - OUTPUT
80 - RECTIFIER

TUBES

The tubes are as follows:- 78 Radio Frequency (Pre-selector)
6A7 1st Detector and Oscillator
78 Intermediate Frequency Amplifier
75 2nd Detector - A.V.C. and Audio Amplifier
6B5 Power Output Tube
6K7 Electron Coupled Beat Oscillator
80 Rectifier

IF PEAK 465 KC.

MODEL S8A
Voltage, Parts
Alignment

HALLICRAFTERS, INC.

To properly align this receiver proceed as follows:- With the input signal from the beat oscillator connected to the grid of the 6A7 tube and set at 465 kc, adjust the I.F. trimmers mounted in the top of the two I.F. transformer cans, to a maximum output reading. Then, with the 465 signal still connected with the modulator off, switch on the beat oscillator and adjust the oscillator pitch control, mounted on the top of the I.F. can and controlled by a black knob to zero beat.

Connect the output of the generator into the antenna and grid terminal with a 400 ohm resistor in series with the antenna lead. Turn the wave change switch to Band No. 1 and set the dial to 15 megacycles. Set the oscillator frequency at 15 megacycles also and adjust the oscillator trimmer mounted in the coil shield under the place - choose the one with the trimmer at the least capacity position, then shift the dial off the frequency and align the RF and antenna trimmers to maximum noise level. This completes the alignment for this point.

Next - tune the receiver to 6000 kc and adjust the low frequency pad, which is located next to the wave change switch to maximum noise level - this trimmer is the one nearest the end switch head.

Follow this procedure for the other ranges, except that in range 3 use a .0001 condenser in place of the resistor, choosing as the alignment frequencies for No. 2 range, 4000 and 1800 kc and for No. 3 Range 1400 and 600 kc. After this is finished the receiver is completely aligned. Never align the No. 3 and No. 2 band first, for when the No. 1 band is aligned the other two will be out.

TUBE VOLTAGES

Sensitivity control at maximum - voltages check to ground.

		PLATE	SCREEN	CATHODE
78	1st R.F.	275	110	3
6A7	Det. Osc.	275 Plate / Osc. 250	110	3
78	I.F.	275	110	3
75	Diode Det. A.V.C. AF Amplifier	150		1½
6K7	Beat Osc.	10	50	0
6A6	Output Tube	270	275	20
80		375		

Weak all bands - check antenna leadin - tubes - voltages I.F. alignment

One Band - Check Switch Points - Leads to Coils - Coils for Continuity.

Hum - Check for Filament Grounded
Filter Condensers
Defective Tubes
Proper Polarization of AC Plug

Set Dead - Check Tubes - Coils - I. F. transformers for voltages and grounds on all circuits.

Weak Audio - Check A.V.C. circuit -6B5 tube - speaker, output trans. and Phone Jack.

Overload - Check A.V.C. tube and circuits - Grids return circuits for grids - alignment.

When service of a highly technical nature is required, get in touch with a competent service man.

To put this receiver into operation on the broadcast range, turn your wave change switch, located under the main tuning control, until the pointer is at Band No. 3 - this is at the extreme left. Next turn your sensitivity to a maximum - your volume up approximately half way and your A.V.C. switch to the "on" position and from any log on broadcast station list, select some frequency which you know is received in your location. Turn the control knob until the black hand corresponds with the number on the dial scale, which is shown on the log.

The dial scale is marked plainly in kc and most station logs are also marked in kc, so this is comparatively simple. Then, with this station being received vary your different controls and familiarize yourself with their action, such as by switching the A.V.C. control on and off and you will notice with extreme volume that the set will overload considerably. However, this can be controlled by reducing the sensitivity control, but on the other hand it cannot be controlled by reducing the volume control, since the volume control is in the audio circuit only and the R.F. circuits in this condition will still overload.

This receiver is equipped with mechanical band spread, which is a dual ratio planetary drive mounted on the main tuning control. This gives a tuning ratio of approximately 65 to 1, which makes it possible by the use of this very high ratio control and the red point to locate and also to separate stations or signals very close together, which you will find is the case in all of the amateur bands and some of the broadcast bands. This type of band spread has an advantage, in that it allows a very good ratio between the main tuning control and the band spread control near the minimum portion of the tuning condenser.

The tuning range of this receiver is as follows:

Band No.1 - Domestic & Foreign S.W. Broadcast
Amateur 40 & 20 Meter Bands
17 to 5.5 megacycles
17000 to 55000 kilocycles

Band No.2 - Amateur 160 & 80 Meter Band -
Police - Aviation
5.4 to 1.65 megacycles
5400 to 1650 kilocycles
55 to 180 meters.

Band No.3 Standard Broadcast Band
1.7 to .54 megacycles
1700 to 540 kilocycles
176 to 555 meters

Each of the above bands are in megacycles, kilocycles and meters. The two shortwave bands are calibrated in megacycles - the broadcast band is calibrated in kilocycles.

OPERATION OF THE RECEIVER

The receiver comes to you in a completely tested condition, with all tubes in their respective sockets, so all that is necessary to plug the A.C. cord into a receptacle and the receiver is ready for operation.

All controls are mounted conveniently on the front panel and identified by their individual markers. The controls mounted on the front panel from right to left are as follows:

STAND-BY-SWITCH

This switch is used to make the receiver inoperative when transmitting and cuts out the plate voltage on the plates of the RF and IF amplifier tubes.

POWER SWITCH AND TONE CONTROL

The power switch is combined with the tone control and operates in a clockwise rotation - that is maximum bass is at extreme right. This control also can be used conveniently to reduce atmospheric interference by reducing the audio frequency range of the receiver. It consisted of a tapered variable resistor, connected from the grid of the power tube to ground with a fixed condenser connected from the variable arm to ground.

BAND CHANGE SWITCH

This switch mounted directly under the tuning control allows any one of the three ranges to be covered by the variable condenser and are marked to correspond with the band marking on the main tuning dial, which are shown at the left center of the dial - for instance if the 40 meter or 7000 kc range is desired, the number on the dial shows this to be band No.1 - then turn the band switch until the pointer is on No. 1.

VOLUME CONTROL

The volume control on this receiver differs somewhat from that on the ordinary broadcast receiver in that it does not affect the sensitivity of the set, but it does control the audio output of the set.

SENSITIVITY CONTROL

The sensitivity control is a special adjustment which controls the sensitivity of

You will find in receiving a straight CW or carrier frequency, which is transmitting code signals, that with the A.V.C. on these signals will have a tendency to run together. This can be eliminated by switching the A.V.C. to the "off" position, which cuts the A.V.C. out of the receiver. By properly adjusting the manual volume control and the sensitivity control, various combinations can be found, which gives the ideal signal to noise ratio for this particular signal being received, where if one alone were used, this would not be possible. This often proves true when listening to foreign broadcast reception. You will find by increasing your manual control to maximum and controlling the output by the sensitivity control only, that it will be possible to reduce the noise to such an extent that the signal will come through very good, where with the A.V.C. on and controlling the output by the volume control only, with the sensitivity in the maximum position, there still will be considerable noise coming through the receiver. This condition of course can only come about by constant use of the receiver and varying controls until one can learn just which position is best for this condition.

The purpose of the "transmit" and "receive" switch is to make the set inoperative when using radio transmitters and need only be used by those operating transmitting stations. The switch does not turn off the radio set entirely. The tubes remain lighted, thereby eliminating the necessity of waiting for the tubes to become hot again when the receiver is to be used. At all other times this switch should always be left in the "on" position.

CIRCUIT

The plate circuit of 6K7 R.F. amplifier has a high inductance plate load which gives maximum transfer by use of capacity coupling at low frequency end of the bands. By use of coupling in C16 this is further increased. The normal characteristics of a coil and condenser are such that the gain varies about 3 to 1 from one end to the other, being maximum at high frequency end. The capacity coupling combines with this to level out the gain in this circuit to get uniformity throughout.

The 6L7 used here as detector-mixer has no parallel in glass tubes. The modulation from the oscillator circuit is supplied to this tube by use of an extra grid. Due to not having oscillator plate current flowing in the first detector, the ratio of translation to noise is considerably better than in composite tubes or in circuits where the cathodes of 2 tubes are connected together.

The 6C5 OSCILLATOR - covers only four bands. The harmonic of No. 4 band is used to supply the oscillator voltage for the conversion of signals to I.F. frequency, when using Band 5. The oscillator circuit is a combination of the Hartley and the Colpitts, having the inherent features of both - the Hartley with the good oscillation at the high frequency ends of bands and the Colpitts where oscillation is better at low frequency ends of bands.

By this method the oscillator generates a fairly constant voltage for impression on grid 3 of 6L7 over the full tuning ranges of the set.

1ST I.F. - this transformer is made up of 3 coils phased in such a relation that maximum signal is impressed upon the low inductance primary of 2nd I.F. transformer. The crystal and crystal phasing circuit is inserted between these transformers in such a manner that when the crystal switch is at "in" position, the crystal and crystal phasing condenser cause single signal action to take place - this action varies by the setting of crystal condenser - when switch is at "out" position the signal is impressed directly on the second transformer.

The 2ND I.F. TRANSFORMER has a step up ratio so that the voltage impressed on grid of 6K7, I.F. amplifier, is increased over the normal I.F. transformer connections. By the use of a transformer the grid circuit of this tube is tuned to the I.F. frequency, so that greater selectivity is achieved. Then, if a choke coil is used to supply this tube.

Transformers used at Intermediate Frequencies are of iron core construction - greater selectivity and gain, due to better Q of the coils is achievable than by the use of air core coils.

The signal to noise ratio if iron core coils, due to a better C, shows a marked improvement over other types of transformers.

The 6K7 (I.F. Amplifier) is coupled through an iron core transformer to single diode plate of 6R6. The single plate being used in order to lessen the load on the secondary of this transformer, making for greater selectivity in this circuit.

The ratios of AC & DC diode load are proportionate so that 100% modulation can be handled without distortion.

As will be noted from the circuit diagram (Fig. 2), the AVC voltage and the audio voltage are taken off slightly below maximum point. This was done to reduce stray R.F. in the circuit and to give better AVC action on the R.F. 1st detector and I.F. stages.

6K7 BEAT FREQUENCY OSCILLATOR - this is electron coupled oscillator - coupled to 6R6 diode plate by two turns of wire. Changes in line voltage and in tubes will not effect the frequency of beat oscillator. The frequency can be controlled by the use of the pitch control in order that a receiving operator can beat on either side of signal getting further selectivity on code reception by choice of audio frequencies.

AUDIO - FIRST STAGE AUDIO 6F5 - is a high MU triode. It is coupled to the diode circuit through its volume control (R20) and condenser (C25). As will be noted from the circuit no DC flows through this control, making for quiet operation.

TONE CONTROL - it will be noted that tone control (R22) is connected on plate of 6F5 and also on its grid circuit, when the control is full counter clockwise (treble position). The tone is normal. As the control is moved to the right up to one-half rotation the bass response is increased without cutting of high notes. Moved through the other half of the rotation the high notes are removed by use of condenser (C27) without further increasing low note response.

In order to avoid frequency discrimination found in cathode - resistor - condenser bias circuits, the Mallory bias cell is used on the grid of 6F5. This proves a boon for phone operators in that it insures greater intelligibility in all voice, short wave broadcasts, etc.

OUTPUT STAGE - a 6F6 pentode, giving 3.5 watts output is connected to the speaker and headphone jack. This jack is arranged in circuit in such way that when phones are inserted the voice coil of speaker is opened. A separate magnetic or permanent magnetic dynamic speaker can be plugged into phone jack if external speaker is desired. Where an electro dynamic speaker has its own field supply, this too may be plugged in. Speaker impedance in these cases should be 7000 ohm, although other types can be used at a sacrifice in tone quality. No DC current flows through headphone circuit.

ALIGNMENT INSTRUCTIONS OF NEW SUPER SKYRIDER

Correct alignment of any receiver is extremely important. The receiver when it leaves the factory is properly aligned with precision instruments and realignment should not be attempted until all other possible causes of faulty operation have been investigated and even then not unless the service technician has the proper equipment. A signal generator that will provide an accurately calibrated signal at .465 m.c. - .6 m.c. - 1.4 m.c. - 1.8 m.c. - 3.6 m.c. - 4.2 m.c. - 9. m.c. - 20. m.c. and 30. m.c. and an output indicating meter are required.

It is practically impossible to align the R.F. unless a satisfactory oscillator and output meter are used. Use a non-magnetic screw driver for adjustments. The complete procedure is as follows:

I.F. Adjustment - in a receiver which has a crystal filter, a crystal controlled oscillator must be used in which the crystal from the radio is used to control the frequency. Connect the output of this through a .1 mfd condenser to the grid of the 6L7. Connect the ground lead of the radio to the ground side of oscillator. (On a receiver without crystal filter, set the signal generator at 465). Turn the band selector switch to band No. 1. Turn the AVC crystal to the "off" position, the audio gain and R.F. gain controls to maximum position (full right). Beat frequency oscillator switch off, set the crystal phasing condenser to one-half capacity that is, plates intermeshed about one-half. Attenuate the signal from the signal generator to prevent overloading the set. Use this procedure in all subsequent adjustments. Then adjust the five trimmers on top of the I.F. cans until maximum output, as indicated by the output meter is observed. The adjustment screws for these trimmers are located in the top of the I.F. transformer cans and may be reached from the top of the chassis. The location of these cans is shown in Fig. 3.

ADJUSTMENT BEAT FREQUENCY OSCILLATOR

Leave signal generator or crystal oscillator on as in alignment I.F.'s, except turn off the modulation. Set the pitch control condenser at one-half capacity. Turn Beat Frequency Oscillator crystal to "on" position and adjust the trimmer in the top of the Beat Frequency Oscillator coil can to "zero" beat.

ALIGNMENT OF R.F. STAGES - ADJUSTMENT OF BAND 5

Turn the band spread dial to 200°, minimum position in this and all subsequent adjustments. Connect the antenna lead of the receiver through a 400 ohm resistor to the output of the signal generator. Use this 400 ohm dummy antenna on all bands except band 1, whereas 200 mmfd condenser is used, turn the signal generator to 20. m.c. Set the main tuning dial at 20 m.c., the band switch at No. 4 position, adjust oscillator trimmer marked bands 4 and 5 - 20 m.c. until maximum output is obtained. The location of this trimmer is shown in Fig. 4. Reset the signal generator to 30 m.c., switch to band No. 5 and tune in the signal with the main tuning condenser. Adjust the antenna and detector coil, trimmers marked band 5 for maximum output.

ADJUSTMENT OF BAND 4

Set the signal generator at 18 m.c., tune in this signal, adjust the antenna and detector coil trimmer until maximum output is obtained. The location of this trimmer is shown in Fig. 4. Leave oscillator trimmer set as in Band 5.

ADJUSTMENT OF BAND 3

Set the signal generator at 9 m.c., set the main tuning dial at 9 m.c., switch on Band 3, adjust oscillator trimmer marked Band 3, 9 m.c. to maximum output, adjust trimmers on the antenna and detector coils until maximum output is obtained. Reset signal generator at 4.2 m.c., tune this signal in with the main tuning condenser and adjust 4.2 m.c. padder for maximum output while gradually rotating the main tuning condenser back and forth. Location of this padder is shown in Fig. 3 and Fig. 4.

ADJUSTMENT OF BAND 2

Set the signal generator to 3.6 m.c. with the band crystal on band No. 2 - turn the main tuning condenser to 3.6 m.c., adjust the band 2 oscillator trimmers until maximum output is obtained, then adjust Band No. 2 trimmer on the antenna and detector coils to maximum output. Reset the signal generator 1.8 m.c., tune this signal in with the main tuning condenser and adjust 1.8 m.c. padder for maximum output, while gradually rotating the main tuning condenser back and forth. Location of this padder is shown in Fig. 3 and Fig. 4.

ADJUSTMENT OF BAND 1

Change the dummy antenna from 400 ohm to 200 mmf condenser. Set the signal generator at 1.4 m.c. with the band switch on band No. 1 - turn the main tuning condenser to 1.4 m.c. Adjust the band 1 oscillator trimmer until maximum output is obtained. Then adjust Band #1 trimmers on the antenna and detector coils to maximum output. Reset the signal generator to .6 m.c. - tune this signal in with the main tuning condenser and adjust .6 m.c. padder for maximum output while gradually rotating the main tuning condenser back and forth. Location of this padder is shown in Fig. 3 and Fig. 4.

The location of the tubes and I. F. transformers and the purpose of each are shown in Fig. 3. The location of all trimmers and padders is shown in Fig. 4. The adjustment of trimmers and padders in another rotation will not give correct alignment of the receiver. These adjustments are accessible from the bottom of the chassis. The location and purpose of all controls are shown in Fig. 1. Schematic diagram of receiver is given in Fig. 2.

HAMMARLUND MFG. CO., INC.

MODEL Super Pro
Alignment, Part 1

VOLTAGES :-

ALL MEASUREMENTS WERE MADE ON A 120 VOLT A.C. POWER SUPPLY LINE WITH LINE VOLTAGE ADJUSTMENT SET AT THE 125 VOLT TAP. R.F.-I.F. AND AUDIO GAIN CONTROLS SHOULD BE SET AT MINIMUM. THE A.V.C. MANUAL SWITCH SHOULD BE IN THE MANUAL POSITION, THE CW-MOD SWITCH IN THE C.W. POSITION, AND THE "SEND-RECEIVE" SWITCH IN THE RECEIVE POSITION. D.C. VOLTAGE READINGS WERE OBTAINED WITH A VOLTMETER HAVING A RESISTANCE OF 1000 OHMS PER VOLT USING THE CHASSIS AS A COMMON TERMINAL. VOLTAGES WITHIN ±10% OF THE VALUES GIVEN SHOULD BE CONSIDERED SATISFACTORY. THE 6.3 VOLT A.C. FILAMENT READING IS OBTAINED BETWEEN CHASSIS AND TERMINAL No 2 ON STRIP. TERMINAL No 10 ON STRIP IS BLANK EXCEPT WHEN USED FOR BATTERY OPERATION IN WHICH CASE IT PROVIDES A SHORT TO CHASSIS WITH POWER SWITCH IN "ON" POSITION AND OPEN WHEN POWER SWITCH IS IN THE "OFF" POSITION.

1 - TEST OSCILLATOR - An accurately calibrated instrument producing modulated signals covering a range of 465 K.C. to 20 M.C. This test oscillator should have an output of the order of 100 micro-volts and an output impedance of 100 Ohms for best results when aligning the R.F. and H.F. Oscillator circuits. For I.F. alignment these values are not critical. The frequency calibration of the test oscillator is extremely important, if the receiver alignment is to be correct.

2 - OUTPUT METER - This meter should respond to the modulation frequency of the test oscillator and should provide at least half-scale deflection for one volt.

3 - INSULATED SCREW DRIVER (9/64" wide - .025" thick at bit)

PRELIMINARY PROCEDURE

Place the "ON-OFF" switch in the "ON" position and allow the receiver to warm up approximately one hour before beginning adjustments. Turn the knurled thumb nuts located on the tops of coil assemblies D.D.-E.E. and H.H. until the tops of the thumb nuts are flush with the tops of the threaded rods. Connect the output meter to the "PHONES" terminals located at the rear of the receiver chassis.

I.F. - A.V.C. - BEAT OSC. ALIGNMENT

Adjust the test oscillator to 465 K.C. and connect the output to the control grid of the 1st Detector tube (6A7) through a fixed condenser. Front panel controls should be set as follows:

- R.F. Gain Control MINIMUM (turn full left)
- I.F. Gain Control MINIMUM (turn full left)
- A.V.C. - MANUAL switch on "MANUAL"
- C.W. - M.O.D. - switch on "MOD"
- PHONES - SPEAKER Switch on "PHONES"
- SEND-RECEIVE Switch on "RECEIVE"
- BAND SWITCH on 540-1160 K.C.
- AUDIO GAIN CONTROL MAXIMUM (turn full right)
- TONE CONTROL (turn full left)
- SELECTIVITY (turn full left)
- BAND SPREAD DIAL set on 100

MAIN TUNING DIAL set near low frequency end of scale, being careful not to conflict with a powerful local signal. Adjust the I.F. gain control so that a reading of approximately one volt is obtained on the output meter. As the various circuits are adjusted for resonance reduce the I.F. gain control to prevent overloading. Adjust the two trimmer capacitors in each of the following coil assemblies for peak voltage readings on the output meter - A.A. - B.B. - C.C. - D.D. - E.E. Then adjust the trimmer capacitor on coil assembly G.G. to minimum (dip) reading on the output meter. Now reduce the A.F. gain to nearly zero and throw the A.V.C. switch to A.V.C. Then adjust the I.F. gain Control until the panel meter reads between 2 and 3. Then adjust the capacitors on H.H. for minimum panel meter reading. There should be a pronounced dip of the panel meter as each of these adjustments is made. It is advisable to switch over to "SPEAKER" at frequent intervals during alignment to make sure there is no overloading. If everything is operating properly the output meter reading will also dip to minimum as the capacitors on coil assembly H.H. are adjusted.

Set the A.V.C.-MANUAL Switch on MANUAL, the C.W.-MOD-switch on C.W. and adjust the trimmer capacitors on coil assembly F.F. for zero beat. For this adjustment the Beat oscillator control knob, on the front panel should be adjusted half-way, or with the stop pin on shaft vertical or pointing upwards. This completes the alignment of the I.F. - A.V.C. and Beat Oscillator circuits all of which are accessible on top of the receiver chassis. After these adjustments have been made, the entire procedure should be repeated to insure accuracy. The knurled thumb nuts on coil assemblies D.D. - E.E. and H.H. should now be returned to their original settings by turning them to the right until the tops of the thumb nuts are 7/16" below the tops of the threaded rods.

CRYSTAL FILTER I.F. ALIGNMENT

The above procedure for aligning the I.F. circuit also applies to receivers with crystal filters, except that the test oscillator must be accurately set to the frequency of the crystal. This can be accomplished by setting the frequency of the test oscillator (when connected to the grid of the first detector) for maximum response with the crystal in circuit and the crystal selectivity control set at maximum. When the frequency of the test oscillator has been correctly adjusted to that of the crystal the I.F. circuits can be tuned as described above with the crystal cut out of circuit. Unless this procedure is carefully carried out, maximum crystal efficiency will not be obtained, since the peak of the I.F. selectivity curve must coincide exactly with the resonant peak of the crystal.

H.F. OSCILLATOR AND R.F. ALIGNMENT

Connect the output of the test oscillator to the "A.A." terminal strip. Keep the output meter in the same position as previous test. The controls on the front panel should be set as follows:

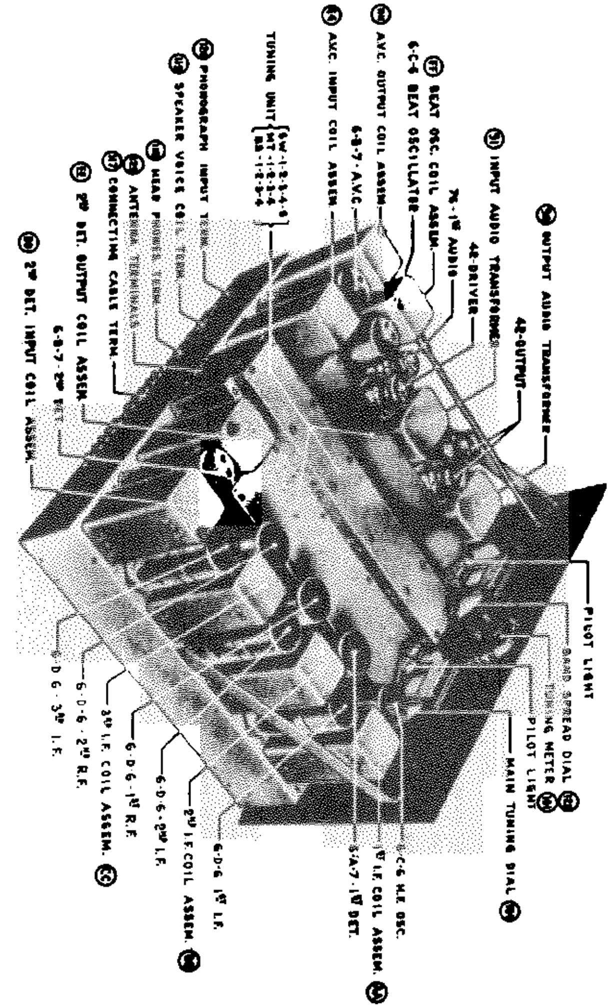
- Band Change Switch on 540 - 1160 K.C.
- Main Tuning Dial on 1100 K.C.
- Band spread Dial on 100
- R.F. Gain Control "Full On"
- I.F. Gain Control "To Produce appropriate output meter reading"
- Audio Gain Control "Full On"
- Tone Control "Turn Full left"
- C.W. - MOD switch on "MOD"
- A.V.C.-MANUAL Switch on "MANUAL"
- SEND - RECEIVE Switch on "RECEIVE"
- PHONES-SPEAKER Switch on "PHONES"

Turn the receiver over, bottom side up, placing a small block of wood under the rear of the switch section to protect the shield cans and tubes. The main tuning unit bottom plate should remain in place while H.F. oscillator and R.F. adjustments are being made. In order to facilitate the alignment of these stages, we have indicated in dotted lines, the coil positions beneath the bottom cover plate, to-gether with all capacity and inductance adjusters. Capacity adjusting condensers are located on the coil bases and inductance adjusters extend through the top of each coil. The coil markings correspond to the designations on the schematic wiring diagram. Set the test oscillator to produce a 1100 K.C. signal. Adjust the trimmer capacitor "Y" until a peak reading is obtained in the output meter. Now set the main tuning condenser dial to 600 K.C. and adjust the test oscillator for a 600 K.C. signal. Turn the inductance adjustment on coil "Y" for a peak reading on the output meter. As these two adjustments react on each other it will be necessary to repeat them until no further change in either capacity or inductance is necessary. This realignment should only be done after making sure that the calibration of main dial is incorrect.

Turn the main tuning dial to 1100 K.C. and set the test oscillator for 1100 K.C. signal. Adjust each capacitor on coil "R" - "K" - "E2" in

MODEL Super Pro
Alignment, Part 2
Socket, Chassis

HAMMARLUND MFG. CO., INC.



the order named, for peak reading on the output meter. The I.F. gain control should be adjusted so that no overloading occurs and an appropriate reading on the output meter is maintained. Now set the main tuning dial at 600 K.C. and the test oscillator on the same frequency and turn the "inductance adjustments" on coil "R" - "K" - "E1" for peak reading on the output meter. These adjustments are also interlocking and should be repeated until no further improvement can be noticed. This completes the H.F. Oscillator and R.F. coil alignment for the frequency range of 540 to 1160 K.C.

The alignment procedure of the H.F. Oscillator and R.F. coils in the remaining frequency ranges is exactly the same as outlined for the 540-1160 K.C. band, test oscillator frequencies and main tuning dial settings vary as follows:

RANGE	CAPACITY ADJUSTING FREQUENCY	COILS	INDUCTANCE ADJUSTING FREQUENCY	COILS
1160 to 2500 K.C.	2500 K.C.	X-P-J-D2	1200 K.C.	X-P-J-D1
2.5 to 5.0 MC	5.0 MC	W-N-H-C2	2.5 MC	W-N-H-C1
5.0 to 10.0 MC	10.0 MC	T-M-G-B2	5.0 MC	T-M-G-B1
10.0 to 20.0 MC	20.0 MC	S-L-F-A2	10.0 MC	S-L-F-A1

The capacity and inductance adjustments in each band should be rechecked until no further peak changes are noted. The receiver will then be completely aligned. On the three highest frequency bands, care should be exercised to avoid adjusting the H.F. oscillator coils to an image frequency.

The check on the alignment of the receiver on all bands is now complete and if instructions have been carefully carried out optimum performance should be obtained.

HAMMARLUND MFG. CO., INC.

MODEL Super Pr
Circuit Data
Operating Note

OPERATING THE RECEIVER

The receiver may now be operated by tuning the OFF-ON SWITCH.

The receiver is equipped with every conceivable control to permit the operator to obtain maximum performance under a wide variety of receiving conditions. The numerous control knobs and switches appearing on the panel, may, at first glance, seem confusing, but in reality their actual manipulation is quite simple and after the receiver has been used for a very short time, no difficulty will be experienced in obtaining the most efficient results.

An AVC-MANUAL switch is provided to enable the operator to use either AVC or MANUAL volume control. For stations transmitting a continuous carrier such as a telephone station, the AVC position is generally the best. In this case, the manual I.F. gain control serves to limit the maximum sensitivity and prevents the high noise level present when the receiver is adjusted to maximum gain with no incoming signal. When the switch is set on MANUAL, the I.F. GAIN control adjusts the gain of the receiver to a given point, which remains fixed regardless of the intensity of the signal being received. When AVC is used a minimum reading on the TUNING METER indicates the signal has been tuned in properly.

The BEAT OSCILLATOR adjustment is brought out on the panel and may be adjusted to give any beat note frequency desired. For C.W. reception, be sure that the signal is tuned to its maximum strength, and then adjust the beat oscillator to the desired frequency.

DO NOT CHANGE THE TUNING TO PRODUCE THE DESIRED BEAT FREQUENCY. The only time the tuning is adjusted to change the beat frequency is after the station is properly tuned in, and has drifted in frequency so as to change the tuning as well as the beat note.

The BEAT OSCILLATOR may also be used for locating the carrier of distant broadcast or phone signals by tuning to the lowest pitch beat note (Zero Beat) with the CW-MOD. switch in the CW position. For this purpose the BEAT OSCILLATOR control should be adjusted in the centre.

A SEND RECEIVE switch is placed on the panel and is used when transmitting on approximately the same frequency as that to which the receiver is tuned. This switch disconnects the plate supply to the R.F. amplifiers and first detector. With this switch in the send position, it is usually possible to use the receiver to monitor the transmissions, although in low powered transmitters it may be necessary to keep this switch in the receive position and reduce the R.F. GAIN, as the shielding and filtering in the receiver is sufficient to keep out any except extremely strong signals from a transmitter located a few feet away.

The frequency band desired for operation may be selected by means of the BAND CHANGE SWITCH located directly beneath the tuning meter. The main tuning dial shutter will at the same time automatically indicate the frequency band, in use. The calibration of the MAIN DIAL is correct only when the BAND SPREAD DIAL is set at 100, except in the two low-frequency ranges from 540 to 2500 K.C. In these two ranges the BAND SPREAD CONDENSER is automatically disconnected by the BAND CHANGE SWITCH. Therefore, with the BAND SPREAD DIAL set at 100, the receiver is a fully calibrated SINGLE DIAL instrument.

In the three high frequency bands tuning is sufficiently smooth on the main dial to permit its use almost entirely for selecting the desired signal and perhaps it would be more simple to disregard the band spread dial until the desired signal is picked up, and then use the band spread dial for the purpose of obtaining a very fine vernier adjustment.

If band spread operation is desired in any of the three high frequency bands, the MAIN TUNING DIAL should be adjusted to the HIGH FREQUENCY limit of the band desired. It will then be possible to tune down over the band by means of the band spread dial only, thereby permitting extremely fine tuning. Lower BAND SPREAD DIAL settings indicate lower frequencies.

THE BAND SPREAD DIAL is not used on the two lowest frequency bands, as the tuning is sufficiently fine on the main tuning dial.

GAIN ADJUSTMENTS:

The R.F. GAIN CONTROL will generally be at maximum, unless the signal being received is very strong, and causes overloading of the first detector. This overloading will be made apparent by a considerable amount of distortion. In this case, reduce the R.F. GAIN. This overloading will rarely be present on the high frequency bands, where the maximum R.F. gain is generally desired.

The AUDIO GAIN should be operated at or near its maximum setting, except when using A.V.C. The AUDIO GAIN should be full on at all times when the receiver is being used for C.W. reception except when using A.V.C. and the proper signal level obtained by the manipulation of the I.F. gain.

In C.W. reception, it will sometimes be found advantageous to reduce the R.F. GAIN when there is interference from a strong station operating very close to the desired signal.

The SELECTIVITY adjustment may be set at any desired point, depending upon conditions. For C.W. reception, it is usually desirable to adjust for maximum selectivity. It should be borne in mind at all times that the atmospheric disturbances and other noises of that character will vary in direct proportion to the width of the response curve of the receiver.

If the receiver becomes completely inoperative, it may be due to a shorted filter or by-pass condenser or an open resistor. By measuring voltages and comparing them with the tabulations in the chart, the defective parts can be easily determined. We do not believe that detailed continuity tests should be described since most operators are familiar with the ordinary procedure for determining defective component parts. In both receiver and power supply units, the bottom cover plates may be removed so that all parts are accessible. Values of any resistor or capacitor may be obtained by locating the number on the schematic wiring diagram, and referring to the parts list.

GENERAL DESCRIPTION

The receiver consists of two major units — the receiver proper and the power supply unit. Both units are supplied with dust covers and suitable for rack or table mounting.

The main tuning unit houses the MAIN TUNING and BAND SPREAD condensers and their respective dial assemblies — the BAND CHANGE SWITCH — and all ANTENNA COUPLING — R.F. and H.F. OSCILLATOR coil assemblies. The BAND CHANGE switch, an exclusive Hammarlund development, embodies the well known knife switch principle and is located in the center of the unit. In the development of this switch, which presents a radical departure from switches commonly used for band changing, considerable thought was given to efficient operation over long periods of active use, and the elimination of faulty switch contacts, which would affect the sensitivity and selectivity of the receiver. All contacts are silver plated phosphor bronze so constructed that a six point contact is provided at each connection. This switch covers the range of 20 mc. to 540 kc. in 5 bands, and also connects the proper band spread condensers into each of the 3 high frequency circuits, and short circuits all coils not actually in use. When the switch is turned the next contact is made before the previous one is broken, thereby eliminating sparking. The switch dial may be turned in either direction, a very convenient feature.

The MAIN TUNING and BAND SPREAD condenser assemblies are located on the left and right hand side respectively of the BAND CHANGE SWITCH when facing the panel. Each tuning gang is controlled by a single control and dial located on the front panel. They are rigidly constructed and so designed that they will not get out of alignment during normal operation.

The MAIN TUNING and BAND SPREAD DIALS are plainly readable through well illuminated escutcheons. Both dials have an easy vernier tuning action without backlash. The main tuning dial is directly calibrated in megacycles in ranges of 2.5 to 5.0; 5.0 to 10.0; 10.0 to 20.0; and in kilocycles from 1160 to 2500 and 540 to 1160. The MAIN TUNING DIAL is equipped with an ingenious mechanical shutter which operates in synchrony with the BAND CHANGE SWITCH, so that only the frequency band in actual use is visible to the operator.

The POWER SUPPLY unit contains a properly filtered rectifier for furnishing D.C. plate voltages and A.C. filament voltage for operating the receiver. A separate rectifier is incorporated for supplying grid bias. All component parts are designed to have a high safety factor. A three terminal strip is located beneath the chassis to permit operation on power supply lines of 105 - 115 - 125 volts, 50-60 cycle alternating current. A cord and plug is provided for connecting the power unit to a wall outlet or receptacle. A connecting cable is furnished for connecting the receiver and power supply units. A special cable for emergency battery operation is also provided.

CONNECTING RECEIVER

The receiver is so designed that it may be located in any convenient position, as a table model or in a standard 19" telephone relay rack. Dust covers may be removed for the insertion of tubes by removing the thumb nuts on both receiver and power supply units.

Tubes:- The receiver has been designed and tested for the following R.C.A. tubes or their equivalent:-

5 - 6D6		
2 - 6C6		
1 - 6A7	Receiver	
2 - 6B7		
1 - 76		
3 - 42		
1 - 5Z3		
1 - 1-V	Power supply	

Care should be taken that the proper tube is inserted in each socket. The type numbers on the tubes should correspond with the markings on the sockets. After the tubes have been correctly inserted the dust covers may be replaced.

The receiver may now be placed in the location previously decided upon and the antenna connections made. The antenna input has been designed to couple either to a balanced transmission line having an impedence of approximately 300 ohms, or to a conventional single wire antenna and ground. In the former case both feeders should be connected to the two antenna terminals located at the rear of the receiver marked "A-A". If a single wire type of antenna is used the lead-in should be connected to one of the terminals marked "A" and the other "A" terminal connected to a good ground. It is not essential to ground the receiver chassis, but it may readily be accomplished by inserting a ground lead under one of the thumb screws holding the dust cover in place at the rear of the receiver.

The RECEIVER and POWER SUPPLY units are connected by a cable. The spade lugs on the terminal strips at each end of the cable should be inserted in the corresponding terminals of the receiver and power supply, with the spade lugs pointing downward.

The output connections to the receiver may be made to the terminals marked "SPEAKER" on the rear of the receiver chassis, or to the pin jacks marked "PHONES". The output of the receiver has been designed to match a load impedence of approximately 600 ohms. A PHONE JACK is provided on the front panel of the receiver connected in parallel to the 600 ohm output terminals.

With the OFF-ON SWITCH in the OFF position, plug the power supply cord in the 60 cycle alternating current supply line. DO NOT ATTEMPT TO OPERATE ON DIRECT CURRENT — OR ALTERNATING CURRENT OTHER THAN 50-60 CYCLES OF THE PROPER VOLTAGE, unless the power supply unit is marked for 25-40 cycle A.C. operation.

An extra connecting cord is supplied with each receiver for emergency battery operation. One end of this cord has a terminal strip that connects to the receiver and the other end has color cc wires for battery connections. The following batteries are requi for emergency operation:-

5 - 45 volt "B" batteries
1 - 45 volt "C" battery
1 - 6 volt "A" storage battery.

Hetro Air-Ace, Series M

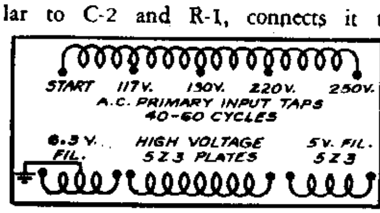
Several changes have been made in the 9-tube receiver, whose schematic is shown on *Hetro page 6-15 of Rider's Volume VI*. The tube complement has been changed and is now as follows:

New Tube	Old Tube	Position
6K7	6D6	R.F.
6A8	6A7	Mixer-Osc.
6K7	6D6	1st-2nd I.F.
6R7	85	2nd Det.
6C5	76	A.F.
6B5	42	O.P.
5Z3	80	Rect.

Note. On models using glass tubes only, the 6A7 is used instead of the 6A8.

A new power transformer is used, Part No. P-836, instead of No. T-789. The connections for this are shown in the accompanying sketch.

The resistor, R-7, in the cathode circuit of the output tubes, has been changed from 600 ohms to 250 ohms and is now known as R-17. The resistor, R-8, 700 ohms, in the cathode circuits of the i-f. tubes, has been changed to 250 ohms and is the same as R-1. Also the second i-f. tube cathode is no longer connected to the condenser C-2 and R-1, which was connected to the cathode of the first i-f. tube, but a condenser and resistor similar to C-2 and R-1, connects it to ground. The condenser, C-2, in the secondary circuit of the second i-f. transformer, has been eliminated and the secondary is now directly connected to ground, instead of R-2.



Terminals for power transformer used in Hetro Air Ace, Series M.

The input transformer to the output stage has been removed and a tapped a-f. choke substituted for it. The center tap is grounded, as was the secondary of the transformer formerly used, and each end goes to the grid of the 6B5 tubes. A 0.05-mf. condenser, C-4, replaces C-14, 0.1 mf., in the plate circuit of the 6C5.

The two condensers, C-15, 0.004 mf., have been removed from across the primary of the output transformer and one of them has been connected from the plate of the 6R7 to ground. The tone control, C-4 and R-15, has been moved from across the plates of the output tubes to the plate circuit of the 6R7. One side of C-4 is connected to the plate and the other side to one end of R-15. The arm of this resistor is connected to the junction of C-11 and R-11, which is grounded. R-15 has been changed to 500,000 ohms instead of 40,000 ohms and R-11 has been changed to 1500 ohms from 5000 ohms. R-14 in the cathode circuit of the 6C5 has been changed to 3000 ohms from 6000.

HOWARD RADIO CO.

ALIGNMENT OF THE OSCILLATOR AND R.F. CIRCUITS

SERVICING EQUIPMENT NECESSARY

The following alignment instructions are given with the assumption that the service station has a signal generator capable of accurately covering the range of the receiver.

A vacuum tube volt meter is preferred to indicate resonance, though an 0 to 3 AC voltmeter can be connected across the voice coil for this purpose.

The two High Fidelity Broad I.F. Stages can not be correctly aligned by the usual methods as a Cathode-Ray oscillograph is required to visually show the resonance curve. Since these stages are broad, they are not liable to get out of adjustment easily after they have once been set, so they should not require any attention unless a replacement has been made of one of the coil units.

Refer to diagram for location of various trimmers.

ALIGNING THE I.F. STAGES

The alignment of the Broad I.F. Channel has been mentioned above. On some sets the trimmers extend through top of can. Also the last stage has a tuned primary.

The regular selective I.F. stages are coded "A" on the diagram and are aligned in the usual manner of feeding the 465 K.C. signal into the grid of the 78 Mixer Tube.

The trimmers should be very carefully tuned to resonance as they are very critical and will greatly affect the performance of the receiver.

The sensitivity of the I.F. stages should be between 25 and 50 Microvolts.

NOTE BEFORE ALIGNING OSCILLATOR AND RF CIRCUITS

(a) Align the I.F. Stages first.
(b) Always adjust oscillator stage before the R.F. in any particular band.
(c) Before aligning be sure dial pointer is set exactly on the 180 degree line which is the line straight across the middle of the dial with tuning condenser in full maximum position.
(d) Bend the plates on the oscillator section only and only on the broadcast band if necessary.
(e) Seal trimmers with wax.
(f) After the high frequency adjustments have been made on short wave bands, a check may be made by advancing the signal generator to 930 K.C. higher in frequency, which is the image of the receiver oscillator. After increasing the output of the signal generator a signal should be heard which will be an indication that the original adjustment has been made on the correct frequency.

1. Set band switch to 2nd (or highest frequency) band.

Set dial hand to 15 M.C. and adjust trimmer "C" to 15 M.C. fed into antenna.

Align R.F. Circuit trimmers "D", "E" and "K" same frequency.

Now set dial hand to 6 M.C. on same band and adjust padding condenser "F" to resonance.

2. Set band switch to next short wave band -- 5.5 to 1.7 M.C.

Rotate dial hand to 5.5 M.C. and adjust trimmer "G" to 5.5 M.C. signal.

Align R.F. circuit trimmers "H" and "I" to same frequency.

Rotate dial to 1.7 M.C. on same band and adjust padding condenser "J" to resonance.

3. Set band switch to Broadcast position.

With dial hand at 1500 K.C. peak trimmer "L" to resonance.

Peak R.F. Trimmers "M" and "N" to 1500 K.C.

Rotate dial hand to 550 and adjust padding condenser "O" to 550 K.C.

Check dial at 950 to K.C. and bend oscillator plates if necessary at any point to align with calibration of dial.

4. The long wave band is aligned with the band switch set on that band and trimmer "P" adjusted to 390 K.C. will dial hand at 390 K.C.

Adjust R.F. circuits with trimmers "Q" and "R".

Rotate dial to 150 K.C. and align padding condenser "S" to resonance.

5. Beat Oscillator Adjustment

Set dial to some frequency, for example --- 7 M.C. and adjust trimmer "T" until note is heard.

6. The Whistle Trap

Located in the amplifier is the high frequency choke with its trimmer, which has been peaked to 10,000 K.C. at factory.

HOWARD RADIO CO.

ALIGNMENT PROCEDURE

PRELIMINARY

Output Meter Connections (Copper Oxide Type Meter) . . Across voice coil
Output Meter reading to indicate 1 Watt output . . . . 1.75 Volts
Average sensitivity in microvolts for 1 Watt output . . See chart below

Generator ground lead connection . . . . Receiver Chassis
Dummy antenna value in series with generator output lead See chart below
Connection of generator output lead . . . . See chart below

Position of volume control . . . . Full on
Position of tone control . . . . OFF (or treble position)
Position of dial card at Maximum Capacity . . . . . . Max. Setting line

BAND RANGE	POSITION OF DIAL POINTER	GENERATOR FREQUENCY	DUMMY ANTENNA	GENERATOR CONNECTION	TRIMMERS ADJUSTED (in order shown)	MICRO-VOLTS
I.F. Stages	540 KC	465 KC	.1 Mfd.	Trans Grid	C31 C32 C33 C34	1000
Regular	1400 KC	1400 KC	.0002	Ant. Lead	C35 C36 C37	2
Regular	600 KC	600 KC	.0002	Ant. Lead	C4 C5	2

IMPORTANT ALIGNMENT NOTES

1. After adjusting the C4 oscillator padding condenser at 600 KC rotate dial back to 1400 KC and recheck the settings made on C35, C36, C37.

2. It will not be necessary to bend the plates of the variable condenser for alignment on other points on the dial.

3. It should be noted that after the receiver is installed in a car that it is not necessary, when preparing to align the set, to remove the control head and cables from the dash. There is a dial card on the variable condenser that will indicate the alignment frequencies and settings.

GENERAL INFORMATION

To examine this receiver for any reason first remove the two screws holding the cover. The speaker which is mounted on this cover will be removed at the same time allowing further inspection of the tubes and radio. The radio, being designed in two parts, having a pair of wire connectors from the chassis itself to the self contained power unit, can be removed from the case by first taking out the power unit.

The power unit has been very carefully designed to avoid any vibrator "Hash" from being picked up. Due to the exceptional sensitivity of the radio this interference must be kept at a minimum and it is advisable that the cover on the power unit be making good contact to the box. Tighten the cover by bending the flanges inward slightly. Also be sure that the .005 Mfd. 1600 Volt condenser across the vibrator is not open.

It is important that the chassis and power unit make contact to the inside of the receiver case. In addition it is advisable that the paint be removed from under the various bolt heads on the outside of the case that are holding power unit.

Harmonics of the I.F. may be noticed when the chassis is being serviced outside its case. This is a normal condition and will not be present when the set is in actual use.

NOTES ON THE ELIMINATION OF UNUSUAL NOISE CONDITIONS OCCURRING IN THE INSTALLATION IN CERTAIN CARS ARE GIVEN IN SECTION IX OF THE INSTRUCTIONS THAT WERE SENT WITH THE RECEIVER.

Car interference can be fed into the receiver through the flexible control cables, and it is suggested that these cables be bonded. Also see page 6 to this instruction book regarding the use of a shield bracket mounted over the tuning shaft coupling on the set.

In some types of installations (Usually inverted mountings) some receivers may experience extreme loss of sensitivity. If the 2nd I.F. transformer (#6532 as shown on can) does not respond to alignment, it should be replaced with a new type. This condition in the I.F. transformer is caused by the position of the iron core being affected by heat generated within the chassis, and is usually indicated by the softening of the wax within the transformer. The new type I.F. transformer (Part #6542) eliminates this difficulty.

WHEN REPLACING THE 2ND. I.F. UNIT FOR THE REASON AS DESCRIBED ABOVE, IT IS OF COURSE NECESSARY TO READJUST THE TRIMMERS TO 465 KC. WHEN MAKING THE ADJUSTMENT ON THIS UNIT AND LIKEWISE WHEN RE-TRIMMING THE 1ST. I.F. STAGE BE SURE NOT TO PULL THE PLATES TOGETHER TOO TIGHT AS THIS MAY BEND THE PLATES PERMANENTLY OUT OF SHAPE AND THEY WILL NOT SPRING BACK WHEN THE SCREW IS TURNED IN THE OTHER DIRECTION. IN THIS EVENT PEAKING OF THE TRIMMERS WOULD NOT BE OBTAINED, AND THE UNIT WOULD HAVE TO BE REPLACED.

ADDITION OF NEW SPECIAL TUNING CABLE SHIELD (3132) TO ELIMINATE EXCESSIVE IGNITION INTERFERENCE. IN MODEL HA6 SERIES 1.

In Ford 1936 V-8 and other automobiles where an excessive amount of ignition noise is present, the bracket described should be used in conjunction with a new type of shield (No. 3132). Both the bracket described and the new type shield described here are necessary for best noise elimination. The bracket and shield need not be ordered for models number above 5000 (series 2).

The new tuning cable shield (3132) will be supplied "No Charge" together with a screw used to fasten it over the tuning cable opening.

SERVICE FIRST AID
EVERY GOOD SERVICEMAN CHECKS TUBES AND THE ANTENNA SYSTEM FIRST.

DEFECT	GENERALLY CAUSED BY	REMEDY
QUALITY POOR	After Checking Voltage, Tubes and Vibrator; Check .02 Condenser in the plate circuit of the 75 tube which may be open	Change if necessary
	Speaker Cone off center	Adjust or change speaker
DEAD RECEIVER	Blown Fuse, Defective Off-On Switch, Open Voice Coil or Speaker Transformer	Check
	Defective Vibrator, Blown Condenser, Open Coil Winding	Check "B" Voltage
LOW VOLUME INSENSITIVE	Poor Antenna System, Receiver not aligned, Speaker Field Coil shorted	Check
	2nd. I.F. Transformer having lost its gain due to the softening of the wax and the shifting of the iron core coupling	Change to new type I.F. (# 6542 on can)
AUDIO OSCILLATION OR HOWL	Possible open .006 in plate circuit of 42	Change if necessary
	Variable Condenser not floating freely in its rubber mountings	Free Condenser
RADIO FREQUENCY OSCILLATION	Open C6 bypass condenser .1 Mfd. 400 volt in B - Circuit	Change
	The grid lead between the mixer tube 6L7 and the variable condenser may be too close to the Antenna Stage of the variable condenser (Top Section)	Push lead away
OFF CALIBRATION	Set not properly aligned	Check
	Dial hand not set to maximum line when condenser is at full capacity	Reset screw on back of drive head
SET NOT SELECTIVE	Check Alignment, especially the I.F. stages.	
SLIPPING OF THE VOLUME CONTROL SHAFT	Cable may not be meshed with slot in control shaft due to cable not being far enough in the coupling, or volume control bracket may be bending back at an angle which does not allow the control to meet the shaft slot.	Correct as described

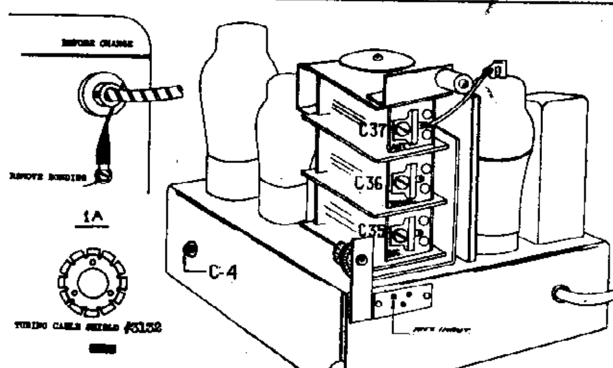

FIG.2

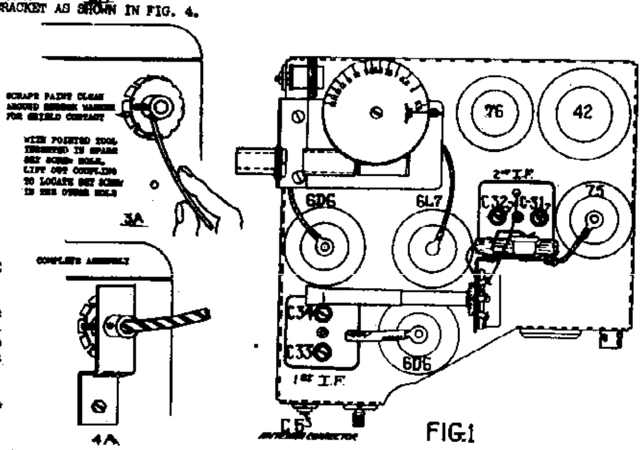

FIG.1

HOWARD RADIO CO.

I — LOCATING AND INSTALLING THE ANTENNA SYSTEM

[illegible] having an all metal top an antenna already installed may be found. Look under [illegible] post where the lead-in from this roof antenna is located (if the car has one). [illegible] be reached with the fingers, use a stiff piece of wire with a hook bent on the [illegible] view. See illustration.

[illegible] does not have any antenna or if the car is of the all metal roof type (in which [illegible] suggest the use of one of the standard underslung types for ground [illegible] the antenna such as the rod type should be covered with molded rubber [illegible] lities of short circuits. Two point suspension and adjustable brackets [illegible]

[illegible] TYPES OF ANTENNAS ON SOME CARS IT MAY BE FOUND NECESSARY TO [illegible] THE LEAD-IN ALL THE WAY FROM THE ANTENNA TO THE RADIO. [illegible] OBTAINABLE AT ANY RADIO SUPPLY STORE. THIS [illegible] AT LEAST OF 3/8" DIAMETER.

[illegible] on the careful installation of the antenna. Never attempt to [illegible] of a car having an all metal top or a car that has screen wire [illegible] roof.

Instructions for connecting the antenna lead-in to the radio are given under the "ELECTRICAL CONNECTIONS" in Section V.

II — HOW TO CHECK POLARITY

When the receiver leaves the factory it has been adjusted for use on cars that have the Positive (+) terminal of the storage battery connected to the frame of the car as shown in Figure 3, below. Observe your battery connections. If they are connected as shown in Figure 3, no polarity change is necessary.

SHOULD THE STORAGE BATTERY BE CONNECTED IN THE CAR AS SHOWN IN FIGURE 3A, THE POLARITY OF THE RADIO MUST BE CHANGED AS FOLLOWS:

1. Remove the four screws around the cover of the radio housing. These screws are on the four sides of the speaker opening.

2. Carefully remove cover.

3. Looking into the radio interior, a copper plated box will be seen on the right. This box has a thumb screw in the center, which should be removed. Remove the cover of this box.

4. At the top of the box a round unit will be seen marked (+-) Pull this unit out of its socket.

5. Rotate this unit until the markings are reversed opposite to their position when found. The correct position of the positive and negative markings are shown in Figure 3A.

6. After complete reassembling the receiver is ready to be installed.

III — HOW TO MOUNT THE RECEIVER

Select a position on the partition (between the motor and driver's compartment) that will not interfere with any of the car's controls. The position where the control head is to be mounted on the dash board must also be considered (read Section IV on mounting control head) due to the need of having the control head cables run to and reach the radio with as few bends as possible. The receiver may be mounted right side up or inverted in order to secure the best position. (See receiver and control cables in figure 1).

IV — HOW TO MOUNT THE CONTROL HEAD

1. Insert the flexible cable shown as "B" in Fig. 5 into the coupling of the receiver having a rubber collar around it. To do this, turn either one of the tuning controls on the control head until the flat metal section at the end of cable "B" revolves and seats itself firmly into the coupling. Tighten the set screws on the collar securely.

When the position for the receiver mounting is selected, proceed as follows.

1. Hold the mounting plate (shown in Figure 4) in the exact position desired and mark any two of the nine holes shown that will be convenient to drill and accessible on the motor side of the partition. Drill these two holes with a 3/8" drill (a small drill should be used first to start the drilling). IF YOU HAVE A LATE MODEL GENERAL MOTORS OR CHRYSLER CORP. AUTOMOBILE READ THE SPECIAL NOTES ON MOUNTING THE RECEIVER BEFORE DRILLING.

2. BEFORE ATTACHING CABLE "C", FIRST:- REACH THROUGH COUPLING (THE ONE WITHOUT THE RUBBER COLLAR AROUND IT) WITH A NARROW SCREW DRIVER AND ROTATE THE VOLUME CONTROL SHAFT AS FAR TO THE LEFT AS IT WILL ROTATE. SECOND:- TURN THE KNOB ON THE CONTROL HEAD AS FAR TO THE RIGHT AS IT WILL ROTATE.

   THIRD:- INSERT THE FLEXIBLE SHAFT INTO THE COUPLING, TURNING IT VERY SLIGHTLY IF NECESSARY TO LOCATE THE FLAT PORTION INTO ITS SLOT.

   FOURTH:- AFTER TIGHTENING THE SET SCREW IN THE COUPLING, ROTATE THE CONTROL KNOB ON THE HEAD TO THE LEFT UNTIL THE SWITCH SNAPS. THIS SHAFT ASSEMBLY IS THEN COMPLETE.

3. Raise the control head to a position on the edge of the dashboard. Holding the control head, shift its location slightly to the left or right until you find a position where the cables will not interfere with other car controls.

4. When this position is determined, mark the locations for the two mounting holes as shown by "D" in Fig. 5. Drill these two holes with a 3/16" drill and bolt the control head into its permanent position.

2. On the motor side of the partition scrape clean all rust, dirt, and paint around these holes until bright metal shows.

3. The bolt heads (shown in Figure 4) used to mount the plate in the driver's compartment are of a key type that fit into the slots of the mounting plate. Insert these bolts in their proper mounting plate holes, fit them into their slots, and then tap them lightly with a hammer. Push the bolts through the partition holes. The nuts may then be attached on the motor side and drawn up tightly.

4. To fasten the receiver to the mounting plate, locate the two holes that are indented on the back of the receiver and fit them into the pointed ears on the mounting plate. Secure the receiver into this position by tightening the wing screw on the opposite end of the mounting plate. The complete mounting details are shown in Figure 4A.

SPECIAL NOTES ON MOUNTING RECEIVER

Late model General Motors and Chrysler Corp. automobiles may not require drilling of the partition. These cars usually have knock-out slugs provided in the partition to correspond with certain holes in the mounting plate. It is only necessary to locate these slugs and punch them out from the motor side.

To mount the receiver right side up in General Motor cars, use holes numbered 2 and 3 as shown in Figure 4, or holes numbered 6 and 7 for inverted mounting.

To mount the receiver right side up in Chrysler Corp. automobiles, use holes numbered 1 and 4 as shown in Figure 4, or holes numbered 5 and 8 for inverted mounting.

SPECIAL NOTE ON MOUNTING CONTROL HEAD

The beauty of the installation may be increased and drilling avoided by using a special plate to mount the Control Head on the dashboard of late model cars. These cars have space provided in the dashboard (such as the space used for an ash tray) into which a special plate, if available for your car, will fit. Information regarding special plates is available in the retail stores. Complete instructions are included.

V — ELECTRICAL CONNECTIONS

Refer to figure #6. Wire lead #1 is a two section wire with the fuse located between the two sections. Connect this wire to a terminal on the ammeter having only one lead already attached. Make this connection short, direct, clean, and tight, using only the required amount of wire and cutting off any not required.

Connect lead #2 as shown by inserting the plug attached to the black wire from the receiver into the socket of the wire from the control head. Press the two sections together firmly and twist to the right.

Cable #3 has a metal braid covering with a three prong plug at one end, to be inserted in the receiver at E in Figure 5. The other end has a blue and black wire together with an extension of the shield (Pigtail). Connect these wires to the car's antenna system as follows:

1. If an antenna was located coming from the corner post of the car, it will probably have an inner wire covered with metal braid. (If it has a plug at its end, cut the plug off). Scrape clean and solder the blue wire of the receiver's antenna lead to the inner wire of the antenna lead in from the car. Be certain these inner wires do not at any time touch the outer shield. See figure 6

2. After the connection has been scraped clean and connected, cover the joint carefully with tape. See figure 7 below.

3. Connect the pigtail of the receiver's antenna wire to the braid of the antenna lead-in from the car. Wrap the pigtail as shown in figure 8 below and solder it with resin core solder. Do not hold the hot soldering iron too long on the wire when making the connection. Connect the black wire to the most convenient spot on the car's frame or dash board by use of solder or a bolt. This connection must be clean and tight.

VI — HOW TO ELIMINATE CAR NOISE

IMPORTANT:- IT MUST BE UNDERSTOOD THAT IT IS NOT NECESSARY TO ATTACH A FILTER CONDENSER FROM ONE SIDE OF THE AMMETER TO GROUND, AS IS NECESSARY IN MOST RECEIVER INSTALLATIONS, THIS FILTER IS A PART OF THIS SET ITSELF.

THE GENERATOR

Clamp and connect the generator by-pass condenser to the generator frame and the cut-out as shown in Figure 11. below. Be sure that all paint and dirt are scraped away from the spot where the condenser is mounted so that it makes perfect connection to the metal. Use any of the available screws on the generator to mount the condenser.

In some cases, interference will be reduced by connecting the condenser lead to the opposite side of the cut-out. The most suitable position for this lead must be determined by trial.

THE DISTRIBUTOR

Connect the distributor suppressor resistor in the center wire of the distributor by cutting the lead and screwing each free end into the ends of the suppressor. See Figure 12. below.

ATTENTION FORD OWNERS

No distributor suppressor can be used on the Ford V8. These Models require a special type of distributor condenser which can be secured from your local Ford Dealer. This special distributor condenser bolts to the frame of the distributor and the wire lead connect to the red wire from the distributor.

VII — HOW TO OPERATE THE RADIO CONTROLS

(REFER TO FIGURES 9 AND 9A)

1. ON-OFF SWITCH & VOLUME CONTROL.

   Turning the small control knob to the right will cause a faint click and the dial will become illuminated. Wait about a minute for tubes to become heated before tuning in stations. When absent from car, operation may be prevented by pulling this knob out. Further rotation to the right increases the volume and to the left decreases it. Before making the final desired adjustment, the station should be tuned in as outlined in the following paragraph.

2. STATION SELECTOR DIAL & CONTROL.

   This receiver will tune in stations operating on frequencies from 540 to 1500 kilocycles. The dial figures with the ZERO omitted, indicate these frequencies. As the station selector control is rotated to the left or right, the red pointer on the dial will indicate the frequency of the station tuned in. (Refer to Figure 9) The correct "tuned in" spot for any station on the dial is the point of clearest reception where no swish is heard on either side.

3. TONE CONTROL.

   This knurled thumb screw is in position to give the most brilliant reproduction when turned completely to the right. When turned toward the left the reproduction is less brilliant and more mellow. This should be adjusted to the taste of the person using the radio. Less interference will be experienced when in the mellow position.

VIII — FINAL ADJUSTMENTS

(REFER TO FIGURES 9 AND 9A)

DIAL POINTER ADJUSTMENT

1. Rotate the station selector knob completely to the right. When this is done, the red pointer may or may not be completely around. This is normal. Do not force the selector knob.
2. Locate the red pointer adjustment screw as shown in Fig. 9A and turn it with a small screw driver until the red pointer is opposite the black line shown in Fig. 9. When this is done, the red pointer will indicate station frequency accurately.

ANTENNA BALANCER

First, tune in a weak station at or very near to 600 KC on the dial. Second, without changing any other control, insert a small screw driver into the antenna balancer screw shown in Figure 10 and turn it either to the left or right until the volume of the station is at its maximum point.

If a signal generator is used do not attempt to connect to the antenna of car but instead allow some means for signal to radiate (wild) by attaching a small piece of wire to signal generator output terminals. Attention is again called to the fact that a very weak signal must be used for this adjustment.

IX — CAUSES AND REMEDIES FOR UNUSUAL NOISE CONDITIONS

Any ignition noise that might remain will always be more noticeable when no station is tuned in. This is due to the fact that the automatic volume control feature of this receiver is exceptionally good. Sensitivity automatically becomes greater when no station is heard.

IF THE INSTALLATION OF THE STANDARD SUPPRESSOR EQUIPMENT AS GIVEN IN SECTION 6 DOES NOT REMOVE OBJECTIONABLE NOISE THE FOLLOWING ITEMS MAY BE OF ASSISTANCE:

1. Spark plug suppressors as illustrated in Figure 1. may be necessary. These suppressors are rated at 15,000 ohms and are available from the retail stores, or may be ordered from the factory.

CONTINUED ON NEXT PAGE

MODEL HA-6
Early
Parts List
Notes

HOWARD RADIO CO.

2. More motor noise will be noticed when the "A" lead is connected in such a way that the receiver current flows through the ammeter.

In many stubborn cases of motor noise trouble it may be advantageous to connect wire #1 shown in Figure 5. to the hot terminal of the starter switch rather than the ammeter terminal. In this case it will be necessary to splice a piece of wire to the end of one furnished. Use a wire no smaller than #12 with good insulation and solder well at splice, also make as short as possible. Should it be necessary to run wire through bulk-head or metal floor boards use a heavy piece of loom insulation to prevent cutting through insulating battery wire.

3. If the low tension wire between the ignition coil and the distributor runs parallel and near to the high tension leads, it must be changed. Run a new wire in its place keeping it as far removed from the high tension leads as possible. It is desirable to run it along the car chassis channels.

4. Check the high tension leads in the distributor and be sure there is no sparking between the ends of the wires and their contacts in the cap. This means that the wires must be pushed all the way down in the cap and leave no gap. Sparking from any of the high voltage leads to ground at any point means noise in the radio.

5. It is sometimes helpful to shield the center high tension lead from the distributor to the bulk-head but if this is done a piece of sleeving or tubing at least 1/2" in diameter must be placed over the wire below the shield is put on as the high voltage otherwise will spark through if the shielding is too close to the wire.

6. In certain cases, interference will be reduced still further by connecting an additional filter condenser ½ Mfd. 200V between the battery side of the ignition coils and the car frame.

7. Excessive gap between the distributor and high tension contacts, also fouled plugs with improperly adjusted gaps are sources of trouble. In other words the whole ignition system should be kept in good condition.

8. Any metal tubes or rods, such as windshield tubing, gas and oil lines, throttle and spark control cables, free wheeling cables, etc., that pass through the dash or bulk-head, should have a piece of heavy copper braid soldered to them and the other end of this braid fastened to the motor side of the bulk-head by means of self threading screws. These pieces of copper braid should be made as short as possible.

9. In some cars the ignition coil or leads come very close to the motor side of the toe board. As a result, interference is picked up by the occupants' body and transferred to the antenna in the roof of the car. Trouble of this sort can often be detected through the fact that the noise increases if the person sitting along side of the driver reaches his hand up to the roof of the car. It can be remedied by tacking a metal plate or screen to the motor side of the toe board or by placing the screen between the floor matting and the toe board. Then connect a piece of wire from this screen to an adjacent metal part of the car or else pass one of the screws that hold the toe board down, through the screen so that it makes an electrical connection to the cap-frame or body.

10. Very often interference may be fed into the antenna through the dome light wiring. This can be determined by disconnecting the dome light lead from the ammeter or lighting switch. If improvement results connect a condenser, of the same type as was used on the generator, to the dome light lead as near as possible to the point where the lead enters the corner post. Cut the insulation from the lead at this point and solder the wire from the condenser, tape the joint and ground the lug of the condenser can to the nearest point where a good connection to the car frame can be obtained. A small R.F. Choke connected in series with the dome light lead is preferred along with the use of the above mentioned condenser.

11. Make certain that the instrument panel has a good ground connection to the frame of the car. Also the motor block itself, especially in cars with floating power, should have 1/2" wide copper braid bonded from the engine block to the bulk-head, also bond engine to frame. Do not use ordinary wire. Make the leads as short as possible. In extreme cases the steering column has had to be bonded. Clamp down hood when testing for noise.

12. In stubborn cases a good grade mica .002 to .006 condenser connected across the breaker points will reduce interference. Whether or not the noise is being picked up by the antenna or through the chassis can be determined by grounding the antenna lead. If the noise continues it would be due to the interference being fed back through the frame of the car or through the storage battery to the receiver.

13. Wheel or brake noise is probably the most peculiar type of interference and is due to the accumulated static charge. This type of interference is very noticeable while the car is in motion and could very easily be confused with ignition interference. Check for this with the car running at a good speed, turn the ignition switch off and if the noise continues it is due to either this wheel static or a loose electrical connection. To overcome the wheel static condition use graphite grease in the wheel bearings or insert grounding springs in the hub caps. In the case of external brakes, it is necessary to ground the brake bands to the frame of the car.

14. Loose connections are a frequent cause of interference. Make certain that light bulb contacts are clean and that they fit tight in their sockets, and that all battery cable connections are tight and well grounded.

15. In cases, such as the V-8 Fords, it is necessary to pull battery and primary leads out of the special tube which houses high tension leads, shield and ground the shielding of these leads.

16. Accessories such as lighters, electric motor heaters, etc., are often sources of interference. Try a condenser from ground to these various accessories until the interference is located and eliminated.

17. Ignition noise should, if possible, be checked in a location that is free from electrical disturbances such as power lines, electrical equipment, neon signs, street car and elevated lines. This receiver is a very sensitive instrument and will pick up over its antenna system electrical disturbances in its immediate vicinity.

X – HOW TO KEEP RADIO IN GOOD OPERATING CONDITION

1. GENERATOR CHARGING RATE

If the receiver is used very much, and the car has other electrical accessories, such as cigar lighter, spot light, electric windshield wiper, heater, etc., it may be advisable to compensate for the additional drain of the battery by advancing the generator charging rate. This is especially advisable, if the car is driven more at night, when the lights are used, than during the day. If you are not familiar with the method of adjusting the charging rate of the generator, have it done by a competent service station. It is important that the charging rate never be advanced beyond the value specified by the car manufacturer as safe. Failure to observe this precaution may result in a burnt out generator.

2. TO CHANGE THE DIAL LIGHT pull straight out on the dial bulb holder from the back side of the control unit, Replace with a bulb of the same type, 6 volt bayonet socket type.

3. TO CHANGE THE FUSE grasp both ends of the metal container, pushing inward and twisting at the same time. The short end may then be pulled out to remove the 15 ampere fuse. When replacing be sure that the fibre lining is in place around the fuse itself.

4. Inspect all installation connections at frequent intervals to assure yourself that they are tight and clean. This is important.

XI – SERVICE NOTES

THE WIRING DIAGRAM AND REPLACEMENT PARTS LIST will be found inside the set on the side of the power unit case, likewise on the back page of these instruction sheets.

TUBE REPLACEMENT. Remove the front cover to get to the tubes. Also when the cover is removed, a layout diagram will be visable on top of the chassis showing the position of the tubes. (Pull out the speaker plug to avoid damaging the speaker).

For convenience in removing tubes it is suggested that a screw driver be used to pry up on the edge of the tube bases and also that the tubes be removed in the order hereby given:

1st. remove	- 6D6	-	I.F.
2nd. "	- 6L7	-	Mixer
3rd. "	- 6D6	-	Antenna
4th. "	- 75	-	1st. Audio
5th. "	- 42	-	Output
6th. "	- 76	-	Oscillator

THE TUBES THEREFORE SHOULD BE REPLACED IN THE OPPOSITE ORDER IN WHICH THEY WERE REMOVED.

TO REMOVE THE CHASSIS for any reason, after removing the cover, the power unit (the rectangle box) must be removed first by taking out the three screws holding the unit to the end of the case. Next unfasten the two bayonet connections leading to the chassis. Next remove the two screws from the bottom of the case holding the chassis. Disconnect the two flexible cables, pull out the antenna plug, unhook the "A" wire connector (running between the set and the control head) then the set can be removed.

XII – REPLACEMENT PARTS LIST

THESE AUTHORIZED REPLACEMENT PARTS MAY BE ORDERED THROUGH THE RETAIL STORES. LIST PRICES SHOWN ARE SUBJECT TO CHANGE WITHOUT NOTICE.

WHEN ORDERING, USE PART NO. AND DESCRIPTION SHOWN ON THIS LIST REGARDLESS OF NUMBER PRINTED ON PART ITSELF. FOR ALL ORDERS OR COMMUNICATIONS REGARDING THIS RECEIVER ALSO MENTION CHASSIS HA6.

WHEN NO PART NUMBER IS ASSIGNED ORDER BY DESCRIPTION AND RATING

Part No.	Schematic Location	Description	List Price
7801		Bias Cell - 1 Volt	.20
5600		Cable - Flexible drive with fittings	.85
5532		Cable - Antenna	.50

FOR INSTALLATION AND OPERATING NOTES SEE MODEL HA-6(Early)

ALIGNMENT PROCEDURE

PRELIMINARY

Output Meter Connections (Copper Oxide Type Meter) . . Across voice coil
Output Meter reading to indicate 1 Watt output . . . . 1.73 Volts
Average sensitivity in microvolts for 1 Watt output . . See chart below

Generator ground lead connection . . . . Receiver Chassis
Dummy antenna value in series with generator output lead See chart below
Connection of generator output lead . . . . See chart below

Position of volume control . . . . Full on
Position of tone control . . . . OFF (or treble position)
Position of dial card at Maximum Capacity . . . . . . Max. Setting line

BAND RANGE	POSITION OF DIAL POINTER	GENERATOR FREQUENCY	DUMMY ANTENNA	GENERATOR CONNECTION	TRIMMERS ADJUSTED (in order shown)	MICRO-VOLTS
I.F.Stages	540 KC	465 KC	.1 Mfd.	Trans Grid	C31 C32 C33 C34	1000
Regular	1400 KC	1400 KC	.0002	Ant. Lead	C35 C36 C37	2
Regular	600 KC	600 KC	.0002	Ant. Lead	C4 C5 C27	2

IMPORTANT ALIGNMENT NOTES

1. After adjusting the C4 oscillator padding condenser at 600 KC rotate dial back to 1400 KC and recheck the settings made on C35, C36, C37.

2. It will not be necessary to bend the plates of the variable condenser for alignment on other points on the dial.

3. The output meter mentioned above is connected across the voice coil and the voice coil is not opened.

4. It should be noted that after the receiver is installed in a car that it is not necessary, when preparing to align the set, to remove the control head and cables from the dash. There is a dial card on the variable condenser that will indicate the alignment frequencies and settings. Also it is possible to align the set without removing the chassis from the case. There are small holes in the case to reach all trimmers in the R.F. circuits. Likewise there is a spring button on the front cover that can be pulled out to allow examination and setting of the dial position.

5. INABILITY TO PEAK I.F. TRANSFORMER MAY BE DUE TO ABSENCE OF TRIMMER CAPACITY VARIATION, EVEN THOUGH TRIMMER SCREW TURNS. THIS OCCURS WHEN THE I.F. TRIMMER IS TURNED TOO TIGHT, CAUSING THE PLATE TO BECOME PERMANENTLY SPRUNG.

The performance of any radio depends on the careful installation of the antenna. Never attempt to tack an aerial to the inside roof of a car having an all metal top or a car that has screen wire between the inside lining and the roof.

In the event the car does not have any antenna or if the car is of the all metal roof type (in which a roof antenna will not work), we suggest the use of one of the standard underslung types for mounting under the car. For best results the antenna such as the rod type should be covered with moulded rubber which will eliminate the possibilities of short circuits. Two point suspension and adjustable brackets simplify installation.

NOTE: WHEN INSTALLING THE UNDERSLUNG TYPES OF ANTENNAE ON SOME CARS IT MAY BE FOUND NECESSARY TO REDUCE IGNITION NOISE BY SHIELDING THE LEAD-IN ALL THE WAY FROM THE ANTENNA TO THE RADIO. THIS IS DONE BY USE OF A SPECIAL SHIELDED SLEEVING OBTAINABLE AT ANY RADIO SUPPLY STORE. THIS SHIELDED SLEEVING MUST BE OF THE LOW CAPACITY TYPE AT LEAST OF 5/8" DIAMETER. See Fig. 1A.

ANTENNA BALANCER

First, tune in a weak station at or very near to 600 KC on the dial. Second, without changing any other control, insert a small screw driver into the antenna balancer screw shown in Figure 10 and turn it either to the left or right until the volume of the station is at its maximum point.

INSTRUCTIONS FOR USING ADDITIONAL REMOTE SPEAKER

If desired, this auto receiver may be also used with an additional remote loud-speaker. This speaker may be mounted in the area directly over the windshield or in any other locality convenient for mounting. Speaker Jack Holes used for connecting an additional speaker are shown in Fig. 10A. THESE JACK HOLES ARE USED ONLY WHEN AN ADDITIONAL SPEAKER IS INSTALLED.

For overhead mounting order Speaker #8922 with cable #5522.

For remote mounting elsewhere order Speaker #8923 with cable #5523.

When an additional remote speaker is used, observe the following instructions:

1. Remove the front cover and observe the position of the plug A as shown in Fig. 13. To use an additional speaker this plug must be removed from the socket it is in, and reinserted into the adjacent socket as indicated by the arrow in Fig. 13A.

2. Replace the cover. Insert the Red coated tip of the speaker cable into the Red coated Jack Hole as shown in Fig. 10A. Insert the other Plain tip of the speaker cable into the Jack Hole on the front of the receiver.

3. The entire length of speaker cable should be well anchored as it runs from speaker to receiver.

TO USE THE REMOTE SPEAKER ONLY

If it is preferred to have only the additional remote speaker operating it will be necessary to disconnect wires on the speaker within the set. This is done after removing the cover by unsoldering the copper braid lead running from the voice coil to ground and likewise the field wire which is at the same point. Tape these wires so they will not touch any metal part and become grounded. With this arrangement the Plug "A" (See Fig. 13-A) will remain as is in position for using one speaker.

SERVICE NOTES

1. The various voltages at the sockets are shown on the schematics. These are taken from ground with a high resistance voltmeter with line voltage at 115 volts. For Model 47-A the voltages will average as follows.

	Plate	S.G.	Cathode	
6-D-6	110V	112V	15V with Volume at Minimum	Cont.
			3V with Volume at Maximum	Cont.
6-C-6	30V		3V	
43	105	112V		

2. The two trimmers on the variable condenser are aligned at 1400 KC on Models 47A, 50 and 50SW.

3. When the variable is at full maximum capacity (all the way to the right) the dial hand should be set above the horizontal dividing line about 1/8" or so that the opposite end of the pointer is on 1700 KC. The hand is adjusted by the set screw and collar on the variable condenser shaft.

4. Should the chassis be serviced at any time it is important to check the position of the pilot light socket brackets and be sure they do not touch the speaker cone on the edges or at any point. They should be in such a position so as to not be forced against the cone by the cabinet panel when installed back in cabinet.

5. The pilot light leads running from the sockets to the resistor should be kept high and away from all nearby wires to avoid pick-up hum.

6. On Model 50SW the short wave range is attained by use of shunt coils with the regular R.F. secondaries.

REPLACEMENT LIST -- Models 47A-50-50SW

8216	Trimmer Condenser 250-550 MMFD	.20
3127	Trimmer 0-30 MMFD.	.18

NOTES ON E-57 LONG WAVE

1. The service notes given on previous page on standard 57 models apply to the E-57 long wave model generally.

2. The proceedure in aligning the set is the same except that the regular Broadcast band 540 to 1500 KC must be aligned before the long wave band.

   The Broadcast band oscillator padding condenser on this model is located near the center of the chassis and mounted through the back side of chassis.

3. To align the 150 to 350 KC band, set dial hand to 300 KC and peak oscillator trimmer (this trimmer is the one behind the variable condenser and under the 6-A-7 tube) to 300 KC.

   Peak the R.F. trimmer (the one near the top of the chassis directly over the variable condenser) to 300 KC after the oscillator trimmer has been set.

4. Rotate dial to 150 KC and peak oscillator padding condenser to 150 KC this is the condenser mounted through the front of the chassis below the dial.

SERVICE NOTES ON MODELS 57-A, 60 AND SHORT WAVE MODELS

1. See the schematics for the various voltages at the sockets.

2. Should the chassis be serviced at any time it is important to check the position of the pilot light socket brackets and be sure they do not touch the speaker cone on the edges or at any point. They should be in such a position so as to not be forced against the cone by the cabinet panel when installed back in cabinet.

3. The pilot light leads running from the sockets to the resistor should be kept high and away from all nearby wires to avoid pick-up hum.

4. The Short Wave Models attain the range by use of shunt coils across the R.F. and oscillator secondaries.

5. The Intermediate Frequency transformers should be aligned to 456 KC.

6. When the variable condenser is a full capacity (all the way to the right) the dial hand should be set on the horizontal dividing line.

7. The back section of the two gang condenser is the oscillator section and the trimmer should be peaked at 1400 KC and then peak the R.F. trimmer (Front section) to 1400.

6601	Tube shield - shell	.06
6602	Tube shield - top	.04
2463	Wire - 20 Ft. antenna roll	.20

THE ALIGNMENT PROCEDURE

The following alignment instructions are given with the assumption that the rvice station has a signal generator capable of accurately covering the range of e receiver.

The only other apparatus necessary is a meter connected in the output stage to dicate resonance. This can be a 0 to 3 volt AC meter connected across the voice il of the speaker or preferably an output meter connected in the plate circuit of e 42 power tube in series with an 8 MFD paper condenser.

The schematic circuit of the set will be found on the back side of the chassis.

THE I.F. STAGES

The I.F.'s are aligned by the usual system of feeding the intermediate frequen- of 465KC into the grid of the 6A7 tube.

The two trimmers in each of the I.F. cans should be very carefully peaked to sonance as they are very critical and will greatly affect the performance of the t. These are trimmers number C1, C2, C3, C4. (See pictorial diagram).

The sensitivity of the I.F. stages will be 25 microvolts for a 50 milliwatt out- ıt.

Always use as low an output as possible from the signal generator in making the ırious adjustments.

ALIGNMENT OF SHORTWAVE BAND 5.5 TO 18 M.C.

First check the position of the dial hand by rotating the tuning knob to the ft to full capacity. At this point the dial hand should be straight across in line th the lines dividing the scale in half. If the hand is off position it can easi- be lined up by removing the dial glass to get at the screw holding the dial hand.

1. Turn wave band switch all the way to the right for the Short Wave Band.

2. Tune dial hand to 17 megacycles.

3. NOTE: FOR ADJUSTMENT AT 17 MEGACYCLES THE OUTPUT FROM THE SIGNAL GENERATOR ST NOT BE COUPLED DIRECT TO THE ANTENNA LEAD OF THE SET. FOR TRUE ALIGNMENT STRETCH T THE RADIO ANTENNA LEAD IN SUCH A MANNER THAT IT WILL PICK UP THE SO CALLED "WILD" GNAL OF 17 MEGACYCLES EMITTING FROM THE GENERATOR. IT IS ALSO IMPORTANT THAT THIS GNAL ONLY BE STRONG ENOUGH TO JUST BE HEARD.

4. When the above set-up is arranged peak oscillator condenser C5 to the 17 gacycle weak signal.

5. After adjusting the oscillator trimmer, peak the S.W. antenna condenser C6 17 megacycles.

NOTE: After adjusting the short wave band at 17 megacycles, the signal genera- r output to antenna should be increased and receiver dial advanced to .9 megacycle ear and note if test oscillator signal is heard.

In case there is no response the oscillator trimmers have been pulled down too ghtly. The trimmers should be released until this condition exists then go back original point of alignment - reduce antenna input voltage and correct the trimmer justment.

EXAMPLE: The receiver has been adjusted to 17 megacycles. Tune receiver to proximately 16.9 MC.

Increase oscillator signal by "opening up" the attenuator. Move the dial back d forth at 16.9 MC.

If no signal is heard, let oscillator trimmer off until it is heard at 16.9 MC.

Reduce signal voltage from generator, go back to 17 MC and slightly correct this st trimmer adjustment.

THE BROADCAST BAND

1. Turn wave band switch all the way to left and dial hand set to 1400 KC (the p scale). The signal generator may be coupled direct to the antenna lead on this nd, through a standard 200 MMFD Condenser.

2. Peak oscillator trimmer C7 to 1400 KC from the signal generator.

3. Peak antenna trimmer C8 to 1400 KC after adjusting oscillator.

4. Set dial hand to 550 KC and adjust oscillator padding condenser C9 to 550 KC.

5. Recheck dial at 1400 KC as in Section 1.

6. Points in the middle of the dial may be checked and if necessary the plates of the back section (oscillator) of the variable condenser may be bent for alignment.

4. NOTES

1. Seal all trimmers after their final adjustment.

2. Be sure that the settings are being made to the true fundamental signal from the oscillator and not on a harmonic or image frequency.

3. Refer to the chart included for the voltages at the tube sockets.

THE TUNING EYE

The movement of the tuning eye or resonance indicator is easily understood, as the station is tuned in, the green sections of the eye will draw together or tend to draw together depending upon the strength of the station. Rotate the tuning knob back and forth until the exact resonance point is found.

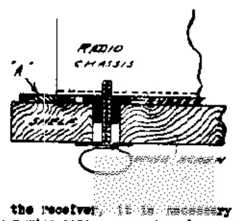
INSTRUCTIONS No. 68
FOR
ALL WAVE SUPERHETERODYNE
TABLE AND CONSOLE MODELS

INSTALLATION

Preparing The Receiver:

The chassis is floated on cushion rubber within the cabinet. However, for shipping purposes this mounting is made rigid by means of wooden strips (A) inserted at the two sides of the chassis, between the chassis and the shelf of the cabinet.



Before operating the receiver, it is necessary to remove these wooden strips. Loosen the four wing screws, one at each corner of the chassis.

USE ONLY WITH ALTERNATING CURRENT

Unless otherwise specified on back of chassis, this receiver is for use only with 105 to 120 Volts Alternating Current.

Antenna and Ground:

The ANTENNA should be about 75 feet in length, including lead-in, and as high as convenient. The BROWN lead extending from the right side of the chassis is the Antenna Lead.

The GROUND is the BLACK lead, and should have a good connection to a water pipe.

OPERATION

Important:

Read the following OPERATING INSTRUCTIONS very carefully and take time to thoroughly understand them. You will be well repaid by the finer performance that you can secure from the receiver, particularly on short waves.

The receiver has four operating controls (refer to diagram on next page). The knob of each control is clearly marked as to its function.

The knob with the three individual colors correspond to the three different colored band ranges covering all frequencies from 540 to 18,000 KC. (On the two short wave ranges the numerals are abbreviated to megacycles). Try the set first on the regular Broadcast band, with the white marker on the knob in the straight up position.

First turn the set on by rotating the combination OFF-ON switch and VOLUME control knob slightly to the right. Further rotation regulates the volume after the station has been tuned in with the TUNING knob.

NEVER REGULATE THE VOLUME BY DETUNING THE STATION, USE THE VOLUME CONTROL.

THE TONE CONTROL when turned to the left softens the tone. This can be set to any position that suits the individual.

TUNING ON THE POLICE AND AMATEUR BAND
(1.7 to 5.6 Megacycles)

Set the band switch to the middle position which is for the blue colored scale.

Rotate the tuning knob slowly until a station is tuned in. This scale is calibrated in megacycles. (One megacycle equals 1000 kc.) If the frequency of a desired station is known, it can be tuned in at the corresponding frequency marking on the dial. In addition to this frequency calibration, there are lettered blocks on this scale. The Station Selector knob must be turned more slowly and carefully for stations on this band than is necessary for the conventional Broadcast Stations.

TUNING ON THE U.S.A. AND FOREIGN SHORT WAVE BAND
(5.5 to 18 Megacycles)

Set the band switch all the way to the right bringing the yellow colored marker in position for the yellow scale.

Rotate the tuning knob very slowly until the desired station is heard. This scale is calibrated in megacycles. Many code stations of all kinds also will be heard. The tuning knob must be turned more slowly and carefully for reception on this band than for reception on the other two bands. The use of a Short Wave "Log" will be of great assistance in picking up Short Wave Stations. Such "logs" list the location, frequency and operating schedule of Short Wave stations.

NOTES ON SHORT WAVE RECEPTION

Short wave reception with ANY short wave receiver differs markedly, in many respects, from the usual broadcast reception. Fading is very much more pronounced. Quite often it is very rapid, making the voice or music seem to flutter. Electrical disturbances are more bothersome. Even the ignition systems of passing automobiles may cause interference on the very short waves.

The difference in time between the United States and foreign countries must constantly be borne in mind when trying for foreign broadcast reception. For instance, when it is 11 P.M. in New York City, it is 4 A.M. of the NEXT day in London and Paris, but early afternoon of the SAME day in Japan and Australia. This difference in time must be remembered constantly for two reasons. First, in order to determine whether or not it is a likely time of day for the foreign station to be broadcasting. Second, because the TIME OF DAY largely determines the portion of the dial that will prove most productive of results for foreign broadcast reception.

Usually, the part of the dial toward the highest frequency end is useful mainly when the path between the broadcast station and the receiver is totally in daylight. Therefore, attempts to obtain good reception on these frequencies at night usually are unsuccessful. The portion of the dial toward the low frequency end will be best when the path between the broadcast station and the receiver is in total darkness. The middle portion of the dial will bring in stations whose path lies partly in daylight and partly in darkness. Keeping the difference in time in mind, the path between a broadcaster in some particular part of the world and your own receiver can be visualized and the proper part of the dial used.

To illustrate, at 4 o'clock in the afternoon in Buffalo, N.Y., the London (Daventry) England, station GSD - 11.75 megacycles - comes in very well. Since it is 9 P.M. in London when it is 4 P.M. in Buffalo, the path of the radio waves lies partly in daylight and partly in darkness and the 11.75 megacycle frequency is very effective. As darkness approaches in Buffalo, GSD fades out, but GSA, the 6.05 megacycle transmitter of the same station will come in strongly since the transmission path then lies in darkness. Very often, the station makes the announcement that it is signing off of the higher frequency and resuming transmission at the lower one.

Allowance must be made for the season of the year since the days are longer in Summer.

Reception on the short waves is much less regular and less consistent than it is on the usual broadcast band. Stations at extreme distances may be picked up while equally powerful nearer ones cannot be heard. Conditions vary from day to day. It may be that for a period of several days foreign broadcasts are heard excellently, only to be followed by a like period during which distant reception becomes practically impossible. Many of the radio magazines report monthly on the sort of reception to be expected on the various frequencies.

IMPORTANT: Tuning for short wave stations must be done very much more SLOWLY and CAREFULLY than is necessary for the regular broadcast stations. The higher the frequency (shorter the wave length) the more this is true. An almost imperceptible movement of the knob may mean the difference between hearing a foreign station and not hearing it. The Station Selector knob MUST be turned VERY slowly, or the station will be completely missed. But, the thrill that one can experience in making direct contact with foreign countries or the eavesdropping on ship and amateur telephony, fully compensates for the extra care needed to tune them in.

SERVICE SUGGESTIONS

1. Be sure that the antenna and ground connections are made according to instructions.

2. Be sure that all of the tubes are in good operating condition, that they are firmly seated in their proper sockets, that the clips are attached to the small caps on the tops of those tubes requiring them and that the speaker plug is pushed all the way into its socket at the rear of the receiver.

3. Be sure that the Wave Band switch is at the proper position for the frequency band desired.

4. See that the power cord plug is making proper contact in its receptacle.

AUTOMATIC VOLUME CONTROL

When the control has been adjusted for the desired volume from any particular station, the Automatic Volume Control feature of the receiver will tend to maintain the volume at this same value for other stations. It does this by automatically changing the sensitivity of the receiver to compensate for changes in the strength of the signal received from different Broadcasting Stations. In some locations noise may be encountered as the receiver is tuned between stations. This noise is normal and is due to the automatic increase in the sensitivity of the receiver. When listening to weak and distant stations the tone may become distorted at times. This is normal and is due to fading of the station beyond the limits which can be compensated for by the Automatic Volume Control.

Alignment
Chassis

HOWARD RADIO CO.

I THE I.F. STAGES

The I.F.'s are aligned by the usual system of feeding the intermediate frequency of 465KC into the grid of the 6A7 tube.

The two trimmers in each of the I.F. cans should be very carefully peaked to resonance as they are very critical and will greatly affect the performance of the set. These are trimmers number T1, T2, T3, T4. (See pictorial diagram).

The sensitivity of the I.F. stages will be 30 microvolts or better.

Always use as low an output as possible from the test oscillator in making the various adjustments.

II ALIGNMENT OF SHORTWAVE BAND 5.5 TO 18 M.C.

First check the position of the dial hand by rotating the condenser shaft to the left to full capacity. At this point the dial hand should be straight across in line with the lines dividing the scale in half. If the hand is off position it can be lined up by removing dial glass and setting hand with screw in center of dial.

1. Set the test oscillator to 17 megacycles.

2. Turn wave band switch all the way to right for highest S.W. band, and set dial hand to 17 M.C.

3. Peak trimmer condenser T5 of the oscillator coil (See pictorial) to resonance with 17 M.C. fed into antenna.

4. Adjust antenna and RF coil trimmers T6 and T7 to same frequency __after__ the above mentioned oscillator trimmer has been set.

5. Turn dial hand to 6 M.C. on the same band and peak padding condenser P-1 to 6 M.C.

III SHORTWAVE BAND 1.7 TO 5.5 M.C.

1. Set band switch to this band and dial hand to 5 M.C.
2. Peak trimmer T8 to 5 M.C.
3. Peak antenna and RF trimmer to T9 and T10 to 5 M.C.
4. Rotate dial to 1.7 M.C. and adjust padding condenser P-2 1.7 M.C.

__NOTE__: After adjusting the two high bands at 17 megacycles and 5 megacycles the test oscillator input to antenna should be increased and receiver dial advanced to .9 megacycle lower and note if test oscillator signal is heard.

In case there is no response the oscillator trimmers have been pulled down too tightly. The trimmers should be released until this condition exists then go back to original point of alignment - reduce antenna input voltage and correct the trimmer adjustment.

__EXAMPLE__: The receiver has been adjusted to 17 megacycles. Tune receiver to approximately 16.9 M.C.

Increase oscillator signal by "opening up" the attenuator. Move the dial back and forth at 16.9 M.C.

If no signal is heard, let oscillator trimmer off until it is heard at 16.9 M.C.

Reduce signal voltage from generator, go back to 17 M.C. and slightly correct this last trimmer adjustment.

The same applies to the 5 M.C. adjustment.

IV THE BROADCAST BAND

1. Turn wave band switch all the way to left and dial hand set to 1400 KC (the top scale).

2. Peak oscillator trimmer T11 to 1400 KC and RF circuit trimmers T12 and T13 to same frequency.

3. Set dial hand to 550 KC and adjust oscillator padding condenser P-3 to 550 KC.

4. Recheck dial at 1400 KC as in number (1) and (2).

5. Points in the middle of the dial may be checked and if necessary the plates of the front section of variable condenser may be bent for alignment.

V NOTES.

1. Seal all trimmers after their final adjustment.

2. Be sure that the settings are being made to the true fundamental signal from the oscillator and not on a harmonic or image frequency.

3. Refer to the schematic for the voltages at the tube sockets.

MODEL 99-T, 99-C
Alignment, Chassis

HOWARD RADIO CO.

I THE I.F. STAGES

The I.F.'s are aligned by the usual system of feeding the intermediate frequency of 465KC into the grid of the 6A7 tube.

The two trimmers in each of the I.F. cans should be very carefully peaked to resonance as they are very critical and will greatly affect the performance of the set. These are the trimmers in the three I.F. cans. (See pictorial).

THE I.F. STAGES MUST BE ALIGNED WITH THE FIDELITY CONTROL IN THE SHARP POSITION, THAT IS WITH THE SHAFT TURNED ALL THE WAY TO THE LEFT.

The sensitivity of the I.F. system in the sharp position is about 200 microvolts. In the high fidelity position the sensitivity is about 20 microvolts.

Always use as low an output as possible from the signal generator when making the various adjustments.

II ALIGNMENT OF SHORTWAVE BAND 5.5 TO 18 M.C.

First check the position of the dial hand by rotating the condenser shaft to the left to full capacity. At this point the dial hand should be straight across in line with the lines dividing the scale in half. If the hand is off position it can be lined up by removing dial glass and setting hand with screw in center of dial.

1. Set the test oscillator to 17 megacycles.

2. Turn wave band switch all the way to right for highest S.W. band, and set dial hand to 17 M.C.

3. Peak trimmer condenser T-5 of the oscillator coil (See pictorial) to resonance with 17 M.C. fed into antenna.

4. Adjust antenna and R.F. coil trimmers T-6 and T-7 to same frequency after the above mentioned oscillator trimmer has been set.

5. Turn dial hand to 6 M.C. on same band and peaks padding condenser P-1 to 6 M.C.

III SHORTWAVE BAND 1.7 TO 5.5 M.C.

1. Set band switch to this band and dial hand to 5 M.C.

2. Peak trimmer T-8 to 5 M.C.

3. Peak antenna and R.F. trimmers T-9 and T-10 to 5 M.C.

4. Rotate dial to 1.7 M.C. and adjust Padding Condenser P-2 to 1.7 M.C.

NOTE: After adjusting the two high bands at 17 megacycles and 5 megacycles the test oscillator input to antenna should be increased and receiver dial advanced to .9 megacycle lower and note if test oscillator signal is heard.

In case there is no response the oscillator trimmers have been pulled down too tightly. The trimmers should be released until this condition exists then go back to original point of alignment - reduce antenna input voltage and correct the trimmer adjustment.

EXAMPLE: The receiver has been adjusted to 17 megacycles. Tune receiver to approximatly 16.9 M.C.

Increase oscillator signal by "opening up" the attenuator. Move the dial back and forth at 16.9 M.C.

If no signal is heard, let oscillator trimmer off until it is heard at 16.9 M.C.

Reduce signal voltage from generator, go back to 17 M.C. and slightly correct this last trimmer adjustment.

The same thing applies to the 5 M.C. adjustment.

IV THE BROADCAST BAND

1. Turn wave band switch all the way to left and dial hand set to 1400KC (the top scale).

2. Peak oscillator trimmer T-11 to 1400 KC and R.F. circuit trimmers T-12 and T-13 to same frequency.

3. Set dial hand to 550 KC and adjust oscillator padding condenser C-8 to 550 KC.

4. Recheck dial at 1400 KC as in number (1) and (2).

5. Points in the middle of the dial may be checked and if necessary the plates of the front section of variable condenser may be bent for alignment.

V NOTES

1. Seal all trimmers after their final adjustment.

2. Be sure that the settings are being made to the true fundamental signal from the oscillator and not on a harmonic or image frequency.

3. Refer to the schematic for the voltages at the tube sockets.

4. It will be noted that the audio transformer is mounted so that it can be pivoted by loosening screw in slot. This is made adjustable to be able to set transformer at point of minimum hum.

5. The alignment instructions are given with the assumption that the service station has an oscillator capable of accurately covering the range of the receiver.

The only other apparatus necessary is a meter connected in the output stage to indicate resonance. This can be 0 to 3 volt AC meter connected across the voice coil of the speaker or preferably an output meter connected in the plate circuit of the 42 power tube in series with an 8 MFD paper condenser.

MODELS 66X,86,96
Socket,Voltage
Alignment

This chassis is designed to operate from 115 volt power li...s, either alternating or direct current. It is a two band receiver covering the American broadcast and police and airport bands.

The following tubes are employed:

6D6 - 1st Detector-Oscillator
6D6 - I. F. Amplifier
6C6 - 2nd Detector
43 - Pentode Output
25Z5 - Rectifier
165R4 - Regulator

ALIGNMENT

ESSENTIAL DATA: The intermediate frequency employed is 448 Kc.

The standard type of output meter should be used to indicate signal strength. It should be connected from the plate of the 43 tube to ground.

Poor sensitivity may be an indication of incorrectly adjusted I. F. trimmers.

Aligning of Broadcast band should be done on 1400, 1000 and 600 kilocycles.

INTERMEDIATES: To align the I. F. circuits, set the signal generator to 448 Kc. and feed its modulated signal direct to the antenna. Adjust the first I. F. transformer trimmers for maximum meter reading. Go over both adjustments at least three or four times for accuracy. Repeat this process on the second I. F. transformer. If adjustments are not made accurately, selectivity will be poor and I. F. oscillation may result. Finally, adjust the trimmer in the tuned wave trap for minimum meter reading.

BROADCAST BAND: Place the band change switch on the Broadcast position. Turn the dial to 1400 Kc. and feed a very weak 1400 Kc. modulated signal from your signal generator to the antenna. Adjust the broadcast oscillator trimmer and detector trimmer (on condenser gang) for maximum reading.

There is no adjustable padder condenser in this model so resonance on lower frequencies is accomplished by bending plates on tuning condensers.

SHORT WAVE BAND: No alignment necessary.

PRODUCTION CHANGES

Referring to the circuit diagram, part R-281, 100 ohm resistor in S. W. oscillator coil circuit has been found unnecessary and will be omitted in future production.

In some chassis a 25,000 ohm resistor has been inserted between the 76 tube plate resistor (part R-264, 100,000 ohm) and the coupling condenser (part A-375, .03 mfd.). The 25,000 ohm resistor carries part number R-274.

MODEL 77 SERIES

February, 1936

ALIGNMENT

ESSENTIAL DATA: The intermediate frequency employed is 448 Kc.

The standard type of output meter should be used to indicate signal strength. It should be connected from the plates of the 43 tubes to ground.

Poor sensitivity may be an indication of incorrectly adjusted I. F. trimmers.

Aligning of Broadcast band should be done on 1400, 1000 and 600 kilocycles.

The three trimmers on the bottom of the chassis are, reading from the end of the chassis toward the center, B. C. oscillator, S. W. detector and S. W. oscillator. No trimmer is used across the B. C. detector coil.

BROADCAST BAND: Place the band change switch on the Broadcast position. Turn the dial to 1400 Kc. and feed a very weak 1400 Kc. modulated signal from your signal generator to the antenna. Adjust the broadcast oscillator trimmer for maximum reading.

There is no adjustable padder condenser in this model so resonance on lower frequencies is accomplished by bending plates on tuning condensers.

INTERMEDIATES: To align the I. F. circuits, set the signal generator to 448 Kc. and feed its modulated signal direct to the antenna. Adjust the first I. F. transformer trimmers for maximum meter reading. Go over both adjustments at least three or four times for accuracy. Repeat this process on the second I. F. transformer. If adjustments are not made accurately, selectivity will be poor and I. F. oscillation may result.

SHORT WAVE BAND: Place the band change switch on the Short Wave position. Turn the dial to 15.5 megacycles and feed a very weak 15.5 megacycle modulated signal from your signal generator to the antenna. Adjust the S. W. oscillator trimmer for maximum reading on the output meter. This trimmer should not be touched again when checking alignment on other frequencies.

Next go to 12 megacycles and adjust the S. W. detector trimmer.

Instead of bending condenser plates at 6 megacycles alignment is accomplished by spreading or crowding turns on the S. W. detector coil. If much crowding or spreading is necessary it is advisable to go back and recheck at 12 megacycles.

MODEL 400 SERIES

Model 400 is a two band, battery operated receiver. The right-hand knob is the wave band switch. It should be turned to the left for broadcast band reception. When turned to the right the receiver tunes the police, airplane and amateur band for 70 to 200 meters.

This receiver requires 4-1/2 volts of "A" battery and 135 volts of "B" battery. For "B" supply, three 45 volt "B" batteries are required. Each should have a 22-1/2 volt connection, or "tap", and the size of each battery should not exceed 2-1/2 x 4-1/4 x 6 inches though the largest battery available within this size should be used. Batteries such as the Eveready No. 762, Burgess No. 5308, Ray-O-Vac No. 5303, etc., are suitable.

For "A" battery supply, three standard "No. 6" dry cells--as used for telephone, ignition and radio--are required. These are 1-1/2 volt batteries--three connected in series providing the necessary 4-1/2 volts. These batteries are approximately 6 inches long and 2-1/2 inches in diameter (or square). Dry cells such as the Eveready No. 7111, Burgess "Little Six", Ray-O-Vac No. 66, etc., are suitable.

ALIGNMENT

The standard type of output meter should be used to indicate signal strength. It may be connected from plate of the 950 tube to ground.

ESSENTIAL DATA: The intermediate frequency employed is 448 Kc.

The rear section of the two gang condenser is the oscillator section; the front section, first detector.

INTERMEDIATES: To align the I.F. circuits, set the signal generator to 448 Kc. and feed its modulated signal direct to the antenna. Short out the oscillator section of the two gang condenser. Adjust the first I.F. transformer trimmers for maximum meter reading. Go over both adjustments at least three or four times for accuracy. Repeat this process on the second I.F. transformer. If adjustments are not made accurately, selectivity will be poor and I.F. oscillation may result. Due to the I.F. trap in the antenna circuit a strong signal is necessary.

BROADCAST BAND: Place the band change switch on Broadcast position. Turn the dial to 1400 Kc. and feed a very weak 1400 Kc. modulated signal from your signal generator to the antenna. Adjust the broadcast oscillator trimmer for maximum reading. On most sets the detector trimmer has its adjusting screw purposely removed.

There is no adjustable padder condenser in this model so resonance on the low frequency end is accomplished by bending plates on the tuning condensers. Check the alignment at 1000 Kc. Insert a thin bakelite, celluloid or mica feeler strip between the plates of the variable condensers to determine whether the circuits are properly matched. The action is this--the dielectric constant of the celluloid feeler strip being higher than that of the air it displaces, results in an increase of capacity. Open the variable condenser just enough to indicate two or three points below maximum signal. As the feeler is inserted the meter reading should indicate increasing signal and then decreasing as the feeler is inserted farther. This procedure should be followed on both sections. Should the meter fail to show an increase in signal as the strip is inserted in one section this indicates too great a capacity for that section. This may be corrected by bending the outside rotor plates out at the point where they begin to mesh with the stator.

After checking the alignment at 1000 Kc. repeat the process at 600 Kc.

SHORTWAVE BAND: No alignment necessary due to untuned detector circuit.

MODEL 500
Alignment
Socket
Battery Connections

INTERNATIONAL RADIO CORP.

MODEL 500

Model 500 is a two band, battery operated receiver. The right-hand knob is the wave band switch. It should be turned to the left for broadcast band reception. When turned to the right the receiver tunes the American-Foreign Short Wave band of 18 to 55 meters.

The following tubes are employed:

1C6 - 1st Detector-Oscillator
34 - I.F. Amplifier
34 - I.F. Amplifier
25S - 2nd Detector-A.V.C.-A.F. Amplifier
33 - Power Amplifier

ALIGNMENT

The standard type of output meter should be used to indicate signal strength. It may be connected from plate of the 33 tube to ground.

ESSENTIAL DATA: The intermediate frequency employed is 448 Kc.

The rear section of the two gang condenser is the oscillator section; the front section, first detector.

INTERMEDIATES: To align the I.F. circuits, set the signal generator to 448 Kc. and feed its modulated signal direct to the antenna. Short out the oscillator section of the two gang condenser. Adjust the first I.F. transformer trimmers for maximum meter reading. Go over both adjustments at least three or four times for accuracy. Repeat this process on the second I.F. transformer. The third I.F. transformer has only one trimmer. If adjustments are not made accurately, selectivity will be poor and I.F. oscillation may result. Due to the I.F. trap in the antenna circuit a strong signal is necessary.

BROADCAST BAND: Place the band change switch on Broadcast position. Turn the dial to 1400 Kc. and feed a very weak 1400 Kc. modulated signal from your signal generator to the antenna. Adjust the broadcast oscillator trimmer for maximum reading. A three gang trimmer will be found on the bottom of the chassis. The oscillator trimmer mentioned is the section nearest the end of the chassis.

There is no adjustable padder condenser in this model so resonance on the low frequency end is accomplished by bending plates on the tuning condensers. Check the alignment at 1000 Kc. Insert a thin bakelite, celluloid or mica feeler strip between the plates of the variable condensers to determine whether the circuits are properly matched. The action is this--the dielectric constant of the celluloid feeler strip being higher than that of the air it displaces, results in an increase of capacity. Open the variable condenser just enough to indicate two or three points below maximum signal. As the feeler is inserted the meter reading should indicate increasing signal and then decreasing as the feeler is inserted farther. This procedure should be followed on both sections. Should the meter fail to show an increase in signal as the strip is inserted in one section this indicates too great a capacity for that section. This may be corrected by bending the outside rotor plates out at the point where they begin to mesh with the stator.

After checking the alignment at 1000 Kc. repeat the process at 600 Kc.

SHORT WAVE BAND: Place the band change switch on the Short Wave position. Turn the dial to 15.5 megacycles and feed a very weak 15.5 megacycle modulated signal from your signal generator to the antenna. Adjust the S. W. oscillator trimmer (at opposite end of three gang trimmer) for maximum reading on the output meter. This trimmer should not be touched again when checking alignment on other frequencies.

Next go to 12 megacycles and adjust the S. W. detector trimmer.

Instead of bending condenser plates at 6 megacycles alignment is accomplished by spreading or crowding turns on the S. W. detector coil. If much crowding or spreading is necessary it is advisable to go back and recheck at 12 megacycles.

Schematic
Voltage

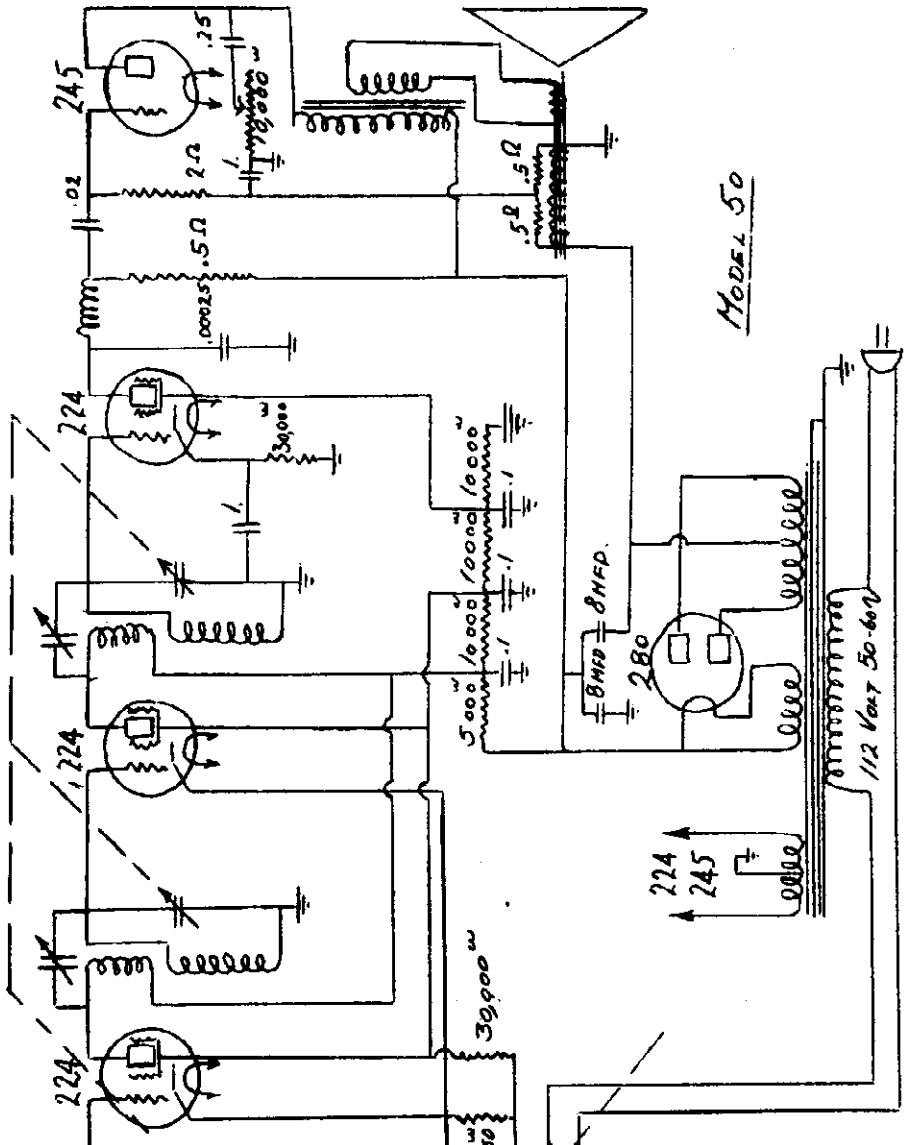
JACKSON-BELL CO., INC.

Voltage readings were made with a 1000 ohm per volt meter, 250 volt range.

*The reading here on a set analyzer will show about 2 volts due to the fact that the 2 meg. ohm resistor is in series with the meter. To check grid voltage, drop across speaker divided by 2 will be the approximate voltage applied to grid. If plate current is about 25 mils and voltage about 220, it is safe to assume that the gri_ bias is O.K.

R. F. Plate Voltage, ...	160	
R. F. Screen Grid Voltage, . . .	75	
R. F. Grid Bias, ...	2.5	
R. F. Plate Current, ...	2.5	M
First A. F. Plate Current, . . .	3½	M
First A. F. Plate Voltage, . . .	115	V
First A. F. Bias.	5	V

'45s Plate Voltage, ...	225	V
'45s Bias, ...	50	V
'45s Plate Current, ...	30	M
Detector Screen Grid Voltage . .	50	V
Detector Bias, ...	5	V
Detector Plate Current, ...	.2	MA#
# no signal in receiver		
Detector Plate Voltage, ...	100	*



**Detector bias reading is taken at the overload point of an incoming signal where it generally reaches a maximum of 5 volts. With zero volume control, the reading here is approximately 4 volts. This, of course, is not the true reading, because resistance of volt meter becomes a parallel circuit, cutting down the resistance, and of course, dropping the voltage. Reading taken in this case was with 10,000 ohm meter (1000 per volt, 10 volt scale.

***This reading is subject to considerable variation with meters of various resistances, as the voltage at this point is measured through a 500,000 ohm resistor. The voltage at the opposite end of the resistor should be 220 volts.

Speaker field resistance 1500 ohm. 110 volts.

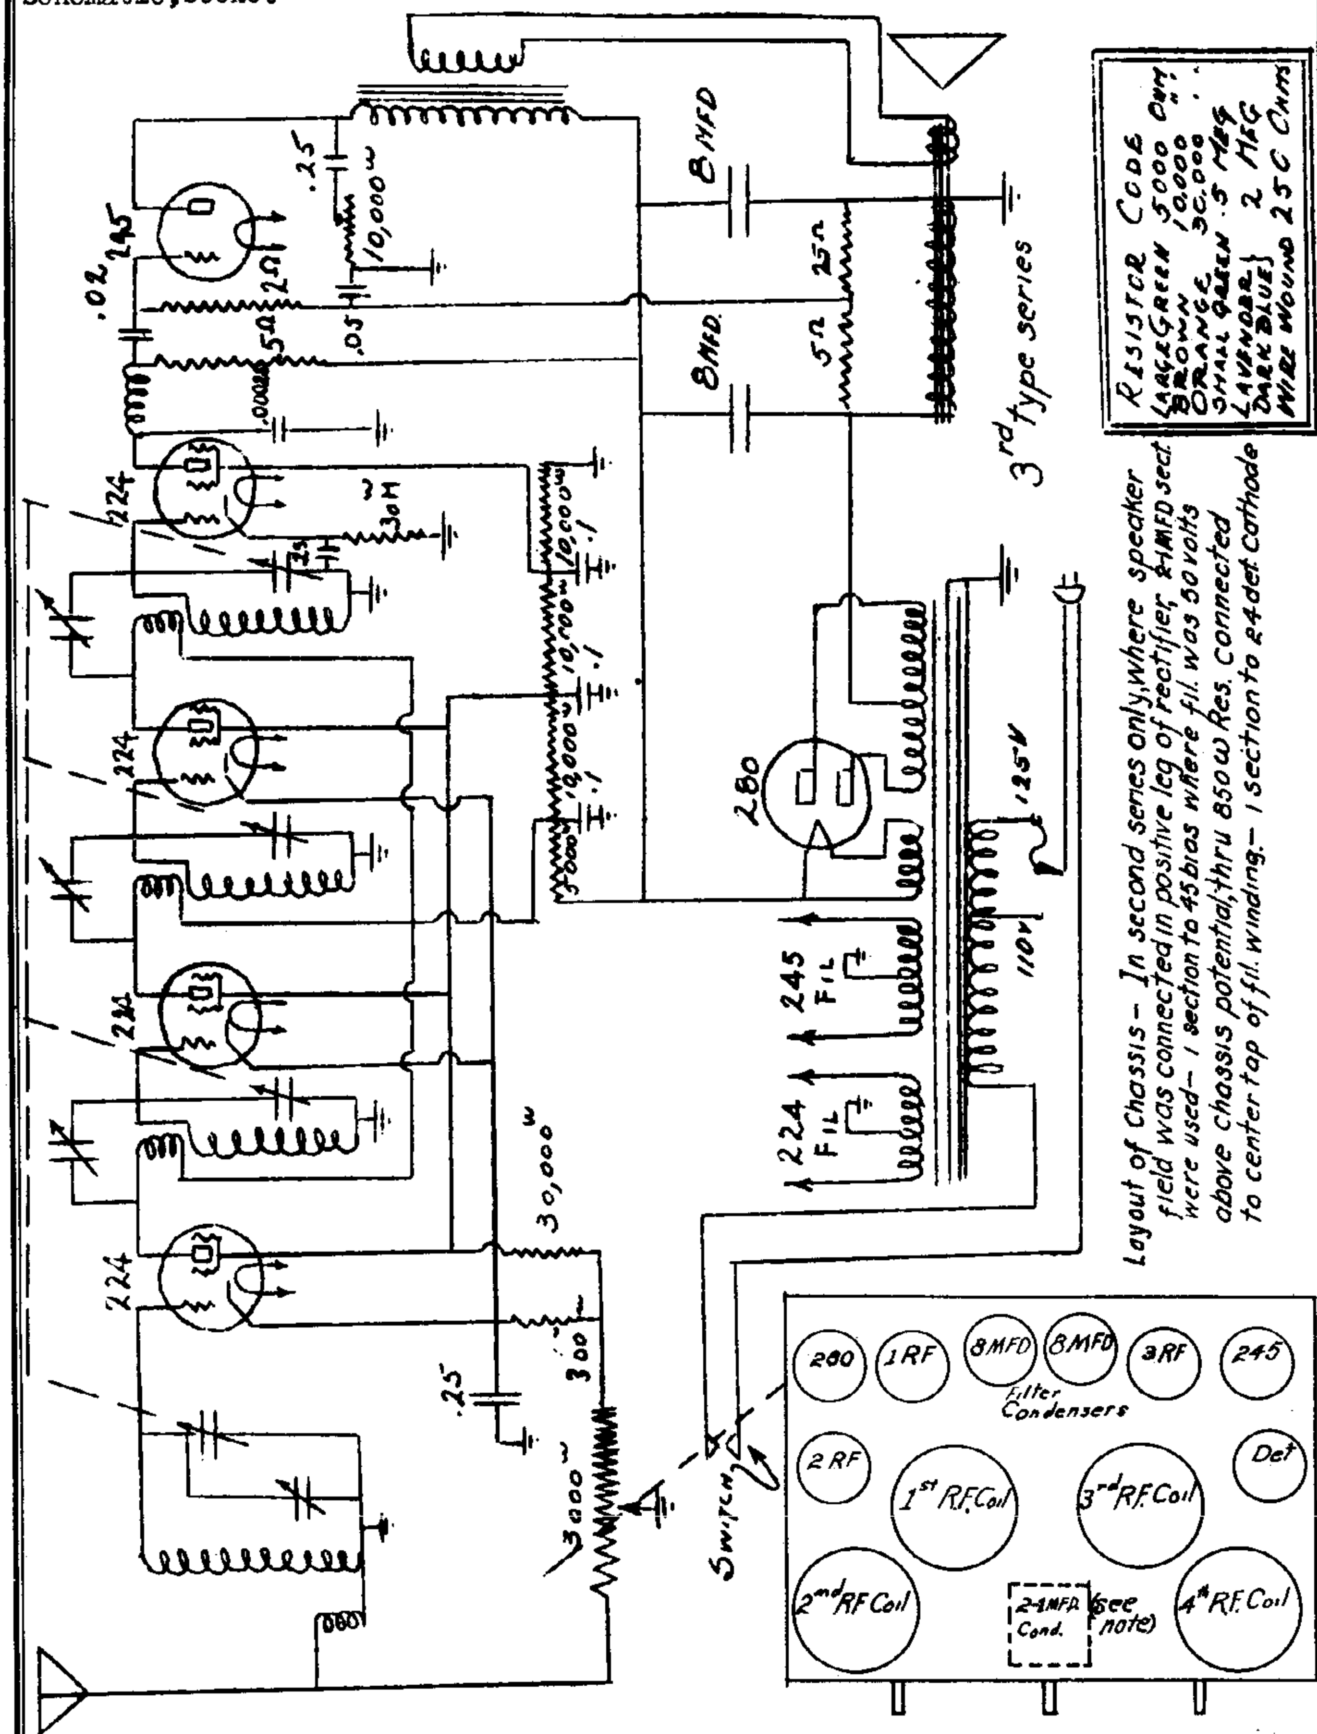
MODEL 62
2nd & 3rd Series
Schematic, Socket

JACKSON-BELL CO., INC.



JACKSON-BELL CO., INC.

VOLTAGE AND CURRENT VALUES - MODEL 60 RECEIVERS

The following values are correct with 1000 ohm speaker field and 110 volts A.C. on the line, or 125 volts on the line when power transformer is thus connected. With volume control at half way position the following voltages should be indicated from ground:

To 280 filaments,	240 volts
To low side of choke,	180 "
To detector screen grid,	28 to 32 volts
To 171 filaments,	30 volts
To R.F. Filaments,	10 to 15 volts

As volume control is rotated from maximum to minimum

The following values of plate current should be read within 20%:

R.F. .00025 to .005 amperes as volume control is rotated from minimum to maximum.
Detector 80 to 100 micro amperes.
First audio .002 amperes.
Second audio .017 to .020 amperes.

CONTINUITY TESTS:

The following resistance values should be observed when making continuity tests without removing the chassis from the cabinet:

R.F. Grid to ground,	800 ohms.
R.F. Plate to ground,	23000 "
R.F. Filament to ground,	1100 to 3200 ohms
as volume control is shifted from maximum to minimum	
Detector grid to ground,	1 ohm
Detector screen grid to ground,	3000 "
Detector cathode to ground,	20000 "
Detector filament to ground,	0
First audio grid to ground,	2 meg
First audio filament to ground,	5000 ohms
First audio plate to ground,	43000 "
Second audio grid to ground,	1500 "
Second audio filament to ground,	750 "
Second audio plate to ground,	23000 "

COILS:

Effective immediately, specifications of the radio frequency transformers used in the Model 60 receiver are changed to the following:-

Primaries,	16 turns
Secondaries,	81 "
Circuit inductance,	240 microhenries

The overall gain throughout the radio frequency amplifier with the new coils is approximately 300% greater than with the old ones. The substantial increase of sensitivity should, therefore, be observed.

When orders for replacement coils are filled they will always be in complete sets of three and of new type.

GRID SUPPRESSORS

Service notes and circuit print of this receiver show 2 - 800 ohm grid suppressors. The grid suppressor of the first radio frequency stage has been reduced to 300 ohms. The second one remains 800.

FILTER SYSTEM:

Specifications of this receiver call for 2 - 8 microfarad electrolytic condensers in the filter. At times when the factory has been unable to obtain these electrolytic condensers it has been necessary to substitute paper condensers and an additional filter choke. The value of the units in the paper condenser block is as follows:

When the block is fastened in the chassis and the chassis is viewed in an inverted position, the bottom terminal is five microfarads, the center terminal one microfarad and the top terminal two microfarads. Only a limited number of these have been installed and regular production will continue to contain the electrolytic condensers.

MODEL 62
2nd & 3rd Series
SERVICE NOTES
FOR SERIAL NO. 120,000 AND UP

If it should become necessary to resonate the radio frequency circuit, proceed as follows:-

Set the dial at about 20 degrees and set all coupling condensers at approximately one full turn to the left of the maximum capacity adjustment. With a grid dip oscillator, check all circuits for resonance, making connection to the caps on top of the screen grid tubes. The tubes should be cold when this is done. If it is necessary to move any of the coupling condensers more than one-half turn in order to obtain resonance, adjustment of capacity in that particular stage should be made by bending the split rotor plate of the variable condenser. This does not apply to the antenna stage where the condenser on the coil does not affect coupling. When resonance has been obtained at this point, the dial should be shifted to 90, and all stages again checked with a grid dip meter. Here all capacity adjustments must be made by bending plates, being careful not to disturb the position of that portion of the split plate which was active when the first adjustment was made.

VOLTAGE AND CURRENT VALUES:

With the volume control at maximum, the following readings should be obtained, with an allowable variation of 10%:-

R.F. Plate voltage.	180
R.F. Screen Grid Voltage.	75
R.F. Grid Bias.	2.5
R.F. Plate current.	2.5M
245 Plate Voltage	225
245 Plate current	30
245 Bias.	50 V.
Detector Screen Grid Voltage.	50 "
Detector Bias	5 "
Detector Plate Current.	.2 M (No signal in Receiver)
Detector Plate Voltage.	100*

*This reading will be obtained with a 300,000 ohm volt-meter as found in a Jewell 199 test set. This reading is subject to considerable variation with meters of various resistances, as the voltage at this point is measured through a 500,000 ohm resistor. The voltage at the opposite end of the resistor should be 250.

MODEL 68

If it should become necessary to resonate the radio frequency circuit, proceed as follows:

Set the dial at about 20 degrees and set all coupling condensers at approximately one full turn to the left of the maximum capacity adjustment. With the grid dip oscillator, check all circuits for resonance, making connection to the caps on top of the screen grid tubes. The tubes should be cold when this is done. If it is necessary to move any of the coupling condensers more than one-half turn in order to obtain resonance, adjustment of capacity in that particular stage should be made by bending the split rotor plate of the variable condenser. This does not apply to the antenna stage where the variable condenser on the coil does not affect coupling. When resonance has been obtained at this point, the dial should be shifted to 90 and all stages again checked with the grid dip meter. Here all capacity adjustments must be made by bending plates, being careful not to disturb the position of that portion of the split plate which was active when the first adjustment was made.

ALIGNMENT PROCEDURE

Realignment of this receiver should not be attempted unless all other possible causes of possible faulty operation have been thoroughly investigated. An accurately calibrated signal generator which will cover the necessary wave-bands and an output meter for indicating the effect of adjustments are required.

I.F. ADJUSTMENT - The signal generator is tuned to 115 kc. and is connected to the grid cap of the first detector (58) tube. The grid clip from the receiver is disconnected. The ground side of the generator is connected to the gnd. post of the receiver. The trimmers are adjusted by turning the screws up and down until maximum response is obtained in the output meter. Both the primary and secondary trimmers of the first i.f. transformer should be adjusted in this manner. The second i.f. transformer is an impedance coupled device and has no trimmers to adjust. The third i.f. transformer is aligned in the same manner as the first, except that the latter has only one trimmer. The first transformer is mounted in back of the short wave coil assembly. The third i.f. transformer is located between the 55 a.v.c. & n.s.c. tube and the 58 second detector. All i.f. trimmers are accessible from the top of the i.f. transformer shield cans.

1400 KC. ADJUSTMENT - The high side of the signal generator is connected to the antenna post of the receiver and the low side to the ground post. The receiver and the signal generator are both tuned to a frequency of 1400 kc. The oscillator trimmer condenser is adjusted for maximum receiver output, with the volume control on full and the signal generator adjusted for minimum input. The antenna preselector and first detector variable condenser trimmers are then adjusted in the order named. The variable condenser sections are, reading from front of the receiver to the rear, the antenna preselector, first detector, and oscillator.

600 KC. ADJUSTMENT - The receiver and signal generator are both tuned to 600 kc. and the 600 kc. padding condenser is adjusted for maximum output. This condenser is located on the left hand side of the chassis closest to the rear. The one toward the front of the chassis immediately adjacent to the 600 kc. padding condenser, is the 9.5 megacycle padding condenser. It may be necessary to rock the variable condenser slightly to the right and left in making this adjustment.

9.5 MEGACYCLE ADJUSTMENT - The band selector switch is adjusted for operation on band no. 1 and the receiver tuned to a point midway between 10 megacycles and the end of the dial. (approximately 9.5 meg.). The signal generator is set for a signal of 9.5 megacycles. The 9.5 megacycle trimmer, located alongside of the 600 kc. padding condenser, is now adjusted to bring in the signal at this dial setting. FAILURE TO HAVE THE CORRECT SIGNAL FREQUENCY OR AN IMPROPER SETTING OF THE RECEIVER DIAL WILL RESULT IN THE CALIBRATION OF THE DIAL BEING INACCURATE. After the 9.5 megacycle padding condenser has been correctly adjusted, the band selector switch should be changed for operation on band no. 2, and the 9.5 megacycle signal should come in at approximately 9.5 megacycles on the dial's calibrated section. If the signal is received too far from the correct dial position it will be necessary to recheck the 9.5 megacycle padding condenser. (NOTE:- The cause may be due to improper adjustment of the signal generator frequency.).

140 KC. ADJUSTMENT - This adjustment can only be made on the Model E-204 when it is necessary to align the no. 5 band (140 to 370 kc.). The signal generator is tuned to a frequency of 140 kc. With the band selector switch adjusted for operation on band no. 5, and the receiver dial set at 140 kc., the 140 kc. padding condenser is adjusted for maximum response on the output meter. This padding condenser is located on the front of the chassis pan below the tuning dial and is accessible through the small hole in the chassis pan. The signal generator is then set at 350 kc. and the receiver dial set at this same frequency. The chassis is turned on end and the signal tuned in by adjusting the trimmer condenser, which is mounted on the back section of the selector switch. After peaking with this trimmer condenser, a further fine adjustment may be had by adjusting the oblong shaped trimmer mounted between the first and second sections of the wave selector switch. After these two trimmers have been correctly adjusted, the 140 kc. adjustment should be rechecked as the alignment of the latter is affected slightly by the adjustment of the former.

PHONOGRAPH OPERATION

On the back of the chassis adjacint to the ant-gnd posts, are located the phonograph jacks into which the two tips of the phonograph pickup are to be inserted. It is necessary that the pickup be equipped with a volume control of its own. The toggle switch located just below the tip jacks, must be snapped in the position marked "p" for phonograph operation and to the position marked "r" for radio operation.

SHORT WAVE TRIMMER

The short wave trimmer is used for a fine tuning adjustment when short wave reception between 1.5 and 24 mc. is desired. It is inoperative when the receiver is operating on the broadcast band.

FREQUENCY BANDS

The model E-204 is designed for the following five frequency bands:

Band #1 24 to 9.8 mc.
Band #2 9.8 to 3.8 mc.
Band #3 3.8 to 1.5 mc.
Band #4 1500 to 550 kc.
Band #5 350 to 130 kc.

Model E-20 is designed for the first four bands listed above only. Band #1 may be selected by placing the wave selector switch in the maximum left hand position. The other bands follow in rotation, as the knob is turned to the right.

ALIGNMENT PROCEDURE

Realignment of this receiver should not be attempted unless all other possible causes of possible faulty operation have been thoroughly investigated. An accurately calibrated signal generator which will cover the necessary wave-bands and an output meter for indicating the effect of adjustments are required.

I.F. ADJUSTMENT - The signal generator is tuned to 115 kc. and is connected to the grid cap of the first detector (58) tube. The grid clip from the receiver is disconnected. The ground side of the generator is connected to the gnd. post of the receiver. The trimmers are adjusted by turning the screws up and down until maximum response is obtained in the output meter. Both the primary and secondary trimmers of the first i.f. transformer should be adjusted in this manner. The second i.f. transformer is an impedance coupled device and has no trimmers to adjust. The third i.f. transformer is aligned in the same manner as the first, except that the latter has only one trimmer. The first transformer is mounted in back of the short wave coil assembly. The third i.f. transformer is located between the 55 a.v.c. & n.s.c. tube and the 58 second detector. All i.f. trimmers are accessible from the top of the i.f. transformer shield cans.

1400 KC. ADJUSTMENT - The high side of the signal generator is connected to the antenna post of the receiver and the low side to the ground post. The receiver and the signal generator are both tuned to a frequency of 1400 kc. The oscillator trimmer condenser is adjusted for maximum receiver output, with the volume control on full and the signal generator adjusted for minimum input. The antenna preselector and first detector variable condenser trimmers are then adjusted in the order named. The variable condenser sections are, reading from front of the receiver to the rear, the antenna preselector, first detector, and oscillator.

600 KC. ADJUSTMENT - The receiver and signal generator are both tuned to 600 kc. and the 600 kc. padding condenser is adjusted for maximum output. This condenser is located on the left hand side of the chassis closest to the rear. The one toward the front of the chassis immediately adjacent to the 600 kc. padding condenser, is the 9.5 megacycle padding condenser. It may be necessary to rock the variable condenser slightly to the right and left in making this adjustment.

9.5 MEGACYCLE ADJUSTMENT - The band selector switch is adjusted for operation on band no. 1 and the receiver tuned to a point midway between 10 megacycles and the end of the dial. (approximately 9.5 meg.). The signal generator is set for a signal of 9.5 megacycles. The 9.5 megacycle trimmer, located alongside of the 600 kc. padding condenser, is now adjusted to bring in the signal at this dial setting. FAILURE TO HAVE THE CORRECT SIGNAL FREQUENCY OR AN IMPROPER SETTING OF THE RECEIVER DIAL WILL RESULT IN THE CALIBRATION OF THE DIAL BEING INACCURATE. After the 9.5 megacycle padding condenser has been correctly adjusted, the band selector switch should be changed for operation on band no. 2. and the 9.5 megacycle signal should come in at approximately 9.5 megacycles on the dial's calibrated section. If the signal is received too far from the correct dial position it will be necessary to recheck the 9.5 megacycle padding condenser. (NOTE:- The cause may be due to improper adjustment of the signal generator frequency.).

140 KC. ADJUSTMENT - This adjustment can only be made on the Model E-204 when it is necessary to align the no. 5 band (140 to 370 kc.). The signal generator is tuned to a frequency of 140 kc. With the band selector switch adjusted for operation on band no. 5, and the receiver dial set at 140 kc., the 140 kc. padding condenser is adjusted for maximum response on the output meter. This padding condenser is located on the front of the chassis pan below the tuning dial and is accessible through the small hole in the chassis pan. The signal generator is then set at 350 kc. and the receiver dial set at this same frequency. The chassis is turned on end and the signal tuned in by adjusting the trimmer condenser, which is mounted on the back section of the selector switch. After peaking with this trimmer condenser, a further fine adjustment may be had by adjusting the oblong shaped trimmer mounted between the first and second sections of the wave selector switch. After these two trimmers have been correctly adjusted, the 140 kc. adjustment should be rechecked as the alignment of the latter is affected slightly by the adjustment of the former.

PHONOGRAPH OPERATION

On the back of the chassis adjacint to the ant-gnd posts, are located the phonograph jacks into which the two tips of the phonograph pickup are to be inserted. It is necessary that the pickup be equipped with a volume control of its own. The toggle switch located just below the tip jacks, must be snapped in the position marked "p" for phonograph operation and to the position marked "r" for radio operation.

SHORT WAVE TRIMMER

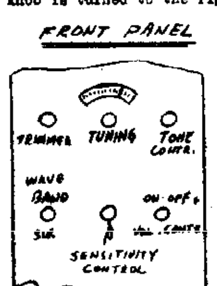
The short wave trimmer is used for a fine tuning adjustment when short wave reception between 1.5 and 24 mc. is desired. It is inoperative when the receiver is operating on the broadcast band.

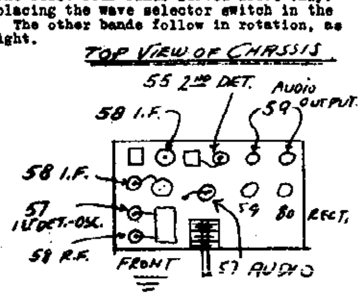
FREQUENCY BANDS

The model E-204 is designed for the following five frequency bands:

Band #1 24 to 9.8 mc.
Band #2 9.8 to 3.8 mc.
Band #3 3.8 to 1.5 mc.
Band #4 1500 to 550 kc.
Band #5 350 to 130 kc.

Model E-20 is designed for the first four bands listed above only. Band #1 may be selected by placing the wave selector switch in the maximum left band position. The other bands follow in rotation, as the knob is turned to the right.





LAFAYETTE RADIO MFG. CO.

OPERATING INSTRUCTIONS FOR THE MODEL C-80
7 TUBE 3 BAND A.C.-D.C. SUPERHETERODYNE RECEIVER

POWER SUPPLY

This receiver is designed to operate on either direct or alternating current of any frequency on voltages between 105 and 130. If voltages in excess of this value are to be applied, a special voltage reducing resistor must be used. For operation on 220-250 volts, a type 220 amperite is substituted for the type 3-40 amperite.

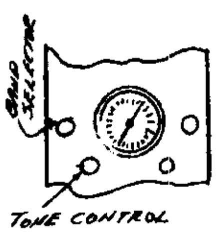
When operating from direct current, the tubes should be allowed about three-quarters of a minute to heat up; if, at the end of this time, no reception is heard, the line plug should be reversed in the socket. Power consumption - 50 watts.

FREQUENCY BAND

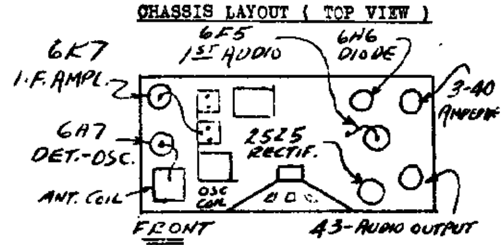
The receiver operates on three frequency bands; either band may be selected by means of the selector switch which is located at the extreme right, on the front panel. This switch has three positions which are marked to correspond to the three frequency bands designated below. The dial is also calibrated with three separate scales for these three bands:

Band #1	short wave	5 to 16 mc.	60. to 18.75 meters
Band #2	broadcast	540 to 1540 kc.	555.5 to 194.8 meters
Band #3	long wave	140 to 326 kc.	2143 to 920.2 meters

FRONT PANEL VIEW



CHASSIS LAYOUT (TOP VIEW)



ALIGNMENT PROCEDURE

Realignment of this receiver should not be attempted unless all other possible causes of faulty operation have first been thoroughly investigated. An accurately calibrated signal generator which will cover the various wave-bands, and an output meter for indicating the effects of adjustments, are required.

MODEL C-80

I.F. ADJUSTMENT - The signal generator is set at 456 kc. The "hot" lead from the signal generator is connected to the grid cap on the 1st detector (6A7) tube, the clip having first been removed from the tube cap. The ground lead is connected to the receiver gnd. post. The oscillator section (front) of the gang tuning condenser is short-circuited and the volume control turned on full. The i.f. trimmers are then adjusted for maximum gain in the receiver. These trimmers are located on top of the i.f. transformer shield cans, which are situated in the rear of the chassis, to the left. The one nearest the front is the 1st i.f. transformer and the rear one is the 2nd i.f. transformer.

16 MEGACYCLE ADJUSTMENT - The short-circuit is removed from the oscillator condenser and the grid clip replaced in its normal position on the cap of the 6A7 tube. The "hot" lead from the signal generator is connected to the antenna post of the receiver and the ground lead to the ground post of the receiver. With the volume control set at maximum and a minimum input signal from the signal generator, the band switch is set at position no. 1 and the receiver dial set at 16 mc. The oscillator trimmer is adjusted for maximum gain at this setting. This trimmer is found on the side of the oscillator coil shield can which is located directly in front of the i.f. transformers. The upper trimmer is the one for this wave-band. After the oscillator is adjusted, the antenna trimmer is adjusted. This is found on the front of the antenna coil can which is directly in front of the 6A7 tube. The lower trimmer is the one for this band.

6 MEGACYCLE PADDER ADJUSTMENT - With all connections as above, the signal generator is set at 6 mc. and the signal tuned in on the dial. The padder for this frequency is found on the front sub-panel of the receiver, in the lower left hand corner. This padder should be adjusted for maximum response of the receiver, while the tuning condenser is rocked slightly back and forth. The 16 mc. adjustment should then be rechecked.

1400 KILOCYCLE ADJUSTMENT - With the receiver and signal generator both set at 1400 kc. the procedure outlined above is repeated. The trimmers are adjusted for maximum gain of the receiver. These trimmers are located on the coil shield cans; the oscillator trimmer for this band is the bottom one on the oscillator can; the detector trimmer, is the upper one on the detector or antenna coil can. The 600 kc. padder is on the front sub-panel, directly under the selector switch.

LONG WAVE ADJUSTMENT - With the receiver and signal generator both set at 325 kc. the procedure outlined above is repeated. The trimmers are located on the left side panel of the chassis; the one towards the rear is the oscillator trimmer, and the one near the front is the antenna trimmer. There is no series padder for this band.

MODEL C-79

The alignment procedure for the Model C-79 is exactly the same as for the model C-80 except for the location of the trimmers, and the designation of the bands. These are as follows:

Short wave band - Oscillator trimmer is the lower one on the osc. coil can.
Antenna trimmer is the upper one on the antenna coil can.
No series padder.

Broadcast band - Oscillator trimmer is the upper one on the antenna coil can.
Antenna trimmer is the lower one on the antenna coil can.
600 kc. series padder is on the lower left hand corner of the front sub-panel.

Police band -- Trimmers are on the left side panel of the chassis. The one towards the rear is the oscillator shunt trimmer; the one towards the front is the antenna shunt trimmer.

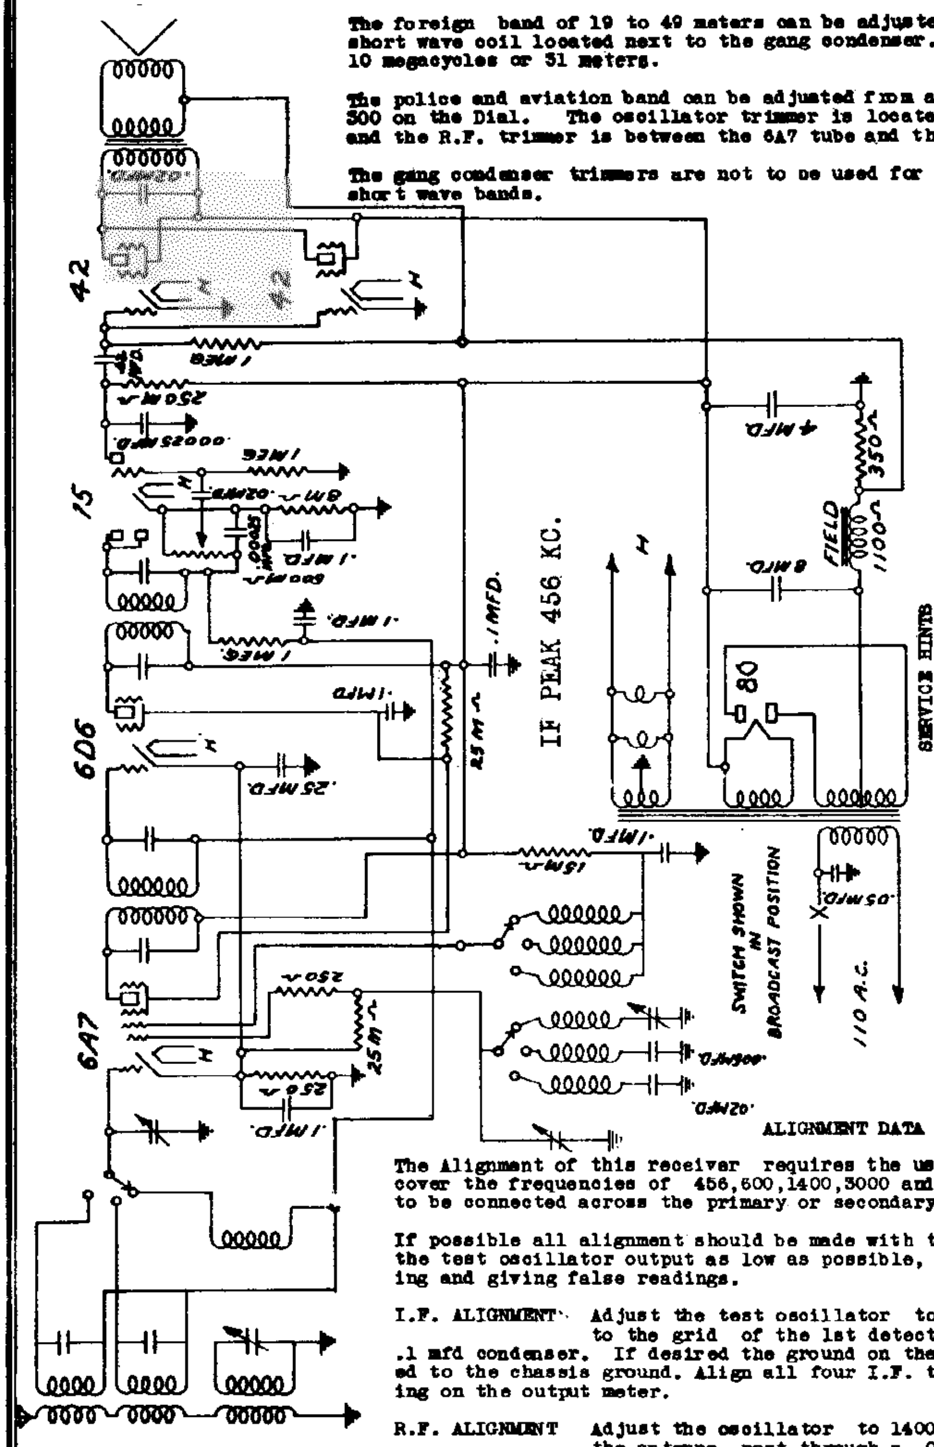
SHORT WAVE BANDS

The foreign band of 19 to 49 meters can be adjusted by the two trimmers on the short wave coil located next to the gang condenser. Set the test oscillator to 10 megacycles or 31 meters.

The police and aviation band can be adjusted from a signal set at 3,000 K.C. or 300 on the Dial. The oscillator trimmer is located underneath the chassis set and the R.F. trimmer is between the 6A7 tube and the wave change switch.

The gang condenser trimmers are not to be used for alignment of either of the short wave bands.



SCHEMATIC DIAGRAM
OF
MODEL ~
137X-150X-171X

SERVICE HINTS

LOW VOLUME This may be caused by weak or defective tubes (Replace with set of tubes known to be in good condition), antenna disconnected from the receiver, open antenna coil, open or shorted by-pass condensers, or defective wave change switch.

LOW VOLTAGE Low voltage may be caused by a defective 80 rectifier, low line voltage, a defective power transformer or shorted by-pass condensers.

HUM Excessive hum may be caused by a defective 80 tube, open filter condenser, or open audio grid lead.

DISTORTED REPRODUCTIONS This may be caused by a defective 75 or 42 tube or a ground or open in the automatic volume control circuits. Check all circuits with an ohmmeter or continuity tester.

OSCILLATION Most trouble from oscillation is due to open by-pass or defective filter condenser. The grid lead on the 75 tube may also cause a howl if it runs too close to the 42 tube.

ALIGNMENT DATA

The Alignment of this receiver requires the use of a test oscillator that will cover the frequencies of 456,600,1400,3000 and 10,000 K.C. and an output meter to be connected across the primary or secondary of the output transformers.

If possible all alignment should be made with the volume control on maximum and the test oscillator output as low as possible, to prevent the AVC from operating and giving false readings.

I.F. ALIGNMENT. Adjust the test oscillator to 456 K.C. and connect the output to the grid of the 1st detector tube (6A7) through an .05 or .1 mfd condenser. If desired the ground on the test oscillator can be connected to the chassis ground. Align all four I.F. trimmers to peak or maximum reading on the output meter.

R.F. ALIGNMENT Adjust the oscillator to 1400 K.C. and connect the output to the antenna post through a .0001 mfd. mica condenser to give the equivalent of an antenna about 60 feet. Set the receiver pointer to 1400 K.C. and adjust the rear gang condenser trimmer to peak.

Next rest the dial pointer on the receiver and the test oscillator to 600 K.C. Slowly increase or decrease the oscillator padding condenser, and at the same time continuously tuning back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment seems a little complicated but is the easiest way to adjust the oscillator to the preselector or R.F. section. The padding condenser is located on the left hand end of the chassis.

Return to 1400 K.C. and again go over the adjustments at that frequency to be sure they have not been thrown out of adjustment.

THE PROCEDURE TO ALIGN THE I.F. STAGES

The IF's are aligned in the usual system of feeding the intermediate frequency of 465 KC into the grid of the 6A7 1st Detector tube.

Make certain that the sensitivity adjustment (which is the knurled shaft extending from the back of the chassis) is turned all the way to the right when aligning the IF, RF or Oscillator circuits.

The two trimmers in each of the three IF Coil Cans should be very carefully tuned to resonance as they are very critical and will greatly affect the performance of the receiver.

The sensitivity of the IF stages should be between 10 and 20 Microvolts.

On some of the models the trimmer screws extend through the bottom of the chassis as per pictorial view. On other styles the trimmers are reached through the top of each IF shield can.

3. NOTES ON ALIGNING THE R.F. AND OSCILLATOR CIRCUITS

(a) After the IF's are aligned, the various circuits may be aligned in the order given below.

(b) Keep the sensitivity adjustment all the way on to the right as before.

(c) It is not necessary that the oscillator be taken out of its socket when aligning any of the RF circuits.

(d) Always adjust the oscillator stage before the RF in any particular band.

(e) Before adjusting any band, make certain that the pointer of the station indicator is set on the last line when the dial is turned all the way to the right, on above 550 - at this point the variable condenser should be all the way in to maximum capacity. See pictorial.

(f) The plates on the variable condenser should be bent to make the KC readings on the dial line up ONLY on the Broadcast Band.

(g) Always seal the trimmers with wax or collidon after their adjustment.

(h) After the high frequency adjustments have been made on short wave bands, the test oscillator or generator should be advanced to 930 KC higher in frequency - the output voltage of generator advanced considerably and notice of the image signal of receiver oscillator falls at this point. In case this signal is not heard, the adjustment of the receiver oscillator has been incorrectly made. As an example:-

After the third short wave band has been adjusted at 20 M.C. it should be possible to move the test oscillator to 20 + 930 KC and hear the signal.

(i) Before starting with the alignment adjust antenna series condenser A - without the use of the signal generator - by turning the screw all the way down to maximum capacity, and then unloosen the screw about one half turn.

(j) Start with the third (highest frequency). Short wave band as follows:-

4. THIRD SHORT WAVE BAND

Refer to the pictorial views of the chassis.

Rotate band switch all the way to left to 25-11 Megacycle setting.

Set dial hand to 24 Megacycles.

Peak trimmer B to 24 Megacycles from the signal generator fed into the antenna.

If the set is far out of alignment, it may be necessary to use a heavy input from the generator and also vary the Antenna Coil and Mixer Coil Trimmers C and D until the heavy signal is not necessary. Make the final adjustment on C and D after the oscillator B trimmer is set.

Next, set the dial hand to 12 Megacycles on the same band and with a 12 Megacycle signal, resonance may be checked and corrected by shifting the ground lead at "V" (see pictorial) by sliding it in either direction as necessary along the bare ground wire for the greatest gain.

As mentioned above in paragraph three - the image signal may be checked to determine if the adjustments have been made on the correct signal.

5. SECOND SHORT WAVE BAND

Rotate band switch to 12-4 Megacycles.

Set dial hand to 12 Megacycles.

Peak trimmer E at 12 Megacycles.

Peak Trimmers F and G in the RF circuits on the same frequency.

Set dial hand to 4½ Megacycles on the same band.

Adjust padding condenser H to the 4½ Megacycle signal.

6. FIRST SHORT WAVE BAND

Rotate band switch to 4-1.5 Megacycles.

Set dial hand to 4 Megacycles.

Peak Trimmer I to 4 Megacycles.

Peak Trimmers J and K in the R.F. circuits to the same frequency.

Set dial hand to 1.5 Megacycles.

Adjust Padding Condenser L to resonance with 1.5 Megacycles.

7. BROADCAST BAND

Rotate band switch to "B" position.

Set dial hand to 1500 Kilocycles.

Peak Trimmer M to 1500 Kilocycles.

Peak Trimmers N and O to 1500 Kilocycles.

Set dial to 550 Kilocycles.

Adjust Padding Condenser P to resonance with 550 Kilocycles.

Recheck dial at 1500 Kilocycles.

Check the middle of the dial at 950 Kilocycles for example and bend the plates of the variable condenser if necessary to line up with the calibration.

8. THE LONG WAVE

This adjustment applies to sets that have the extra band from 150 Kilocycles to 350 Kilocycles attached.

The alignment trimmers are shown in dotted lines on the Pictorial Diagram.

Rotate band switch to its fifth position - all the way to the right.

Set dial hand to 350 Kilocycles.

Peak Trimmer Q to 350 Kilocycles from the signal generator.

Peak Trimmers R and S in the RF circuits to the same frequency.

Set dial hand to 150 Kilocycles.

Adjust Padding Condenser T at 150 Kilocycles.

9. NOTES

(a) On some series the two resistors - 800 and 2000 ohm, have been added.

(b) Refer to schematic #4903 showing changes, if any, that have been made since sets were in production.

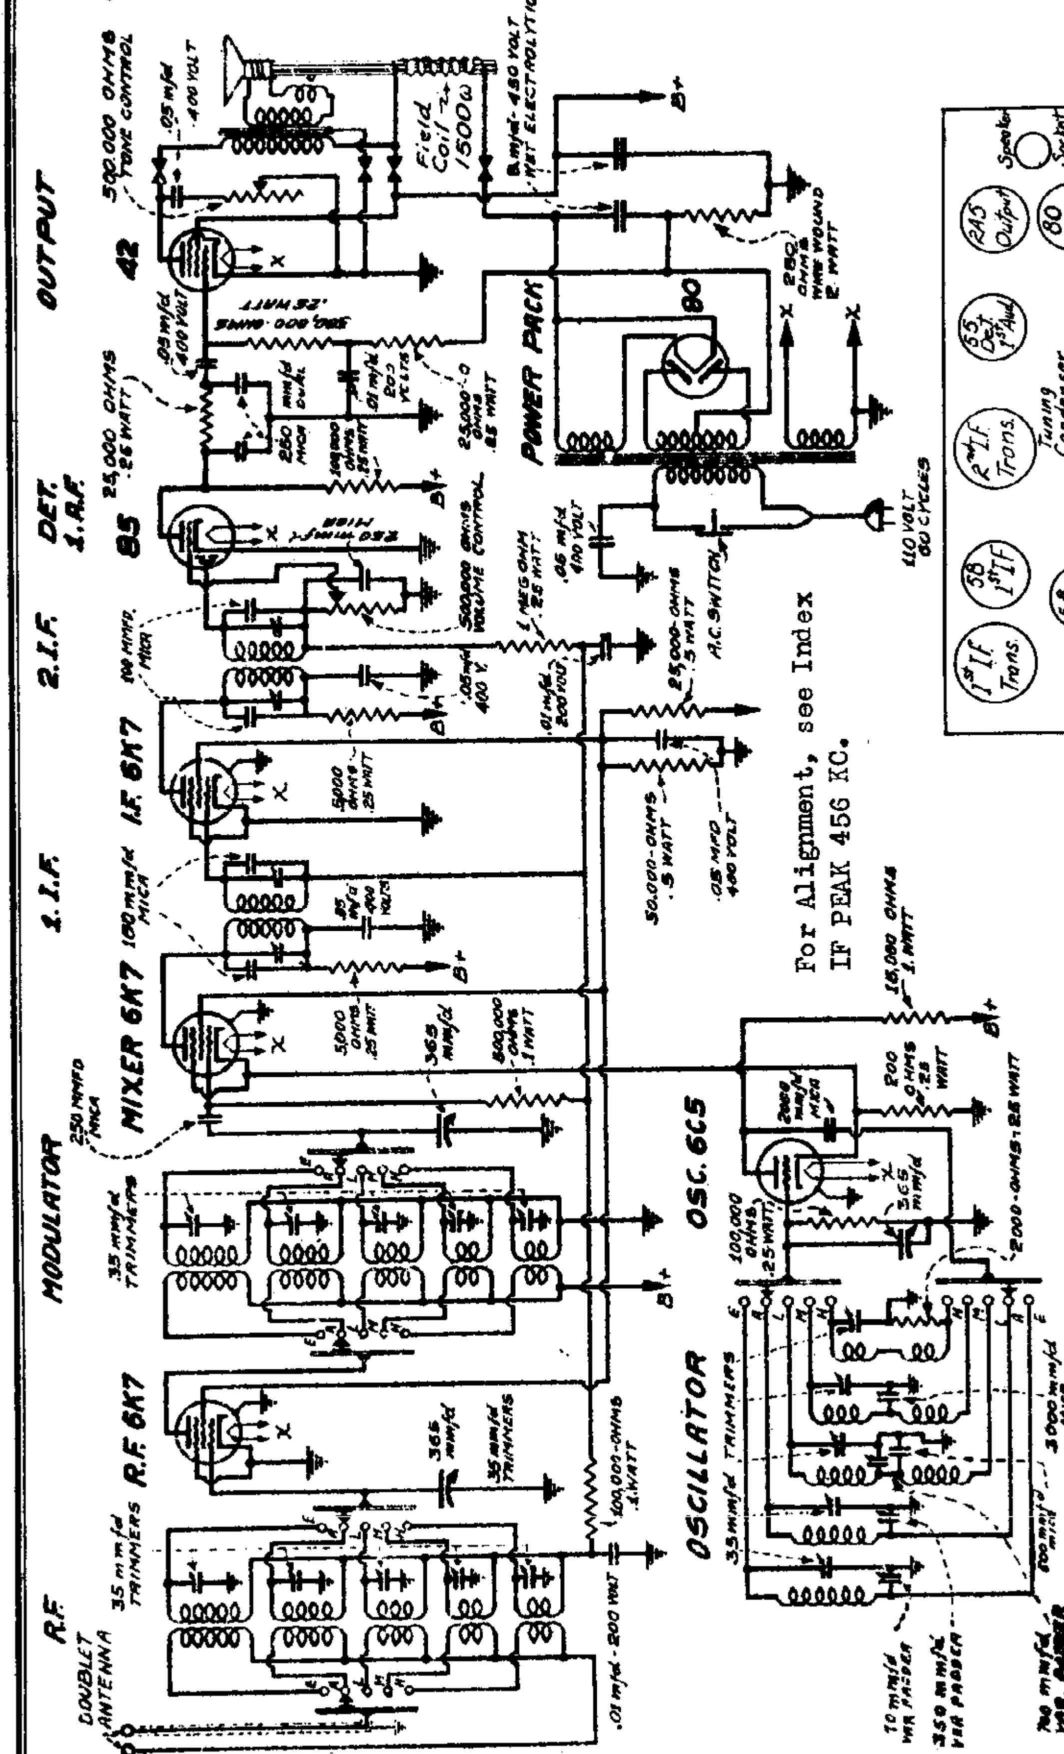
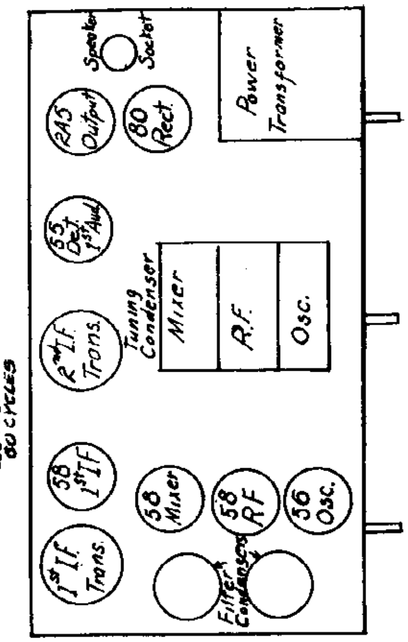
MODEL 7-36 Early, Late
Schematic
Socket

MID-WEST RADIO CORP.



For Alignment, see Index
IF PEAK 456 KC.



In early Model 7-36 the tube complement was: R-f. 58; Modulator 58; Osc. 56; I-f. 58; Detector 55; Output 2A5, and the rectifier 80.
The 100-mmf. condensers across the 1st i-f. transformer were 50 mmf. and no fixed condensers shunted the trimmers of the 2nd i-f. transformer.
A .01-mf. condenser was connected between the "H" Osc. winding and ground.

Alignment

MID-WEST RADIO CORP.

INSTRUCTIONS FOR ALIGNING THE MIDWEST 24 TUBE RECEIVER (ROYALE)

A good signal generator with accurate frequency calibration and an output meter are required. An intermediate frequency of 456 kc is used.

(1) Set the signal generator to 456 kc and connect it from the mixer grid to ground.
(2) Remove the oscillator tube from the receiver.
(3) Connect the output meter from the plate of the output tube to positive B, or from the plates of one pair of tubes to the plates of the other pair of tubes.
(4) Set the selectivity control to the maximum right hand position
(5) Using a weak signal approximately 20 micro-volts, align the I.F. transformers to maximum output.
(6) Increase the input from the generator to approximately 100 micro-volts. Align the A.V.C. transformer for minimum output.
(7) Repeat using weaker signal strengths for the I.F. and stronger signal strength for the A.V.C. adjustment until an absolute peak is assured.

This completes the alignment of the I.F. in the sharp position.

(1) Turn the selectivity control to the extreme left position.
(2) Adjust the two I.F. trimmers underneath the chassis for minimum output.
(3) Check this setting on the air for a symmetrical selectivity curve, (ie, that the tuning is broadened the same amount on both sides of the station being received.

This completes the alignment of the I.F. Amplifier.

Insert the oscillator tube. Connect the signal generator and mixer grid lead between antenna and ground.

(1) Set the wave change switch to the "E" band.
(2) Set the signal generator to 525 kc.
(3) Adjust the "E" oscillator trimmer to maximum gain, then adjust the "E" band R.F. and the "E" band mixer trimmers for maximum gain.
(4) Reset the signal generator to 155 kc and rotate the receiver dial to 155 kc.
(5) Adjust the "E" band padder for maximum signal.
(6) Repeat the adjustment of trimmers and padder until the adjustment of one does not effect that of the other.

This completes the alignment of the "E" band.

(1) Set the wave change switch to the "A" band.
(2) Set the signal generator to 1490 kc.
(3) Adjust the A oscillator trimmer to maximum gain, then adjust the A band R.F. and A band mixer trimmers for maximum gain.
(4) Reset the signal generator to 550 kc and rotate the receiver dial to 550 kc.
(5) Adjust the A band padder for maximum signal.
(6) Repeat adjustment of trimmers and padders until adjustment of one does not effect that of the other.

This completes the alignment of the "A" band.

(1) Set the wave change switch to the "L" band.
(2) Set the signal generator to 5.8 mc.
(3) Adjust "L" oscillator trimmer to maximum gain, then adjust "L" Band to R.F. and "L" band mixer trimmers to maximum gain.
(4) Reset signal generator to 1.6 mc and rotate receiver dial to 1.6 mc.
(5) Adjust the "L" band padder for maximum signal.
(6) Repeat adjustment of trimmers and padder until adjustment of one does not effect that of the other.

This completes the alignment of the "L" band.

(1) Set the wave change switch to the "M" band.
(2) Set the signal generator to 11.5 mc.
(3) Adjust the "M" oscillator trimmer to maximum gain, then adjust the "M" band R.F. and the "M" band mixer trimmers for maximum gain.

This completes the alignment of the "M" band.

(1) Set the wave change switch to the "H" band.
(2) Set the signal generator to 28 mc.
(3) Adjust the "H" band oscillator trimmer to maximum gain, then adjust the "H" band R.F. and the "H" band mixer trimmers for maximum gain.

This completes the alignment of the "H" band.

(1) Set the wave change switch to the "U" band.
(2) Set the signal generator to 60 mc.
(3) Tune receiver until signal is received.
(4) Adjust the "U" band R.F. and the "U" band mixer trimmers for maximum gain.

This completes the alignment of the "U" band.

INSTRUCTIONS FOR ALIGNING THE MIDWEST 18-36 MODEL TUBE RECEIVER

A good signal generator with accurate frequency calibration and an output meter are required. An intermediate frequency of 456 k.c. is used.

(1) Set the signal generator to 456 k.c. and connect it from the mixer grid to ground.
(2) Remove the oscillator tube from the receiver.
(3) Connect the output meter from the plate of the output tube to positive B, or from the plates of one pair of tubes to the plates of the other pair of tubes.
(4) Using a weak signal approximately 20 micro-volts, align the I.F. transformers to maximum output.
(5) Increase the input from the generator of approximately 100 micro-volts. Align the A.V.C. transformer for minimum output.
(6) Repeat using weaker signal strengths for the I.F. and stronger signal strength for the A.V.C. adjustment until an absolute peak is assured.

This completes the alignment of the I.F. amplifier.

Insert the oscillator tube. Connect the signal generator and mixer grid lead between antenna and ground.

(1) Set the wave change switch to the "E" band.
(2) Set the signal generator to 525 k.c.
(3) Adjust the "E" oscillator trimmer to maximum gain, then adjust the "E" band R.F. and the "E" band mixer trimmers for maximum gain.
(4) Reset the signal generator to 155 k.c. and rotate the receiver dial to 155 k.c.
(5) Adjust the "E" band padder for maximum signal.
(6) Repeat the adjustment of trimmers and padders until the adjustment of one does not effect the adjustment of the other.

This completes the alignment of the "E" band.

(1) Set the wave change switch to the "A" band.
(2) Set the signal generator to 1490 k.c.
(3) Adjust the "A" oscillator trimmer to maximum gain, then adjust the "A" band R.F. and the A band mixer trimmers for maximum gain.
(4) Reset the signal generator to 550 k.c. and rotate the receiver dial to 550 k.c.
(5) Adjust the "A" band padder for maximum signal.
(6) Repeat the adjustment of trimmers and padders until the adjustment of one does not effect the adjustment of the other.

This completes the alignment of the "A" band.

(1) Set the wave change switch to the "L" band.
(2) Set the signal generator to 5.8 m.c.
(3) Adjust the "L" oscillator trimmer to maximum gain, then adjust the "L" band R.F. and the "L" band mixer trimmers for maximum gain.
(4) Reset the signal generator to 1.6 m.c. and rotate the receiver dial to 1.6 m.c.
(5) Adjust the "L" band padder for maximum signal.
(6) Repeat the adjustment of trimmers and padder until the adjustment of one does not effect the adjustment of the other.

This completes the alignment of the "L" band.

(1) Set the wave change switch to the "M" band.
(2) Set the signal generator to 11.5 m.c.
(3) Adjust the "M" oscillator trimmer to maximum gain, then adjust the "M" band R.F. and the "M" band mixer trimmers for maximum gain.

This completes the alignment of the "M" band.

(1) Set the wave change switch to the "H" band.
(2) Set the signal generator to 28 m.c.
(3) Adjust the "H" band oscillator trimmer to maximum gain, then adjust the "H" band R.F. and the "H" band mixer trimmers for maximum gain.

This completes the alignment of the "H" band.

(1) Set the wave change switch to the "U" band.
(2) Set the signal generator to 60 m.c.
(3) Tune receiver until signal is received.
(4) Adjust the "U" band R.F. and the "U" band mixer trimmers for maximum gain.

This completes the alignment of the "U" band.

INSTRUCTIONS ON ALIGNING THE MIDWEST 7 TUBE 1936 AND 11 TUBE 1936 MODEL RECEIVERS

A good signal generator with accurate frequency calibration and an output meter are required. An intermediate frequency of 456 k.c. is used.

(1) Set the signal generator to 456 k.c. and connect it from the mixer grid to ground.

(2) Remove the oscillator tube from the receiver.

(3) Connect the output meter from the plate of the output tube to positive B.

(4) Using a moderately weak signal approximately 40 micro-volts, align the three I.F. transformers to maximum output.

(5) Keep decreasing the oscillator input and realigning for maximum gain.

This completes the alignment of the I.F. amplifier.

Insert the oscillator tube. Connect the signal generator and mixer grid lead between antenna and ground.

(1) Set the wave change switch to the "E" Band.

(2) Set the signal generator to 525 k.c.

(3) Adjust the "E" oscillator trimmer to maximum gain, then adjust the "E" Band R.F. and the "E" Band mixer trimmers for maximum gain.

(4) Reset the signal generator to 155 k.c. and rotate the receiver dial to 155 k.c.

(5) Adjust the "E" Band padder for maximum signal.

(6) Repeat the adjustment of trimmers and padders until the adjustment of one does not effect the adjustment of the other. This completes the alignment of the "E" Band.

(1) Set the wave change switch to the "A" Band.

(2) Set the signal generator to 1490 k.c.

(3) Adjust the "A" oscillator trimmer to maximum gain, then adjust the "A" Band R.F. and the "A" Band mixer trimmers for maximum gain.

(4) Reset the signal generator to 550 k.c. and rotate the receiver dial to 550 k.c.

(5) Adjust the "A" Band padder for maximum signal.

(6) Repeat the adjustment of trimmers and padders until the adjustment of one does not effect the adjustment of the other.

This completes the alignment of the "A" Band.

(1) Set the wave change switch to the "L" Band.

(2) Set the signal generator to 3.8 m.c.

(3) Adjust the "L" oscillator trimmer to maximum gain, then adjust the "L" Band R.F. and the "L" Band mixer trimmers for maximum gain.

(4) Reset the signal generator to 1.6 m.c. and rotate the receiver dial to 1.6 m.c.

(5) Adjust the "L" Band padder for maximum signal.

(6) Repeat the adjustment of trimmers and padders until the adjustment of one does not effect the adjustment of the other.

This completes the alignment of the "L" Band.

(1) Set the wave change switch to the "M" Band.

(2) Set the signal generator to 11.5 m.c.

(3) Adjust the "M" oscillator trimmer to maximum gain, then adjust the "M" Band R.F. and the "M" band mixer trimmers for maximum gain.

This completes the alignment of the "M" Band.

(1) Set the wave change switch to the "H" Band.

(2) Set the signal generator to 23 m.c.

(3) Adjust the "H" band oscillator trimmer to maximum gain, then adjust the "H" Band R.F. and the "H" Band mixer trimmers for maximum gain.

This completes the alignment of the "H" Band.

Other filaments	2.4 A.C.

Circuit Description

The antenna feeds into a 455 K.C. wave trap which tends to prevent any 455 K.C. signals from entering the I.F. amplifier and causing interference. A lead from this coil connects to one of the movable arms of the band changing switch and from there through the primary of the R.F. transformer to ground when the switch is thrown to the purple or green high frequency band. When receiving on the broadcast and red bands, the antenna is directly coupled to the secondary of the first R.F. transformer, through the .001M.M.F series condenser, the 350 ohm resistor and image suppressor coil. An 8000 ohm potentiometer is connected from the movable arm of the antenna switch to ground. This volume control performs a dual function by controlling the grid bias to the two type 58 intermediate frequency tubes as well as varying the signal input to the first radio frequency transformer.

The type 57 first detector or mixer is self biased by the 7000 ohm resister connected in series with the cathode and ground.

The intermediate frequency transformers are of the conventional type and are plainly shown in the diagram figure 1.

Bias voltage for the second detector type 56 is obtained by the voltage drop across the 150,000 ohm and 225 ohm resister connected between the cathode and ground.

The 47 audio stage is of the conventional type and receives its bias from the voltage drop across the 225 ohm Candohm resistor connected between the 400,000 ohm grid resistor and ground.

Short Wave Switch

Four circuits are switched with each change of the wave band switch. Diagram Figure 1, shows the position of each one of these switches when receiving on the broadcast band. Although this diagram may at first glance, appear complicated, it is comparatively simple if the receiver is first considered as a regular broadcast receiver with the switches in the position shown in the diagram Figure 1. In this position the antenna is directly coupled to the secondary of the first R.F. transformer, and the total secondary inductance of the first R.F. transformer as well as the secondary of the oscillator transformer are connected in circuit. When the wave band switch is changed to the shorter wave length, the wave band switch merely cuts out part of the secondary of the R.F. transformer, and secondary of the oscillator transformer and at the same time, short circuits or dead-ends the unused portion of these coils. The first R.F. stage consists of fixed inductances and fixed condensers which are automatically in resonance on the shorter wave band. If the receiver is operating properly on the broadcast band, no adjustments are necessary in this stage when the switch is in any one of the short wave positions. The oscillator stage is tuned automatically in like manner with the exception that one trimming condenser is provided for operation on the short wave band.

Condenser Alignment

This receiver is aligned on the broadcast band in the same manner as any of our other superheterodynes previously described. Turn the wave band changing switch to the black or broadcast band and align the R.F., oscillator, and I.F., stages, either on a broadcast signal or an oscillator as explained in the Blue Service manual insert on aligning. The 600 kilocycle tracking condenser is located adjacent to the 56 oscillator tube. If the broadcast circuits are properly aligned the short wave band circuits automatically are in alignment unless there is a defect in the short wave section of the R.F. coil or oscillator coil, or unless one of the oscillator fixed tracking condensers are defective. Only one aligning adjustment is provided for the short wave band, this is the oscillator tracking condenser and is located on the side of the chassis directly beneath the 600 kilocycle tracking condenser adjustment. In order to properly adjust the short wave band oscillator tracking condenser, turn the band selector switch to the red band and tune in a short wave station such as a police broadcast or a broadcasting station of approximately 1500 to 1350 kilocycles and adjust the oscillator tracking condenser for maximum speaker volume, at the same time rocking the tuning dial slowly back and forth across the signal. In order to make this adjustment it is necessary to remove the chassis from the cabinet. It is advisable to use a bakelite or non metallic screw driver when adjusting these screws.

Twenty-Five Cycle Chassis

The 25 cycle chassis uses 25 cycle power transformer, part No. U3443 instead of power transformer No. U3441.

Phonograph Connections

The connections are made by opening the diode circuit at the volume control. Unsolder the condenser C24 from the lug on the volume control and reconnect this condenser to the new terminal strip provided (see parts list). This terminal strip should be secured to the inside of the front panel of the chassis base at a point near the volume control and should be soldered in position. From the terminal lug on the above strip, and from the volume control lug from which the condenser C24 was removed, connect leads to the phono switch on the rear panel of the chassis as shown in Fig. 7. Before connecting these two leads permanently to the switch, twist them together and enclose them in the shielded sleeving provided, being sure to ground the shielding at the extreme ends to the chassis base. At the point where the shielding passes the electrolytic condenser cover the cable with insulating tape. Complete the connections as shown in Fig. 7.

A high impedance phonograph pickup of good quality should be used. If a low impedance pickup is used, a step-up transformer will be required for sufficient volume. The volume control and tone control of the set will regulate the phono volume and tone.

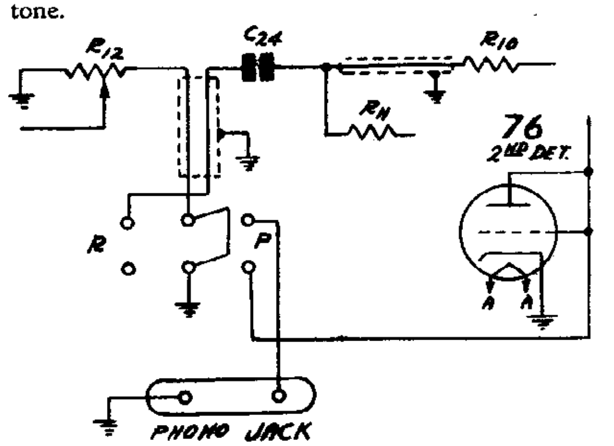

Fig. 7—Phonograph Connections

Changes in Early Models

In early models all chassis had two speaker sockets as shown in the schematic diagram—Fig. 2. In later models the 5 prong socket (No. 1 in schematic) is not in the chassis. The leads shown between the two speaker sockets, the lead from the B+ line and the lead from the Output Transformer to this socket are, therefore, eliminated. In both types of chassis the same speaker is used (No. 3 speaker with 6 prong plug).

Alignment and Calibration

PRICES SUBJECT TO CHANGE WITHOUT NOTICE

Correct alignment is extremely important in connection with all wave receivers. The receivers are all properly aligned at the factory with precision instruments and realignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment.

A signal generator that will provide an accurately calibrated signal at 456, 1730, 1500, 600, 5800, 5000, 18,300, 15,000 and 6000 KC and an output indicating meter are required. It will be practically impossible to align the receiver if unsatisfactory apparatus is used. If a station is tuned in with the selectivity control in the broad position and this control is then turned to the sharp position, the station may disappear. This is not an indication that the receiver is out of alignment.

Use a non-metallic screwdriver for the adjustments. The complete procedure is as follows:

I. F. Adjustment

Set the signal generator for a signal of 456 KC.

Connect the output of the signal generator to the grid of the 1st detector through a 0.1 MF condenser.

Connect the ground lead of the receiver to the ground post of the signal generator.

Turn the band selector to the Range B position (standard wave band—purple dial color).

Turn the selectivity control to the sharp position and keep it in this position for all adjustments.

Turn the volume control to the maximum position

Attenuate the signal from the signal generator to prevent the levelling-off action of the A.V.C.

Then adjust the five I.F. trimmers until maximum output is obtained. The adjusting screws for these condensers are reached from the top of the chassis, and the location is shown in Fig. 5.

Range B Alignment

1730 KC Adjustment

Set the signal generator for 1730 KC.

Turn the rotor of the tuning condenser to the full open position.

Keep the band selector in the standard wave position.

Connect the antenna lead of the receiver through a 200 mmf. condenser to the output of the signal generator.

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the oscillator Range B trimmer (C38) until maximum output is obtained. The location of this trimmer is shown in Fig. 3.

1500 KC Adjustment

Set the signal generator for 1500 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Loosen the pointer set screw and set the large pointer at the 1500 KC mark on the standard wave band scale. Retighten the set screw.

Adjust the 1st and 2nd interstage Range B trimmers (C8 and C13) and antenna Range B trimmer (C2) to maximum.

Do not change the setting of the oscillator Range B trimmer.

600 KC Adjustment

Set the signal generator for 600 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 600 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

Be sure to use a non-metallic screwdriver for this adjustment.

Range C Alignment

5800 KC Adjustment

Set the signal generator for 5800 KC.

Connect the antenna lead of the receiver through a 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band selector to the Range C position (1st short wave band—green dial color).

As mentioned above, keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the oscillator Range C trimmer (C40) until maximum output is obtained. See Fig. 3 for location of this trimmer.

5000 KC Adjustment

Set the signal generator for 5000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the 1st and 2nd interstage Range C trimmers (C9 and C12) and antenna Range C trimmer (C3) to maximum.

Do not change the setting of the oscillator Range C trimmer.

Range D Alignment

18,300 KC Adjustment

Set the signal generator for 18,300 KC.

Keep the antenna lead of the receiver connected through the 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band selector to the Range D position (2nd short wave band—red dial color).

As mentioned above, keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the oscillator Range D trimmer (C41) until maximum output is obtained. See Fig. 3 for location of this trimmer.

15 000 KC Adjustment

Set the signal generator for 15,000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the 1st and 2nd interstage Range D trimmers (C10 and C11) and antenna Range D trimmer (C4) to maximum.

When adjusting the 2nd interstage Range D trimmer, it will be necessary at the same time to turn the tuning condenser rotor slowly back and forth until the peak of greatest intensity is obtained.

Then go back and repeat the procedure as given for the 18,300 KC adjustment. If it is found necessary to make any appreciable change in the setting of the oscillator Range D trimmer, the 15,000 KC adjustment must be repeated.

Do not make any further change in the setting of the oscillator Range D trimmer.

6000 KC Adjustment

Set the signal generator for 6000 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 6000 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

Use a non-metallic screwdriver for this adjustment.

Twenty-five Cycle Receivers

The twenty-five cycle receiver differs from the sixty cycle receiver only in the fact that a different power transformer is used. The correct power transformer is shown in the parts list.

The twenty-five cycle receiver can be operated satisfactorily from a sixty cycle power supply. However, the reverse is not true, the sixty cycle receiver cannot be operated from a twenty-five cycle power supply.

A 115-230 Volt, 40 to 60 cycle as well as other power transformers with special power ratings are also available for this model.

Chassis Schematic Circuit Diagram

MODEL 62-197
Alignment, Phono.
Changes

MONTGOMERY-WARD & CO.

Alignment and Calibration

I. F. Adjustment

Set the signal generator for a signal of 456 KC.

Connect the output of the signal generator to the grid of the 1st detector through a 0.1 mf. condenser.

Connect the ground lead of the receiver to the ground post of the signal generator.

Turn the band selector to the Range B position (standard wave band purple dial color).

Turn the selectivity control to the sharp position and keep it in this position for all adjustments.

Turn the volume control to the maximum position.

Attenuate the signal from the signal generator to prevent the levelling-off action of the A.V.C.

Then adjust the five I.F. trimmers until maximum output is obtained. The adjusting screws for these condensers are reached from the top of the chassis, and the location is shown in Fig. 4.

Range B Alignment

1730 KC Adjustment

Set the signal generator for 1730 KC.

Turn the rotor of the tuning condenser to the full open position.

Keep the band selector in the standard wave position.

Connect the antenna lead of the receiver through a 200 mmf. condenser to the output of the signal generator.

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the oscillator Range B trimmer (C54) until maximum output is obtained. The location of this trimmer is shown in Fig. 6.

1500 KC Adjustment

Set the signal generator for 1500 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Loosen the pointer set screw and set the large pointer at the 1500 KC mark on the standard wave band scale. Re-tighten the set screw.

Adjust the 1st and 2nd interstage Range B trimmers (C17 and C18) and antenna Range B trimmer (C3) to maximum.

Do not change the setting of the oscillator Range B trimmer.

600 KC Adjustment

Set the signal generator for 600 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 600 KC trimmer until the peak of greatest intensity is obtained. See Fig. 6 for location of this trimmer.

Be sure to use a non-metallic screwdriver for this adjustment.

Range C Alignment

5800 KC Adjustment

Set the signal generator for 5800 KC.

Connect the antenna lead of the receiver through a 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band selector to the Range C position (1st short wave band—green dial color).

As mentioned above, keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the oscillator Range C trimmer (C56) until maximum output is obtained. See Fig. 6 for location of this trimmer.

5000 KC Adjustment

Set the signal generator for 5000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the 1st and 2nd interstage Range C trimmers (C16 and C19) and antenna Range C trimmer (C4) to maximum.

Do not change the setting of the oscillator Range C trimmer.

Range D Alignment

18,300 KC Adjustment

Set the signal generator for 18,300 KC.

Keep the antenna lead of the receiver connected through the 00 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band selecter to the Range D position (2nd short wave band—red dial color).

As mentioned above, keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the oscillator Range D trimmer (C57) until maximum output is obtained. See Fig. 6 for location of this trimmer.

15,000 KC Adjustment

Set the signal generator for 15,000 KC. Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the 1st and 2nd interstage Range D trimmers (C15 and C20) and antenna Range D trimmer (C5) to maximum.

When adjusting the 2nd interstage Range D trimmer, it will be necessary at the same time to turn the tuning condenser rotor slowly back and forth until the peak of greatest intensity is obtained.

Then go back and repeat the procedure as given for the 18,300 KC adjustment. It it is found necessary to make any appreciable change in the setting of the oscillator Range D trimmer, the 15,000 KC adjustment must be repeated.

Do not make any further change in the setting of the oscillator Range D trimmer.

6000 KC Adjustment

Set the signal generator for 6000 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 6000 KC trimmer until the peak of greatest intensity is obtained. See Fig 6 for location of this trimmer.

Use a non-metallic screwdriver for this adjustment.

Range E Alignment

48,000 KC Adjustment

Set the signal generator for 48,000 KC.

Keep the antenna lead of the receiver connected through the 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band selector to the Range E position (3rd short wave band—brown dial color).

Adjust the oscillator Range E trimmer (C58) until maximum output is obtained. See Fig. 6 for location of this trimmer.

40,000 KC Adjustment

Set the signal generator for 40,000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the interstage Range E trimmer (C14) and antenna Range E trimmer (C6) to maximum.

Do not change the setting of the oscillator Range E trimmer.

Twenty-five Cycle Receivers

The twenty-five cycle receiver differs from the sixty cycle receiver in the fact that special twenty-five cycle filament and "B" power transformers must be used. It also has two additional condensers in the power unit—C67 and C68 as illustrated in Fig. 3. The twenty-five cycle transformers and the condensers are shown in the parts list.

The twenty-five cycle receiver can be operated satisfactorily from a sixty cycle power supply if the two condensers C67 and C68 are removed. However, the reverse is not true, that is, a sixty cycle receiver cannot be operated from a twenty-five cycle power supply.

115-230 Volt, 40 to 60 cycle filament and "B" power transformers are also available for this model.

Changes in Early Models

In the early models condenser C65, shown in the R.F. Schematic Fig. 2, was not used. A 20 mmf. condenser, also designated as C65, was connected in parallel with condenser C14.

Condenser C10 from B+ to ground was not used in early models. Another condenser in the early models, also designated as C10 and 250 mmf. in value, was connected from the A.V.C. amplifier plate to ground.

Resistor R38 was not used in early models.

On the A.F. chassis the speaker sockets were wired with ground to the opposite side of voice coil.

A phonograph socket is provided on the R.F. chassis by means of which phonograph connections can be made without electrical changes in the chassis. The receiver is shipped from the factory with a plug in this socket. If no phonograph is used this plug must be inserted as it completes the signal diode circuit for radio reception.

Two sets of accessories are supplied for phonograph connections for this model. One set is used when the phonograph is contained in a separate cabinet, and the other set is used when the phonograph and radio are in a combination cabinet. The electrical connections are the same in both cases and are illustrated in Fig. 13 (A). Parts required in either case are shown in the parts list in this manual.

Phonograph in Separate Cabinet

For this assembly, a 5 conductor cable and a small metal panel assembly are supplied. This assembly has the radio-phono switch, tip jacks for pick-up leads and terminal plate for phono cable.

The phono panel is mounted at the most convenient place in the cabinet at which connections can be completed. The switch is secured to the motor board as illustrated in Fig. 14.

The socket at the end of the cable is secured to the terminal plate on the panel and the plug at the other end of the cable is inserted into the phono socket on the R.F. chassis.

When the switch is thrown to the radio side, the phono pick-up is excluded from the signal diode circuit. When it is thrown to the phono side, the signal diode circuit is opened and the phonograph connections completed to this circuit. Resistor R23 is short circuited. This brings the grid and cathode of the 76 A.V.C. amplifier to the same potential and causes a plate current in this tube of sufficient intensity to bring the R.F. and 1st I.F. tubes to the point of cut off (See article on circuit for further information regarding operation of A.V.C. system).

Phonograph and Radio in Combination Cabinet

For this assembly, a number of separate items as shown in the parts list are supplied. The phono short circuiting plug supplied with the receiver is used after certain changes have been made.

First take off the shell of this plug by twisting the shell in either direction. The shell is then drilled and equipped with a rubber grommet as shown in Fig. 13 (B). Next unsolder and remove the jumper wire from the plug as shown in Fig. 13 (A). Extend the leads through the hole in the shell and solder the leads to the prongs on the plug as illustrated. Complete the connections to the switch and tip jacks as shown. The switch is mounted on the motor board and the tip jacks at the nearest convenient place.

The description of the connections as given for the separate phonograph cabinet also applies to the combination.

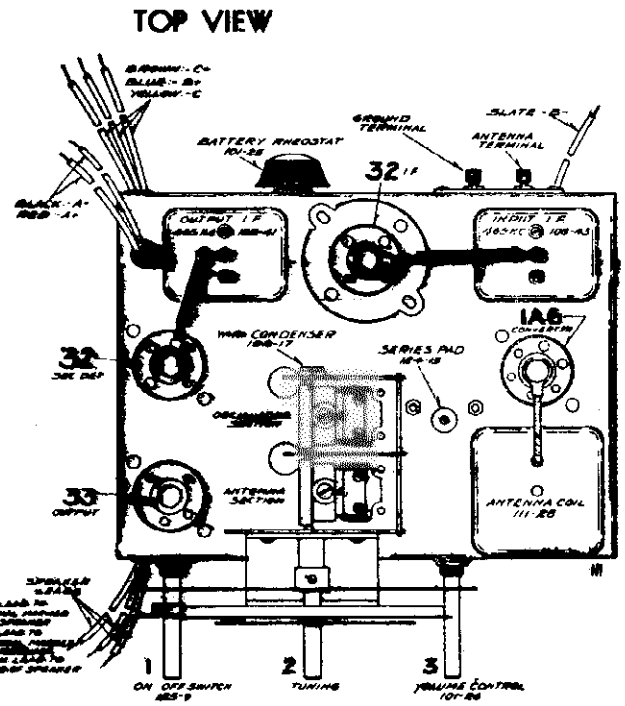
TOP VIEW



BROADCAST BAND ALIGNMENT:

1. Set external oscillator to 1720 K.C. and connect it in series with a 200 mmfd. condenser to the antenna and ground posts.
   - (a) With variable condenser in its minimum capacity position, plates entirely out of mesh, adjust oscillator trimmer (rear section of variable condenser) to resonance.
   - (b) Re-set external oscillator to 1400 K.C. Rotate variable condenser, pick up signal and adjust antenna trimmer (front section of variable condenser) to resonance.
   - (c) Re-set external oscillator to 600 K.C., move dial pointer to 600 K.C., and adjust series pad, part number 124-13 (see top view), to resonance. While making this adjustment, slowly rock variable condenser to and fro until maximum output is obtained.
   - (d) Check for sensitivity at 800, 1000, 1200 K.C. DO NOT BEND PLATES.

ALIGNING I.F. TRANSFORMERS: (465 K.C.)

1. With volume control full on and with variable condenser at its minimum capacity position, plates entirely out of mesh, and with external oscillator set at 465 K.C. connected in series with a .1 mfd. condenser, to the grid of the 1A6 tube (cap at top of tube), adjust I.F. transformers, parts number 108-41 and 108-43, to resonance. Both of these transformers have two (2) adjustments each, they are accessible from the tops of the cans (for location see top view).

Alignment, Parts

MONTGOMERY-WARD & CO.

Alignment and Calibration

Correct alignment is extremely important in connection with all wave receivers. The receivers are all properly aligned at the factory with precision instruments and realignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment.

A signal generator that will provide an accurately calibrated signal at 456, 1730, 1500, 600, 4800, 4200, 16,000, 15,000 and 6000 KC and an output indicating meter are required. It will be practically impossible to align the receiver if unsatisfactory apparatus is used. If a station is tuned in with the selectivity control in the broad position and this control is then turned to the sharp position, the station may disappear. This is not an indication that the receiver is out of alignment.

Use a non-metallic screwdriver for the adjustments. The complete procedure is as follows:

I. F. Adjustment

Set the signal generator for a signal of 456 KC.

Connect the output of the signal generator through a 0.1 mf. condenser to the switch end of condenser C11—see Fig. 2. There is a lead which goes to the lug on top of the center stator section of the tuning condenser—see Fig. 11. The connection can be made at this lug.

Connect the ground lead of the receiver to the ground post of the signal generator.

Turn the band selector to the Range B position (standard wave band—purple dial color).

Turn the selectivity control to the sharp position and keep it in this position for all adjustments.

Turn the volume control to the maximum position.

Attenuate the signal from the signal generator to prevent the levelling-off action of the A.V.C.

Then adjust the five I.F. trimmers until maximum output is obtained. The adjusting screws for these condensers are reached from the top of the chassis, and the location is shown in Fig. 11.

Range B Alignment

1730 KC Adjustment

Set the signal generator for 1730 KC.

Turn the rotor of the tuning condenser to the full open position.

Keep the band selector in the standard wave position.

Connect the antenna lead of the receiver through a 200 mmf. condenser to the output of the signal generator.

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the oscillator Range B trimmer (C32) until maximum output is obtained. The location of this trimmer is shown in Fig. 9.

1500 KC Adjustment

Set the signal generator for 1500 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Loosen the pointer set screw and set the large pointer at the 1500 KC mark on the standard wave band scale. Retighten the set screw.

Adjust the interstage Range B trimmer (C8) and antenna Range B trimmer (C2) to maximum.

Do not change the setting of the oscillator Range B trimmer.

600 KC Adjustment

Set the signal generator for 600 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 600 KC trimmer until the peak of greatest intensity is obtained. See Fig. 9 for location of this trimmer.

Be sure to use a non-metallic screwdriver for this adjustment.

Range C Alignment

4800 KC Adjustment

Set the signal generator for 4800 KC.

Connect the antenna lead of the receiver through a 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band selector in the Range C position (1st short wave band—green dial color).

As mentioned above, keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the oscillator Range C trimmer (C30) until maximum output is obtained. See Fig. 9 for location of this trimmer.

4200 KC Adjustment

Set the signal generator for 4200 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the interstage Range C trimmer (C9) and antenna Range C trimmer (C3) to maximum.

Do not change the setting of the oscillator Range C trimmer.

Range D Alignment

16,000 KC Adjustment

Set the signal generator for 16,000 KC.

Keep the antenna lead of the receiver connected through the 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band selector to the Range D position (2nd short wave band—red dial color).

As mentioned above, keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the oscillator Range D trimmer (C29) until maximum output is obtained. See Fig. 9 for location of this trimmer.

15,000 KC Adjustment

Set the signal generator for 15,000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the interstage Range D trimmer (C10) and antenna Range D trimmer (C4) to maximum.

When adjusting the interstage Range D trimmer, it will be necessary at the same time to turn the tuning condenser rotor slowly back and forth until the peak of greatest intensity is obtained.

Then go back and repeat the procedure as given for the 16,000 KC adjustment. If it is found necessary to make any appreciable change in the setting of the oscillator Range D trimmer, the 15,000 KC adjustment must be repeated.

Do not make any further change in the setting of the oscillator Range D trimmer.

6000 KC Adjustment

Set the signal generator for 6000 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 6000 KC trimmer until the peak of greatest intensity is obtained. See Fig. 9 for location of this trimmer.

Use a non-metallic screwdriver for this adjustment.

Batteries Required

The batteries and voltages required are shown in Figs. 2 and 3. The "A" drain is .74 amperes at 2 volts while the "B" drain is discussed below.

"B" Battery

Class "B" amplification is used in the output stage and the "B" battery consumption will, therefore, depend upon the output volume. The "B" consumption will also depend, to some extent, upon the strength of the incoming signal as the latter affects the A.V.C. voltage. When no signal is being received the "B" drain is 20 milliamperes. When the volume control is at maximum and with high output volume, the "B" drain can become 40 milliamperes. A milliammeter in the "B" line will quickly determine if the "B" drain is excessive or normal.

"C" Batteries

For the "C" battery a special battery with 4½, 9 and 16½ volt taps as indicated in Fig. 3 may be used, or one standard 22½ volt and one standard 4½ volt "C" battery can be connected as shown in Fig. 4 to supply the necessary voltages.

"A" Battery and Regulator

This receiver is designed to operate with a 2 volt storage cell, but may be operated with a 3 volt dry "A" battery if used with a voltage regulator. The receiver may also be used with an air cell "A" battery provided a series resistor is used.

3 Volt "A" Battery—The voltage regulator required with this type of battery as illustrated in Fig. 5 is not supplied with the receiver unless specified. This device consists of a rheostat which controls the voltage, a voltmeter for measuring its value as supplied to the receiver and a small push button switch for cutting the voltmeter in and out of the circuit. It has two prongs at the bottom which plug into the socket at the rear left corner of the chassis. The circuit diagram of the regulator is shown in Fig. 6.

When a new 3 volt "A" battery is connected, the adjusting knob must be turned to the left hand position and then turned up until the voltmeter indicates 1.9 to 2 volts. The push button must be held in until the adjustment is completed. **Caution the user never to operate the receiver with the adjustment beyond 2 volts.**

Air Cell "A" Battery—If an air cell "A" battery is used, a series resistor will be required to reduce the voltage to the proper level of 2 volts for the tube filaments. Although the voltage regulator mentioned above can be used, the series resistor is cheaper and is satisfactory as the voltage of one of these batteries drops very little during the useful life of the battery.

Battery Connections—CAUTION

CAUTION: Do not turn the switch on unless ALL the tubes are in the sockets.

CAUTION: Be sure that the battery clips are properly connected to the battery. If the connections are reversed, the receiver may be damaged.

MODEL 62-215
Coil Data, Resistance

MONTGOMERY-WARD & CO.

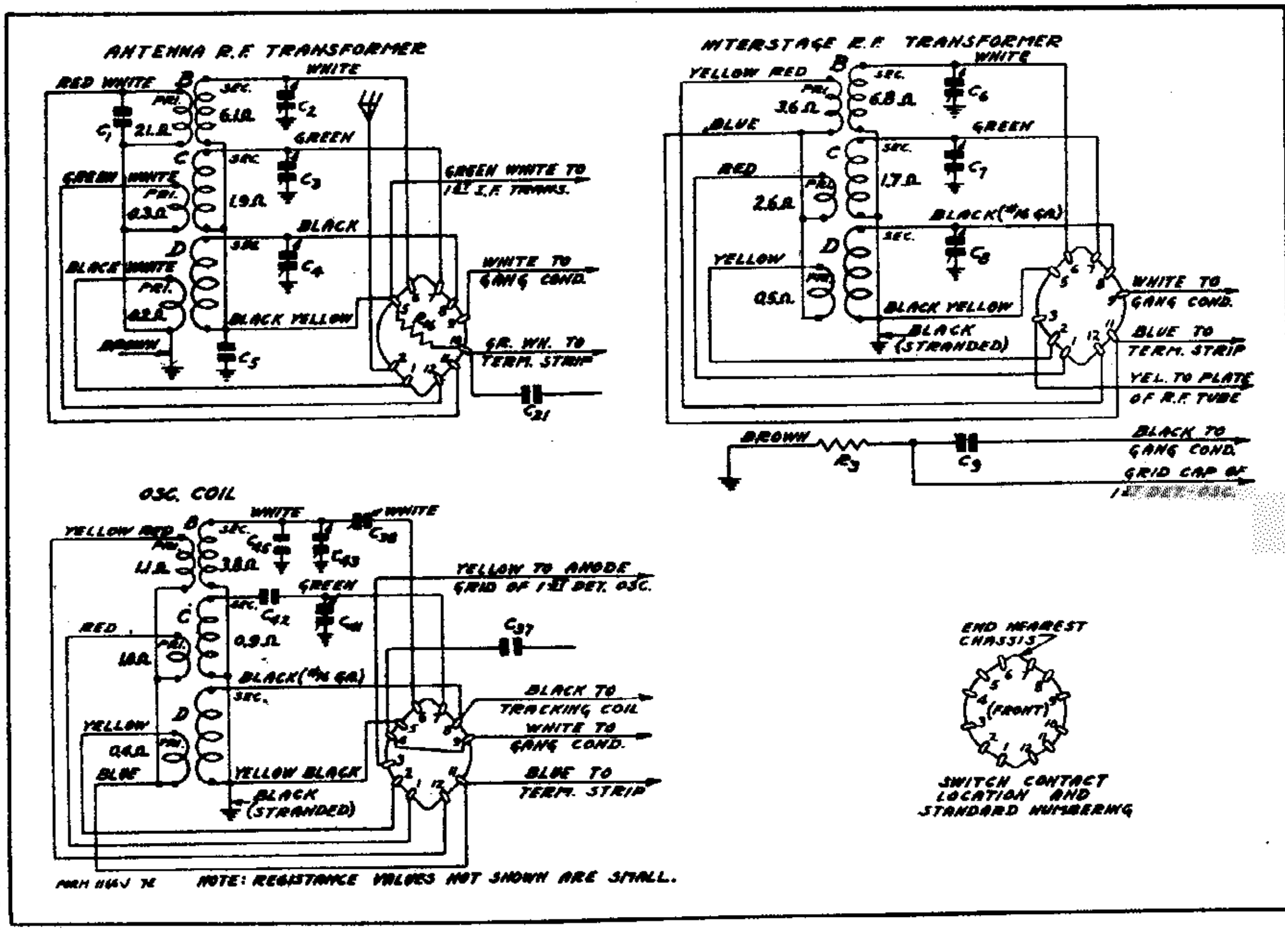

Fig. 5—Color Coding of Coil Wires and D. C. Resistance of Windings.
(Also see complete D. C. Resistance List Below)

D. C. Resistance of Windings

Refer to Figs. 5 & 2

Following are the D. C. resistances of the various coil windings in the chassis. The values given below will vary slightly in different sets.

Part No.	Winding	Code	D. C. Resistance in Ohms
P-9A419	Antenna R. F. Transformer	T1	
	Range B Primary Winding		21.0
	Range C Primary Winding		0.3
	Range D Primary Winding		0.2
	Range B Secondary Winding		6.1
	Range C Secondary Winding		1.9
	Range D Secondary Winding		Small
P-9A420	Interstage R. F. Transformer	T2	
	Range B Primary Winding		3.6
	Range C Primary Winding		2.6
	Range D Primary Winding		0.5
	Range B Secondary Winding		6.8
	Range C Secondary Winding		1.7
	Range D Secondary Winding		Small
P-9A421	Oscillator Coils	T7	
	Range B Plate Coil		1.1
	Range C Plate Coil		1.0
	Range D Plate Coil		0.4
	Range B Grid Coil		3.8
	Range C Grid Coil		0.9
	Range D Grid Coil		Small
P-9A422	1st I. F. Transformer	T3	
	Primary Winding		11.4
	Secondary Winding		11.4
P-9A423	2nd I. F. Transformer	T4	
	Primary Winding		11.4
	Secondary Winding		11.4
P-9A424	3rd I. F. Transformer	T5	
	Primary Winding (either section)		8.4
	Secondary Winding		130.8
P-50X11	Audio Input Transformer	T6	
	Primary Winding		1005.0
	Secondary Winding		
	Center Tap to Inside		580.0
	Center Tap to Outside		630.0
*P-12A218	8 Inch Magnetic Speaker		
	Speaker Coil		
	Center Tap to Inside		275.0
	Center Tap to Outside		300.0
P-9A403	Single Filament Reactor	L1	.65
P-9A404	Double Filament Reactor - (either section)	L2 & L3	.65
P-9A391	High Frequency Oscillator Tracking Coil	L12	0.7

*Speakers with other part numbers may have slightly different values of D. C. Resistance.

MODEL 62-215
Alignment, Drive Cord
Parts List

MONTGOMERY-WARD & CO.

Alignment and Calibration

A signal generator that will provide an accurately calibrated signal at 456, 1730, 1500, 600, 4800, 4200, 16,000, 15,000 and 6000 KC and an output indicating meter are required. It will be practically impossible to align the receiver if unsatisfactory apparatus is used.

Use a non-metallic screwdriver for the adjustments. The complete procedure is as follows:

I. F. Adjustment

Set the signal generator for a signal of 456 KC.

Connect the output of the signal generator through a 0.1 mf. condenser to the switch end of condenser C9—see Fig. 2. There is a lead which goes to the lug on the top of the center stator section of the tuning condenser—see Fig. 4. The connection can be made at this lug.

Connect the ground lead of the receiver to the ground post of the signal generator.

Turn the band selector to the Range B position (standard wave band—purple dial color).

Turn the volume control to the maximum position.

Attenuate the signal from the signal generator to prevent the levelling-off action of the A.V.C.

Then adjust the five I.F. trimmers until maximum output is obtained. The adjusting screws for these condensers are reached from the top of the chassis, and the location is shown in Fig. 4.

Range B Alignment

1730 KC Adjustment

Set the signal generator for 1730 KC.

Turn the rotor of the tuning condenser to the full open position.

Keep the band selector in the standard wave position.

Connect the antenna lead of the receiver through a 200 mmf. condenser to the output of the signal generator.

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the oscillator Range B trimmer (C43) until maximum output is obtained. The location of this trimmer is shown in Fig. 3.

1500 KC Adjustment

Set the signal generator for 1500 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Loosen the pointer set screw and set the large pointer at the 1500 KC mark on the standard wave band scale. Retighten the set screw.

Adjust the interstage Range B trimmer (C6) and antenna Range B trimmer (C2) to maximum.

Do not change the setting of the oscillator Range B trimmer.

600 KC Adjustment

Set the signal generator for 600 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 600 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

Be sure to use a non-metallic screwdriver for this adjustment.

Range C Alignment

4800 KC Adjustment

Set the signal generator for 4800 KC.

Connect the antenna lead of the receiver through a 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band selector to the Range C position (1st short wave band—green dial color).

As mentioned above, keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the oscillator Range C trimmer (C41) until maximum output is obtained. See Fig. 3 for location of this trimmer.

4200 KC Adjustment

Set the signal generator for 4200 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the interstage Range C trimmer (C7) and antenna Range C trimmer (C3) to maximum.

Do not change the setting of the oscillator Range C trimmer.

Range D Alignment

16,000 KC Adjustment

Set the signal generator for 16,000 KC.

Keep the antenna lead of the receiver connected through the 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band selector to the Range D position (2nd short wave band—red dial color).

As mentioned above, keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the oscillator Range D trimmer (C40) until maximum output is obtained. See Fig. 3 for location of this trimmer.

15,000 KC Adjustment

Set the signal generator for 15,000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the interstage Range D trimmer (C8) and antenna Range D trimmer (C4) to maximum.

When adjusting the interstage Range D trimmer, it will be necessary at the same time to turn the tuning condenser rotor slowly back and forth until the peak of greatest intensity is obtained.

Then go back and repeat the procedure as given for the 16,000 KC adjustment. If it is found necessary to make any appreciable change in the setting of the oscillator Range D trimmer, the 15,000 KC adjustment must be repeated.

Do not make any further change in the setting of the oscillator Range D trimmer.

6000 KC Adjustment

Set the signal generator for 6000 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 6000 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

Use a non-metallic screwdriver for this adjustment.

Replacing Drive Cord

Remove the chassis from the cabinet.

Take off the station pointer by removing the screw at the center of the dial.

Loosen the two set screws in the collar on the band selector shaft.

Loosen the dial assembly by taking out the two screws which secure the bottom of this assembly to the chassis and one screw at the top which secures this assembly to the bracket.

Pull the dial assembly forward until the collar is free of the band selector shaft; and lay the assembly face downward in front of the chassis.

Turn the drive drum until the opening in this drum is approximately vertical and with the hole at the top as shown in Fig. 7.

Remove the tension spring and the old drive cord.

When replacing this drive cord a 30 lb. test cord as regularly supplied by the factory should be used.

See that the eyelet is in the hole in the drive drum as shown in Fig. 7. Insert one end of the new drive cord from the outside through the hole in the eyelet in the drive drum.

Tie the end of the cord, which has been inserted through the hole, to one end of the tension spring.

Wrap the cord in a counter clockwise direction (facing front of chassis) around the drive drum approximately one and one half turns, progressing toward the front.

Then tilt the chassis up on its back panel and bring the cord mentioned in the previous paragraph down to the drive shaft. Wrap it two and one half times around this shaft as shown in Fig. 7, progressing toward the back of chassis.

Wrap the cord on directly in line with the drive drum above.

Then bring this cord up to the drive drum until it is up to the eyelet in the drive drum as shown in the illustration.

Now insert the free end of the cord through the hole in the eyelet and tie it to the end of the tension spring. The end of the spring when hanging free and with the slack taken out of the drive cord should be 3/4" or less from the flange of the drum as shown in Fig. 7. Cut off the surplus length of cord after it is knotted.

Then secure the other end of the tension spring over the spur on the drive drum.

Turn the drive shaft back and forth several times.

Replace the dial assembly and pointer.

Replace the chassis in the cabinet.

MONTGOMERY-WARD & CO.

Alignment and Calibration

I. F. Adjustment

Set the signal generator for a signal of 175 KC.

Connect the output lead of the signal generator through a .1 mf. condenser to the grid of the 1st detector.

Connect the ground lead of the receiver to the ground post of the signal generator.

Turn the volume control to the maximum position.

Then adjust the four I.F. trimmers until maximum output is obtained. The adjusting screws for these condensers are reached from the top of the chassis, and the location is shown in Fig. 4.

As stated above, use a non-metallic screwdriver to make the adjustments.

1750 KC Adjustment

Set the signal generator for 1750 KC.

Turn the rotor of the tuning condenser to the full open position.

Connect the antenna lead of the signal generator to the antenna lead of the receiver through a 200 mmf. condenser.

Keep the volume control at the maximum position.

Adjust the trimmer of the oscillator section of the three gang condenser until maximum output is obtained. The location of this trimmer is shown in Fig. 4.

1500 KC Adjustment

Set the signal generator for 1500 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Loosen the pointer screw and set the pointer at the 1500 KC mark on the dial scale. Retighten the pointer screw.

Adjust the 1st detector and antenna trimmers for maximum output.

Do not change the setting of the oscillator trimmer.

32 Volt Power Supply

This receiver is designed for use on farms and in those places where the power supply consists of a 32 volt direct current generating plant.

Polarity of Power Supply

There is a red mark on the plug at the end of the power supply cord of the receiver. The prong of the plug at which the red mark is placed must be plugged into the positive side of the line.

Use a receptacle on the 32 volt line from which the plug will not have to be removed after it has once been inserted correctly.

If the polarity of the line is not known, that is, if it is not known which side of the line is positive, a meter may be used to indicate the polarity. A voltmeter of 50 volt range or up is used. Connect the meter across the line. If the pointer deflects correctly, then the positive post of the meter is connected to the positive side of the line.

If the polarity of the line is not known and there is no way of determining it, insert the power supply plug, turn on the set, advance the volume control and proceed to tune the receiver. If the tubes are all lighted and no sounds are heard from the speaker after the plug has been in two minutes, withdraw the plug, turn it around and re-insert it. This time sounds should be heard after the tubes have been heated up.

Caution

If used on any other type of power supply than 32 volt D.C., severe damage may be done to the receiver.

Do not turn the set on unless all of the tubes and the pilot lamps are in their proper sockets. Use only a No. 46 Pilot Lamp (6.3 volt .25 amp.).

Do not leave the plug inserted for more than five minutes if it is found that the set does not operate.

Line Voltage Range

The receiver will operate satisfactorily within a line voltage range of 25 to 42 volts.

Series Resistor

If the line voltage is higher than 42, it will be necessary to use a series resistor to cut it down. If the voltage varies, a variable resistor may be required.

Starting Current

When first turned on the drain for a few seconds is slightly higher than normal until the tubes heat up. Some automatic plants are adjusted to start under a load of 200 to 300 watts. If a number of devices such as lights or motors are being used and the radio set is turned on the total drain may be sufficient to start the plant.

Replacing Drive Cord

Take off the station pointer by removing the screw at the center of the dial.

Remove the pilot lamp assembly by pulling the socket clips upward off the dial assembly.

Loosen the dial assembly by removing the two screws which secure this assembly to the chassis brackets.

Then lay the complete dial assembly face down in front of the chassis. It is not necessary to remove the volume control and tone control collars which hold the indicator cords of these two controls in position.

Turn the drive drum until the opening in this drum is approximately vertical and with the hole at the top as shown in Fig. 6.

Remove the tension spring and the old drive cord.

See that the eyelet is in the hole in the drive drum as shown in Fig. 6. Insert one end of the new drive cord from the outside through this eyelet in the drive drum.

Tie the end of the cord which has been inserted through the eyelet to one end of the tension spring.

Wrap the cord in a counter clockwise direction (facing front of chassis) around the drive drum approximately one and one-quarter turns progressing toward the front.

Then tilt the chassis up on its back panel and bring the cord mentioned in the previous paragraph down to the drive shaft. Wrap this cord directly below the drive drum three and one-half turns around the drive shaft, as shown in Fig. 6, progressing toward the back of chassis.

Then bring this cord up to the drive drum and wrap it around the drum in back of cord already on the drum until it is up to the eyelet as shown in Fig. 6.

Now insert the free end of the cord through the hole in the eyelet and tie it to the end of the spring. The end of the spring when hanging free and with all slack removed from the drive cord should be ½" or less from the flange of the drum, as shown in Fig. 6. Cut off the surplus length of cord after it is tied to the spring.

Then secure the other end of the tension spring over the spur on the drive drum.

Turn the drive shaft back and forth several times.

Replace the dial assembly, pointer and pilot lamp assembly.

Eliminating Ignition and Generator Noise

After the receiver is in working order, the following procedure must be followed in practically all cases to eliminate ignition and generator noise caused by the charging plant. If the charging plant causes no noise, then of course, these steps do not have to be taken.

One spark plug suppressor must be placed on each spark plug of the engine. One spark plug for example would be required on a one-cylinder engine and four must be used on a four-cylinder engine. To connect the spark plug suppressor, remove the wire from the top of the plug, put the suppressor on and attach the wire to the other end of the suppressor.

A generator condenser must be used. This consists of two .5 mfd. sections in one unit. The two sections have one side grounded to the metal case of the condenser. Mount the condenser on the frame of charging plant. This will ground it. Then connect the two leads to the charging switch, one on each side of the line.

In some large installations, where the charging unit is on only two or three times a week, the above steps do not have to be taken, as interference is only caused when the generating plant is in operation.

PRICES SUBJECT TO CHANGE WITHOUT NOTICE

Noisy Operation

Noisy operation may be due to a faulty antenna system. The action of the automatic volume control, due to the low pickup, causes the set to operate at its maximum sensitivity, thereby increasing noisy reception due both to external pickup and internal conditions.

The receiver may be partially detuned, causing it to operate at maximum sensitivity. The signal should be very carefully tuned in until it is clearest and strongest.

If the reception is noisy only when the generating plant is in operation, then the noise is due to the latter and several things can be done. There may be loose parts in the generator plant rubbing together. Tighten up all parts and be sure that all parts of the engine are well grounded. Dirty spark plugs may cause noise. Clean and respace the plugs or try out a new set. In some instances it may be necessary to filter the power supply line to the receiver.

If any motor driven devices, such as pumps, are operated from the 32 volt line, the motor may cause noisy reception in the receiver. This can be corrected in most cases by connecting one of the dual .5 mfd. condensers mentioned above across the line at the motor. The common connection to the two condensers which is grounded to the can is grounded externally by mounting the unit on the motor frame.

CAUTION—Read the Following

To avoid the danger of damage to the receiver and accidental short circuit, the following facts should be understood.

The metal chassis is connected to one side of the line—See Fig. 2. 32 volt lines are generally grounded on one side—either side may be used. If the side of the line, not connected to the metal chassis, is grounded and the metal chassis comes in contact with the external ground, the line will be short circuited and an excessive current may result.

In any service work, therefore, on this chassis keep it on a wood or other insulated surface. Disconnect the antenna and ground leads to avoid the possibility of any external ground contacts with the chassis. The person working on the set should avoid coming in contact with any ground

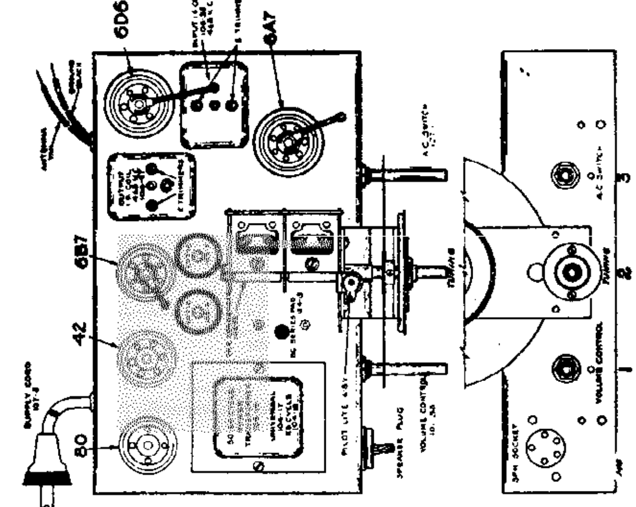
C.13	8 mfd. lytic x 300 V.—P-103-7



Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a voltmeter having a resistance of 1000 ohms per volt. These voltages are clearly indicated on the circuit diagram.

All voltages are measured with 119 volts on the primary of the power transformer.

Resistance of coils and transformer windings are indicated in ohms on schematic circuit diagram.

Transformers are available and chassis are sometimes equipped with universal transformers for operation on 40 and 60 cycles and with primary taps for 108, 125, 150, 220 and 250 volts (see illustrations) and also sometimes equipped with 25 cycle transformers with 105-115 volt or 220 volt primaries, not universals.

Aligning Instructions

Description of various dummy antennas used and referred to in these instructions:

(1) I.F. Dummy—Consists of a .1 mfd. condenser connected in series with the external oscillator.

(2) Broadcast Dummy—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

RESONANCE INDICATOR:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer, or by means of an adapter between the plate and screen terminals of the type 42 output tube. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range voltmeter should be used.

ALIGNMENT:

No aligning adjustments should be attempted without first thoroughly checking over all other possible causes of trouble, such as poor installations, open or grounded antenna systems, low line voltages, defective tubes, condensers and resistors. In order to align this chassis properly, an oscillator (generator) is absolutely necessary. No aligning adjustments should be attempted with the chassis in the cabinet. To remove the knobs, pull them off. To take the chassis out of the cabinet, remove the three bolts by which it is fastened and the speaker plug which you will find on the front flange of the chassis panel.

Aligning I. F. Transformers

1. With gang condenser in its minimum capacity position, and plates entirely out of mesh, connect an external oscillator in series with broadcast dummy antenna to tan antenna and black ground leads and make the following adjustments:
   (a) Connect external oscillator which has been adjusted to 465 kilocycles in series with I.F. dummy antenna, to the control grid cap of the type 6D6 tube and chassis ground. Adjust output I.F transformer, part number 108-47, to resonance.
   (b) Move generator output clip from grid of 6D6 to grid cap of 6A7 tube and align input I.F. transformer, part number 108-53.
   (c) With generator connected to grid of type 6A7 tube, readjust output I.F. transformer, part number 108-47, to resonance.

R. F. Alignment—
(530 - 1720 Kilocycles)

1. With gang condenser in its minimum capacity position, plates entirely out of mesh, connect an external oscillator in series with broadcast dummy antenna to tan antenna and black ground leads and make the following adjustments:
   (a) With external oscillator set at 1720 kilocycles, adjust oscillator trimmer, (rear of gang condenser).
   (b) Re-set external oscillator to 1400 kilocycles, rotate condenser, pick up oscillator signal and adjust antenna trimmer to resonance, (front section of gang condenser).
   (c) Re-set external oscillator to 600 kilocycles and adjust series pad to resonance, rotate condenser and move dial pointer to 600 kilocycles by gently rocking condenser to and fro. Pick up oscillator signal while adjusting series pad to resonance, maximum deflection on an output meter. This adjustment is accessible from the top of the chassis and is located between variable condenser and power transformer.

25 Cycle Chassis differ only from 60 cycle chassis in that part number 104-18 transformer is used in place of 50/60 cycle transformer, part number 104-14.

DESCRIPTION

The Tube complement of this chassis is as follows:
1 Type 6F7—triode pentode as oscillator and first detector.
1 Type 6K7—remote cut-off pentode as I.F. amplifier.
1 Type 75—duplex diode triode as diode detector, A.V.C. and A.F.
1 Type 6F6—pentode output tube.
1 Type 80—high vacuum rectifier.

Transformers are available and chassis are sometimes equipped with universal transformers for operation on 40 and 60 cycles and with primary taps for 108, 125, 150, 220 and 250 volts (see instructions) and also sometimes equipped with 25 cycle transformers with 105-115 volt or 220 volt primaries, not universals.

ALIGNING INSTRUCTIONS

No aligning adjustments should be attempted without first thoroughly checking over all other possible causes of trouble, such as poor installations, open or grounded antenna systems, low line voltages, defective tubes, condensers and resistors. In order to properly align this chassis, an oscillator (generator) is absolutely necessary. No aligning adjustments should be attempted with the chassis in the cabinet. To remove the knobs, pull them off and to take the chassis out of the cabinet, remove the three bolts by which it is fastened and the speaker plug which you will find on the front flange of the chassis panel.

Aligning I. F. Transformers

1. With volume control full on, the extreme right of its rotation, and with wave changing switch in the broadcast position, extreme left of its rotation, and with variable condenser at its minimum capacity position, plates entirely out of mesh, adjust the I.F. transformers (two adjustments at the top of parts number 108-38 and 108-40—see top view).
   (a) Connect external oscillator which has been adjusted to 465 kilocycles in series with I.F. dummy antenna, to the control grid cap of the type 6K7 tube and chassis ground. Adjust output I.F. transformer, part number 108-40, to resonance.
   (b) Move generator output clip from grid of 6K7 to grid cap of type 6F7 tube and align input I.F. transformer, part number 108-38.
   (c) With generator connected to grid of type 6F7 tube, readjust output I.F. transformer, part number 108-40, to resonance.

Broadcast Band Alignment—
(540 - 1720 Kilocycles)

1. With wave changing switch in the broadcast position, extreme left of its rotation, and with gang condenser in its minimum capacity position, plates entirely out of mesh, connect an external oscillator in series with broadcast dummy antenna to tan antenna and black ground leads and make the following adjustments:
   (a) With external oscillator set at 1720 kilocycles, adjust oscillator trimmer to resonance, for location of this adjustment, number 6, see diagram.
   (b) Re-set external oscillator to 1400 kilocycles, rotate condenser, pick up oscillator signal and adjust antenna trimmer to resonance. For location of this adjustment, number 3, see diagram.
   (c) Re-set external oscillator to 600 kilocycles and adjust series pad to resonance, rotate condenser and move dial pointer to 600 kilocycles by gently rocking condenser to and fro. Pick up oscillator signal while adjusting series pad to resonance, maximum deflection on an output meter. This adjustment is accessible from the top of the chassis and is located between variable condenser and power transformer, see top view—part number 124-16.
   (d) Check for tracking and sensitivity at 1000 kilocycles.

NOTE (Series "B", "C" and "D" only)

Short Wave Band Alignment—
(7.6 - 19.0 Megacycles)

1. This band is aligned after the I.F. adjustments have been completed. Set wave changing switch to short wave position, extreme right of its rotation, set dial pointer to 18 megacycles.
   (a) With external oscillator adjusted to 18 megacycles and connected in series with short wave dummy antenna to tan antenna and black ground leads, adjust the oscillator short wave trimmer until generator signal is picked up. For location of this adjustment, number 4, see diagram.
   (b) Adjust short wave antenna trimmer to resonance. For location of this adjustment, number 1, see diagram.
   (c) Re-set external oscillator to 9 megacycles, rotate condenser, move dial pointer to 9 megacycles and check for tracking and sensitivity. Do not bend plates. NOTE: It is extremely necessary in making all of the above adjustments that the fundamental signal of the oscillator be tuned in and not the image frequency, which will fall below the fundamental.

Intermediate Band Alignment—
(2.35 - 7.7 Megacycles)

1. With wave changing switch in center position, and with dial pointer set to 7 megacycles, make the following adjustments:
   (a) With external oscillator set at 7 megacycles and connected in series with short wave dummy antenna, as for short wave adjustments, adjust trimmer of oscillator coil, part number 110-22 until 7 megacycle signal is picked up. For location of this adjustment, number 5, see diagram.
   (b) Adjust antenna trimmer to resonance, adjustment number 2, see diagram.
   (c) Re-set external oscillator to 2.5 megacycles (2500 kilocycles), rotate variable condenser, move pointer, pick up oscillator signal and check for tracking and sensitivity. NOTE: It is extremely necessary in making all of the above adjustments that the fundamental signal of the oscillator be tuned in and not the image frequency, which will fall below the fundamental.

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt. These voltages are clearly indicated on the circuit diagrams

IN ORDER TO PREVENT SIGNAL FROM ACTING UPON AVC AND AFFECTING ACCURACY OF VOLTAGE MEASUREMENTS, AERIAL AND GROUND LEADS SHOULD BE SHORT CIRCUITED WHILE MAKING MEASUREMENTS.

All voltages are to be measured with 119 volts on the primary of the power transformer.

Resistances of coils and transformer windings are indicated in ohms on schematic circuit diagrams.

25 Cycle Chassis differ only from 60 cycle chassis in that part number 104-18 transformer is used in place of 50/60 cycle transformer, part number 104-14.

Location of trimmers on Arvin Model 41

Alignment:

Adjust padders 1, 2, 3 and 4 with the test oscillator connected to the grid cap of the 6A7. Frequency of test oscillator is 456 kc

Adjust No. 5 with the oscillator connected to the antenna wire (red) and the ground side to the set's ground wire. Set the oscillator and the dial to 1500 kc.

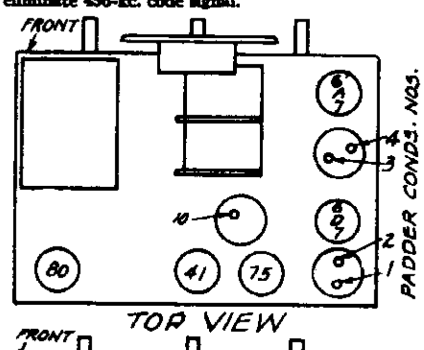
Adjust No. 6 with the oscillator connected as above with the same settings to 1500 kc.

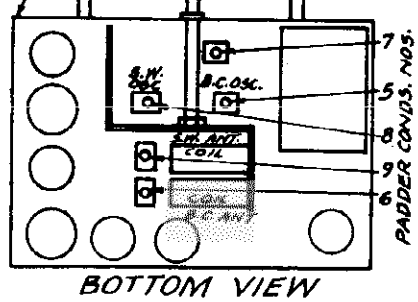
Trimmer	Test Osc. Frequency	Set Radio Dial to	Set Wave Switch to
5	1,500 kc.	150	Broadcast .55—1.75
	"	"	"
7	600 kc.	0.60	"
8*	15 mc.	15.0	Short Wave 18—5.5 mc.
9	"		"
10**	456 kc.	.0	Broadcast

*To adjust oscillator padder on 6-18 mc. band, unscrew padder wide open, then tighten until first signal is reached and tuned to resonance.

**Balance for minimum signal. Wave trap to eliminate 456-kc. code signal.

For the remainder of the adjustments the test oscillator is connected to the antenna and ground wires of the receiver





Socket layout and trimmer locations of the Arvin Model 51

Alignment: Set test oscillator to 456 kc. Connect to 6A7 grid cap. Adjust trimmers 1, 2, 3, and 4 in the order named.

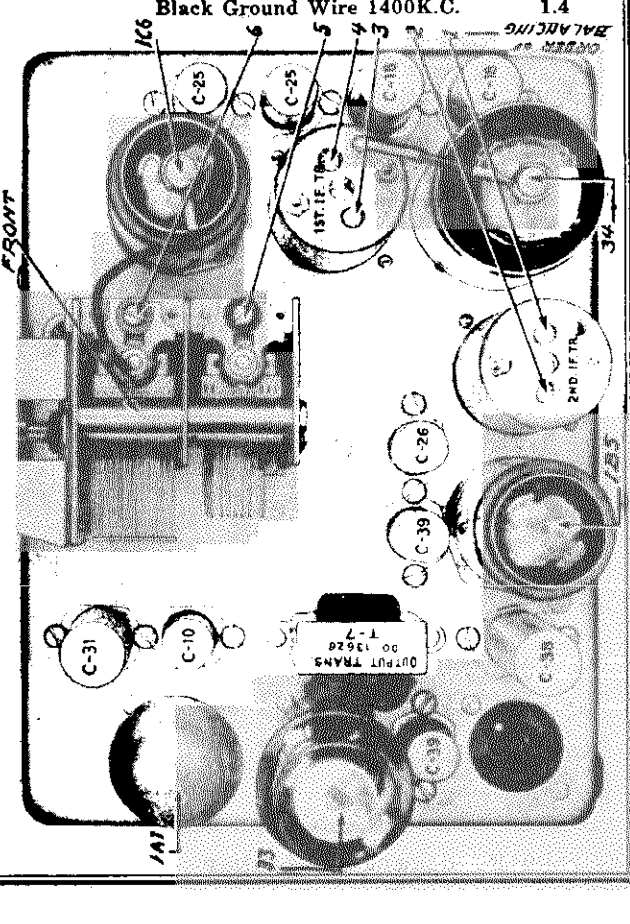
*Measured with Vacuum Tube Voltmeter.

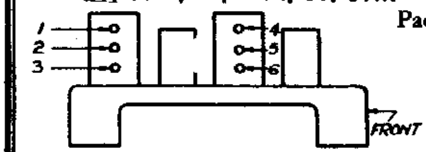
Socket Voltages to be taken with 135 Volts of B Battery and Eveready Air Cell.

CAUTION—Use only 135 volts of B Battery for testing. If these are not available a 5000 Ω Resistor in series with the B supply of an average A. C. Radio will supply sufficient voltage for testing.

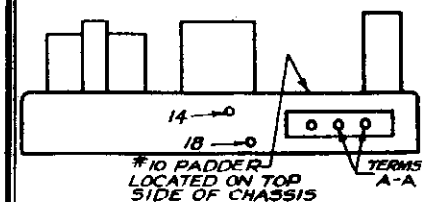


NOBLITT SPARKS INDUSTRIES

Arvin 61, 61M, 62, 62M, 81, 81M



LEFT END VIEW



REAR VIEW

The locations of the trimmers of the Arvin 61 series are shown in the left end and rear views.

Padders numbered 7, 8, 9, 11, 12, 13, 15, 16, and 17 are accessible from the bottom of the chassis, where their locations are plainly indicated on the tuning unit cover label, through which holes must be punched in order to adjust the padders.

I-f Alignment:

I-f. peak is 456 kc. for all models. For Models 61, 62, and 81 connect the signal generator to the 6A7 tube and for Models 61M, 62M and 81M connect to the 6A8 tube. Adjust padders in their numerical order, *i.e.* 1, 2, 3, 4, 5, and 6.

R-f. Alignment:

Connect signal generator to terminals A-A on rear of chassis. Adjust padders in the following order only:

Padder Number	Signal Gen. Frequency	Adjust Radio Dial to	Set Wave Switch to
			Standard Broadcast
7	1500 kc.	1.5	.55—1.7
8	"	"	"
9	"	"	"
10	600 kc.	.60	"
			Aviation-Police
11	4.7 mc.	4.7	1.8—5.5
12	"	"	"
13	"	"	"
14	1.9 mc.	1.9	"
			S-W. Foreign
15	15.0 mc.	15.	6.0—18.0
16	"	"	"
17	"	"	"
18	6.0 mc.	6.0	"

Note: To adjust oscillator padder on 6-18 mc. band, unscrew wide open, then tighten until first signal is reached and tuned to resonance.

Adjust padder condensers 1,2,3 and 4 in the order designated by their numbering for maximum output. Connect oscillator to antenna lead (red wire). Rotate condenser entirely out of mesh and adjust padder number 5 for resonance at 1650 KC. Reset the balancing oscillator to 1400 KC. and rotate the tuning condenser until this signal is received. Adjust padder number 6 for maximum output. Align padder #7 at 600 KC. Align trimmer #8 at 1400 KC. Adjust trimmer #9, beginning with the trimmer set at minimum capacity and taking the first peak.

BALANCING INSTRUCTIONS

1. Connect the balancing oscillator (456 K. C.) to grid cap of the 1st Det. Connect an output meter or cathode ray oscillograph to speaker output transformer or across speaker voice coil.
2. Adjust padder condensers 1, 2, 3, 4, 5 and 6 for maximum output in the order designated by their numbering.
3. Recheck the adjustment of each padder beginning with number 1 to prevent interlocking of circuits.
4. Disconnect oscillator from Det. grid cap and replace grid clip.
5. Connect oscillator to terminal on rear of set marked "A." Ground oscillator cable shield to terminals marked "D" and "G."
6. Set the wave band switch to broadcast position. Rotate the condenser fully out of mesh and adjust padder number 7 for resonance at 1650 K. C.
7. Rotate the dial pointer until it is opposite 140 on the broadcast band and adjust padders 8 and 9 for maximum output.
8. Reset the balancing oscillator to 600 K. C. and rotate the tuning condenser until this signal is received. Adjust padder number 10 for maximum output while rotating the tuning condenser slightly to follow the drift in frequency caused by the change in padder adjustment.
9. Reset the wave switch to the mid band position (5500-1750 K. C. range). Readjust the balancing oscillator to 4800 K. C. and set the dial pointer to 4.8 on the center dial calibration.
10. Adjust padder number 11 for resonance.
11. Adjust padders 12 and 13 for maximum output.
12. Reset balancing oscillator to 1800 K. C. Set the dial point to 1.8 on the center dial calibration.
13. Adjust padder number 14 for maximum output while rotating tuning condenser slightly to follow drift in frequency caused by the change in padder adjustment.
14. Reset the band switch to the short wave position (5.5-18.5 megacycles). Readjust the balancing oscillator to 16 megacycles and set the dial pointer opposite 16 on the short wave band.
15. Unscrew screw in padder number 15 until padder condenser plates are wide open. Then tighten selecting the first resonance point reached. (The short wave band will not function unless this precaution is taken.)
16. Adjust padders 16 and 17 until maximum output is obtained.

MODEL 1127

BALANCING INSTRUCTIONS

1. Connect the balancing oscillator (456 K. C.) to grid cap of the 6A8G tube. Connect an output meter or cathode ray oscillograph to speaker output transformer or plate of 6N6G tube.
2. Adjust padder condensers 1, 2, 3, 4, 5, 6, 7, 8, and 9 for maximum output in the order designated by their numbering until oscillograph trace shown in Fig. A is obtained.
3. Recheck the adjustment of each padder beginning with number 1 to prevent interlocking of circuits.
4. Disconnect oscillator from 6A8G grid cap and replace grid clip.
5. Connect oscillator to terminal on rear of set marked "A." Ground oscillator cable shield to terminals marked "D" and "G."
6. Set the wave band switch to broadcast position. Rotate the condenser fully out of mesh and adjust padder number 10 for resonance at 1650 K. C.
7. Rotate the dial pointer until it is opposite 140 on the broadcast band and adjust padders 11 and 12 for maximum output.
8. Reset the balancing oscillator to 600 K. C. and rotate the tuning condenser until this signal is received. Adjust padder number 13 for maximum output while rotating the tuning condenser slightly to follow the drift in frequency caused by the change in padder adjustment.
9. Reset the wave switch to the mid band position (5500-1750 K. C. range). Readjust the balancing oscillator to 4800 K. C. and set the dial pointer to 4.8 on the center dial calibration.
10. Adjust padder number 14 for resonance.
11. Adjust padders 15 and 16 for maximum output.
12. Reset balancing oscillator to 1800 K. C. Set the dial point to 1.8 on the center dial calibration.
13. Adjust padder number 17 for maximum output while rotating tuning condenser slightly to follow drift in frequency caused by the change in padder adjustment.
14. Reset the band switch to the short wave position (5.5-18.5 megacycles). Readjust the balancing oscillator to 16 megacycles and set the dial pointer opposite 16 on the short wave band.
15. Unscrew screw in padder number 18 until padder condenser plates are wide open. Then tighten selecting the first resonance point reached. (The short wave band will not function unless this precaution is taken).
16. Adjust padders 19 and 20 until maximum output is obtained.

ALIGNMENT DATA

AN ALL-WAVE TEST OSCILLATOR AND VACUUM-TUBE VOLTMETER TO MEASURE A.V.C. BIAS, WILL SUFFICE TO ASSIST IN SECURING NORMAL BALANCED CONDITION OF THE COILS AND CONDENSERS. AN OUTPUT OF APPROXIMATELY 500 MICRO-VOLTS WILL BE DESIRABLE TO PROVIDE GOOD V.T.V. READINGS OF THE A. V. C. BIAS. THE SENSITIVITY CONTROL SHOULD BE FULLY ADVANCED, AND IT ALSO WILL BE NECESSARY TO USE A .008 CONDENSER IN SERIES WITH THE TEST OSCILLATOR OUTPUT AND THE 6A8 CONTROL GRID. THE DIAL SHOULD BE SET TO APPROXIMATELY 1600 KC AND THE I.F. TRIMMERS ADJUSTED FOR MAXIMUM A.V.C. BIAS AT 458 KC.

ALL SERIES PADDER CONDENSERS ARE FIXED AND DIAL TRACKING AT THE LOW FREQUENCY END OF ALL WAVE BANDS MUST BE ACCOMPLISHED BY VARYING THE OSCILLATOR COIL INDUCTANCE. THE COILS ARE DESIGNED TO PERMIT THE NECESSARY AMOUNT OF VARIATION. HOWEVER, PARALLEL TRIMMER CONDENSERS ARE PROVIDED TO LINE UP THE HIGH FREQUENCY END OF EACH BAND.

THE DIAL POINTER SHOULD BE SET PARALLEL TO THE LINE OF THE DIAL WITH THE CONDENSER PLATES FULLY MESHED. WITH THE TEST OSCILLATOR ADJUSTED TO 1400 KC, THE OSCILLATOR TRIMMER SHOULD BE ADJUSTED FOR MAXIMUM OUTPUT WITH THE DIAL POINTER AT 1400 KC. NOW SET THE TEST OSCILLATOR AT 600 KC AND TUNE THE SET TO RECEIVE 600 KC SIGNAL. IF NECESSARY VARY THE COUPLING BETWEEN THE TWO PORTIONS OF THE OSCILLATOR COIL IN ORDER THAT THE DIAL MAY TRACK. AFTER LINING UP THE DIAL AT THE LOW FREQUENCY END THE HIGH FREQUENCY TRIMMERS MAY REQUIRE SLIGHT READJUSTMENT.

THE SAME PROCEDURE SHOULD BE FOLLOWED WITH THE NUMBER 2 BAND USING TWO MC. TO SET THE OSCILLATOR INDUCTANCE AND 5 MC TO ADJUST THE OSCILLATOR AND ANTENNA TRIMMERS, SIMILARLY ON THE NUMBER 3 BAND USING 6 MC AND 16 MC. A CAREFUL EXAMINATION OF THE WAVE BAND SWITCH WILL DIFFERENTIATE THE COILS USED FOR EACH BAND.

THE DISTRIBUTED CAPACITIES IN THE R.F. COILS AND ASSOCIATED WIRING IS HELD TO EXTREMELY CLOSE TOLERANCES AND OBVIATES THE NECESSITY FOR TRIMMERS ON THE NUMBER 1 AND NUMBER 2 BANDS FOR SAID COILS.

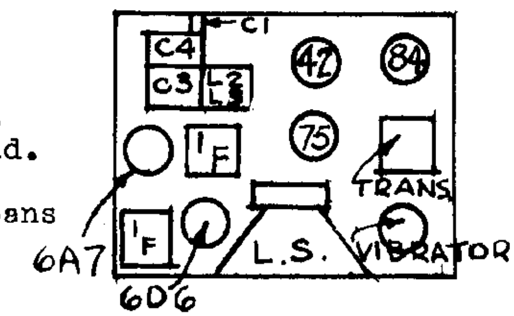
L4 Spark Filter



8. **ANTENNA COMPENSATOR** is located in upper left hand corner of box and may be trimmed with a quarter-inch socket wrench, preferably insulated.

Turn station selector knob to right until stop is reached; adjust dial pointer to right hand stop line mark on dial face. This sets pointer for calibration.

Tune in a weak signal between 550 and 650 Kcs. and adjust compensator for maximum volume . . . no other adjustments are necessary as radio will be perfectly matched to your antenna.

In cases where antenna or lead wire contribute excessive capacity to system a small series by-pass condenser of from 250 to 500 micro-microfarads capacity must be connected in series at the receiver and shielded.

Excessive antenna capacity may be detected by an apparent broad trimming action when adjusting compensator.

THE TUNING METER adjustment is located on the back panel just below the "Phono" Terminals. The adjustment may be made as directed above for Standard Broadcast or Phone Reception, and with automatic volume control in action. Now with dial, Band Switch and Volume Control set in any position turn Manual Control to extreme left, minimum position. Now adjust the screw marked "Tuning Set" on the back panel until the indicating vane on the Tuning Meter rests at the point on meter face marked "Set" at the extreme left of the scale. The Manual Control may now be increased toward the right for normal operation.

An auxiliary adjustment screw for the Beat Oscillator is located in the hole in the same shield can, directly back of the long adjustment handle. THIS SHOULD NEVER BE TOUCHED unless it is impossible to get a beat note by adjusting the long handle. This adjustment screw will be found to be quite critical as compared to the long handle. UNDER NO CIRCUMSTANCES should the intermediate adjustment screws within the other square shield cans be touched! To do so will result in COMPLETE FAILURE of the receiver to operate unless, of course, these adjustments are made by a competent service man who is thoroughly equipped to make such adjustments.

COMMUNICATION SWITCH—The use of the Communication Switch will be found to be of most value to amateurs. It permits the operator to "kill" the receiver while transmitting without allowing the filaments to cool down or altering the setting of the receiver.

PATTERSON RADIO CO.

MODEL PR-16
Series C
Alignment
Voltage

CRYSTAL FILTER: During Broadcast or Phone reception the Crystal Filter is seldom of any value, if used in the series position. For most satisfactory results the Crystal Filter may be placed in parallel by throwing the right hand Toggle Switch down. When in this position the only effect noticeable will be in reduction of interference from an interfering station, particularly on the Amateur Phone Bands. By careful tuning it is possible to completely separate badly heterodyning phone signals that would otherwise be totally unreadable. The series position is intended primarily for C. W. (code) reception. It is seldom of any value for phone reception. To put the Crystal in series position it is necessary that the right hand Toggle Switch on front panel be in "Up" position, which is the normal receive position (Crystal not in use). Now turn front panel control marked "Crystal Phasing" toward the left: this control automatically puts the Crystal in the series position as well as controls the series position Crystal selectivity, maximum selectivity being reached about mid-point of the control range. It should be further noted that for either normal operation (Crystal not in use) or with Crystal Switch in parallel position the Phasing Control must be turned to and left at the extreme right end of its range for satisfactory performance.

Alignment Procedure

I.F. ALIGNMENT

As explained below, the "R" meter will be found invaluable, and extremely flexible, in all line-up procedure, making it unnecessary to use any other external resonance indicating device. On all sets equipped with crystal filters it is extremely important that the intermediate be aligned *exactly* to the crystal's fundamental frequency, if satisfactory crystal performance is to be accomplished.

Few service men are equipped with a proper service oscillator designed for use with the crystal in the PR-16, and therefore, the method described below will undoubtedly be the most practical, and if carefully followed, will prove most satisfactory.

Production crystals vary as much as 2 K.C. plus or minus 458 K.C., so it is inadvisable to attempt alignment by merely setting the service oscillator at 458 K.C., without making the final adjustment described below. The variation mentioned above, while less than 1%, is sufficient to cause very poor crystal performance unless great care is exercised, and all instructions are followed exactly.

If the intermediate trimmers have been tampered with, or are badly out of line, the service oscillator should just be set at 458 K.C., and with all controls on radio set for broadcast or phone reception, manual control extreme clockwise position, phasing control extreme clockwise position, band switch on any band, crystal switch off (right hand toggle-switch handle pointing up) A.V.C. in action (left hand toggle-switch handle pointing down), R.F. gain control in maximum position (extreme clockwise position facing back of radio), communication switch in clockwise position, "on", beat oscillator switch in counter-clockwise position, "off", volume control about midpoint of its range (optional).

With service oscillator in operation at 458 K.C., remove the grid cap from the third I.F. tube (tube and I.F. transformer positions indicated in Fig. 4), connect output lead from test oscillator to grid cap of this tube; if no signal is heard or if no reading is indicated, the output attenuator on service oscillator should be increased until a reading of "R6" or "R7" is indicated on "R" meter. The trimmer screws on I.F. transformer No. 4 may now be adjusted for maximum reading on "R" meter reducing service oscillator output attenuator when necessary to keep "R" meter within a readable range.

A standard bakelite or fibre screw driver should be used. After maximum setting of trimmer screws has been reached, the grid cap may be replaced on third I.F. tube, and removing grid cap on second I.F. tube, connect service oscillator to the grid of this tube and continue as above, this time making adjustment of trimmer screws on I.F. transformer No. 3, continually reducing service oscillator attenuator when necessary to keep "R" meter within a readable range (about "R" 6 or 7).

The same procedure may now be followed out on first I.F. tube, replacing grid cap on second I.F. tube, removing grid cap on first I.F. tube and connecting service oscillator output lead to grid on this tube, and this time making trimmer adjustments on I.F. transformer No. 2, reducing service oscillator attenuator as necessary. If difficulty is experienced at this point, or any point hereafter, in getting a low enough output from service oscillator to obtain a reading on "R" meter below "R" 7 or 8.

First make sure you have a good ground connection between service oscillator and radio chassis. (The usual ground or shielding on output lead from service oscillator is usually sufficient) If the ground is good and meter still reads high, you may now reduce the manual control on radio counter-clockwise until "R" meter again reads "R" 6 or 7. The trimmers on I.F. transformer No. 2 should now be adjusted for maximum reading on "R" meter, reducing manual control when necessary in line of service oscillator attenuator to obtain readable indication on "R" meter, if above difficulties are experienced; otherwise, you may continue to reduce service oscillator attenuator as necessary.

The grid cap may now be replaced on first I.F. tube, and service oscillator out-put lead moved to grid of modulator tube, removing cap before making connection. Then adjust trimmers on I.F. transformer No. 1 for maximum reading on "R" meter as before, reducing service oscillator attenuator or manual control for readable indication on "R" meter. When this is done you may now re-check all trimmers carefully for maximum reading on "R" meter, leaving service oscillator connected to modulator tube grid. If the radio is not equipped with crystal filter, the above procedure will complete the I.F. alignment.

If the set is equipped with crystal filter the instructions below should be followed closely.

If the selectivity and I.F. gain is good when set is tried, before alignment is attempted the above instructions may be omitted, following only instructions given below.

Leave service oscillator connected to grid of modulator tube in the position last described above. Service oscillator out-put attenuator set for quite low out-put and, if necessary, manual control reduced; "R" meter reading about "R" 6 or 7.

Next turn phasing control toward counter-clockwise position to about midpoint of its tuning range (crystal toggle switch handle up). Now very slowly and carefully tune the service oscillator through resonance until the maximum peak is found as indicated on maximum reading on "R" meter. This peak will be very sharp, and extreme care must be exercised to tune the service oscillator to exact peak and keep it there. This should be checked several times during the following procedure.

Now start at No. 4 I.F. transformer and carefully tune trimmers for maximum peak on "R" meter and proceed up to, and including, No. 3 and No. 2 I.F. transformers, checking and then re-checking all I.F. trimmers, except trimmers on No. 1 I.F. transformer; these should never be touched while the crystal is in series position, as indicated above. When the maximum peak has been reached the phasing control may be returned to its original extreme clockwise position, (crystal toggle switch handle up), and without touching the service oscillator tuning, the trimmers on No. 1 I.F. transformer may now be re-set for maximum peak on "R" meter.

The above completes the I.F. alignment; the crystal filter may be further checked by throwing the right hand toggle switch down, (parallel position) and tuning the radio through a broadcast station, or un-modulated signal from service oscillator set somewhere in the broadcast band; as the radio is tuned through exact resonance, a sharp dip in the "R" meter reading will be noticed, or if the dial is tuned fast through resonance, a decided "plop" will be heard in the speaker at exact center of resonance peak.

If it should be necessary at any time to remove the crystal from its holder for inspection, do not handle the crystal or its associate mounting plates any more than absolutely necessary. Wash all parts thoroughly with alcohol or carbon tetra chloride (carbona) and wipe with a clean dry rag before replacing in holder, using care not to handle parts with your bare hands after they are washed.

BROADCAST AND SHORT-WAVE ALIGNMENT

Make sure that adjustments are necessary before proceeding.

Before attempting further alignment, the diagram in Fig. 3 should be studied, particularly in reference to trimmer and padder, or locations and functions.

It is highly improbable that any adjustments will be necessary other than a slight touch-up of the various oscillator coil trimmers and broadcast padding condenser, and possibly a check on all other trimmers for alignment, although this latter is usually unnecessary because the coil design is such that resonance is reached with very little capacity in affect on all R.F. and osl. coils, so that a large change in the mechanical setting would have to take place before any noticeable capacity change or impaired performance could result, particularly so since all trimmer adjustments are sealed at the factory.

The broadcast band can be easily checked for calibration by tuning in stations of known frequency at various points on the dial, and corrections can be made without use of service oscillator, if desired, by using "R" meter to indicate exact peak, reducing manual control, (I.F. gain) where necessary to obtain a readable peak on meter. If discrepancies appear near the high frequency, end of B.C. band or all over the scale, they may be corrected, first with main tuning dial set to a frequency near 1400 K.C. where a local station of known frequency should appear, being sure first that the desired station is in operation at the time. Turn trimmer screw 01 very slowly and carefully, until the desired station is tuned to exact peak, as indicated by maximum reading of "R" meter.

Now set tuning dial to a frequency near 600 K.C., where a local station of known frequency is in operation. If the desired station appears at the proper setting no further adjustment will be necessary, but if it does not appear on exact setting, as indicated by maximum reading of "R" meter as tuning dial is tuned through the signal, it may be brought into place by setting tuning dial on exact frequency where station should appear, and carefully turning padder condenser adjustment screw "BP" until signal is peaked, as indicated by maximum reading on "R" meter.

If a large discrepancy has been corrected at this point it will be necessary to re-set tuning dial to its original position near 1400 K.C. and re-set trimmer 01 for maximum peak, as before. No further adjustment should be necessary on B.C. band, and all other stations will automatically fall on the proper reading, if the above instructions have been followed carefully.

An accurate check of calibration on all short-wave bands can be made by use of service oscillator, which is set at 1000 K.C. Extreme care should be used to set the service oscillator at exactly 1000 K.C. before continuing calibration check, the reason being that the checks below make use of harmonics as high as the 37th harmonic, and any discrepancy in the 1000 K.C. setting is multiplied by the particular harmonic where the check is being made. One sure method of arriving at exactly 1000 K.C. is, first: If a known station whose frequency is 1000 K.C. is within range, it should be tuned in on the radio, then connect the out-put lead from service oscillator to the antenna terminal on radio, leaving the antenna connected also. *Do not* connect the ground or shielded lead from service oscillator to radio chassis. Next tune the service oscillator through 1000 K.C., adjusting out-put attenuator on service oscillator until a loud whistle (Heterodyne beat note) is produced as the oscillator is tuned across the station.

Now carefully adjust the service oscillator for zero beat with the station. Zero beat is that point where the whistle (beat note) starts at a low frequency and rapidly rises in pitch as service oscillator is tuned either way from the center "quiet" spot. Now, leaving service oscillator tuning dial set at zero beat, increase oscillator attenuator to maximum out-put. Leave the out-put lead of service oscillator connected to antenna terminal of radio, but remove antenna lead from radio.

In the event that no station of 1000 K.C. is within range, or on the air, and if the service oscillator is known to have an accurate calibration, merely setting the service oscillator at 1000 K.C. should be accurate enough for all practical purposes. This can be easily checked, of course, by checking service oscillator calibration against various stations near to 1000 K.C., using the method of antenna connected to set and tuning for zero beat, as described above.

The band change switch should now be changed to No. 2 short-wave band. Next set tuning dial near 3 M.C. and tune back and forth until the 3rd harmonic of service oscillator is found; it should appear exactly on the 3 M.C. point. If it does not, it may be brought into place by carefully adjusting trimmer condenser 02. The rest of this band will then be automatically in calibration.

Next change the band switch to No. 3 short-wave band, and set tuning near 7 M.C. and tune back and forth slowly until the 7th harmonic of service oscillator is located. It should appear exactly on the 7 M. C. point; if it does not, it may be brought into place by careful adjustment of trimmer screw "03." If the signal from the service oscillator is very strong at this point, a second peak slightly higher in frequency may also be found, but it will be much weaker than the lower frequency peak on the 7 M.C. point on dial. The second weak peak is the image of the 9th harmonic and should be disregarded. This band now is automatically in line all over; it may now be checked all across, a harmonic from the service oscillator appearing on 7 M.C., 6 M.C., 5 M.C., 4 M.C.

If this is not the case, an error has been made in adjusting trimmer "03," and should be checked again until a harmonic falls on each successive 1 M.C. point on tuning dial.

However, some of the points may be weaker than others, particularly the odd harmonics. This is perfectly natural, and should cause no concern.

It would be well, at this point, to replace antenna on radio, set band switch on broadcast at 1000 K.C. and check again for zero beat with station at this frequency before continuing to No. 4 band for check. Be sure to remove antenna again, and set service oscillator out-put attenuator back to maximum position after zero beat has been checked. Then change band switch to No. 4 band and tune for the 14th harmonic at 14 M.C. point on tuning scale; if the calibration is off at this point it may now be corrected with trimmer ".04." Extreme care should be used in making this adjustment, as it is quite possible to get the 13th harmonic where the 14th should be at 14 M.C., thereby throwing the whole dial off. However, it is easy to check this by tuning over the whole scale; if the adjustment has been made properly there will be a harmonic from service oscillator on each 1 M.C. point, namely, 14 M.C., 13 M.C., 12 M.C., 11 M.C., 10 M.C., 9 M.C., 8 M.C. As in the case of the No. 3 band, care should be used in respect to the image of 15 M. C. when making adjustments at 14 M.C. the image being weaker and higher in frequency than the desired fundamental.

In checking the 5th band the procedure should be changed somewhat, as the harmonics come so very close together on this band as to be very confusing. However, before continuing, a check may be made on this band by the present method to determine if adjustment is necessary. If a harmonic from service oscillator appears on each M.C. point throughout its range, no further adjustment or check will be necessary.

If adjustment is necessary, the following procedure should be followed:

Set the band switch to No. 3 band, and set tuning dial at exactly 7 M.C. Since this band has just been checked, or adjusted, this will be quite accurate.

Now change service oscillator to 7 M.C. band and true to 7 M.C. position; leaving radio dial set at 7 M.C. as described above, turn service oscillator slowly past 7 M.C., watching "R" meter and tuning for maximum peak. When peak has been accurately reached, the service oscillator should be left at that setting and radio band switch changed to No. 5 band. Then set the radio tuning dial to, or near, 28 M.C. and tune for the harmonic at this point from service oscillator. When it has been located, it should appear on 28 M.C. If it does not it may be brought into place by very careful adjustment of trimmer screw "05", taking care to avoid the higher frequency image as in the case of No. 3 and No. 4 band.

When this adjustment has been made properly, set the main tuning dial to 21 M.C. A service oscillator harmonic will also appear at this point.

A further check may now be made on No. 4 band, if desired, by changing radio band switch to No. 4 band and tuning the radio dial to 14 M.C., where the 7 M.C. service oscillator second harmonic should be found. If it does not appear, it is probable that an error has been made in the original adjustment. Trimmer screw "04" may be adjusted again to bring this point into line at 14 M.C.

The original adjustment can, of course, be made in this way also, and in the case of where the service oscillator harmonics are weak in this region when set at 1000 K.C., will prove the most practical method.

MODEL FT-6 Ford
Alignment

PHILCO RADIO & TELEV. CORP.

I. F. TRANSFORMER AND PADDERS

The I. F. transformers are assembled complete with padding condensers.

The padders are placed in the top of the shield can one above the other.

The primary padder is adjusted by means of the screw slot, accessible through the hole in the top of the shield can. The secondary padder is adjusted by means of the small hex nut, also accessible through the hole in the top of the shield. (See Figs. 1 and 2.)

The coil windings terminate in leads instead of terminals or lugs. The color scheme of the leads is given in Fig. 1.

If replacements are ever necessary, replace the entire coil assembly 32-1329 for the first I. F. stage and 32-1237 for the second I. F. stage. Neither the coil nor the padders will be furnished separately. Order only by the above numbers.

MODEL FT-6 RECEIVER

THE new Ford auto radio incorporates new advanced principles of circuit and tube design. A totally new idea in sound distribution and musical fidelity is built into a dynamic speaker located above the occupants' heads in the header-bar of the car. Other features of the set are two-unit construction with separate speaker, highly developed Automatic Volume Control, illuminated custom-built instrument panel control, mounting in the ash receptacle opening.

The Receiver is mounted directly above the steering column out of sight and out of the way.

MODEL FT-6 ADJUSTMENTS

All adjustments have been carefully checked at the factory. If, however, it is found necessary to readjust the padding condensers, this procedure must be followed carefully. Do not attempt to make any adjustments until the procedure is clearly understood or without the use of a good oscillator or signal generator and output meter. The PHILCO Set Tester 048 is highly recommended for this procedure and for all service work.

The Receiver must be connected to a six-volt storage battery and set up for operation. It is assumed that tubes have been checked and that the Receiver is in good condition except for the padding adjustments.

Remove the cover from the Receiver and disconnect the grid clip from the 77 tube. (For location see Fig. 2.)

Set up the signal generator and adjust it to exactly 260 K.C. Connect the generator lead to the grid cap of the 77 tube, and ground the shield to the Receiver housing.

Connect one lead from the output meter to the plate of the 42 tube and the other lead to the receiver housing. The Receiver volume control must be turned to approximately full volume and the attenuator in the generator set for a half-scale reading of the output meter.

The primary screw padders ㉔ and ⑭ must be screwed all the way in. (Figs. 2 and 3.) The secondary nut padders ㉖ and ⑲ must then be adjusted. These padders should be adjusted for maximum reading on the output meter.

The screw padders ㉔ and ⑭ must be adjusted next.

Adjust the screw on each padder for maximum reading on the meter. This adjustment is critical. Note the maximum reading obtainable. Turn the screw in again and readjust, just bringing the adjustment up to the maximum reading. Do not pass it and then back off.

After padding the I. F. stages, remove the generator lead from the 77 tube and reconnect the grid clip to the 77 tube. Adjust the generator to 1580 K.C. and then connect the generator lead to the antenna lead. Ground the shield to the receiver housing.

Using a piece of paper approximately .006 inch in thickness, place it under the heel of the tuning condenser between the stator and rotor plates and turn the tuning condenser until the rotor plates strike this paper.

With the tuning condenser in this position, adjust the high-frequency padder ⑰ until the maximum reading is obtained in the output meter. This is the true setting for 1580 K.C., 158 on the dial scale. Adjust condensers ⑪ and ⑦ in the same manner.

Remove the paper and turn the tuning condenser plates in mesh to approximately 60 on the scale, and adjust the signal generator to 600 K.C. Roll the tuning condenser and adjust the series padder ⑲ for the maximum meter reading.

Readjust the padder ⑰ at 1580 K.C.

Tune the gang to 1400 K.C. and adjust padders ⑪ and ⑦ to maximum.

If this procedure has been carefully followed and an accurately calibrated oscillator or signal generator used, the receiver will be adjusted properly.

PHILCO RADIO & TELEV. CORP.

Chrysler DeLuxe Custom Built Radio Model CT11

NOVEMBER 15th, 1935

I. F. Transformers and Padders Model CT11

The I. F. transformers are assembled complete with padding condensers.

Both the primary and the secondary padders are placed side by side in the top of the transformer shield can. The adjusting screws are accessible thru the holes in the top of the shield. (See Fig. 2).

The coil windings terminate in leads instead of terminals or lugs. The color scheme of the leads is given in Fig. 1.

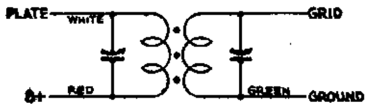

FIGURE 1

If replacements are ever necessary, replace the entire coil assembly, 32-1928 for the first I. F. stage and 32-1929 for the second I. F. stage. Neither the coil nor the padders will be furnished separately. Order only by the above numbers.

Model CT11 Adjustments

All padding adjustments are carefully made at the factory and ordinarily no readjustments are necessary. However, when readjustments to the Model CT-11 are required, the procedure given below must be followed in detail.

Equipment

Fully charged heavy duty storage battery or 6-volt power pack, 046A Philco Set Tester, 3164 Padding wrench, 27-7159 Padding screw driver.

General

OUTPUT METER — The output meter must be connected by means of an adapter to the plate of the type 41 output tube and to the Receiver chassis.

SIGNAL GENERATOR — With the Receiver and signal generator set up for operation at the prescribed frequency, turn the Receiver volume control on full and set the signal generator attenuator so that a half scale reading is obtained on the output meter. The signal in the speaker should be audible but not loud.

The shielding on the signal generator output lead must be connected to the Receiver housing.

The sensitivity switch must be in the "distance" position. The tone control should be turned to the brilliant position.

Procedure

I. F. — Adjust the signal generator to exactly 260 K. C. Connect the generator lead to the grid cap of the 78 I. F. tube in series with a .1 mfd. condenser.

Adjust the secondary screw padder (28) on the second I. F. transformer for maximum reading on the output meter. Then adjust the primary screw padder (27) for maximum reading. (See Fig. 2 for location of padders).

Remove the generator lead from the 78 tube.

Connect the generator lead to the grid cap of the 6A7 tube in series with a .1 mfd. condenser. Adjust the secondary screw padder (26) on the first I. F. transformer for maximum reading on the output meter. Then adjust the primary screw padder (24) for maximum reading. (See Figure 2 for location of padders).

HIGH FREQUENCY AND R. F. — After padding the first I. F. stage remove the generator lead from the 6A7 tube. Adjust the signal generator to 1600 K. C. and then connect the generator lead to the grid cap of the 78 R. F. tube in series with a .1 mfd. condenser.

Turn the tuning condenser plates out of mesh as far as they will go. With the tuning condenser in this position, adjust the high frequency padder (16) and the R. F. padder (17) until the maximum reading is obtained on the output meter. This is the true setting for 1600 K. C., 160 on the dial scale.

LOW FREQUENCY — Turn the tuning condenser plates in mesh to approximately 580 K. C., 58 on the dial scale and adjust the signal generator to the 580 K. C. Roll the tuning condenser and adjust the low frequency padder screw (21) for maximum reading on the output meter.

HIGH FREQUENCY RE-ADJUSTMENT — Turn the tuning condenser plates out of mesh as far as they will go and adjust the signal generator to 1600 K. C. Then adjust the high frequency padder (16) again for maximum reading on the output meter.

ANTENNA — Connect the generator lead to the antenna cable assembly (made up of Part No. L1915 loom and 40 inches of 16 strand No. 30 wire), using a 110 mmfd. condenser in series between the two leads. Plug the cable into the antenna socket marked "fabric top."

Turn the tuning condenser to 1400 K. C. and set the generator for 1400 K. C. Adjust the padders (6) and (7) for the maximum reading on the output meter.

When the antenna stage adjustment is made with the Receiver installed in the car, the Receiver antenna lead must be connected to the car antenna in the usual manner. The signal generator output lead should be connected to a wire placed near the car antenna but not connected to it.

If this procedure has been carefully followed and an accurately calibrated oscillator or signal generator has been used, the Receiver will be adjusted properly.

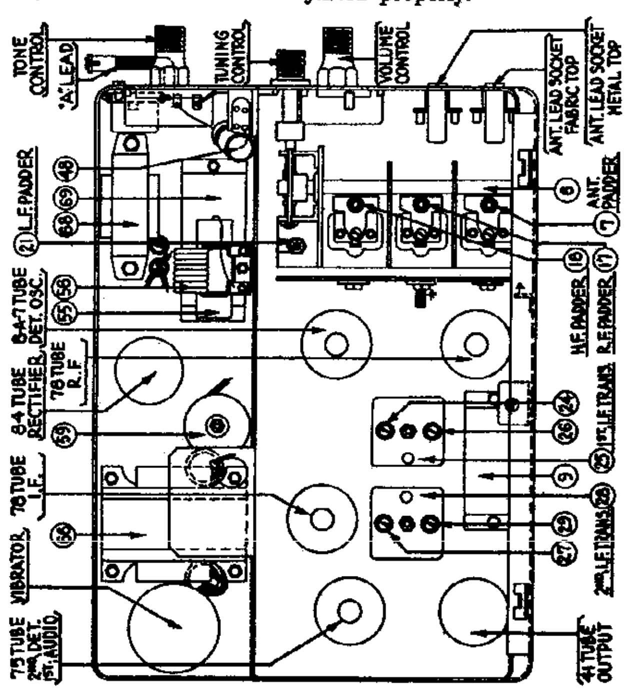

FIGURE 2

Schematic, Chassis Parts — PHILCO RADIO & TELEV. CORP. — MODELS NT12X, NT12X2 Nash, Lafayette

Nash-Philco Model NT12X and NT12X2 Two Unit Receiver

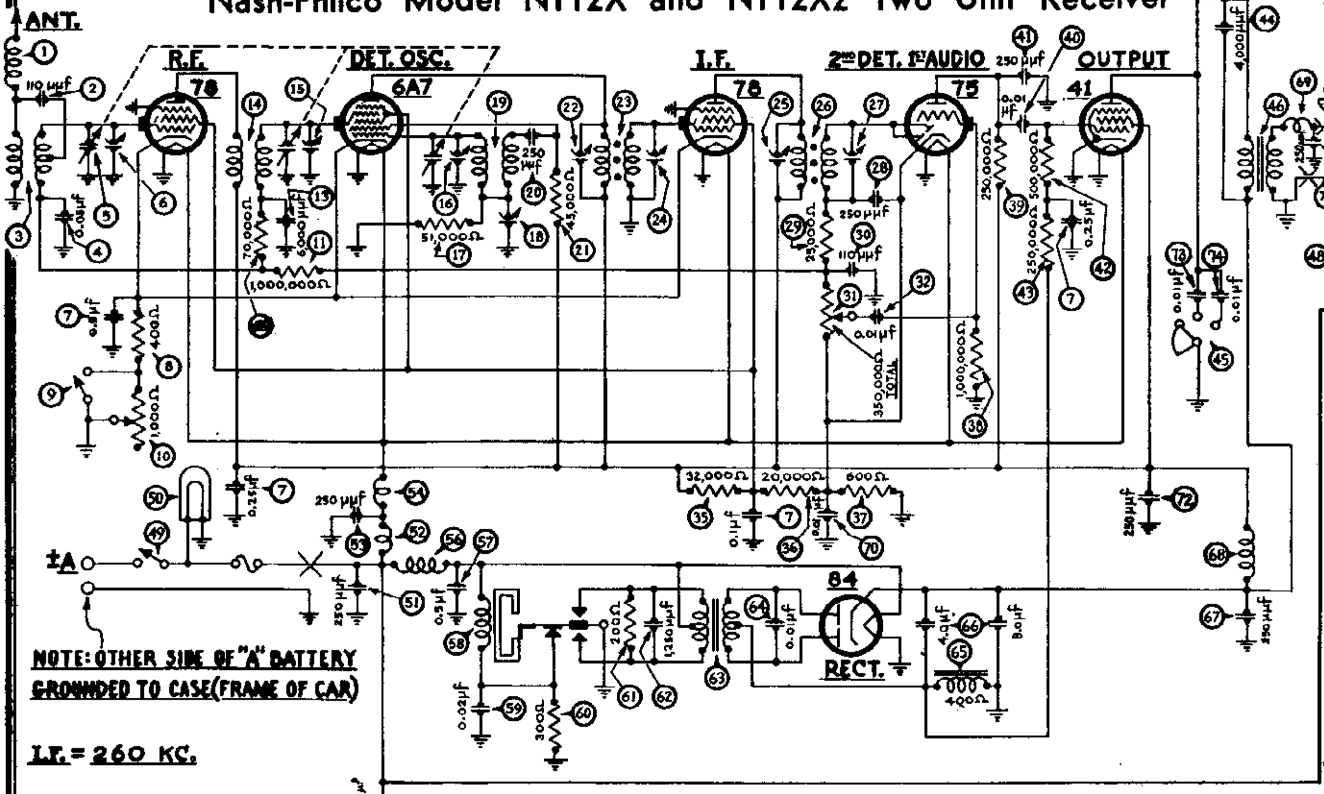

FIGURE 1 *Model NT12X Schematic*

The Model NT12X Receiver (Nash—AC-1889) is made for the Nash 400 and Lafayette 3610 cars, using the Nash under-car Ant. The Model NT12X2 Receiver (Nash—AC1789) is made for the Nash 3620 — 3680 cars using the insulated metal top antenna. The Models NT12X and NT12X2 Receivers are not interchangable.

PHILCO RADIO & TELEV. CORP.

I. F. Transformers and Padders
Model NT12X and NT12X2

The I. F. transformers are assembled complete with padding condensers.

Both the primary and the secondary padders are placed side by side in the top of the transformer shield can. The adjusting screws are accessible thru the holes in the top of the shield. (See Figure 8).

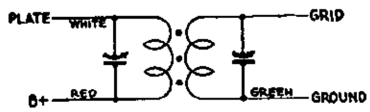

FIGURE 7

The coil windings terminate in leads instead of terminals or lugs. The color scheme of the leads is given in Figure 7.

If replacements are ever necessary, replace the entire coil assembly, 32-1928 for the first I. F. stage and 32-1929 for the second I. F. stage. Neither the coil nor the padders will be furnished separately. Order only by the above numbers.

Model NT12X Adjustments

All padding adjustments are carefully made at the factory and ordinarily no readjustments are necessary. However, when readjustments to the Model NT12X and NT12X2 are required, the procedure given below must be followed in detail.

Equipment

Fully charged heavy duty storage battery or 6-volt power pack, 048A Philco Set Tester, 3164 Padding wrench, 27-7159 Padding screw driver.

General

OUTPUT METER — The output meter must be connected by means of an adapter to the plate of the type 41 output tube and to the Receiver chassis.

SIGNAL GENERATOR — With the Receiver and signal generator set up for operation at the prescribed frequency, turn the Receiver volume control on full and set the signal generator attenuator so that a half scale reading is obtained on the output meter. The signal in the speaker should be audible but not loud.

The shielding on the signal generator output lead must be connected to the Receiver housing.

The sensitivity switch must be in the "distance" position. The tone control should be turned to the brilliant position.

Procedure

I. F. — Adjust the signal generator to exactly 260 K. C. Connect the generator lead to the grid cap of the 78 I. F. tube in series with a .1 mfd. condenser.

Adjust the secondary screw padder (27) on the second I. F. transformer for maximum reading on the output meter. Then adjust the primary screw padder (25) for maximum reading. (See Figure 8 for location of padders).

Remove the generator lead from the 78 tube.

Connect the generator lead to the grid cap of the 6A7 tube in series with a .1 mfd. condenser. Adjust the secondary screw padder (24) on the first I. F. transformer for maximum reading on the ouput meter. Then adjust the primary screw padder (22) for maximum reading. (See Figure 8 for location of padders).

HIGH FREQUENCY AND R. F. — After padding the first I. F. stage remove the generator lead from the 6A7 tube.

Adjust the signal generator to 1600 K. C. and then connect the generator lead to the grid cap of the 78 R. F. tube in series with a .1 mfd. condenser.

Turn the tuning condenser plates out of mesh as far as they will go. With the tuning condenser in this position, adjust the high frequency padder (16) and the R. F. padder (15) until the maximum reading is obtained on the output meter. This is the true setting for 1600 K. C., 160 on the dial scale.

LOW FREQUENCY — Turn the tuning condenser plates in mesh to approximately 580 K. C., 58 on the dial scale and adjust the signal generator to the 580 K. C. Roll the tuning condenser and adjust the low frequency padder screw (18) for maximum reading on the ouput meter.

HIGH FREQUENCY RE-ADJUSTMENT — Turn the tuning condenser plates out of mesh as far as they will go and adjust the signal generator to 1600 K. C. Then adjust the high frequency padder (16) again for maximum reading on the output meter.

ANTENNA

(NT12X only) — Connect the generator lead to the antenna cable assembly (made up of Part No. L1915 loom, 1-27-7133 terminal and 40 inches of 16 strand No. 30 wire), using a 200 mmfd. condenser in series between the two leads. Plug the cable into the antenna socket.

(NT12X2 only) — Connect the generator lead to the antenna lead using a 1250 mmfd. condenser and 50 ohms (non-inductive) as a dummy antenna. Plug the antenna lead into the antenna socket.

(NT12X and NT12X2) — Turn the tuning condenser to 1400 K. C. and set the generator for 1400 K. C. Adjust the padders (15) and (6) for the maximum reading on the output meter.

When the antenna stage adjustment is made with the Receiver installed in the car, the Receiver antenna lead must be connected to the car antenna in the usual manner. The signal generator output lead should be connected to a wire placed near the car antenna but not connected to it.

If this procedure has been carefully followed and an accurately calibrated oscillator or signal generator has been used, the Receiver will be adjusted properly.

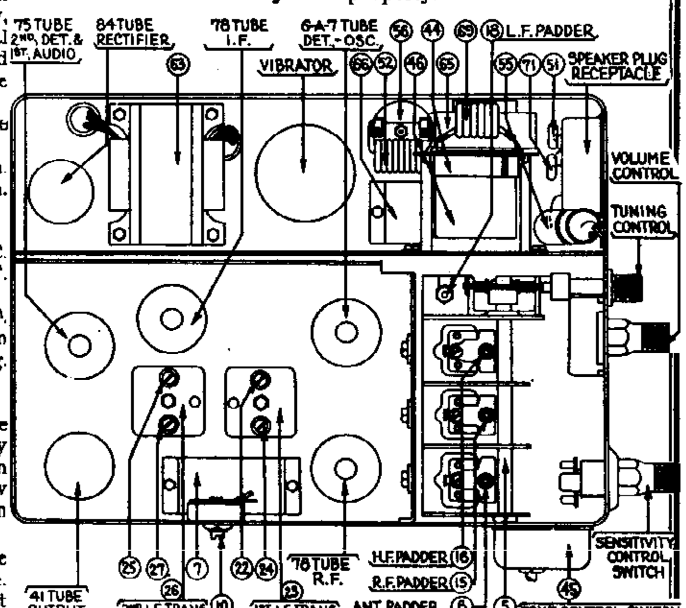

FIGURE 8

The Model NT12X Receiver (Nash—AC-1889) is made for the Nash 400 and Lafayette 3610 cars, using the Nash under-car Antenna.
The Model NT12X2 Receiver (Nash—AC1789) is made for the Nash 3620—3680 cars, using the insulated metal top Antenna.
The Models NT12X and NT12X2 Receivers are not interchangeable.

PHILCO RADIO & TELEV. CORP.

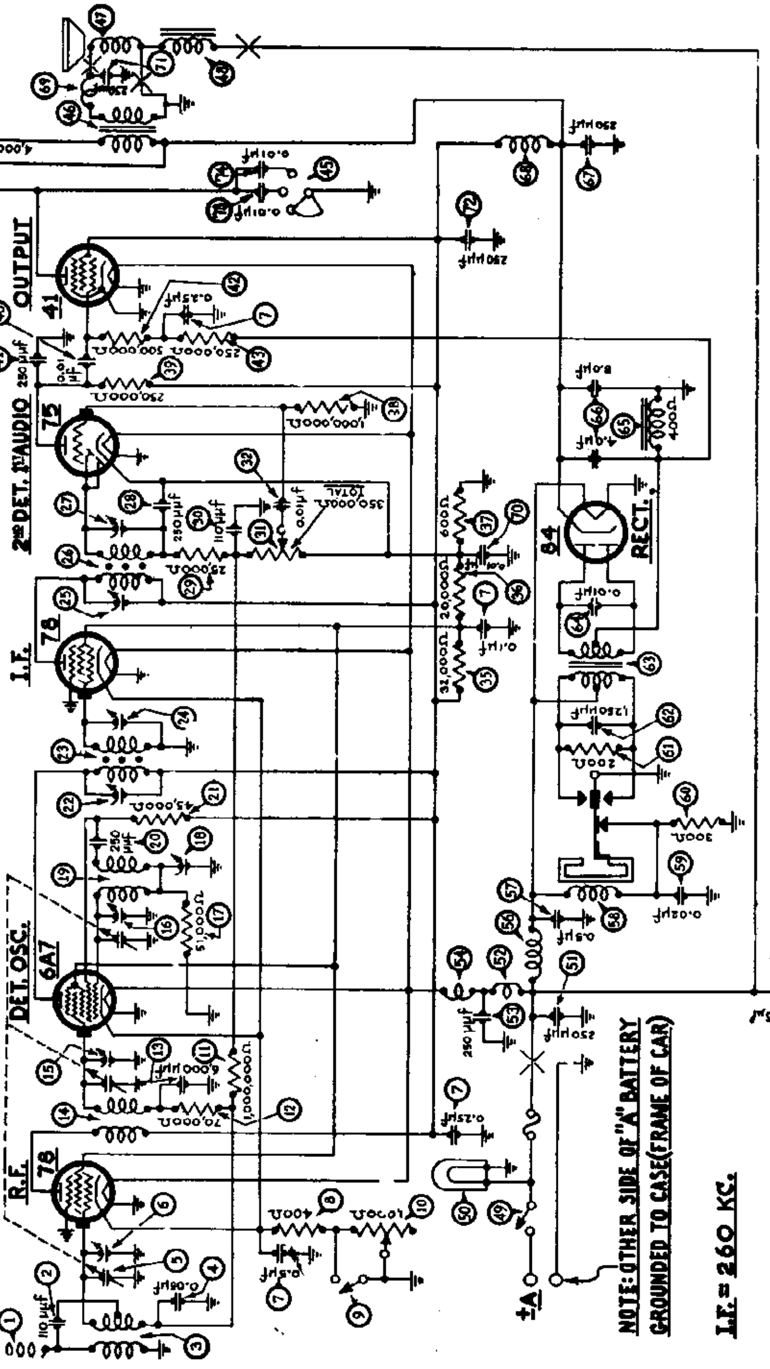

FIGURE 1 — *Model ST12 Schematic*

HIGH FREQUENCY RE-ADJUSTMENT — Turn the tuning condenser plates out of mesh as far as they will go and adjust the signal generator to 1600 K. C. Then adjust the high frequency padder ⑯ again for maximum reading on the output meter.

Adjust the signal generator to 1600 K. C. and then connect the generator lead to the grid cap of the 78 R. F. tube in series with a .1 mfd. condenser.

Turn the tuning condenser plates out of mesh as far as they will go. With the tuning condenser in this position, adjust the high frequency padder ⑯ and the R. F. padder ⑮ until the maximum reading is obtained on the output meter. This is the true setting for 1600 K. C., 160 on the dial scale.

LOW FREQUENCY — Turn the tuning condenser plates in mesh to approximately 580 K. C., 58 on the dial scale and adjust the signal generator to the 580 K. C. Roll the tuning condenser and adjust the low frequency padder screw ⑱ for maximum reading on the ouput meter

December 15, 1935

General

OUTPUT METER — The output meter must be connected by means of an adapter to the plate of the type 41 output tube and to the Receiver chassis.

SIGNAL GENERATOR — With the Receiver and signal generator set up for operation at the prescribed frequency, turn the Receiver volume control on full and set the signal generator attenuator so that a half scale reading is obtained on the output meter. The signal in the speaker should be audible but not loud.

The shielding on the signal generator output lead must be connected to the Receiver housing.

The sensitivity switch must be in the "distance" position. The tone control should be turned to the brilliant position.

Procedure

I. F. — Adjust the signal generator to exactly 260 K. C. Connect the generator lead to the grid cap of the 78 I. F. tube in series with a .1 mfd. condenser.

Adjust the secondary screw padder ㉗ on the second I. F. transformer for maximum reading on the output meter. Then adjust the primary screw padder ㉕ for maximum reading. (See Figure 8 for location of padders).

Remove the generator lead from the 78 tube.

Connect the generator lead to the grid cap of the 6A7 tube in series with a .1 mfd. condenser. Adjust the secondary screw padder ㉔ on the first I. F. transformer for maximum reading on the output meter. Then adjust the primary screw padder ㉒ for maximum reading. (See Figure 8 for location of padders).

LINCOLN CUSTOM BUILT CAR RADIO

I. F. Transformers and Padders
Model LT14X3

The I. F. transformers are assembled complete with padding condensers.

Both the primary and the secondary padders are placed side by side in the top of the transformer shield can. The adjusting screws are accessible thru the holes in the top of the shield. (See Fig. 2).

The coil windings terminate in leads instead of terminals or lugs. The color scheme of the leads is given in Fig. 1.

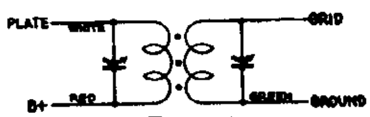

FIGURE 1

If replacements are ever necessary, replace the entire coil assembly, 32-1928 for the first I. F. stage and 32-1929 for the second I. F. stage. Neither the coil nor the padders will be furnished separately. Order only by the above numbers.

Model LT14X3 Adjustments

All padding adjustments are carefully made at the factory and ordinarily no readjustments are necessary. However, when readjustments to the Model LT14X3 are required, the procedure given below must be followed in detail.

Equipment

Fully charged heavy duty storage battery or 6-volt power pack, 048A Philco Set Tester, 3164 Padding wrench, 27-7159 Padding screw driver.

General

OUTPUT METER — The output meter must be connected by means of an adapter to the plate of the type 41 output tube and to the Receiver chassis.

SIGNAL GENERATOR — With the Receiver and signal generator set up for operation at the prescribed frequency, turn the Receiver volume control on full and set the signal generator attenuator so that a half scale reading is obtained on the output meter. The signal in the speaker should be audible but not loud.

The shielding on the signal generator output lead must be connected to the Receiver housing.

The tone control should be turned to the brilliant position.

Remove the cover from the Receiver. The antenna lead must be disconnected.

I. F. — Adjust the signal generator to exactly 260 K. C. Connect the generator lead to the grid cap of the 78 I. F. tube in series with a .1 mfd. condenser.

Adjust the secondary screw padder (23) on the second I. F. transformer for maximum reading on the output meter. Then adjust the primary screw padder (25) for maximum reading. (See Fig. 2 for location of padders).

Remove the generator lead from the 78 tube.

Connect the generator lead to the grid cap of the 6A7 tube in series with a .1 mfd. condenser. Adjust the secondary screw padder (20) on the first I. F. transformer for maximum reading on the output meter. Then adjust the primary screw padder (21) for maximum reading. (See Figure 2 for location of padders).

HIGH FREQUENCY AND R. F. — After padding the first I. F. stage remove the generator lead from the 6A7 tube. Adjust the signal generator to 1600 K. C. and then connect the generator lead to the grid cap of the 78 R. F. tube in series with a .1 mfd. condenser.

Turn the tuning condenser plates out of mesh as far as they will go. With the tuning condenser in this position, adjust the high frequency padder (14) and the R. F. padder (13) until the maximum reading is obtained on the output meter. This is the true setting for 1600 K. C., 160 on the dial scale.

LOW FREQUENCY — Turn the tuning condenser plates in mesh to approximately 580 K. C., 58 on the dial scale and adjust the signal generator to 580 K. C. Roll the tuning condenser and adjust the low frequency padder (18) for maximum reading on the output meter.

HIGH FREQUENCY RE-ADJUSTMENT — Turn the tuning condenser plates out of mesh as far as they will go and adjust the signal generator to 1600 K. C. Then adjust the high frequency padder (14) again for maximum reading on the output meter.

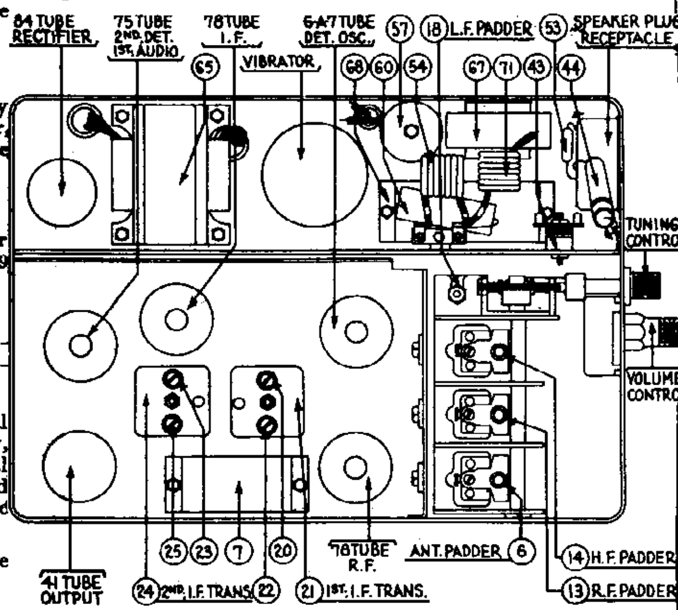

FIGURE 2

ANTENNA — Connect the generator lead to the antenna cable assembly (made up of Part No. L1963 loom, 1-27-7133 terminal and 64 inches of 16 strand No. 30 wire), using a 530 mmfd. condenser in series between the two leads. Plug the cable into the antenna socket.

Turn the tuning condenser to 1400 K. C. and set the generator at 1400 K. C. Adjust the padders (13) and (6) for the maximum reading on the output meter.

When the antenna stage adjustment is made with the Receiver installed in the car, the Receiver antenna lead must be connected to the car antenna in the usual manner. Connect the signal generator output lead to a wire placed near the car antenna but not connected to it.

If this procedure has been carefully followed and an accurately calibrated oscillator or signal generator has been used, the Receiver will be adjusted properly.

I. F. Transformers and Padders

The I. F. transformers are assembled complete with padding condensers.

Both the primary and the secondary padders are placed side by side in the top of the transformer shield can. The adjusting screws are accessible thru the holes in the top of the shield. (See Figure 6).

The coil windings terminate in leads instead of terminals or lugs. The color scheme of the leads is given in Figure 5.

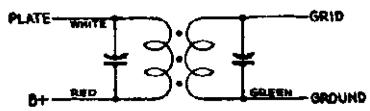

FIGURE 5

If replacements are ever necessary, replace the entire coil assembly, 32-1928 for the first I. F. stage and 32-1929 for the second I. F. stage. Neither the coil nor the padders will be furnished separately. Order only by the above numbers.

Model NT15 Adjustments

All padding adjustments are carefully made at the factory and ordinarily no readjustments are necessary. However, when readjustments to the Model NT15 are required, the procedure given below must be followed in detail.

Equipment

Fully charged heavy duty storage battery or 6-volt power pack, 048A Philco Set Tester, 3164 Padding wrench, 27-7159 Padding screw driver.

General

OUTPUT METER — The output meter must be connected by means of an adapter to the plate of the type 41 output tube and to the Receiver chassis.

SIGNAL GENERATOR — With the Receiver and signal generator set up for operation at the prescribed frequency, turn the Receiver volume control on full and set the signal generator attenuator so that a half scale reading is obtained on the output meter. The signal in the speaker should be audible but not loud.

The shielding on the signal generator output lead must be connected to the Receiver housing.

Procedure

I. F. — Adjust the signal generator to exactly 260 K. C. Connect the generator lead to the grid cap of the 78 I. F. tube in series with a .1 mfd. condenser.

Adjust the secondary screw padder 25 on the second I. F. transformer for maximum reading on the output meter. Then adjust the primary screw padder 23 for maximum reading. (See Figure 6 for location of padders).

Remove the generator lead from the 78 tube.

Connect the generator lead to the grid cap of the 6A7 tube in series with a .1 mfd. condenser. Adjust the secondary screw padder 22 on the first I. F. transformer for maximum reading on the output meter. Then adjust the primary screw padder 20 for maximum reading. (See Figure 6 for location of padders).

HIGH FREQUENCY AND R. F. — After padding the first I. F. stage remove the generator lead from the 6A7 tube.

Adjust the signal generator to 1600 K. C. and then connect the generator lead to the grid cap of the 78 R. F. tube in series with a .1 mfd. condenser.

Turn the tuning condenser plates out of mesh as far as they will go. With the tuning condenser in this position, adjust the high frequency padder 16 and the R. F. padder 13 until the maximum reading is obtained on the output meter. This is the true setting for 1600 K. C., 160 on the dial scale.

LOW FREQUENCY — Turn the tuning condenser plates in mesh to approximately 580 K. C., 58 on the dial scale and adjust the signal generator to the 580 K. C. Roll the tuning condenser and adjust the low frequency padder screw 15 for maximum reading on the output meter.

HIGH FREQUENCY RE-ADJUSTMENT — Turn the tuning condenser plates out of mesh as far as they will go and adjust the signal generator to 1600 K. C. Then adjust the high frequency padder 16 again for maximum reading on the output meter.

ANTENNA — Connect the generator lead to the antenna cable assembly (made up of Part No. L1915 loom, 1-27-7133 terminal and 40 inches of 16 strand No. 30 wire), using a 200 mmfd. condenser in series between the two leads. Plug the cable into the antenna socket.

Turn the tuning condenser to 1400 K. C. and set the generator for 1400 K. C. Adjust the padders 13 and 6 for the maximum reading on the output meter.

When the antenna stage adjustment is made with the Receiver installed in the car, the Receiver antenna lead must be connected to the car antenna in the usual manner. The signal generator output lead should be connected to a wire placed near the car antenna but not connected to it.

If this procedure has been carefully followed and an accurately calibrated oscillator or signal generator has been used, the Receiver will be adjusted properly.

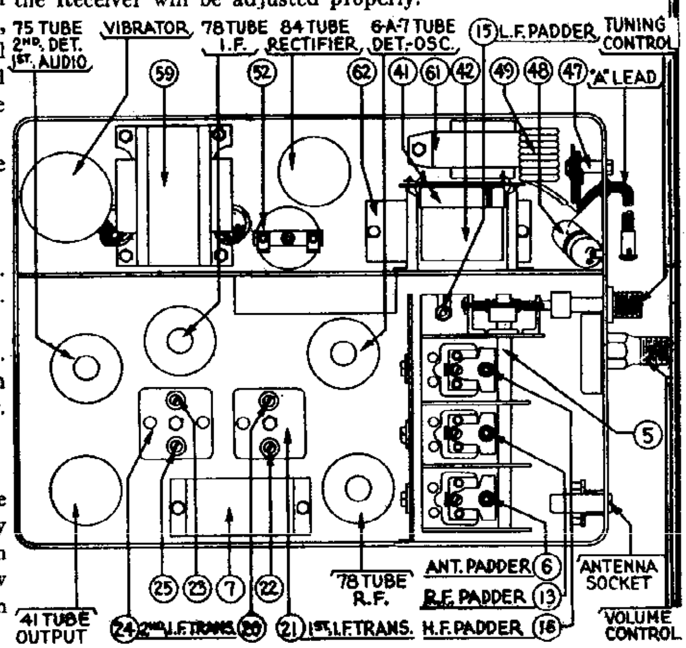

FIGURE 6

The Model NT15 Receiver (Nash — AC1989) is made for the Nash 400 and Lafayette 3610 cars using the Nash under-car Antenna.

I. F. Transformers and Padders Model ST15

The I. F. transformers are assembled complete with padding condensers.

Both the primary and the secondary padders are placed side by side in the top of the transformer shield can. The adjusting screws are accessible thru the holes in the top of the shield. (See Figure 6).

The coil windings terminate in leads instead of terminals or lugs. The color scheme of the leads is given in Figure 5.

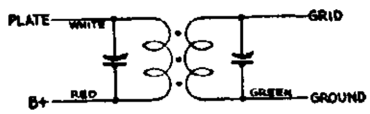

Figure 5

If replacements are ever necessary, replace the entire coil assembly, 32-1928 for the first I. F. stage and 32-1929 for the second I. F. stage. Neither the coil nor the padders will be furnished separately. Order only by the above numbers.

Model ST15 Adjustments

All padding adjustments are carefully made at the factory and ordinarily no readjustments are necessary. However, when readjustments to the Model ST15 are required, the procedure given below must be followed in detail.

Equipment

Fully charged heavy duty storage battery or 6-volt power pack, 048A Philco Set Tester, 3164 Padding wrench, 27-7159 Padding screw driver.

General

OUTPUT METER — The output meter must be connected by means of an adapter to the plate of the type 41 output tube and to the Receiver chassis.

SIGNAL GENERATOR — With the Receiver and signal generator set up for operation at the prescribed frequency, turn the Receiver volume control on full and set the signal generator attenuator so that a half scale reading is obtained on the output meter. The signal in the speaker should be audible but not loud.

The shielding on the signal generator output lead must be connected to the Receiver housing.

Procedure

I. F. — Adjust the signal generator to exactly 260 K. C. Connect the generator lead to the grid cap of the 78 I. F. tube in series with a .1 mfd. condenser.

Adjust the secondary screw padder (25) on the second I. F. transformer for maximum reading on the output meter. Then adjust the primary screw padder (23) for maximum reading. (See Figure 6 for location of padders).

Remove the generator lead from the 78 tube.

Connect the generator lead to the grid cap of the 6A7 tube in series with a .1 mfd. condenser. adjust the secondary screw padder (22) on the first I. F. transformer for maximum reading on the output meter. Then adjust the primary screw padder (20) for maximum reading. (See Figure 6 for location of padders).

HIGH FREQUENCY AND R. F. — After padding the first I. F. stage remove the generator lead from the 6A7 tube.

Adjust the signal generator to 1600 K. C. and then connect the generator lead to the grid cap of the 78 R. F. tube in series with a .1 mfd. condenser.

Turn the tuning condenser plates out of mesh as far as they will go. With the tuning condenser in this position, adjust the high frequency padder (16) and the R. F. padder (13) until the maximum reading is obtained on the output meter. This is the true setting for 1600 K. C., 160 on the dial scale.

LOW FREQUENCY — Turn the tuning condenser plates in mesh to approximately 580 K. C., 58 on the dial scale and adjust the signal generator to the 580 K. C. Roll the tuning condenser and adjust the low frequency padder screw (15) for maximum reading on the output meter.

HIGH FREQUENCY RE-ADJUSTMENT — Turn the tuning condenser plates out of mesh as far as they will go and adjust the signal generator to 1600 K. C. Then adjust the high frequency padder (16) again for maximum reading on the output meter.

ANTENNA — Connect the generator lead to the antenna cable assembly (made up of Part No. L1915 loom, 1-27-7133 terminal and 40 inches of 16 strand No. 30 wire), using a 200 mmfd. condenser in series between the two leads. Plug the cable into the antenna socket.

Turn the tuning condenser to 1400 K. C. and set the generator for 1400 K. C. Adjust the padders (13) and (6) for the maximum reading on the output meter.

When the antenna stage adjustment is made with the Receiver installed in the car, the Receiver antenna lead must be connected to the car antenna in the usual manner. The signal generator output lead should be connected to a wire placed near the car antenna but not connected to it.

If this procedure has been carefully followed and an accurately calibrated oscillator or signal generator has been used, the Receiver will be adjusted properly.

Chassis

PHILCO RADIO & TELEV. CORP.

MODEL 37-33
Socket, Chassis
Alignment, Voltage

Electrical Specifications

Type Circuit: Superheterodyne, with push-pull pentode audio output, battery operated.

Batteries Required:

"A" supply— **Philco 172R** 2 volt storage battery or a dry A battery **Philco Part No. 41-8011**. If a dry A supply is used, a ballast lamp (**Philco Part No. 1Y1**) must be inserted in the socket provided in the dry A battery **Part No. 41-8011**. This lamp acts as a voltage regulator, and maintains a constant potential of two volts on the filaments of the receiver tubes.

"BC" supply—Philco battery Part No. 41-8007 is used to supply B and C voltages. This battery contains a socket into which the receiver battery cable plug is inserted.

Current Drain: A Battery, 540MA. B Battery, 13MA.

Philco Tubes Used: 1D7G, Detector Oscillator; 1D5G, I.F. Amplifier; 1H6G, 2nd Detector, 1st audio; 1H4G, Phase inverter; and 1E7G, Output.

Frequency Range: 530-1720 K.C.

Intermediate Frequency: 470 K.C.

Speaker: Permanent Magnet Model L2B.

Aligning Compensators

To accurately adjust this receiver precision test equipment is necessary. A signal generator such as the **Philco Model 088,** covering from 110 to 20,000 K.C. is recommended for adjusting the various compensators at the frequencies specified. A visual indication of the receiver output is also necessary, **Philco Model 025 Circuit Tester** contains a sensitive output meter and is recommended for this purpose.

Philco fibre handle screw-driver **No. 27-7059** and wrench **Part No. 3164** complete the equipment necessary for the following adjustments. The locations of the various compensators are shown in Fig. (2).

OUTPUT METER—The 025 Output Meter is connected between one of the plate contacts of the 1E7G tube and ground. Adjust the meter to use the (0-30) volt scale.

INTERMEDIATE FREQUENCY CIRCUIT

Frequency 470 K. C.

1. Connect the 088 Signal Generator output lead through a .1 mfd. condenser to the control grid of the 1C7G tube; and the ground connection of the output lead to the chassis. Then turn the tuning condenser to approximately 580 K.C. and adjust the signal generator for 470 K.C.

2. Now adjust compensators [illegible]s. 2nd I. F. Sec., [illegible]p 2nd I. F. Pri., [illegible]s 1st I. F. Sec., and [illegible]p 1st I. F. Pri. for maximum output.

RADIO FREQUENCY CIRCUIT

530 to 1720 K.C.

1. Remove the signal generator output lead from the 1C7G tube and connect it through a 200 mmfd. condenser to the antenna post of the receiver, and the generator ground lead to the chassis.

2. Turn signal generator to 1700 K.C. Rotate receiver tuning condenser to minimum capacity position (clockwise); then place a 006" gauge between the rotor and stator plates (left side of tuning condenser facing front of receiver), and turn condenser until rotor and stator gauge touch gauge. Now remove gauge without disturbing setting of the plates. Compensators (4)b Osc. and (4)a Ant. are then adjusted for maximum output.

3. Turn signal generator and receiver dials to 580 K.C. and adjust compensator (7) as follows:

First tune compensator (7) for maximum output. Then vary the tuning condenser for maximum output. Now retune compensator (7) and again vary the tuning condenser back and forth about 580 K.C. for maximum output. This operation of first tuning the compensator, then the tuning condenser is continued until maximum output is obtained at the 580 K.C. frequency.

4. Readjust the 1700 K.C. end of dial as given in paragraph 2 above.

5. Then turn signal generator and receiver dials to 1500 K.C. and adjust compensator (4)a Ant. for maximum output.

DIAL CALIBRATION—After the above adjustments have been performed, the dial pointer is adjusted to track properly with the tuning condenser. To do this turn signal generator to 1000 K.C. and tune the receiver tuning condenser for maximum output at this frequency. When maximum output is obtained dial pointer is adjusted to the 1000 K.C. mark on dial.

MODEL 37-38
Socket, Trimmers
Voltage, Alignment

PHILCO RADIO & TELEV. CORP.

Electrical Specifications

Type Circuit: Superheterodyne, with class "B" audio output, battery operated.

Batteries Required:

"A" supply—**Philco 172R** 2 volt storage battery or a dry A battery Philco Part No. 41-8011. If a dry A supply is used, a ballast lamp Philco type **1F1 must be** inserted in the socket provided in the dry A battery **(Part 41-8011)**. This small lamp acts as a voltage regulator, and maintains a constant potential of two volts on the filaments of the receiver tubes.

"BC" supply—Philco battery Part No. 41-8007 is used to supply B and C voltages. This battery contains a socket into which the receiver battery cable plug is inserted.

Current Drain: A Battery, 720 M. A.; B Battery, 20 M. A.

Philco Tubes Used: 1C7G, Detector Oscillator; 1D5G, I.F. Amplifier; 1H4G, 2nd Detector, A.V.C.; 1E5G, 1st Audio; 1H4G, Driver; 1J6G, Output.

Frequency Range: Range 1, 530-1720 K. C.; Range 2, 2.3-7.4 M. C.

Intermediate Frequency: 470 K. C.

Speaker: KR-17—B, F Cabinets; HR-12—J Cabinet.

Alignment of Compensators

To accurately adjust this receiver, precision test equipment is necessary. A signal generator such as the PHILCO MODEL 088 Signal Generator, covering from 110 to 20,000 K. C. is recommended for use in adjusting the compensators at the various frequencies specified. A visual indication of the receiver output is also necessary to obtain correct adjustment of the compensators. PHILCO MODEL 025 Circuit Tester contains a sensitive output meter and is recommended for these adjustments.

Philco Fibre Wrench No. 3164 and Fibre Handle Screw-Driver No. 27-7059 complete the necessary equipment for these adjustments. The locations of the various compensators are shown in Figs. 2 and 3.

The following procedure must be observed in adjusting the compensators:—

DIAL ADJUSTMENT—The tuning condenser is set at the maximum capacity position, by turning the tuning knob clockwise. Loosen the set screw of dial hub and set dial, with Glowing Indicator centered between the first and second index lines at the low frequency end of scale.

OUTPUT METER—The 025 Output Meter is connected between one of the plate prongs of the 1J6G tube and the chassis. Then adjust the meter to use the (0-30) volt scale.

INTERMEDIATE FREQUENCY CIRCUIT

Frequency 470 K. C.

1. Connect the 088 Signal Generator output lead through a .1 mfd. condenser, to the control grid of the 1C7G tube, and the generator ground lead to the chassis.

2. Set the range switch in position No. 1 (Broadcast), then rotate the tuning condenser of the receiver to the maximum capacity position (clockwise) and adjust the signal generator for 470 K. C. Now adjust compensators (28s) 2nd I.F. Sec., (28p) 2nd I.F. Pri., (15s) 1st I.F. Sec. and (15p) 1st I.F. Pri. for maximum output.

RADIO FREQUENCY CIRCUIT

Tuning Range 2.3 M. C. to 7.4 M. C.

1. Remove the signal generator output lead from the grid of the 1C7G tube and connect it through a 200 mmf Condenser to the antenna terminal on input panel (rear of chassis), and the generator ground lead to the ground terminal of this panel.

2. Set the range switch in position No. 2. Turn the receiver and signal generator dials to 7.0 M. C. Now adjust compensator (12) for maximum output.

3. Turn signal generator and receiver dials to 6.0 M. C. and adjust compensator (5)a for maximum output.

Tuning Range 530 to 1720 K. C.

1. Set range switch in position No. (1) (Broadcast). Turn signal generator and receiver dials to 1600 K. C. Then adjust (14) Osc. "Screw", and (5) antenna for maximum output.

2. Turn signal generator and receiver dials to 580 K. C. and adjust compensator (14a) Osc., "nut"—see Fig. 3—as follows: To adjust compensator (14a) the tuning condenser must be rolled for maximum output, thusly: First turn the compensator (14a) for maximum output. Then vary the tuning condenser for maximum output about 580 K. C. Now retune compensator (14a) and again vary the tuning condenser back and forth about the 580 K. C. dial mark for maximum output.

This operation of first tuning the compensator, then the tuning condenser is continued until maximum output is obtained at the 580 K. C. dial mark. If the signal generator is not accurately calibrated the maximum point on the dial of the receiver may fall slightly above or below the 580 K. C. dial mark.

3. Turn signal generator and receiver dials to 1600 K. C. and readjust compensator (14) Osc. "screw" for maximum output.

4. Turn signal generator and receiver dials to 1500 K. C. and readjust compensator (5) for maximum output.

SOCKET VOLTAGES

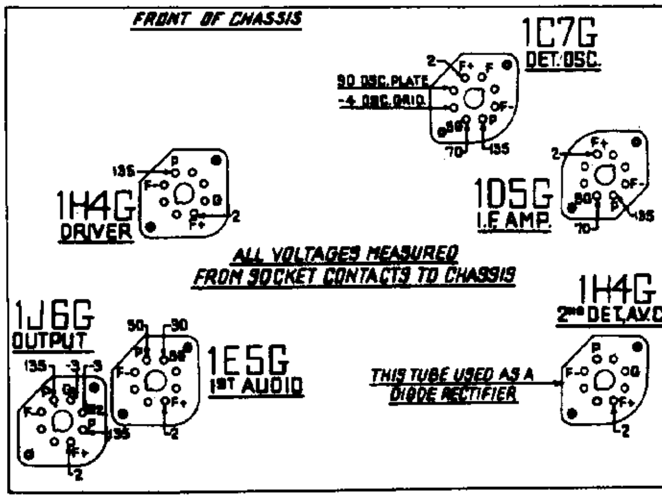

Fig. 1—Socket Voltages—Underside of Chassis View

The voltages indicated by arrows were measured with a Philco 025 Circuit Tester which contains a voltmeter having a resistance of 1000 ohms per volt. Volume Control at minimum, range switch in broadcast position.

Circuit Data,
Transformer Data

PHILCO RADIO & TELEV. CORP.

Model 37-60

General Description

Model 37-60 is a 5 tube superheterodyne receiver for operation on alternating current and has two tuning ranges, covering Standard Broadcast and American short-wave reception up to 7 megacycles. The new Philco High Efficiency self-centering glass tubes are used.

The circuit incorporates the Philco Aerial Tuning System—controlled by the range switch—which provides maximum sensitivity and noise reduction when used with the Philco All Wave Aerial.

The red and black leads of the All Wave Aerial "transmission line" are connected to terminals 1 and 2 respectively, of the terminal panel provided at the rear of the chassis. Connect the jumper of the terminal panel across terminals 3 and 4.

If a temporary aerial is used, the jumper should be across terminal 2 and 3. The aerial connects to terminal 1 and the ground to terminals 3. A good ground connection is required in all installations.

CONSTRUCTION

The chassis is constructed in three basic assembly units.

The Radio Frequency unit contains a 6A8G tube which functions as a Detector-Oscillator, tuning condenser, antenna and oscillator coils for each tuning range, selector switch—compensating condensers for all coils and other parts necessary for the associated circuits. The unit is separately mounted on rubber grommets, cushioning it from the main chassis.

The Intermediate Frequency unit, mounted on the right-hand side of the chassis (facing the front) consists of the Intermediate Frequency coils compensating condensers, a 6K7G tube for I. F. Amplifier stage, and a 6Q7G tube as the second detector-automatic volume control and first audio stage.

All voltages supplied to the I. F. and R. F. units are furnished from a terminal strip mounted in this unit.

The Power Pack and audio output circuits, together with the required Voltage dividers and filter condensers are mounted in the power unit. All high Voltage A. C. Wiring is housed in the power transformer assembly which includes the rectifier socket.

Although unit construction has changed the appearance of this model, the service bulletin will be of great assistance in checking through all stages of the receiver. The Wiring Diagram, as usual, is numbered, indicating all important parts. These numbers correspond with the parts layout shown in Fig. 6. In addition, the range switch wafers are shown on the schematic diagram. The contacts on each wafer are lettered and numbered to indicate their connection points in the schematic diagram, which are also lettered and numbered. The physical drawings of each coil used in the receiver are also shown on schematic diagram Fig. 5. The connections of these coils are numbered on the coil itself and on the schematic diagram.

Fig. 1 shows the Voltage measurements taken from the bottom of the socket at each contact. In Fig. 2, the correct position of the dial indicator, for proper adjustment of the compensators is shown. Figs. 3 and 4, are the location of the I. F. and R. F. compensators respectively.

This Receiver is supplied in two models, type B and type F. These instructions, however, are used for both types.

Electrical Specifications

Voltage Rating) 115 Volts. A. C.
Frequency Rating: 50-60 Cycle.
For 25-40 cycle operation use Power Transformer, marked with asterisks in Parts List.
Power Consumption: 60 Watts.
Type and Number of Philco Tubes: 1 type 6A8G First Detector-oscillator; 1 type 6K7G I. F. Amplifier; 1 type 6Q7G 2nd Detector, A. V. C., and 1st Audio; 1 type 6F6G Pentode Output and 1 type 5Y4G, Rectifier.
Speaker: S7.
Type of Circuit: Superheterodyne with Pentode Power Output.
Intermediate Frequency: 470 K. C.
Undistorted Power Output: 3 Watts.
Tuning Ranges: Two—(1): 530 to 1720 K.C., (2): 2.3 to 7.4 M.C.

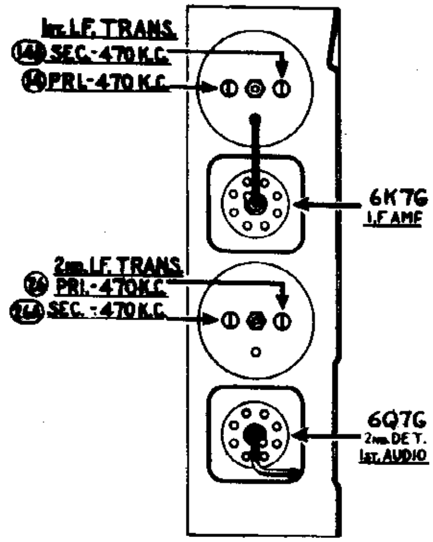

Fig. 3—Locations of I. F. Compensators Top of Chassis

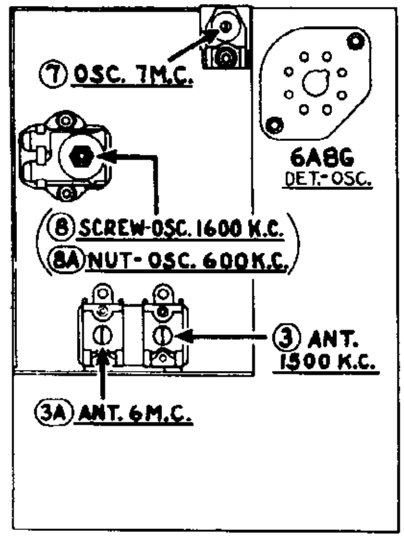

Fig. 4—Locations of R. F. Compensators Underside of Chassis

Adjustment of Compensators

The accurate adjustment of the various compensating condensers is vital to the proper functioning of this receiver. There are four compensating condensers in the I. F. Circuit, three in the Oscillator Circuit, and two in the Antenna Circuit. Incorrect adjustment will cause loss of sensitivity, unsatisfactory tone, and poor selectivity.

To accurately adjust this receiver, precision test equipment is necessary. A signal generator such as the PHILCO MODEL 088 SIGNAL GENERATOR, covering from 110 to 20,000 K. C. is recommended to adjust the compensators at the various frequencies specified. A visual indication of the receiver output is also necessary to obtain correct adjustment of the compensators. PHILCO MODEL 025 CIRCUIT TESTER contains a very sensitive output meter and is recommended for these adjustments.

Philco Fibre Wrench No. 3164 and Fibre Handle Screw-driver No. 27-7059 complete the necessary equipment for these adjustments. The locations of the various compensators are shown in Figs. 3 and 4.

The following procedure must be observed in adjusting the compensators:

DIAL ADJUSTMENT—The Tuning condenser is set at the maximum capacity position, by turning the tuning knob counterclockwise. Loosen the set screw of dial hub and set dial, (see Fig. 2) with Glowing Indicator centered between the index lines at the low frequency end of scale.

OUTPUT METER—The Output Meter is attached to the Plate and Cathode terminals of the (6F6G tube) and adjusted to use the (0-30) volt scale. When adjusting each circuit, care should be taken to have the signal generator attenuator set to give approximately ¼ scale reading on output meter.

INTERMEDIATE FREQUENCY CIRCUIT

1 Turn wave band switch to Range 1. Rotate the tuning control to approximately 600 K. C. Connect the 088 Signal Generator output lead through a .1 mfd. condenser to the grid of the 6A8G tube, and the ground lead of Signal Generator to the chassis.

2 Set Signal Generator indicator for 470 K. C., adjust attenuator for approximately ¼ scale reading on output meter. Then adjust compensators (26)a 2nd I. F. Sec., (26) 2nd I. F. Pri., (14)a 1st I. F. Sec., (14) 1st I. F. Pri., for maximum reading on output meter.

RADIO FREQUENCY CIRCUIT—Range 2: 2.3 to 7.4 M. C.

1 Turn Range switch to Range 2. Remove signal generator output lead from the grid of 6A8G tube.

2 Attach signal generator output lead through a 0.1 mfd. condenser to the ANT. TERMINAL No. 1, on aerial panel, and the generator ground to chassis. Connect TERMINAL No. 2, to GROUND TERMINAL No. 3, with connector link provided on the panel.

3 Set Signal Generator and receiver dials for 7.0 M. C. Now adjust compensator (7) for maximum reading on output meter. Then turn Signal Generator and Receiver to 6.0 M. C., and adjust compensator (3)a for maximum output.

RANGE 1: 530 to 1720 K. C.

1 Turn range switch to Range 1. Turn the Receiver dial to 1600 K. C. Then adjust compensators (8) and (3) for maximum reading on output meter.

The 088 Signal Generator dial is set at 800 K. C. and the second harmonic of this frequency (1600 K. C.) is used in making the above adjustment.

2 The low frequency end of the band is now tuned by turning Signal Generator and Receiver dials to 600 K. C. and adjusting compensator (8)a—see note (a) below—for maximum output.

(a) When compensator (8)a osc. series is being adjusted, the Tuning Condenser must be rolled for maximum output. This is accomplished as follows: First tune compensator (8)a for maximum output. Then vary the Tuning Condenser for maximum output at 600 K. C. Now retune Compensator (8)a, and again vary the tuning condenser back and forth about 600 K. C., for maximum output. This operation of first tuning the Compensator, then the Tuning Condenser is continued until maximum output is obtained at the 600 K. C. frequency.

3 Set the Signal Generator and Receiver dials for 1600 K. C. and re-adjust Compensator (8) for maximum output. Then turn the dials to 1500 K. C. and re-adjust compensator (3) for maximum reading on output meter.

PHILCO RADIO & TELEV. CORP.

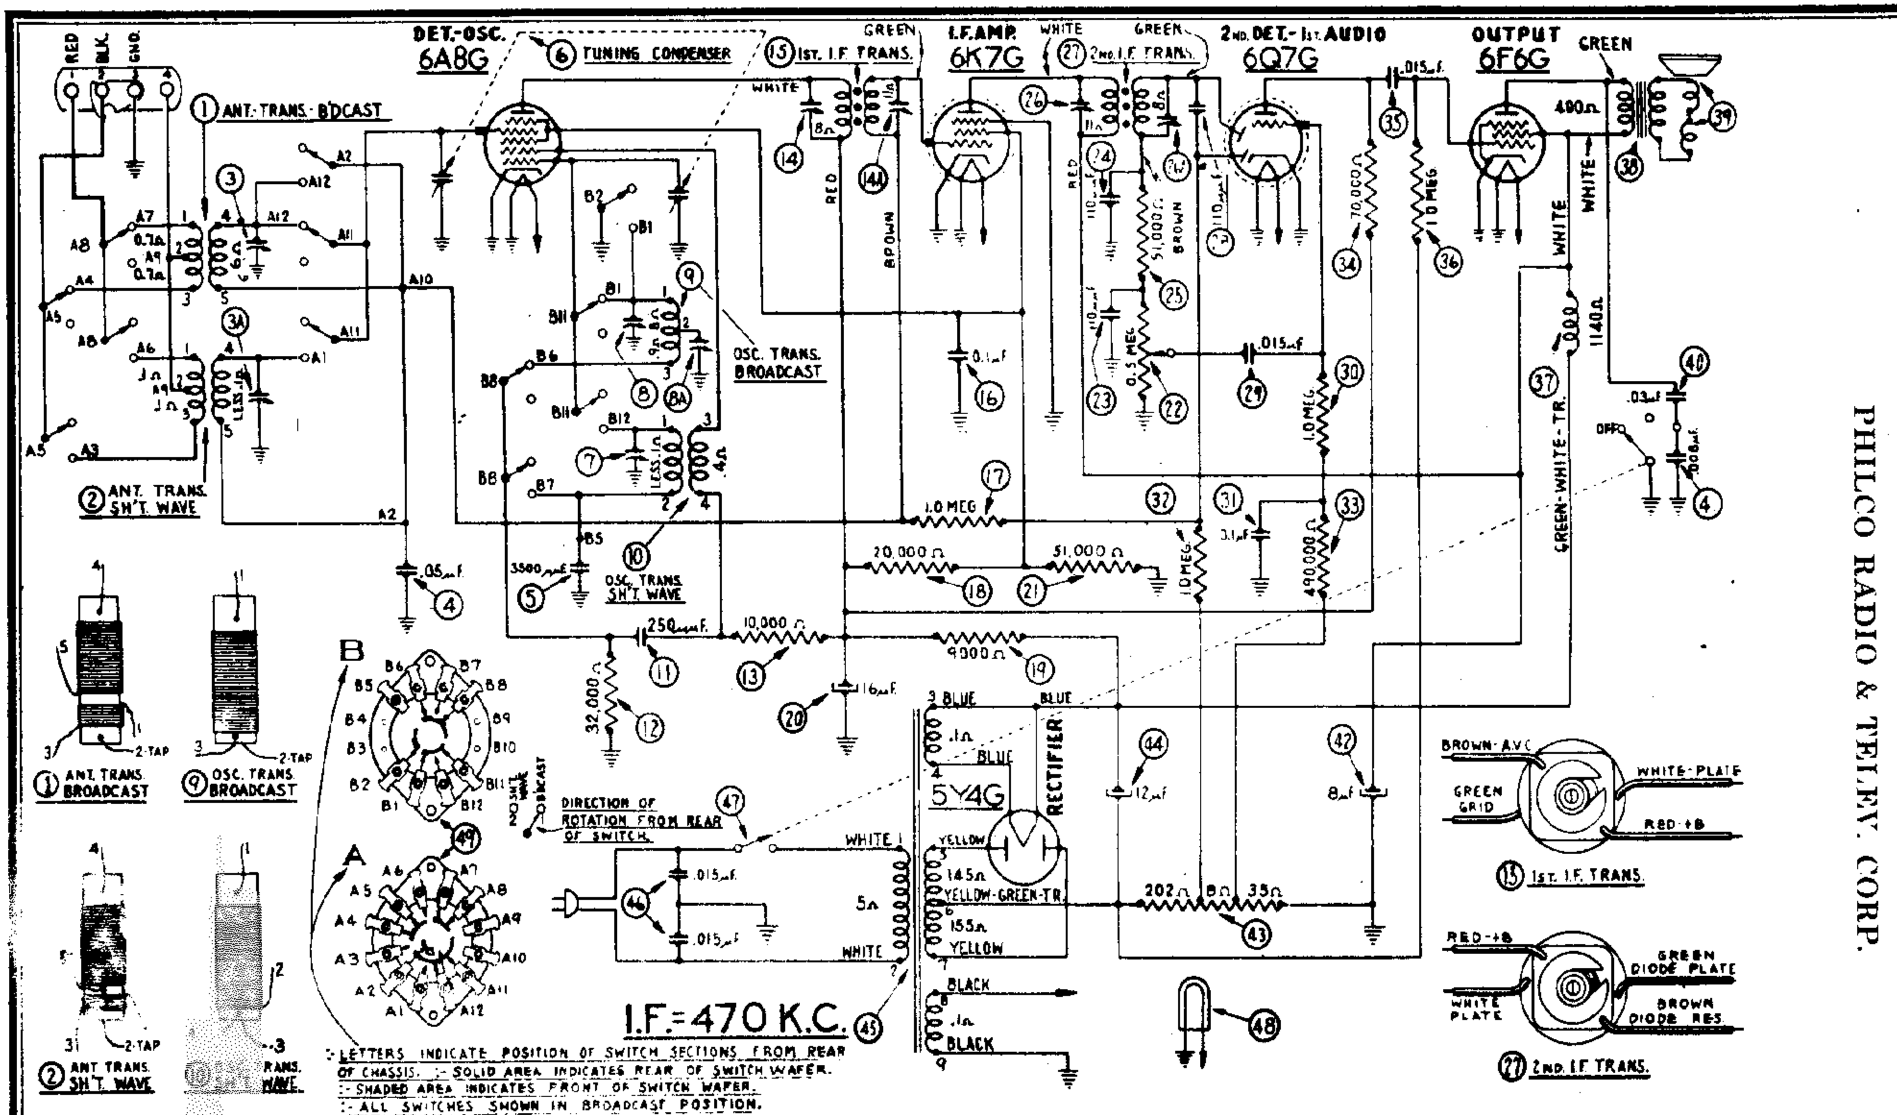

Fig. 5—Schematic Diagram—Model 37-61

The red and black leads of the High-Efficiency Aerial "transmission line" are connected to terminals 1 and 2 respectively, of the terminal panel provided at the rear of the chassis. Connect the jumper of the terminal panel across terminal 3 and 4. A good ground connection is required in all installations. Make the ground connection to terminal 3 on the terminal panel.

If a temporary aerial is used, the jumper should be across terminal 2 and 3. The aerial connects to terminal 1 and the ground to terminal 3.

Voltage Rating: 115 Volts. A. C.
Frequency Rating: 50-60 Cycle.
For 25 to 40 cycle operation use Power Transformer, marked with asterisks in Parts List.
Power Consumption: 60 Watts.

2nd Detector, A. V. C., and 1st Audio; 1 type 6F6G Pentode Output and 1 type 5Y4G, Rectifier.
Speaker: S7.
Type of Circuit: Superheterodyne with Pentode Power Output.
Intermediate Frequency: 470 K. C.
Undistorted Power Output: 3 Watts.
Tuning Ranges: Two—(1): 530 to 1720 K. C.; (2): 5.7 to 18.2 M. C.

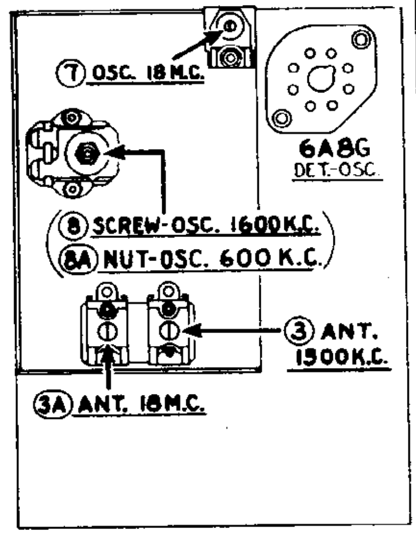

Fig. 4—Locations of R. F. Compensators Underside of Chassis

Adjustment of Compensators

The accurate adjustment of the various compensating condensers is vital to the proper functioning of this receiver. There are four compensating condensers in the I. F. Circuit; three in the Oscillator Circuit; and two in the Antenna Circuit. Incorrect adjustment will cause loss of sensitivity, unsatisfactory tone, and poor selectivity.

To accurately adjust this receiver, precision test equipment is necessary. A signal generator such as the PHILCO MODEL 088 SIGNAL GENERATOR, covering from 110 to 20000 K. C. is recommended to adjust the compensators at the various frequencies specified. A visual indication of the receiver output is also necessary to obtain correct adjustment of the compensators. PHILCO MODEL 025 CIRCUIT TESTER contains a very sensitive output meter and is recommended for these adjustments.

Philco Fibre Wrench No. 3164 and Fibre Handle Screw-driver No. 27-7059 complete the necessary equipment for these adjustments. The locations of the various compensators are shown in Figs. 3 and 4.

The following procedure must be observed in adjusting the compensators:—

DIAL ADJUSTMENT—The Tuning Condenser is set at the maximum capacity position, by turning the tuning knob counter-clockwise. Loosen the set screw of dial hub and set dial, (see Fig. 2) with Glowing Indicator centered between the index lines at the low frequency end of scale.

OUTPUT METER—The Output Meter is connected to the Plate and Cathode terminals of the (6F6G) tube and adjusted to use the (0-30) Volt scale. When adjusting each circuit, care should be taken to have the Signal Generator attenuator set to give approximately ¼ scale reading on output meter.

INTERMEDIATE FREQUENCY CIRCUIT

1 Turn range switch to Range 1. Rotate the tuning control to approximately 600 K. C. Connect the 088 Signal Generator output lead through a .1 mfd. condenser to the grid of the 6A8G tube.

2 Set Signal Generator indicator for 470 K. C. adjust attenuator for approximately ¼ scale reading on output meter. Then adjust compensators 15a 2nd I. F. Sec., 15 2nd I. F. Pri., 14a 1st I. F. Sec., 14 1st I. F. Pri., for maximum reading on output meter.

RADIO FREQUENCY CIRCUIT

Range 2.—5.7 to 18 M. C.

1 Remove the signal generator output lead and series condenser from the 6A8G tube and connect them to the ANT. TERMINAL No. 1, on aerial input panel (rear of chassis) and the generator ground lead to GND. TERMINAL No. 3, rear of chassis. Connect TERMINAL No. 2 to GROUND TERMINAL No. 3 with connector link provided on the panel.

2 Set range switch in position No. 2 (S. W.). Turn signal generator and receiver dials to 18 M. C. and adjust compensator (7) Osc. for maximum output.

3 The adjustment of the antenna compensator on the high frequency range causes a slight detuning of the oscillator circuit. In order to overcome this detuning effect, connect a variable condenser of approximately 350 mfd., having a good vernier drive, across the oscillator section of the tuning condenser. Leaving the signal generator and receiver dials at 18 M. C., tune the added condenser so that the second harmonic of the receiver oscillator will beat against the signal from the signal generator. The antenna compensator 3a should then be adjusted to give maximum output.

4 Now remove the external condenser from the tuning condenser of receiver and turn compensator 7 osc. to the maximum capacity position (clockwise), then without moving signal generator or receiver tuning condenser, turn compensator 7 (counter-clockwise) until a second peak is reached on the output meter. The first peak is caused by tuning to the image frequency signal and must be neglected. Compensator 7 is adjusted on the second peak to give maximum output.

RANGE 1: 530 to 1720 K. C.

1 Turn range switch to Range No. 1. Turn the Receiver dial to 1600 K. C. Then adjust compensators 8 and 3 for maximum reading on output meter.

The 088 Signal Generator dial is set at 800 K. C. and the second harmonic of this frequency (1600 K. C.) is used in making the above adjustment.

2 The low frequency end of the band is now tuned by turning Signal Generator and Receiver dials to 600 K. C. and adjusting compensator 8a—see note (a) below—for maximum output.

(a) When compensator 8a osc. series is being adjusted, the Tuning Condenser must be rolled for maximum output. This is accomplished as follows: First tune compensator 8a for maximum output. Then vary the Tuning Condenser for maximum output at 600 K. C. Now retune Compensator 8a and again vary the tuning condenser back and forth at 600 K. C., for maximum output. This operation of first tuning the Compensator, then the Tuning Condenser is continued until maximum output is obtained at the 600 K. C. frequency.

3 Set the Signal Generator and Receiver Dials for 1600 K. C. and re-adjust Compensator 8 for maximum output. Then turn the dials to 1500 K. C. and re-adjust compensator 3 for maximum reading on output meter.

Notes, Parts

PHILCO RADIO & TELEV. CORP.

MODEL 37-61
Chassis, Voltage

Model 37-61 is a 5 tube superheterodyne receiver for operation on alternating current and has two tuning ranges, covering standard broadcast and short wave reception. It, also, uses the new Philco High Efficiency self-centering glass tubes.

The circuit includes the Philco Foreign Tuning System—controlled by the range switch—providing maximum sensitivity and noise reduction when used with the New Philco High-Efficiency Aerial, supplied with the receiver.

Fig. 1 shows the Voltage measurements taken from the botto of the socket at each contact. In Fig. 2, the correct position of the dial indicator, for proper adjustment of the compensato is shown. Figs. 3 and 4 show the location of the I. F. and R. I compensators respectively.

This receiver will be supplied in two model cabinets type I and F. These instructions, however, will cover both typ cabinets.

Changes Parts Numbering System

RUN NUMBER CHANGE DATA

The run numbers are stamped both on the top side and the underneath side of the sub-base. They are usually stamped on the sub base but when this is not practical, due to all the space being taken up with the parts, then the numbers will be found on the vibrator section partition or in some other conspicuous place. The numbers are stamped in black ink with 1/4" rubber stencils and should not be confused with various other numbers, also stamped inside the housing in black ink, but of a larger size.

The run number and the conveyor number appear together. The run number is the first number given and the conveyor number, which can de disregarded, is the second number.

Not all run number changes affect the parts or the wiring of the Receiver so that information on only those runs, having to do with major changes or part changes will be furnished.

The following run number change data are an invaluable aid in service work and should be kept with other circuit service data.

MODEL 806

RUN No. 3—Second I.F. Transformer, ([illegible] on the schematic), has been replaced with a new type having the same part number. The new Transformer can be identified by the white paint mark on the fibre. The 50 mmfd. Condenser, Part No. 30-1029 ([illegible] on the schematic), has been replaced with another 50 mmfd. Condenser, Part No. 4587.

RUN No. 5—Part No. 33-1177, a 15,000 ohm resistor, ([illegible] on the schematic), has been replaced with a 51,000 ohm resistor Part No. 33-1163.

RUN No. 7—An additional "A" choke, Part No. 32-1438, has been added in series between the "A" choke ([illegible] on the schematic), and the tube filaments. A 250 mmfd. condenser, Part No. 30-1062, has been added. One side is connected between the new choke and the choke [illegible]. The other side of the condenser is connected to ground.

RUN No. 8—An antenna interference choke, Part No. 32-1673, has been added in series with the antenna lead and the antenna transformer and condenser (① and ②) on the schematic).

RUN No. 10—A wiring panel is used for mounting the large tubular condensers on the sub-base to prevent the condenser leads from breaking off.

RUN No. 11—Part No. 30-4227, a .5 mfd. condenser, (⑦ on the schematic), has been replaced with another .5 mfd. condenser, Part No. 30-4147. This new condenser is mounted on the sub-base under the R. F. transformer shields.

MODEL 808

RUN No. 2—A 250 mmfd. condenser, Part No. 30-1062, has been added across the secondary of the output transformer ([illegible] on the schematic).

RUN No. 3—Remove the condenser that was added in run number 2

MODEL 809

RUN No. 2—Part No. 30-4227, a .5 mfd. condenser, (⑦ on the schematic), has been replaced with another .5 mfd condenser, Part No. 30-4147. This new condenser is mounted on the sub-base under the R. F. transformer shield.

MODEL PHD

RUN No. 4—Part No. 30-1029, a 50 mmfd. condenser, ([illegible] on the schematic), has been replaced with a 250 mmfd. condenser, Part No. 30-1062.

An interference choke, Part No. 32-1374, has been added in series between the pilot lamp and the condenser, and resistor ([illegible] and [illegible] on the schematic).

The dial, Part No. 27-5022, has been replaced with a new dial, Part No. 27-5070.

MODEL FN

RUN No. 8—The first I. F. transformer, ([illegible] on the schematic) has been replaced with a new type having the same part number. The new transformer can be identified by the green paint mark on the fibre.

Part No. 33-3047, a 1500 ohm resistor, ([illegible] on the schematic) has been replaced with a 2000 ohm resistor, Part No. 33-3048

MODEL CT-2

RUN No. 3—The oscillator transformer, Part No. 32-1537, ([illegible] on the schematic), has been replaced with a new type having the same part number. The new transformer can be identified by the red paint mark on the fibre.

RUN No. 4—An antenna interference choke, Part No. 32-1382, has been added in series with the antenna lead and the antenna transformer and condenser (① and ②) on the schematic).

Part No. 33-1194, a 11,000 ohm resistor, ([illegible] on the schematic), has been replaced with a 10,000 ohm resistor, Part No. 33-1000.

MODEL ST3

RUN No. 2—The oscillator transformer, Part No. 32-1537, ([illegible] on the schematic), has been replaced with a new type having the same part number. The new transformer can be identified by the red paint mark on the fibre.

RUN No. 3—The white lead of the output transformer is connected directly to the plate of the type 42 tube instead of to the pin-jack. This prevents audio feedback.

RUN No. 4—The tone control, Part No. 30-4243, and the 2000 mmfd. condenser, Part No. 30-4177 ([illegible] and [illegible] on the schematic), have been removed. These parts are replaced with the new tone control, Part No. 30-4298.

RUN No. 5—A wire is connected from the ground spring between the antenna and R. F. stage of the tuning condenser, to the ground lug on the antenna transformer (① on the schematic), to reduce vibrator interference.

MODEL CT5

RUN No. 2—An antenna interference choke, Part No. 32-1382, has been added in series with the antenna lead, and the antenna transformer and condenser, (① and ②) on the schematic).

MODEL FT6

RUN No. 3—The oscillator transformer, Part No. 32-1537, ([illegible] on the schematic), has been replaced with a new type having the same part number. The new transformer can be identified by the red paint mark over the white and blue marking on the fibre.

RUN No. 4—A 110 mfd. condenser has been added. One side is connected between the switch and choke ([illegible] and [illegible] on the schematic), and the other side is connected to ground. Part No. 30-4047, a .5 mfd. condenser, ([illegible] on the schematic), has been replaced with another .5 mfd. condenser, Part No. 30-4227.

RUN No. 5—The 4000 mmfd. condenser, ([illegible] on the schematic), has been relocated. One side of the condenser is connected to the tone control pin jack and the other side connected to ground.

Part No. 33-1000, a 10,000 ohm resistor, ([illegible] on the schematic), has been replaced with an 11,000 ohm resistor, Part No. 33-1194.

RUN No. 8—The series padder, ([illegible] on the schematic), has been removed from the tuning condenser and relocated on the sub-base.

MODEL NT-7

RUN No. 2—Part No. 30-4227, a .5 mfd. condenser, (⑦ on the schematic), has been replaced with another .5 mfd. condenser, Part No. 30-4147. This new condenser is mounted on the sub-base under the R. F. transformer shields.

RUN No. 3—The .05 mfd. condenser, Part No. 30-4020, ([illegible] on the schematic), has been relocated. It is now between the antenna and R. F. transformer shields. Connections are the same.

PARTS NUMBERING SYSTEM

The first radio part numbers started at 3000 and progressed upward in order as new radio parts were added. Speaker part numbers started at 2999 and progressed downward as new speaker parts were added. There was no attempt made to classify the various kinds of parts and make identification easier until several years later. Part No. 3025 was a mica condenser but almost any other number could be a mica condenser also. The old parts numbering system was practically blind but with the new system now in effect, a part number indicates immediately the kind of part it represents. It consists of a two digit group classification number and a four digit identification number. Since it was not practical to re-number the old parts, they are still the same, but all new parts numbers are assigned in accordance with the following classification:

27—Fibre, bakelite—moulded parts.
- 1000-4999—forms, moulded parts, etc.
- 5000-5999—Celluloid parts.
- 6000-6999—Sockets.
- 7000-9999—finished parts—miscellaneous.

28—Metal parts—Unplated—unfinished.

29—Metal parts—plated and painted.

30—Fixed condensers
- 1000-1999—mica condensers.
- 2000-2999—electrolytic condensers.
- 4000-9999—paper condensers, sections, etc.

31—Variable condensers.
- 1000-5999—tuning condensers.
- 6000-9999—padding condensers.

32—Transformers.
- 1000-6999—R. F., I. F. and other assemblies.
- 7000-8999—Power and audio transformers and other assemblies.
- 9000-9999—Field coils, etc.

33—Resistances.
- 1000-2999—carbon (fixed).
- 3000-4999—wire wound (fixed).
- 5000- —variable (carbon and wire wound) and volume controls.

34—Tubes and Lamps.
- 1000-2999—tubes.
- 3000- —tube kits.

35—Phonograph parts.

36—Speakers and speaker sub-assemblies.
- 1000-2999—complete speakers.
- 3000- —speaker sub-assemblies.

37—Chassis and sub-assemblies, etc.

38—Sub-base and assemblies.

39—Printed matter.

40—Accessory kits.
- 5000- —Accessory kits.
- 7000-7999—Transitone master kits.
- 8000-8999—Transitone hardware kits.
- 9000- —Transitone suppression kits.

41—Dynamotor and Chargers.
- 1000-4999—Dynamotors, etc.
- 5000-7999—Chargers.

42—Controls and switches.
- 1000-4999—Switches and jacks.
- 5000-5999—Control units, etc.

43—Major sub-assemblies.

44—Silks and cloth.

45—Miscellaneous.
- 1000-1999—Display kits.
- 2000-2999—Miscellaneous parts.

PHILCO RADIO & TELEV. CORP.

Model 37-84, Code-122

General Specifications

TYPE CIRCUIT: Superheterodyne with Pentode output.
POWER SUPPLY: 115 V., 60 cycle A.C.
TUBES USED: 1 type 6J7G, Det Osc., 1 type 6J7G 2nd detector—first audio, 1 type 6F6G output, 1 type 5Y4G Rectifier.
FREQUENCY RANGE: 540-1700 K.C.
INTERMEDIATE FREQUENCY: 470 K.C.
POWER CONSUMPTION: 45 watts.
SPEAKER: SB.
POWER OUTPUT: ½ watt.

Adjusting Compensating Condensers

To accurately adjust the compensating condensers in the Model 37-84 receiver, it is necessary to use a signal generator of high stability on all frequencies, such as the PHILCO MODEL 088 Signal Generator. This instrument has a continuous frequency range from 110 to 20,000 K.C., and is designed to meet every requirement of the serviceman.

An output meter is also needed,—**PHILCO Model 025 Circuit Tester** includes a very sensitive output meter.

Convenient tools to use in adjusting the compensators are the **PHILCO No. 3164 Fibre Wrench and No. 27-7059 Fibre Handled Screw-driver.**

The locations of the various compensating condensers are shown in Fig. 1. Connect the output meter to the plate and cathode contacts of the 6F6G power tube, and adjust it to use the 0-30 volt range.

When adjusting each circuit, care should be taken to have the signal generator attenuator set to approximately ¼ scale reading on output meter.

Intermediate Frequency Circuit

1. Turn gang condenser to maximum capacity (counter-clockwise) and set the volume control of the receiver in the maximum position (clockwise).
2. Connect the 088 signal generator output lead through a .1 mfd. condenser, to the grid of the 6J7G Detector-oscillator tube and the generator ground to the chassis.
3. Turn the sensitivity control (17) to maximum capacity position (clockwise), and then release 1½ turns (counter-clockwise).
4. Set signal generator at 470 K.C. and adjust compensators (11) and (19) for maximum reading on the output meter. Then turn sensitivity control (17) clockwise until a hiss (oscillation) is heard. Now turn sensitivity control (17) counter-clockwise until the hiss ceases, then continue for ¼ turn more.

Radio Frequency Circuit

1. Turn the gang condenser to the minimum capacity position (extreme clockwise) and place a .006" (six-thousandths inch) gauge between the stator and rotor plates. Now turn the gang counter-clockwise until stator and rotor plates touch gauge.
2. Remove gauge from gang condenser. Now place signal generator output lead through a 100 mmfd. condenser to the aerial post of the receiver. Set signal generator at 850 K.C., (using second harmonic, 1700 K.C.). Adjust compensators (13) osc., and (5) ant., for maximum reading on output meter.
3. Turn signal generator to 1400 K.C. and adjust gang condenser for maximum output. Then adjust compensator (5) for maximum reading on output meter.
4. After the above adjustments are completed, the dial pointer is checked for calibration by turning signal generator to 1000 K.C. Then tune receiver for maximum signal. The dial pointer should then indicate 1000 K.C.

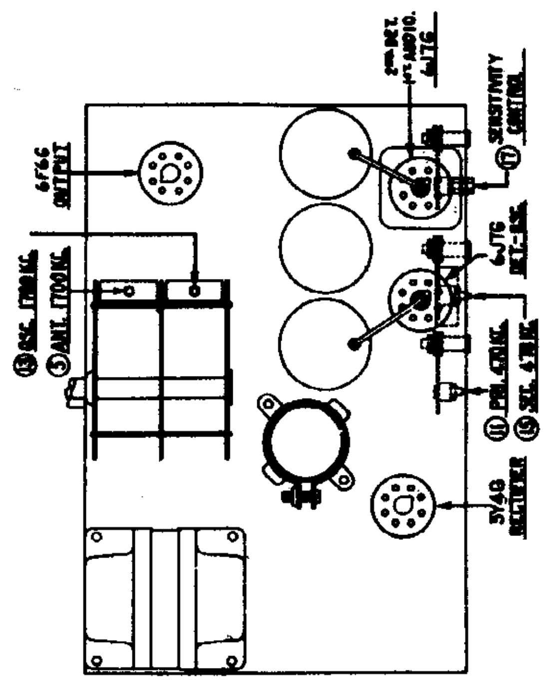

Fig. 1. Locations of Compensating Condensers

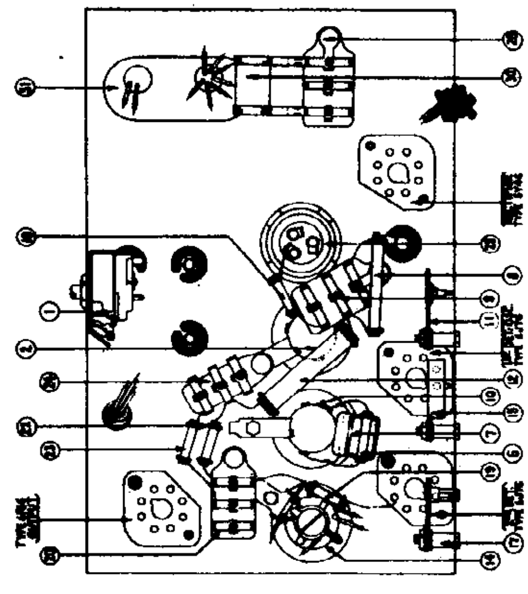

Fig. 3. Base view of Chassis

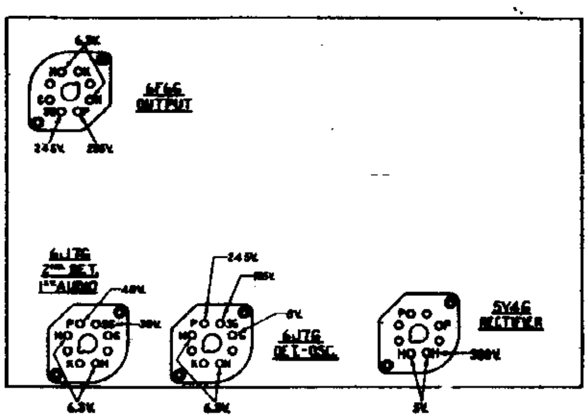

TUBE SOCKET VOLTAGES
(Measured from Tube Contact to Chassis)

Fig. 2. Tubes as viewed from underside of Chassis

The voltages at the points indicated by the arrows above were obtained with a Philco type 025 Circuit Tester which contains a high resistance (1000 ohms per volt) voltmeter.

PHILCO RADIO & TELEV. CORP.

Electrical Specifications

Type of Circuit: Superheterodyne. Pentode Power Output.
Power Supply: 115 volts A. C. 50 to 60 or 25 to 40 cycles.
Power Consumption: 65 Watts.
Philco Tubes Used: 2 type 6K7G, R. F. and I. F. Circuit; 1 type 6A8G, Detector Oscillator; 1 type 6Q7G, 2nd Detector, A. V. C., and 1st Audio; 1 type 6F6G, Output and 1 type 5Y4G, Rectifier.
Intermediate Frequency: 470 K. C.
Tuning Ranges: Two. Range 1—530 to 1650 K. C. Range 2—1500 to 3700 K. C.
Speaker: S-16.
Power Output: 3 watts.
Aerial Connections: The Philco ALL Wave Aerial is recommended for use with this receiver, to obtain maximum sensitivity and noise reduction. The red and black leads of the "transmission line" (lead-in) are connected to terminals 1 and 2 respectively on the terminal panel provided at the rear of the chassis. Connect the link provided on the terminal panel across terminals 3 and 4.

If a temporary aerial is used, the link is connected across terminals 2 and 3, the aerial connects to terminal 1.

A good ground connection is desirable in all installations. Make the ground connection from the nearest water or radiator pipe to terminal 3 on the terminal panel.

Adjusting Compensator

To accurately adjust this receiver, precision test equipment is necessary. A signal generator such as the PHILCO MODEL 088 Signal Generator, covering from 110 to 20,000 K. C. is recommended for use in adjusting the compensators at the various frequencies specified. A visual indication of the receiver output is also necessary to obtain correct adjustment of the compensators. PHILCO MODEL 025 Circuit Tester contains a sensitive output meter and is recommended for these adjustments.

Philco Fibre Wrench No. 3164 and Fibre Handle Screw-Driver No. 27-7059 complete the necessary equipment for these adjustments. The locations of the various compensators are shown in Figs. 2 and 3.

The following procedure must be observed in adjusting the compensators:

DIAL ADJUSTMENT—The tuning condenser is set at the maximum capacity position, by turning the tuning knob clockwise. Loosen the set screw of dial hub and set dial, with Glowing Indicator centered between the first and second index lines at the low frequency end of scale.

OUTPUT METER—The 025 Output Meter is connected to the plate and cathode terminals of the 6F6G tube. Adjust the meter to use the (0-30) volt scale.

During the I. F. and R. F. adjustment, the signal generator output should be maintained at the lowest possible level that will give an indication on the output meter.

INTERMEDIATE FREQUENCY CIRCUIT

1. Turn selector switch to range 1 (counter-clockwise). Rotate the tuning control to approximately 600 K. C. Connect the 088 Signal Generator output lead through a .1 mfd. condenser to the grid of the 6A8G tube and the output ground lead to the receiver chassis.

2. Set signal generator dial indicator for 470 K. C. Adjust attenuator for approximately ¼ scale reading on output meter. Then adjust compensators (20s) 2nd I. F. Sec., (20p) 2nd I. F. Pri., (19s) 1st I. F. Sec., and (19p) 1st I. F. Pri. for maximum reading on output meter.

RADIO FREQUENCY CIRCUIT

Tuning Range 1—530-1650 K. C.

1. Leave selector switch in range 1. Remove the signal generator output lead and .1 mfd. condenser from the grid of the 6A8G tube

2. Attach the signal generator output lead through the .1 mfd. condenser to the antenna terminal No. 1 on the aerial panel and the generator ground lead to terminal 3. Connect Terminal No. 2 to ground Terminal No. 3 with connector link provided on the panel.

3. Set signal generator and receiver dials for 1500 K. C. Now adjust compensators (12) Osc. (screw), (10) R. F., and (2) Ant. for maximum reading on output meter.

4. The low frequency end of the band is now tuned by turning signal generator and receiver dials to 600 K. C. and adjusting compensator (12)a (see note A below) for maximum output.

(A) When compensator (12)a Osc. series (nut) is being adjusted, the tuning condenser must be rolled for maximum output. This is accomplished as follows: First tune compensator (12)a for maximum output at 600 K. C. Then vary the tuning condenser back and forth about the 600 K. C. dial mark for the maximum output point. Now retune compensator (12)a and again varying the tuning condenser back and forth about 600 K. C. until the maximum output point is reached. This operation of first tuning the compensator, then the tuning condenser is continued until the maximum output is obtained at the 600 K. C. frequency.

5. Turn signal generator and receiver tuning dials to 1500 K. C., then readjust compensators (12) Osc.; (10) R. F.; (2) Ant. for maximum reading on output meter.

Tuning Range 2:

1. The compensating condenser adjustments of Band 1, takes care of Band 2, therefore no compensating condensers are required on the band.

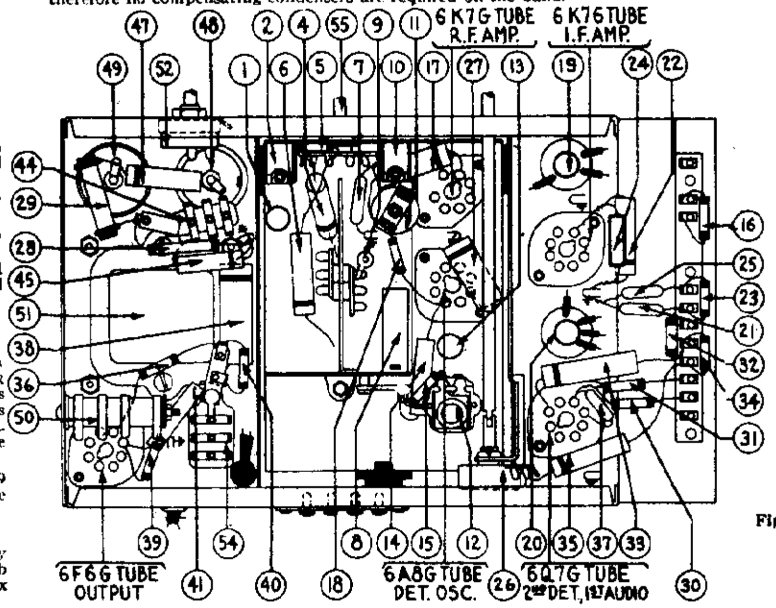

Fig. 4—Base View Chassis

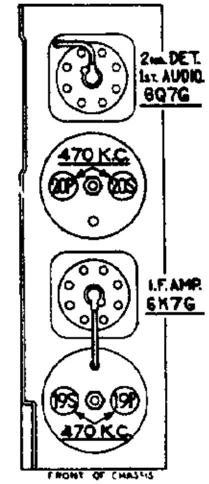

Fig. 2—I. F. Compensator

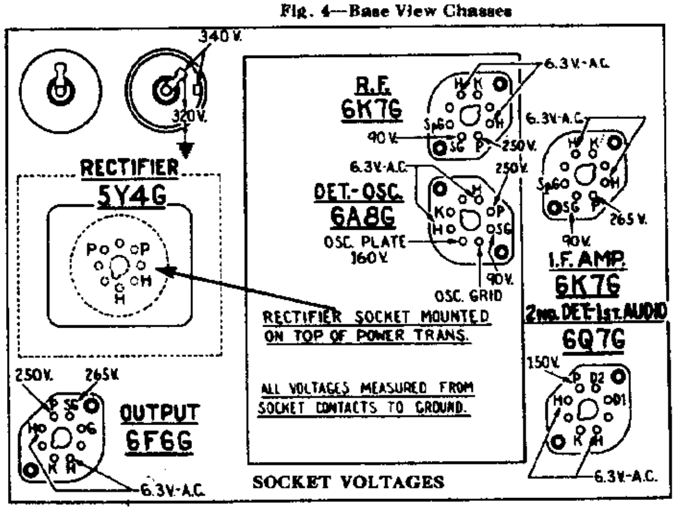

Fig. 1. View of Sockets from Underside Chassis

The voltages indicated by arrows were measured with a Philco 025 Circuit Tester which contains a voltmeter having a resistance of 1000 ohms per volt. Volume Control at minimum, range switch in broadcast position, line voltage 115 A. C.

PHILCO RADIO & TELEV. CORP.

MODEL 37-116 (Codes 121, 122)
Coils, Voltage, Trimmers, Note

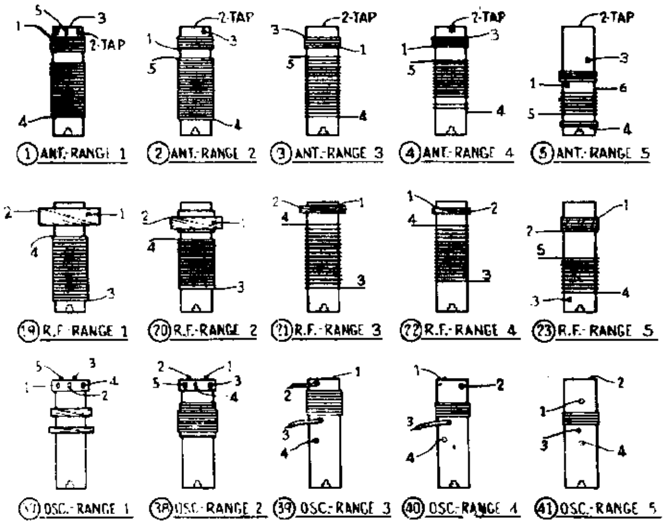

Fig. 5—Coil Wiring

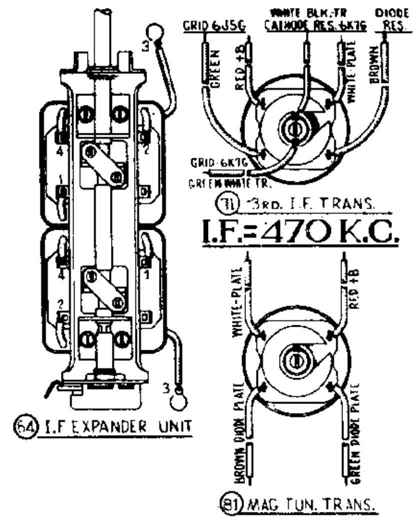

The numbers on the coil leads correspond to those shown on the schematic diagram. For example: On Antenna transformer (1) lead No. 1 is connected to range switch wafer contact A6.

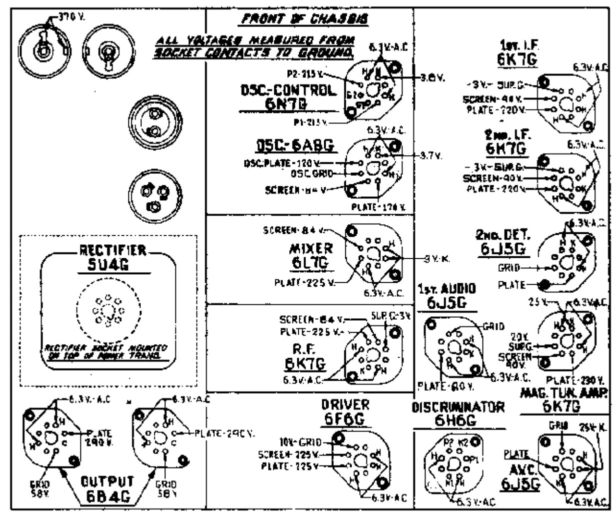

Fig. 2—Socket Voltages, Measured from Underside of Chassis

The voltages indicated by arrows were measured with a Philco 025 Circuit Tester which contains a voltmeter having a resistance of 1000 ohms per volt. Volume Control at minimum, range switch in broadcast position, line voltage 115 A. C.

HUM ADJUSTMENT

With Volume control at minimum volume position, adjust Potentiometer (128) on power unit for minimum hum.

SHADOWMETER ADJUSTMENT

Code 121

Remove aerial and allow tubes to warm up. Then adjust shadow meter as follows:

1. Move the shadow meter coil backwards and forwards, until the opposite edges of the shadow are ¼ of an inch from each end of the shadow screen, measuring along the bottom edge of the screen. Adjustment of the shadow meter light bracket may be necessary for perfect centering.

2. Remove the rectifier tube from its socket, and rotate coil until shadow reaches minimum width. This width must not exceed ⅛ of an inch.

3. Replace the 5U4G rectifier tube in its socket. The shadow should then widen to not more than ¼ inch or less than ⅛ inch from each side of the screen measuring along the bottom edge. If these limits are not obtained readjust the shadow meter as given in paragraphs 1 and 2 until they are reached.

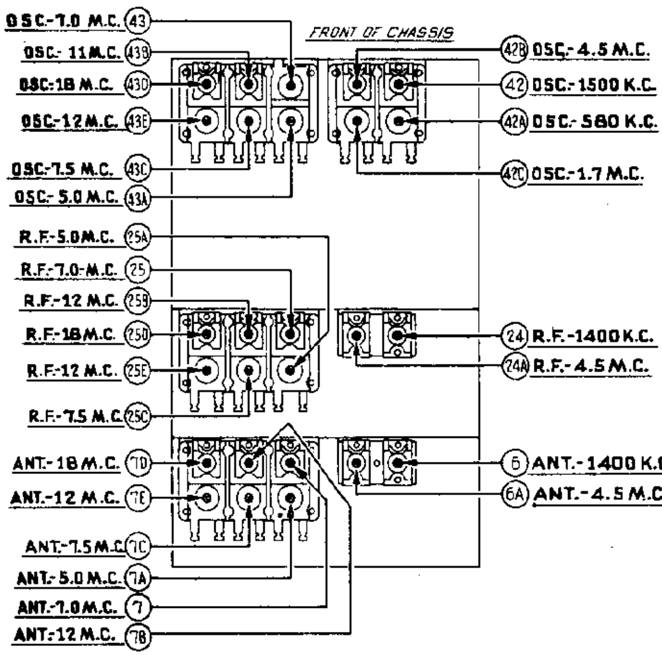

Fig. 8—Locations of R.F. Compensators Underside of Chassis View

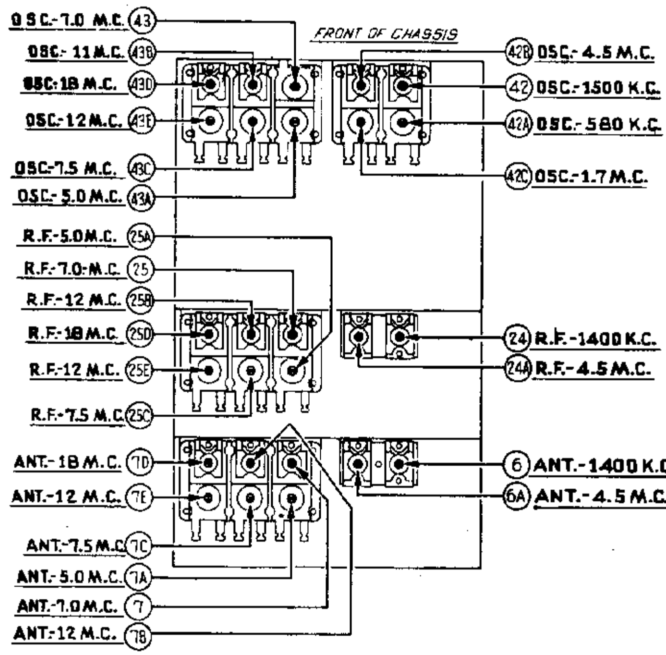

Fig. 8—Locations of R.F. Compensators

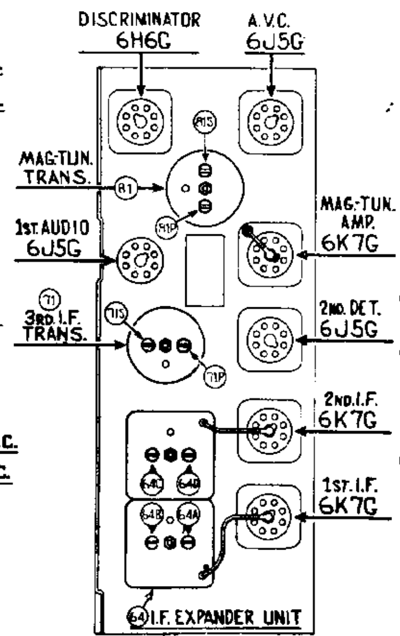

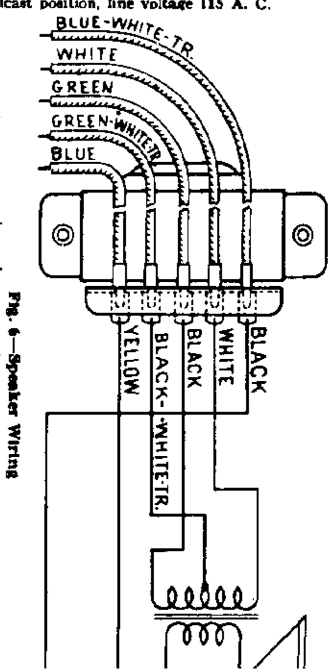

Fig. 6—Speaker Wiring

PHILCO RADIO & TELEV. CORP.

MODEL 37-116(Codes 121,122)
Alignment

To accurately adjust this receiver, precision test equipment is necessary. A signal generator such as the PHILCO MODEL 088 SIGNAL GENERATOR, covering from 110 to 20,000 K. C. is recommended for adjusting the compensators at the various frequencies specified. A visual indication of the receiver output is also necessary to obtain correct adjustment of the compensators. PHILCO MODEL 025 CIRCUIT TESTER contains a sensitive output meter and is recommended for these adjustments.

Philco Fibre Handle Screw-driver No. 27-7059 completes the necessary equipment for these adjustments. The locations of the various compensators are shown in Figs. 7 and 8.

NOTE—The receiver should be allowed to heat for at least 15 minutes before adjusting the compensators.

OUTPUT METER

The 025 Output Meter is connected to the plate and cathode terminals of the 6F6G tube. Adjust the meter to use the (0-30) Volt Scale.

DIAL CALIBRATION

In order to adjust this receiver correctly the dial must be aligned to track properly with the tuning condenser. To do this proceed as follows:

1. Loosen the set screws on the shaft coupling of the tuning condenser. Then turn the tuning condenser until the plates are in the maximum capacity position. Now set the glowing beam indicator on the index line at the low frequency end of the broadcast band. With dial and tuning condenser in this position tighten set screws.

2. Turn the tuning condenser control until the indicator is on the first division from the index line.

3. With the dial in this position, loosen the shaft coupling set screws. Then turn the dial until the indicator is again on the index line. Tighten the set screws in this position.

NOTE: Be careful when turning the dial that the position of the tuning condenser is not disturbed.

INTERMEDIATE FREQUENCY CIRCUIT

Frequency 470 K. C.

1. Connect the 088 Signal Generator output lead in series with a .1 mfd. condenser to the grid of the 6L7G tube, and the ground connection of the output lead to the chassis.

2. Set the receiver volume control in the maximum position. Turn the fidelity-selectivity control clockwise; magnetic tuning control in the "off" position (counter-clockwise); range switch in position No. 1 (Broadcast); tuning condenser to approximately 580 K. C., and adjust the signal generator for 470 K. C.

3. Now adjust compensators (64B) 1st I.F. Sec., (64A) 1st I.F. Pri., (64D) 2nd I.F. Sec., (64C) 2nd I.F. Pri., (71S) 3rd I.F. Sec., and (71P) 3rd I.F. Pri. for maximum output.

4. Turn the fidelity-selectivity control to the expanded position (counter-clockwise). The intermediate frequency curve is now checked for symmetry as follows: Slowly shift the signal generator dial between 460 K. C. and 480 K. C. As the dial is turned two peaks will be indicated on the output meter—one about 465 K. C., and the other about 475 K. C. These peaks should give the same deflection or reading on the output meter. If they are unequal, compensator (71S) must be readjusted slightly to the right or left—depending on which peak gives the lowest reading—until they are equalized.

Each time the compensator is set in another position, rotate the signal generator dial through 460 to 480 K. C. and note the reading of each peak on the output meter. If the peaks become more equal when compensator (71S) is turned to the left, continue in this direction until they are equal. If they become more unequal turn the compensator to the right. Continue this adjustment in either direction until the peaks equalize.

5. After adjusting the third I.F. transformer, turn the fidelity-selectivity control clockwise (selective position) and adjust the attenuator of the signal generator for maximum output. Now tune the primary compensator (81P) of the magnetic tuning transformer for minimum output.

RADIO FREQUENCY CIRCUIT

Tuning Range 11.5-18.2 M. C.

1. The signal generator output lead with the .1 mfd. condenser, is connected to terminal No. 1 on the aerial input panel (rear of chassis) and the generator ground lead to terminal No. 3. Terminals 2 and 3 must be connected with the shorting link provided on the panel.

2. Set the magnetic tuning control in the "off" position, and the fidelity-selectivity control in the extreme clockwise position. Set the range switch in position No. 5 (11.5 to 18.2 M. C.) Turn the receiver and signal generator dials to 18 M. C. and adjust the generator attenuator for a readable indication on the output meter. Now adjust compensator (43D) by turning the screw (clockwise) to the maximum capacity position, then slowly turn it counter-clockwise until a second maximum peak is reached on the output meter. The first peak from maximum capacity is the image signal and the receiver *must not* be adjusted to this signal. On some receivers, however, only one peak will be found, therefore, adjust compensator (43D) to this peak. If the above procedure is correctly performed, the image signal will be found at 17.060 M. C. by advancing the signal generator input, and turning the receiver dial to this frequency mark on the scale.

3. Leaving the signal generator and receiver dials at 18 M. C. the antenna and R. F. compensators (7D) and (25D) are now adjusted by connecting a variable condenser (Philco Part No. 45-2325) across the oscillator compensator (43D) contact (first contact from the left side of the receiver facing rear underside view of the chassis) and ground. Now tune the added condenser until the second harmonic of the receiver oscillator beats against the signal from the generator, resulting in a maximum indication on the output meter. Note: It may be necessary to increase the signal generator output to obtain a signal of sufficient strength for reading on the output meter. Compensators (7D) and (25D) are now adjusted for maximum output. After these adjustments, remove the external condenser and readjust compensator (43D) as given in paragraph 2 above.

4. Turn the signal generator and receiver dials to 12 M. C. and adjust compensators (43E), (25E) and (7E) for maximum output.

5. Readjust compensator (43D) as given in paragraph 2 above, for maximum output.

6. Readjust compensators (7D), (25D) and (43D) as given in paragraph 3 above. This readjustment is to correct any variation that the low frequency compensator may have caused in the high end of this range.

Tuning Range (7.35-11.6 M. C.)

1. Turn selector switch to Range 4. Set the signal generator and receiver dials to 11.0 M. C. Now adjust compensator (43B) for maximum output. Check for image at 10.06 M. C.

2. Leaving signal generator and receiver dial turned to 11.0 M. C., connect the external variable condenser across the oscillator compensator (43B) contact (third contact from left side of the receiver facing rear underside view of chassis) and ground. Tune the added condenser for maximum output, then adjust compensators (7B) and (25B) for maximum output. Remove the added condenser and adjust (43B) for maximum.

3. Turn the signal generator and receiver dials to 7.5 M. C. and adjust compensators (43C), (25C) and (7C) for maximum output.

4. Readjust compensator (43B) as given in paragraph 1 above.

5. Readjust compensators (7B), (25B) and (43B) as given in paragraph 2 above.

Tuning Range (4.7 to 7.4 M. C.)

1. Turn selector switch to range 3. Set the signal generator and receiver dials for 7.0 M. C. and adjust compensators (43), (25) and (7) for maximum output.

2. Rotate the signal generators and receiver dials to 5.0 M. C., then adjust compensators (43A), (25A) and (7A) for maximum output.

3. Readjust compensators (43), (25) and (7) on the 7.0 M. C. signal.

Tuning Range (1.58 to 4.75 M. C.)

1. Turn the selector switch to range 2. Set the signal generator and receiver dials to 4.5 M. C. Now adjust compensators (42B), (24A) and (6A) for maximum output.

2. Rotate the signal generator and receiver dials to 1.7 M. C. Compensator (42C) Osc. series is now adjusted for maximum output as follows:

First tune compensator (42C) for maximum output, then vary the tuning condenser of the receiver for maximum output about the 1.7 M.C. dial mark. Now turn compensator (42C) slightly to the right or left and vary the receiver tuning condenser for maximum output. If the output reading increases, turn compensator (42C) in the same direction a trifle more, and again vary the tuning condenser for maximum output. If the output decreases, set the compensator in the opposite direction. This procedure of first setting the compensator and then varying the tuning condenser is continued until there is no further gain in output reading.

3. Readjust compensators (42B), (24A) and (6A) for maximum output as given in paragraph 1 above.

Tuning Range (530 to 1600 K. C.)

1. Set selector switch in range 1. Rotate the signal generator and receiver dial to 1500 K. C. Adjust compensators (42), (24) and (6) for maximum output.

2. Turn the signal generator and receiver dials to 580 K. C. Compensator (42A) Osc. series is now adjusted, using the same procedure as given in paragraph 2 under Tuning Range (1.58 to 4.75 M. C.). The only difference in the two adjustments is the frequency and compensator used.

3. Readjust compensator (42) on 1500 K. C. and compensators (24) and (6) on a 1400 K. C. signal.

ADJUSTMENT OF THE MAGNETIC TUNING CONTROL

1. Leave the selector switch in position 1. Set the fidelity-selectivity control in the "selective" position (clockwise). Magnetic tuning in the "out" position. Turn the signal generator and dial to 1000 K. C., then adjust the receiver tuning condenser for maximum output.

NOTE: It is very important to accurately adjust the receiver tuning condenser, also, adjust the signal generator attenuator to maximum output.

2. Turn the (Magnetic Tuning Control) to the "on" position (clockwise). Compensator (81S) Sec. of magnetic tuning transformer is now adjusted for maximum output. If the indicator of the output meter goes off scale, turn the volume control of the receiver toward the minimum position until a readable indication is obtained.

3. The above adjustment is now checked for accuracy, by turning the magnetic tuning control "off". When this is done there should be no change in the tone of the receiver signal. If a change of tone or a hiss develops, it indicates a shift in frequency and the adjustment must be made again.

MODEL 37-116(Codes 121,122)
Parts List

PHILCO RADIO & TELEV. CORP.

Replacement Parts—Model 37-116

Schem. No.	Description	Part No.	List Price
1	Antenna Transformer (Range 1)	32-2108	$0.80
2	Antenna Transformer (Range 2)	32-2146	.80
3	Antenna Transformer (Range 3)	32-2183	.60
4	Antenna Transformer (Range 4)	32-2185	.70
5	Antenna Transformer (Range 5)	32-2175	.80
6	Compensator, 2 Gang	31-6093	.40
7	Compensator (6 Sections)	31-6112	1.40
8	Resistor (51000 ohms ½ watt)	33-351339	.20
9	Condenser (.05 mfd. Tubular)	30-4020	.20
10	Tuning Condenser	31-1892	3.75
11	Condenser (40 mmfd.)	30-1076	....
12	Condenser (5 mmfd.)	30-1077	....
13	Condenser (.05 mfd. Tubular)	30-4123	.20
14	Resistor (1. megohm, ½ watt)	33-510339	.20
15	Resistor (1000 ohms, ½ watt)	33-210339	.20
16	Resistor (400 ohms wirewound)	33-3016	.20
17	Condenser (.05 mfd. Tubular)	30-4444	.20
18	Resistor (10000 ohms, ½ watt)	33-310339	.20
19	R. F. Transformer (Range 1)	32-2105	.75
20	R. F. Transformer (Range 2)	32-2147	.60
21	R. F. Transformer (Range 3)	32-2177	.60
22	R. F. Transformer (Range 4)	32-2178	.60
23	R. F. Transformer (Range 5)	32-2176	.70
24	R. F. Compensator (2 Section)	31-6093	.40
25	R. F. Compensator (6 Section)	31-6113	1.40
26	Condenser (.05 mfd. Tubular)	30-4123	.20
27	Resistor (51000 ohms, ½ watt)	33-351339	.20
28	Condenser (.05 mfd. Tubular)	30-4020	.20
29	Resistor (99000 ohms, ½ watt)	33-399339	.20
30	Resistor (99000 ohms, ½ watt)	33-399339	.20
31	Condenser (250 mmfd. Mica)	30-1032	.25
32	Condenser (250 mmfd. Mica)	30-1032	.25
33	Resistor (700 ohms Wirewound)	[illegible]	.20
34	Resistor (20 ohms, ½ watt)	33-020339	.20
35	Resistor (20 ohms, ½ watt)	33-020339	.20
36	Condenser (.02 mfd. Tubular)	30-4481	....
37	Oscillator Transformer (Range 1)	32-2191	.80
38	Oscillator Transformer (Range 2)	32-2194	.80
39	Oscillator Transformer (Range 3)	32-2197	.50
40	Oscillator Transformer (Range 4)	32-2198	.50
41	Oscillator Transformer (Range 5)	32-2199	.50
42	Compensator Oscillator (4 Section)	31-6124	1.00
42X	Condenser (600 mmfd.)	30-1049	....
43	Compensator Oscillator (6 Section)	31-6117	1.20
44	Condenser (.05 mfd. Tubular)	30-4123	.20
45	Resistor (8000 ohms, ½ watt)	33-280339	.20
46	Resistor (200 ohms Wirewound)	7217	.20
47	Condenser (.02 mfd. Tubular)	30-4481	.20
48	Resistor (160 ohms Wirewound)	33-3023	.25
49	Resistor (75000 ohms, ½ watt)	33-375339	.20
50	Resistor (20000 ohms, ½ watt)	33-320339	.20
51	Condenser (250 mmfd. Mica)	30-1032	.25
52	Condenser (600 mmfd. Mica)	30-1049	.25
53	Condenser (600 mmfd. Mica)	30-1049	.25
54	Coil (Osc. Plate)	32-2242	.25
55	Condenser (200 mmfd. Mica)	30-1047	.25
56	Condenser (155 mmfd. Mica)	30-1045	.20
57	Condenser (25 mmfd. Mica)	30-1067	.20
58	Resistor (10000 ohms, ½ watt)	33-310339	.20
59	Condenser (.05 mfd. Tubular)	30-4169	.25
60	Resistor (32000 ohms, ½ watt)	33-332339	.20
61	Resistor (20000 ohms, ½ watt)	33-320339	.20
62	Electrolytic Condenser (2, 3, 8 mfd.)	30-2169	1.60
63	Condenser (.05 mfd. Tubular—Code 121 only)	30-4123	....
64	Expander Unit	38-7929	....
65	Condenser (.1 mfd. Bakelite)	4989DG	.35
66	Condenser (.05 mfd. Tubular)	30-4123	.20
67	Resistor (1000 ohms, ½ watt)	33-210339	.20
68	Shadowmeter	45-2189	....
69	Resistor (1000 ohms, ½ watt)	33-210339	.20
70	Resistor (1000 ohms, ½ watt)	33-210339	.20
71	Third I. F. Transformer	32-2215	....
72	Condenser (110 mmfd. Dual Bakelite)	8035DG	.25
73	Resistor (51000 ohms, ½ watt)	33-351339	.20
74	Condenser (.004 mfd. Tubular)	30-4185	.25
75	Resistor (160,000 ohms, ½ watt)	33-416339	.20
76	Condenser (.25 mfd. Tubular)	30-4134	.25
77	Resistor (500 ohms, ½ watt)	33-150339	.20
78	Resistor (4000 ohms, ½ watt)	33-240339	.20
79	Condenser (.05 mfd. Dual Bakelite)	3615DG	.40
80	Condenser (110 mmfd. Mica)	30-1031	.20
81	Magnet Tuning Transformer	32-2217	....
82	Resistor (490,000 ohms, ½ watt)	33-449339	.20
83	Resistor (490,000 ohms, ½ watt)	33-449339	.20
84	Condenser (110 mmfd. Dual Bakelite)	8035DG	.25
85	Resistor (490,000 ohms, ½ watt)	33-449339	.20
86	Resistor (1 meg. ohm, ½ watt)	33-510339	.20
87	Resistor (1 meg. ohm, ½ watt)	33-510339	.20
88	Resistor (490,000 ohms, ½ watt)	33-449339	.20
89	Condenser (Three section .1, .1, .8 mfd.)	[illegible]	1.40
90	Condenser (.01 mfd. Dual Bakelite)	[illegible]	.30
91	Resistor (20,000 ohms, ½ watt)	33-320339	.20
92	Resistor (1.0 meg., ½ watt)	33-510339	.20
93	Switch (Mag. Tuning)	[illegible]	.75
94	Flood Lamp (Code 122)	34-2039	....
95	Resistor (490,000 ohms, ½ watt)	[illegible]	.20
96	Condenser (.05 mfd. Tubular)	30-4123	.20
97	Resistor (51,000 ohms, ½ watt)	33-351339	.20
97X	Condenser (110 mmfd. Mica)	30-1031	....
98	Condenser (.05 mfd. Tubular)	30-4123	.20
99	Resistor (99,000 ohms, ½ watt)	33-399339	.20
100	Resistor (1 meg., ½ watt)	33-510339	.20
101	Condenser (.01 mfd. Tubular)	30-4124	.25
102	Volume Control	33-5158	1.00
103	Resistor (70,000 ohms, ½ watt)	33-370339	.20
104	Condenser (.008 mfd. Tubular)	30-4112	.20
105	Condenser (.006 mfd. Tubular)	30-4445	.20
106	Potentiometer (Expander unit)	33-5172	....
107	Condenser (100 mmfd. Mica)	30-1035	....
108	Resistor (240,000 ohms, ½ watt)	33-424339	.20
109	Input Audio Transformer	32-7057	3.50
110	Resistor (25,000 ohms, ½ watt)	33-325339	.20
111	Resistor (25,000 ohms, ½ watt)	33-325339	.20
112	Output Transformer	32-7717	2.00
113	Cone and Voice Coil	36-3647	2.25
114	Resistor (330,000 ohms, ½ watt)	33-433339	.20
115	Resistor (160,000 ohms, ½ watt)	33-416339	.20
116	Condenser (.1 mfd. Dual Bakelite)	4989DG	.40
117	Resistor (51,000 ohms, ½ watt)	33-351339	.20
118	Resistor (14,000 ohms, ½ watt)	33-3291	....
119	Resistor (20000 ohms, 1 watt)	33-320439	$0.20
120	Choke (Filter)	32-7491	.95
121	Resistor (18 ohms, ½ watt)	33-020439	.20
122	Field Coil (W. Speaker)	36-3788	....
123	Electrolytic Condenser (8 and 10 mfd.)	30-2123	1.60
124	Resistor (1000 and 4000 ohms)	33-3289	.50
125	Choke (Filter)	32-7056	2.20
126	Electrolytic Condenser (8 mfd.)	30-2026	1.05
127	Electrolytic Condenser (8 mfd.)	30-2026	1.05
128	Potentiometer (Dual 60 ohms)	33-5176	....
129	Power Transformer 115 Volts, 60 Cycle	32-7688	7.50
	Power Transformer 115 Volts, 25 to 40 Cycle	32-7689	....
	Power Transformer, 220 Volts	32-7690	....
130	Power and Tone Switch	42-1196	.75
131	Condenser (.015 mfd. Dual Bakelite)	4989DG	.40
132	Range Switch (Osc)	42-1217	2.00
133	Range Switch (R. F.)	42-1212	1.60
134	Range Switch (Ant.)	42-1211	1.60
135	Pilot Lamp (Codes 121-122)	34-2039	.15
136	Shadowmeter Lamp (Code 121 only)	34-2039	.15

Adjusting Compensating Condensers

To accurately adjust the compensating condensers in the **Model 37-600** receiver, it is necessary to use a signal generator of high stability on all frequencies, such as the **PHILCO Model 088 Signal Generator.** This instrument has a continuous frequency range from 110 to 20,000 K.C., and is designed to meet every requirement of the serviceman.

An output meter is also needed.—**PHILCO MODEL 025 Circuit Tester** includes a very sensitive output meter.

Convenient tools to use in adjusting the compensators are the **Philco No. 3164 Fibre Wrench** and **No. 27-7059 Fibre Handled Screw-driver.**

The locations of the various compensating condensers are shown in Fig. 1. Connect the output meter to the plate and cathode contacts of the 6K6G power tube, and adjust it to use the 0-30 volt range.

When adjusting each circuit, care should be taken to have the signal generator attenuator set for approximately ¼ scale reading on output meter.

Intermediate Frequency Circuit

1. Connect the 088 signal generator output lead through a .1 mfd. condenser to the grid of the 6A8G tube and the ground lead to the chassis.

2. Turn the sensitivity compensator ㉘ to maximum capacity position (clockwise), and then release it; 1½ turns (counter-clockwise).

3. Turn gang condenser to approximately 600 K.C. Set the signal generator at 470 K.C.

4. Adjust the compensator ⑱ and ⑳ for maximum reading on the output meter. Then turn the sensitivity compensator ㉘ clockwise until a hiss, (oscillation) is heard. Now turn the compensator ㉘ counter-clockwise until hiss ceases, then continue for ¼ turn more.

Radio Frequency Circuit

1. Remove the signal generator output lead from the 6A8G tube, and connect it to the aerial lead of the receiver through a 100 mmfd. condenser.

2. Turn the gang condenser to minimum capacity position, (counter-clockwise) and place a .006" (six-thousands inch) gauge between the stator and rotor plates. Now turn the gang clockwise until stator and rotor plates touch gauge.

3. Remove gauge from gang condenser. Now set signal generator at 900 K.C., (using second harmonic 1800 K.C.), adjust compensators ⑥ and ⑤ for maximum reading on output meter.

4. Turn the signal generator and receiver gang condenser to 600 K.C., and adjust compensator ⑯. In doing so, the gang condenser must be rolled slightly above and below the 600 K.C. signal until the maximum reading is indicated on the output.

5. Turn the gang condenser to 1800 K.C. and signal generator to 900 K.C., (using second harmonic of signal generator 1800 K.C.), readjust compensator ⑥ for maximum reading on output meter. Set gang as per paragraph 2, for this adjustment.

6. Turn the gang condenser and signal generator to 1400 K.C., readjust compensator ⑤ for maximum reading on output meter. After the above adjustments are completed and receiver is placed in the cabinet, the dial pointer is properly placed by turning the signal generator to 1000 K.C. Then tune receiver for maximum signal. The dial pointer is then placed on gang shaft, so that it indicates 1000 K.C. on dial.

Adjusting Compensating Condensers

To accurately adjust the compensating condensers in the Model 37-602 receiver, it is necessary to use a signal generator of high stability on all frequencies such as the **PHILCO Model 088 Signal Generator.** This instrument has a continuous frequency range from 110 to 20,000 K.C., and is designed to meet every requirement of the serviceman.

An output meter is also needed,—**PHILCO Model 025 Circuit Tester** includes a very sensitive output meter.

Convenient tools to use in adjusting the compensators are the **PHILCO No. 3164 Fibre Wrench** and **No. 27-7059 Fibre Handled Screw-driver.**

The locations of the various compensating condensers are shown in Fig. 1. Connect the output meter to the plate and cathode contacts of the (25A6G) power tube and adjust it to use the 0-30 volt range.

Intermediate Frequency Circuit

1. Turn the gang condenser to the maximum capacity position (extreme clockwise) and set the Volume Control of the receiver at the maximum position (extreme clockwise).

2. Connect the signal generator output lead through a .1 mfd. condenser to the grid of the 6K7G tube, and the generator ground lead to any point of chassis.

3. Set the signal generator at 470 K.C. and adjust (27) and (29) for maximum reading on the output meter.

4. Remove signal generator output lead and .1 mfd. condenser, from the grid of 6K7G and connect it to the grid of 6A8G. Now adjust condensers (21) and (25) for maximum reading on the output meter.

Radio Frequency Circuit

1. Remove the signal generator output lead from the 6A8G tube and connect it to the aerial lead of the receiver through a 100 mmfd. condenser. Turn the gang condenser to the minimum capacity position (extreme counter clockwise) and place a .006" (six thousandth inch) gauge between the stator and rotor plates. Now turn the gang clockwise until stator and rotor plates touch gauge.

2. Remove gauge from gang condenser. Now set signal generator at 900 K.C. (using second harmonic (1800 K.C.) adjust compensators (6)A and (3) for maximum reading on the output meter.

3. Turn the signal generator and receiver gang condenser to 600 K.C., and adjust compensator (8). In doing so, the gang condenser must be rolled slightly above and below the 600 K.C. signal until the maximum reading is indicated on the output meter.

4. Turn the gang condensor to 1800 K.C. and signal generator to 900 K.C., (using second harmonic of signal generator 1800 K.C.), readjust compensator (6)A for maximum reading on output meter. Set gang as given in paragraph 1, for this adjustment.

5. Turn the gang condenser and signal generator to 1400 K.C., readjust compensator (3) for maximum reading on output meter. After the above adjustments are completed and receiver is placed in the cabinet, the dial pointer is properly placed by turning the signal generator to 1000 K.C. Then tune receiver for maximum signal. The dial pointer is then placed on gang shaft, so that it indicates 1000 K.C. on dial.

Range 2.—6.0 to 18.0 M. C.

MODEL 37-604
Alignment
Notes

PHILCO RADIO & TELEV. CORP.

Adjusting Compensating Condensers

The following procedure must be observed in adjusting the compensators:

DIAL ADJUSTMENT—In order to adjust this receiver correctly, the dial must be aligned to track properly with the tuning condenser. To do this, rotate the tuning condenser control to the extreme counter-clockwise position (maximum capacity). Loosen the set screw of dial hub, then turn dial until the glowing indicator is centered on the first index line of dial scale (see Fig. 5). Now tighten the dial hub set screw in this position.

OUTPUT METER—The 025 Output Meter is connected to the plate and cathode terminals of the 25A6G tube. Adjust the meter to use the (0-30) volt scale. Before adjusting the compensators of each circuit, the signal generator attenuator should be set to give approximately ¼ scale reading on output meter.

INTERMEDIATE FREQUENCY CIRCUIT

1—Connect the 088 Signal Generator output lead through a .1 mfd condenser to the control grid of the 6K7G tube and the ground connection of the output lead to the chassis.

2—The range switch is set in position No. 1 (Broadcast). Rotate the tuning condenser of the receiver to the maximum capacity position (counter-clockwise) and adjust the signal generator for 470 K. C.

3—Now adjust compensators ㉞a 2nd I. F. Sec. and ㉞ 2nd I. F. Pri. for maximum output.

4—Remove the signal generator output lead and .1 mfd. condenser from the 6K7G tube and connect them to the grid of the 6A8G tube. Now adjust compensators ⑱a 1st I. F. Sec. and ⑱ 1st I. F. Pri. for maximum output.

RADIO FREQUENCY CIRCUIT

Tuning Range—6.0 to 18.0 M. C.

1—Remove the signal generator output lead and series condenser from the 6A8G tube and connect them to terminal No. 1 on aerial input panel, and the generator ground lead to terminal No. 3, front of chassis.
(a) Terminal 4 and 5 of aerial input panel must be shorted with connector link provided on the panel, during the following adjustments.

2—Set range switch in position No. 2 (Shortwave). Turn signal generator and receiver dials to 18 M. C. and adjust compensator ③c Osc. for maximum output.

3—The adjustment of the antenna compensator on the high frequency range causes a slight detuning of the oscillator circuit. In order to overcome this detuning effect, connect a variable condenser of approximately 350 mmfd. having a good vernier drive, across the oscillator section of the tuning condenser (bottom section). Leaving the signal generator and receiver dials at 18 M. C., tune the added condenser so that the second harmonic of the receiver oscillator will beat against the signal from the signal generator bringing in the signal. The antenna compensator ③a should then be adjusted to give maximum output.

4—Now remove the external condenser from the tuning condenser of receiver and turn compensator ③c Osc. to the maximum capacity position (clockwise). Then without moving signal generator or receiver tuning condenser, turn compensator ③c (counter-clockwise) until a second peak is reached on the output meter. The first peak is caused by tuning to the image frequency signal and must not be used. Compensator ③c is adjusted on the second peak to give maximum output.
A further check on the image signal may be obtained by turning the signal generator attenuator to maximum output. Then turn dial of receiver to approximately 17.060. If the receiver is aligned correctly and the signal from the generator is strong enough, the image signal will be heard at this point.

5—The low frequency compensator ⑥a is now adjusted by turning signal generator and receiver dials to 6 M. C. and adjusting compensator ⑥a Osc. series (see note (a) below) for maximum output.
(a) When compensator ⑥a Osc. series is being adjusted, the tuning condenser must be rolled for maximum output. This procedure is accomplished as follows:—First tune compensator ⑥a for maximum output at 6.0 M. C. Then vary the tuning condenser back and forth about the 6.0 M. C. dial mark until maximum output is obtained. Now retune compensator ⑥a, and again vary the tuning condenser back and forth at 6.0 M. C. for maximum output.
This operation of first tuning the compensator, then the tuning condenser is continued until the maximum output is obtained at or near the 6.0 M. C. frequency. The maximum output point of this adjustment may fall slightly above or below the 6 M. C. dial setting.

6—Compensator ③c Osc. and ③a Ant. are now retuned as given in paragraphs 3 and 4 above.

Tuning Range—530 to 1750 K. C.

1—Set range switch in position No. 1 (Broadcast). Turn the 088 Signal Generator indicator to 800 K. C. and the receiver dial to 1600 K. C. The second harmonic of the 800 K. C. signal, to which the signal generator is tuned, is used for the 1600 K. C. adjustment.
Now adjust compensators ③b Osc. and ② Ant. for maximum output.

2—Turn the signal generator and receiver dials to 600 K. C. and adjust compensator ⑥ Osc. series (screw)—see note (a) below—for maximum reading on the output meter.
(a) When compensator ⑥ Osc. series is being adjusted, the tuning condenser must be rolled for maximum output. This procedure is accomplished as follows:—First tune compensator ⑥ for maximum output at 600 K. C. Then vary the tuning condenser back and forth until the maximum output point is reached. Now retune compensator ⑥ and again vary the tuning condenser back and forth at 600 K. C. for maximum output. This operation of first tuning the compensator then the tuning condenser is continued until the maximum output is obtained at, or near, the 600 K. C. frequency. The maximum output point of this adjustment may fall slightly above or below the 600 K. C. dial mark.

3—After the low frequency (600 K. C.) end of the range is adjusted, the 1600 K. C. end is readjusted, as given in paragraph (1) above, to correct any variation that the low frequency series compensator may have caused in the alignment of the high frequency end.

4—Now turn signal generator and receiver dials to 1400 K. C. and readjust compensator ② Ant. for maximum output.

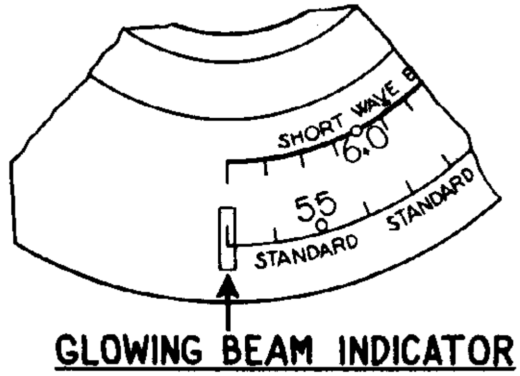

Fig. 5—Dial Calibration

Equipment for Adjusting Receiver

The accurate adjustment of the various compensating condensers is vital to the proper functioning of this receiver. There are four compensating condensers in the I. F. Circuit, four in the Oscillator Circuit, and two in the Antenna Circuit. Incorrect adjustment will cause loss of sensitivity, unsatisfactory tone, and poor selectivity.

To accurately adjust this receiver, precision test equipment is necessary. A signal generator such as the PHILCO MODEL 088 SIGNAL GENERATOR, covering from 110 to 20,000 K. C. is recommended to adjust the compensators at the various frequencies specified. A visual indication of the receiver output is also necessary to obtain correct adjustment of the compensators. PHILCO MODEL 025 CIRCUIT TESTER contains a sensitive output meter and is recommended for these adjustments.

Philco Fibre Wrench No. 3164 and Fibre Handle Screw-driver No. 27-7059 complete the necessary equipment for these adjustments. The locations of the various compensators are shown in Fig. 6.

Antenna Connections

On the lower front corner of the chassis is a panel containing five terminals. When using the Philco High Efficiency Aerial terminals 4 and 5 are connected by the metal strap provided on the panel. The red and black leads of the PHILCO High Efficiency Aerial are connected to terminals 1 and 3 respectively and the ground lead to terminal 2.

If a temporary aerial is used shift the strap to rest across terminals 3 and 4 and connect the aerial to terminal 1. A ground connection must not be used when terminals 3 and 4 are connected.

Pilot Lamp Replacement

Facing the front top of the receiver, the pilot lamp housing will be found directly under the dial scale. Two screws will be found on this housing. The right hand screw holds the housing to the tuning condenser and should be removed only when replacing the housing. The center screw holds the pilot lamp socket assembly to the housing. By removing this center screw, the socket assembly may be removed from the housing for replacement of Pilot Lamps.

Parts List

PHILCO RADIO & TELEV. CORP.

General Description

Philco Model 37-604 is a 5 tube superheterodyne receiver using the new Philco High Efficiency self-centering glass tubes and designed for operation on either alternating or direct current. This receiver has two tuning ranges, covering standard broadcast and short wave reception.

The circuit consists of the Philco Foreign Tuning System—controlled by the range switch which provides maximum sensitivity and noise reduction when used with the **New Philco High Efficiency Aerial.** A 6A8G tube is used as the detector-oscillator; 6K7G tube as the I. F. amplifier; 6Q7G tube for the second detector, first audio and automatic volume control; 25A6G tube for Pentode Power Output, and a 25Z6G tube as the Rectifier.

Automatic Bass Compensation is built into the volume control circuit and a Bias cell is used for supplying grid voltage to the first Audio tube.

The Radio Frequency circuit is assembled in one unit and mounted on the left side of the receiver (facing the front). This unit contains the antenna and oscillator coils for each tuning range, range switch, compensating condensers and other parts necessary for the operation of the associated circuits.

Mounted vertically and cushioned on the chassis is the tuning condenser. The bottom section of this condenser is for the oscillator tuning and the top section for the antenna circuit Attached to the condenser is the pilot lamp housing.

PHILCO RADIO & TELEV. CORP.

Model 37-610

Codes, 121–122

General Description

Model 37-610 is a 5 tube superheterodyne receiver for operation on alternating current, having three tuning ranges, covering standard broadcast and short-wave frequencies and using the New Philco High-Efficiency self-centering glass tubes.

The circuit includes the Philco Foreign Tuning System—controlled by the range switch—providing maximum sensitivity and noise reduction when used with the Philco High Efficiency Aerial, supplied with the receiver.

The red and black leads of the High-Efficiency Aerial "transmission line" are connected to terminals 1 and 2 respectively, of the terminal panel provided at the rear of the chassis. Connect the jumper of the terminal panel across terminal 3 and 4.

If a temporary aerial is used, the jumper should be across terminal 2 and 3. The aerial connects to terminal 1 and the ground to terminal 3.

A good ground connection is desirable in all installations—with the Philco High-Efficiency Aerial, a ground lead and ground clamp are provided. Make the ground connection from the nearest water or radiator pipe to terminal 3 on the terminal panel.

CONSTRUCTION

The chassis is constructed in three basic assembly units.

The Radio Frequency unit contains a 6A8G tube which functions as a Detector-Oscillator, tuning condenser, antenna and oscillator coils for each tuning range, selector switch—compensating condensers for all coils and other parts necessary for the associated circuits. The unit is separately mounted on rubber grommets, cushioning it from the main chassis.

The Intermediate Frequency unit, mounted on the right-hand side of the chassis, facing front, consists of the Intermediate Frequency coils, compensating condensers, a 6K7G tube for I. F. Amplifier stage, and a 6Q7G tube as the second detector-automatic volume control and first audio stage.

All voltages supplied to the I. F. and R. F. units are furnished from a terminal strip mounted in this unit.

The Power Pack and audio output circuits, together with the required Voltage dividers and filter condensers are mounted in the power unit.

Although unit construction has changed the appearance of this model, the service bulletin will be of great assistance in checking through all stages of the receiver. The Wiring Diagram, as usual, is numbered, indicating all important parts. These numbers correspond with the parts layout shown in Fig. (6). In addition, the range switch wafers are shown on the schematic diagram. The contacts on each wafer are lettered and numbered to indicate their connection points in the schematic diagram, which are also lettered and numbered. The physical drawings of each coil used in the receiver are also shown on schematic diagram Fig. (5). The connections of these coils are numbered on the coil itself and on the schematic diagram.

Fig. 1 shows the Voltage measurements taken from the bottom of the sockets at each contact. In Fig. 2, the correct position of the dial indicator, for proper adjustment of the compensators is shown. Fig. 3, and 4, are the location of the I. F. and R. F. compensators respectively.

The Model 37-610 code 121 receiver is used in cabinets type B and J. In code 122 receiver, Type T cabinet is used. This receiver differs from code 121, only in the rectifier socket mounting and power transformer. The socket is placed adjacent to the 6F6G output tube and power transformer (Part No. 32-7626) is used. Location of rectifier socket is shown in Figs. 1 and 6.

Electrical Specifications

Voltage Rating) 115 Volts. A. C.
Frequency Rating: 50-60 and
For 25 to 40 cycle operation, use Power Transformer marked with asterisk in parts list.
Power Consumption: 60 Watts.
Type and Number of Tubes: 1 type 6A8G, Detector-Oscillator; 1 type 6K7G, I. F.; 1 type 6Q7G; 2nd Detector, A. V. C. and 1st audio; 1 type 6F6G, Output; and 1 type 5Y4G Rectifier.

Undistorted Output: 3 Watts.
Type Circuit: Superheterodyne with Pentode Output.
Intermediate Frequency: 470 K. C.
Tuning Ranges: 3. Range 1; 530 to 1720 Kilocycles.
Range 2; 2.3 to 7.4 Megacycles.
Range 3; 7.35 to 22 Megacycles.
Speaker Code: 121.—HS.
Speaker Code: 122.—S7.

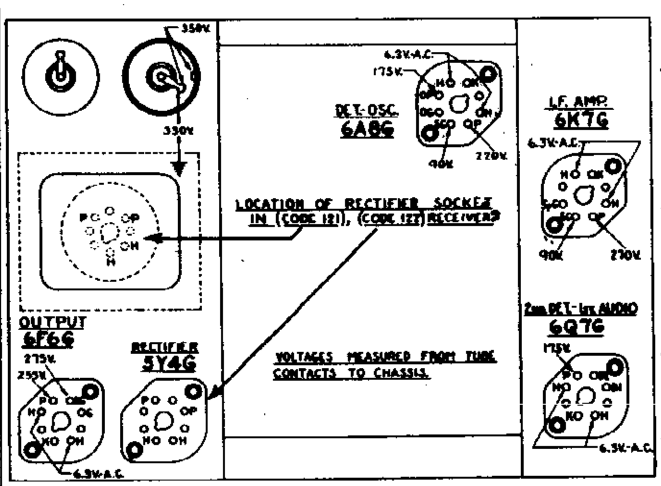

Fig 1—Tube Socket Voltages Viewed from Underside of Chassis

The Voltages Indicated by Arrows were Measured with a PHILCO 025 CIRCUIT TESTER which contains a 1000 ohm per volt Voltmeter. Range Switch in Broadcast Position. 115 volt line.

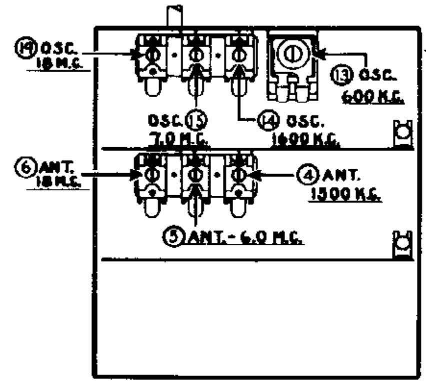

Fig. 4—Locations of R.F. Compensators Underside of Chassis

Alignment of Compensators

The accurate adjustment of the various compensating condensers is vital to the proper functioning of this receiver. There are four compensating condensers in the I. F. Circuit, four in the Oscillator Circuit, and three in the Antenna Circuit. Incorrect adjustment will cause loss of sensitivity, unsatisfactory tone, and poor selectivity.

To accurately adjust this receiver, precision test equipment is necessary. A signal generator such as the PHILCO MODEL 088 SIGNAL GENERATOR, covering from 110 to 20000 K. C. is recommended to adjust the compensators at the various frequencies specified. A visual indication of the receiver output is also necessary to obtain correct adjustment of the compensators. PHILCO MODEL 025 CIRCUIT TESTER contains a sensitive output meter and is recommended for these adjustments.

Philco Fibre Wrench No. 3164 and Fibre Handle Screw-driver No. 27-7059 complete the necessary equipment for these adjustments. The locations of the various compensators are shown in Figs. 3 and 4.

The following procedure must be observed in adjusting the compensators:—

DIAL ADJUSTMENT—In order to adjust this receiver correctly, the dial must be aligned to track properly with the tuning condenser. To do this, rotate the tuning condenser control to the extreme counter-clockwise position (maximum capacity). Loosen the set screw of dial hub, then turn dial until the glowing indicator is centered between the index lines of dial scale (see Fig. 2). Now tighten the dial hub set screw in this position.

OUTPUT METER—The 025 Output Meter is connected to the plate and cathode terminals of the (6F6G) tube. Adjust the meter to use the (0-30) volt scale.

Before adjusting the compensators of each circuit, the signal generator attenuator should be set to give approximately ¼ scale reading on output meter.

INTERMEDIATE FREQUENCY CIRCUIT

Frequency 470 K. C.

1 Connect the 088 signal generator output lead through a .1 mfd. condenser to the control grid of the 6A8G and the ground connection of output lead to the chassis.
2 The tuning range switch is set in position No. 1 (Broadcast). Rotate the tuning condenser of receiver to the maximum capacity position (counter-clockwise), and adjust the signal generator for 470 K. C.
3 Adjust compensators (29) 2nd I. F. Sec., (28) 2nd I. F. Pri., (26) 1st I. F. Sec. and (25) 1st I. F. Pri. for maximum reading on output meter.

RADIO FREQUENCY CIRCUIT

Tuning Range—7.3 to 22.0 M. C.

1 Remove the signal generator output lead from grid of 6A8G tube and connect it through a 0.1 mf. condenser to terminal No. 1 on aerial input panel, rear of chassis. Connect generator ground lead to chassis. Terminals 2 and 3 of aerial input panel must be connected with connector link provided on the panel.
2 Set tuning range switch in position No. 3. Turn signal generator and receiver dial to 18.0 M. C. and adjust compensators (19) osc., and (6) ant. for maximum output.
The adjustment of the antenna compensator on the high frequency range causes a slight detuning of the oscillator circuit. In order to overcome this detuning effect, connect a variable condenser of approximately 350 mmf., having a good vernier drive, across the oscillator section of the tuning condenser. Leaving the signal generator and receiver dials at 18.0 M.C., tune the added condenser so that the second harmonic of the receiver oscillator will beat against the signal from the 088 signal generator. The antenna compensator (6) should then be adjusted to give maximum output. Now remove the external condenser and turn compensator (19) to maximum capacity (clockwise) then without moving signal generator or receiver tuning condenser, back off compensator (19) (counter-clockwise) until a second peak is reached on the output meter. Note:—The first peak is caused by tuning to the image signal and must be neglected.

Tuning Range: 2.3 to 7.4 Megacycles.

1 Turn range switch to position No. 2 (Police). Rotate signal generator and receiver dials to 7.0 M.C. Then adjust compensator (15) for maximum output. Now turn signal generator and receiver dials to 6.0 M.C. and adjust compensator (5) for maximum reading on output meter.

Tuning Range: 530 to 1720 Kilocycles.

1 Set range switch in position No. 1 (standard broadcast). The 088 signal indicator is set at 800 K. C. and the receiver dial at 1600 K. C.
(a) In adjusting the receiver at 1600 K. C., the second harmonic of 800 K. C., to which the signal generator is tuned, is used.
Now adjust compensator (14) osc., (4) ant. for maximum output.
2 The low frequency end of the band is now tuned by turning signal generator and receiver dials to 600 K. C. and adjust compensator (13) for maximum output. When compensator (13) osc. series is being adjusted, the tuning condenser must be rolled for maximum output. This is accomplished as follows: First tune compensator (13) for maximum output. Then vary the tuning condenser for maximum output about 600 K. C. Now retune compensator (13), and again vary the tuning condenser back and forth at 600 K. C. for maximum output. This operation of first tuning the compensator, then the tuning condenser is continued until maximum output is obtained at the 600 K. C. frequency.
3 After the low frequency (600 K. C.) end of range 1 is adjusted, the 1600 K. C. end is re-adjusted, as given in Paragraph 1 above, to correct any variation that the low frequency series compensator may have caused in the alignment of the high frequency end.
4 Now turn signal generator and receiver dial to 1500 K. C. and re-adjust compensator (4) for maximum output.

Alignment

PHILCO RADIO & TELEV. CORP.

Alignment of Compensators

To accurately adjust this receiver, precision test equipment is necessary. A signal generator such as the **Philco Model 088 Signal Generator**, covering from 110 to 20,000 K.C. is recommended to adjust the compensators at the various frequencies specified. A visual indication of the receiver output is also necessary to obtain correct adjustment of the compensators. **Philco Model 025 Circuit Tester** contains a sensitive output meter and is recommended for these adjustments. Philco Fibre Handle Screw-driver No. 27-7050 and Tuning Condenser Part No. 45-2325 complete the necessary equipment for these adjustments. The locations of the various compensators are shown in Figs. 2 and 3.

The following procedure must be observed in adjusting the compensators:—

DIAL ADJUSTMENT—In order to adjust this receiver correctly, the dial must be aligned to track properly with the tuning condenser. To do this, rotate the tuning condenser control to the extreme counter-clockwise position (maximum capacity). Loosen the set screw of dial hub, then turn dial until the glowing indicator is centered between the index lines of dial scale. Now tighten the dial hub set screw in this position.

OUTPUT METER—The 025 Output Meter is connected to the plate and cathode terminals of the (25A6G) tube. Adjust the meter to use the (0-30) volt scale.

INTERMEDIATE FREQUENCY CIRCUIT

Frequency 470 K. C.

1. Connect the 088 Signal Generator output lead through a .1 mfd. condenser to the control grid of the 6A8G, and the ground connection of output lead to the chassis.

2. The tuning range switch is set in position No. 1 (Broadcast). Rotate the tuning condenser of the receiver to the maximum capacity position (counter-clockwise), and adjust the signal generator for 470 K. C.

3. Adjust compensators (**23S**) 2nd I. F. Sec., (**23P**) 2nd I. F. Pri., (**20S**) 1st I. F. Sec. and (**20P**) 1st I. F. Pri. for maximum reading on the output meter.

RADIO FREQUENCY CIRCUIT

Tuning Range—7.3 to 22.0 M. C.

1. Remove the signal generator output lead from the grid of the 6A8G tube and connect it with the .1 mfd. condenser to terminal No. 1 on the aerial input panel and the generator ground lead to terminal No. 3, rear of chassis. Terminals 2 and 3 must be connected by the shorting link provided on the panel.

2. Set the range switch in position 3. Turn the receiver and signal generator dials to 18 M. C. Now adjust compensator (**9B**) by turning the screw (clockwise) to the maximum capacity position, then slowly turning it (counter-clockwise) until a second peak signal is reached on the output meter. The first peak from maximum capacity is the image signal and must not be used. If the above procedure is correctly performed, the image signal will be found at 17.06 M. C., by advancing signal generator attenuator and turning receiver dial to this frequency mark on the scale.

3. The antenna compensator (**5B**) is now adjusted by connecting a variable condenser of approximately 350 mmfd., Philco Part No. 45-2325, across the oscillator section of the gang condenser and ground. Leaving the signal generator and receiver dials at 18 M. C. tune the added condenser from the maximum capacity point until the second harmonic of the receiver oscillator beats against the signal from the generator thereby bringing in the signal. The antenna compensator (**5B**) is then adjusted for maximum output. Now remove the external condenser and readjust compensator (**9B**) as given in paragraph 2 above.

Tuning Range: 2.3 to 7.4 Megacycles.

1. Turn the range switch to position No. 2 (Police). Rotate the signal generator and receiver dials to 7.0 M. C. Then adjust compensator (**9A**) for maximum output. Now turn the signal generator and receiver dials to 6.0 M. C. and adjust compensator (**5A**) for maximum reading on output meter.

Tuning Range: 530 to 1720 Kilocycles.

1. Set the range switch in position No. 1 (Broadcast). Rotate the signal generator and receiver dials to 1600 K. C. Now adjust compensators (9) Osc., and (5) Ant. for maximum output.

2. Rotate the signal generator and receiver dials to 580 K. C. Compensator (10) Osc. series is now adjusted for maximum output as follows:

First tune compensator (10) for maximum output, then vary the tuning condenser of the receiver for maximum output about the 580 K. C. dial mark. Now turn the compensator (10) slightly to the right or left and vary the receiver tuning condenser for maximum output. If the output reading increases, turn compensator (10) in the same direction a trifle more, and again vary the tuning condenser for maximum output. If the output decreases, set the compensator in the opposite direction. This procedure of first setting the compensator and then varying the tuning condenser is continued until there is no further gain in output reading.

3. Readjust compensator (9) for maximum output, by turning signal generator and receiver dials to 1600 K. C.

4. Turn the signal generator and receiver dials to 1500 K. C. and adjust compensator (5) Ant. for maximum output.

Electrical Specifications

Voltage Rating: 115 Volts AC.

Frequency Rating: 50 to 60 cycles.
For 25 to 40 cycle operation, the Power Transformer marked with asterisk in the parts list is used.

Power Consumption: 65 Watts

Types and Number of Tubes: 2 type 6K7G, R. F. and I. F. Amplifiers; 1 type 6A8G, Detector-Oscillator; 1 type 6Q7G, 2nd Detector, Automatic Volume Control and 1st Audio; 1 type 6F6G, Output; and 1 type 5Y4G Rectifier.

Undistorted Output: 3 watts.

Intermediate Frequency: 470 K. C.

Tuning Ranges: Three, Range 1.—530 to 1720 Kilocycles; Range 2.—2.3 to 7.4 Megacycles; Range 3.—7.35 to 22 Megacycles.

Speakers: B Cabinet—S-7.
J Cabinet—HS.

General Description

Model 37-620 is a 6 tube superheterodyne receiver for operation on alternating current, having three tuning ranges, covering standard broadcast and short-wave frequencies, and using the new Philco High-Efficiency self-centering glass tubes.

The circuit includes the Philco "Foreign Tuning System"—controlled by the tuning range switch—which provides maximum sensitivity and noise reduction, when used with the **Philco High Efficiency Aerial** supplied with the receiver. One stage of Radio Frequency amplification which greatly increases the signal-to-noise ratio, automatic bass compensation in the volume control circuit, and a separate diode circuit for automatic volume control are also incorporated in this receiver.

The red and black leads of the High-Efficiency Aerial "transmission line" are connected to terminals 1 and 2 respectively, of the terminal panel provided at the rear of the chassis. Connect the jumper on the terminal panel across terminals 3 and 4.

If a temporary aerial is used, the jumper should be across terminals 2 and 3. The aerial connects to terminal 1 and the ground to terminal 3.

A good ground connection is desirable in all installations. Make the ground connection from the nearest water or radiator pipe to terminal 3 on the terminal panel.

CONSTRUCTION

The chassis is constructed in three basic assembly units, concentrating each circuit in a single unit.

(1) The Radio Frequency unit, located in the center of the chassis, contains a 6K7G tube which functions as a Radio Frequency Amplifier; a 6A8G tube, for the Detector-Oscillator circuit; individual Antenna, R. F. Amplifier and Oscillator coils for each tuning range; selector switch; compensating condensers for all coils; and other parts necessary for the associated circuits. The unit is separately mounted on rubber grommets, cushioning it from the main chassis.

(2) The Intermediate Frequency unit, mounted on the right hand side of the chassis (facing front of set) consists of the Intermediate Frequency transformers, compensating condensers, a 6K7G tube for the I. F. Amplifier stage, and a 6Q7G tube as the second detector—automatic volume control and first audio stage. All voltages supplied to the I. F. and R. F. units are furnished from a terminal strip mounted on this unit.

(3) The Power Pack and Audio Output circuits, together with the required voltage dividers and filter condensers are mounted in the power unit. This unit contains a 6F6G tube and a 5Y4G tube for the Power output and rectifier circuits respectively; and the combined tone control and power switch. The socket for the 5Y4G tube is mounted on the power transformer.

Schematic Diagram Fig. 5 is numbered, indicating all important parts. These numbers correspond with the parts layout shown in Fig. 6. In addition, the range switch wafers are shown on the schematic diagram. The contacts on each wafer are lettered and numbered to indicate their connection points in the schematic diagram, which are also lettered and numbered. The physical drawings of each coil used in the receiver are also shown on schematic diagram Fig. 5. The connections of these coils are numbered on the coil Drawing and on the schematic diagram.

Fig. 1 shows the Voltage measurements taken from the bottom of the sockets at each contact. In Fig. 2, the correct position of the dial indicator, for proper adjustment of the compensator condenser is shown. Fig. 3 and 4 are the locations of the I. F. and R. F. compensators respectively.

This receiver is used in cabinets type B and J. These instructions, however, will cover both types.

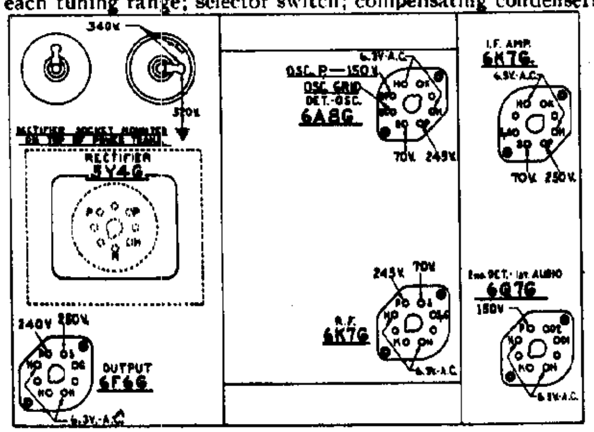

Fig. 1—Socket Voltages
Measured from Socket Contact to Ground
Underside of Chassis View

The voltages indicated by arrows were measured with a **Philco 025 Circuit Tester** which contains a voltmeter having a resistance of 1000 ohms per volt. Volume Control at minimum. Range Switch in broadcast position. Line voltage 115 A. C.

POWER TRANSFORMER DATA

Lead No. Shown on Schematic	A.C. Volts	Current	Circuit	Color	Resistance
1-2	120	—	Pri.	White	5 ohms
3-4	5.0	2.0 A.	Fil. Rectifier	Blue	.1 ohm
5-7	670	70 Ma.	High Voltage Sec.	Yellow	145 ohms 155 ohms
6	—	—	Center Tap of 5-7	—	—
8-9	6.7	2.1 A.	Fil.	Black	.1 ohm

Run 2.

While the circuit arrangement remains the same, the position of the parts is slightly changed in this Run. Bakelite condenser 49 Part No. 3793-DG is removed from front and placed in the rear of the chassis. Tubular condenser 49 Part No. 30-4380 is replaced with a Part No. 8318-SU bakelite condenser, placed in the position formerly held by 3793-DG.

PHILCO RADIO & TELEV. CORP.

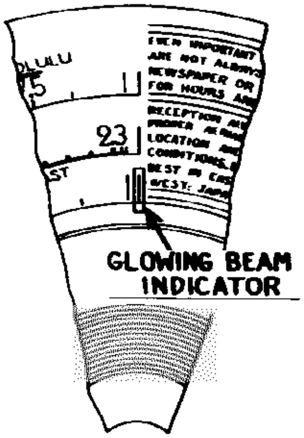

Fig. 2—Dial Calibration

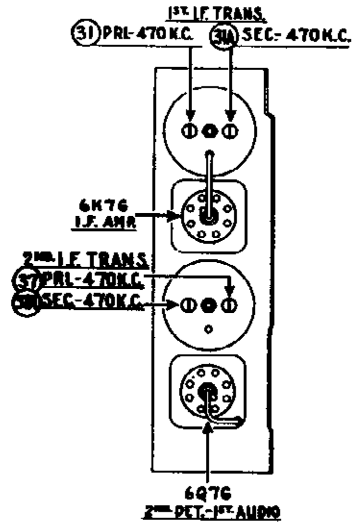

Fig. 3—Locations of I. F. Compensators

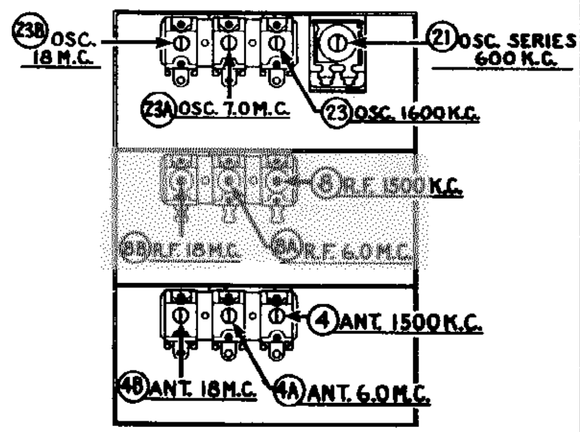

Fig. 3—Locations of R. F. Compensators

Adjustment of Compensators

The accurate adjustment of the various compensating condensers is vital to the proper functioning of this receiver. There are four compensating condensers in the I. F. Circuit, four in the Oscillator Circuit, three in the R. F. Amplifier Circuit and three in the Antenna Circuit. Incorrect adjustment will cause loss of sensitivity, unsatisfactory tone, and poor selectivity.

To accurately adjust this receiver, precision test equipment is necessary. A signal generator such as the PHILCO MODEL 088 SIGNAL GENERATOR, covering from 110 to 20,000 K. C. is recommended for adjusting the compensators at the various frequencies specified. A visual indication of the receiver output is also necessary to obtain correct adjustment of the compensators. PHILCO MODEL 025 CIRCUIT TESTER contains a sensitive output meter and is recommended for these adjustments.

Philco Fibre Handle Screw-driver No. 27-7059 completes the necessary equipment for these adjustments. The locations of the various compensators are shown in Figs. 3 and 4.

The following procedure must be observed in adjusting the compensators:—

DIAL CALIBRATION—In order to adjust this receiver correctly, the dial must be aligned to track properly with the tuning condenser. To do this, rotate the tuning condenser control to the extreme counter-clockwise position (maximum capacity). Loosen the screw of dial hub, then turn dial until the glowing indicator is centered on the first index line of dial scale (see Fig. 2). Now tighten the dial hub set screw in this position.

OUTPUT METER—The 025 Output Meter is connected to the plate and cathode terminals of the (6F6G) tube. Adjust the meter to use the (0-30) Volt Scale.

During the I. F. and R. F. adjustments, the signal generator output should be maintained at the lowest possible level that will give indication on the output meter.

INTERMEDIATE FREQUENCY CIRCUIT

Frequency 470 K. C.

1 Connect the 088 Signal Generator output lead, through a .1 mfd. condenser, to the control grid of the 6A8G tube; and the ground connection of the output lead to the chassis.

2 Set the range switch in position No. 1 (Broadcast), then rotate the tuning condenser of the receiver to the maximum capacity position (counter-clockwise), and adjust the signal generator for 470 K. C.

3 Adjust compensators (37)a 2nd I. F. Sec., (37) 2nd I. F. Pri., (31)a 1st I. F. Sec., and (31) 1st I. F. Pri. for maximum reading on output meter.

RADIO FREQUENCY CIRCUIT

Tuning Range—7.3 to 22.0 M. C.

1 Remove the signal generator output lead from the grid of 6A8G tube, and connect it through a .1 mfd. condenser to terminal No. 1 on aerial input panel, and the generator ground lead to terminal No. 3, rear of chassis.

(a) Terminals 2 and 3 of aerial input panel must be connected with connector link provided on the panel, during these adjustments.

2 Set the tuning range switch in position No. 3 (Short Wave). Turn the signal generator and receiver dials to 18. M. C. and adjust compensators (23)b Osc., (8)b R. F. and (4)b Ant. for maximum output. (See Note (a) below).

(a) The adjustment of the Radio Frequency compensator on the high frequency range causes a slight detuning of the oscillator circuit. In order to overcome this detuning effect, connect a variable condenser of approximately 350 mmfd., having a good vernier drive, across the oscillator section of the tuning condenser. Leaving the signal generator and receiver dials at 18 M. C., tune the added condenser so that the second harmonic of the receiver oscillator will beat against the signal from the 088 signal generator bringing in the signal. The antenna and R. F. compensator (4)b and (8)b should then be adjusted to give maximum output. Now remove the external condenser and turn compensator (23)b to maximum capacity (clockwise) then without moving signal generator or receiver tuning condenser, back off compensator (23)b (counter-clockwise) until a second peak is reached on the output meter. The first peak is caused by tuning to the image frequency signal and must not be used.

Tuning Range 2.3 to 7.4 M. C.

1 Turn the range switch to position No. 2 (police). Rotate the signal generator and receiver dials to 7.0 M. C. Then adjust compensator (23)a for maximum output. Now turn the signal generator and receiver dials to 6.0 M. C. and adjust compensators (8)a R. F. and (4)a Ant. for maximum reading on the output meter.

Tuning Range 530 to 1720 K. C.

1 Set the range switch in position No. 1 (Broadcast). Set the 088 Signal Generator indicator at 800 K. C. and the receiver dial at 1600 K. C.

(a) In adjusting the receiver at 1600 K. C. the second harmonic of 800 K. C., to which the signal generator is tuned, is used. The second harmonic of 800 K. C. is 1600 K. C. Now adjust compensators (23) Osc., (8) R. F. and (4) Ant. for maximum reading on output meter.

2 The low frequency end of the range is now tuned by turning the signal generator and receiver dials to 600 K. C. and adjusting compensator (21) Osc. Series—(see Note (a) below)—for maximum reading on output meter.

(a) While compensator (21) is being adjusted, the tuning condenser must be rolled for maximum output. This is accomplished as follows:—First tune compensator (21) for maximum output. Then vary the tuning condenser for maximum output at 600 K. C. Now retune compensator (21), and again vary the tuning condenser back and forth at 600 K. C. for maximum output. This operation of first turning the compensator then the tuning condenser is continued until maximum output is obtained at the 600 K. C. frequency.

3 After the low frequency (600 K. C.) end of the range is adjusted, the 1600 K. C. end is readjusted, as given in Paragraph (1) above, to correct any variation that the low frequency series compensator may have caused in the alignment of the high frequency end.

4 Now turn the signal generator and receiver dials to 1500 K. C. and readjust compensators (4) ant., and (8) R. F., for maximum output.

MODEL 37-623
Chassis, Voltage
Socket, Trimmers
Alignment

PHILCO RADIO & TELEV. CORP.

Electrical Specifications

Type of Circuit: Superheterodyne; battery operated; with class "B" output, the Philco Automatic Aerial Tuning System and built in connections for the Philco High Efficiency Aerial.

Batteries Required: "A"—Philco 172-R two volt storage battery or a dry "A" battery **Philco Part** No. 41-8011. If a dry "A" battery is used, a ballast lamp PHILCO type 1F1 must be inserted in the socket provided in the dry "A" battery. This lamp acts as a voltage regulator, and maintains a constant potential of two volts on the filaments of the receiver tubes.

"BC" Philco battery Part No. 41-8007 is used to supply B and C voltage. This battery contains a socket into which the receiver battery cable plug is inserted.

Current Drain: A Battery, 720 M.A.; B Battery, 21 M.A.

Philco Tubes Used: R. F. Amp. 1D5G, Det.—Osc. 1C7G I. F. Amp. 1D5G, 2nd Det. A. V. C.; 1st audio; 1F7G, Driver 1H4G, Output 1J6G.

Frequency Ranges: Range 1—530 to 1720 K. C.; Range 2—2.3 to 7.4 M. C.; Range 3—7.35 to 22 M. C.

Intermediate Frequency: 470 K. C.

Speakers: KR-17-"B" Cabinet HR-12-"J" Cabinet

Alignment of the Compensators

To accurately adjust this receiver, precision test equipment is necessary. A signal generator such as the **Philco Model 088** Signal Generator, covering from 110 to 20,000 K. C. is recommended for use in adjusting the compensators at the various frequencies specified. A visual indication of the receiver output is also necessary to obtain correct adjustment of the compensators. **Philco Model 025** Circuit Tester contains a sensitive output meter and is recommended for these adjustments.

Philco Fibre Handle Screw-Driver No. 27-7059 and Variable Condenser Part No. 45-2325 complete the necessary equipment for these adjustments. The locations of the various compensators are shown in Figs. 2 and 3.

The following procedure must be observed in adjusting the compensators:—

DIAL ADJUSTMENT—The tuning condenser is set at the maximum capacity position, by turning the tuning knob counter-clockwise. Loosen the set screw of dial hub and set dial, with Glowing Indicator centered between the first and second index lines at the low frequency end of the broadcast scale.

OUTPUT METER—The 025 Output Meter is connected between one of the plate prongs of the 1J6G tube and the chassis. Then adjust the meter to use the (0-30) volt scale.

INTERMEDIATE FREQUENCY CIRCUIT

Frequency 470 K. C.

1. Connect the 088 Signal Generator output lead, through a .1 mfd. condenser to the control grid of the 1C7G tube, and the ground connection of the output lead to the chassis.
2. Set the range switch in position No. 1 (Broadcast). Rotate the tuning condenser of the receiver to approximately 580 K. C. Then adjust the signal generator for 470 K. C.
3. Adjust compensators (30S), (30P), (28S), and (28P) for maximum output, see Fig. 2.

RADIO FREQUENCY CIRCUIT

Tuning Range (7.35 to 22 M. C.)

1. Remove the signal generator output lead from the grid of the 1C7G, and connect it through the .1 mfd. condenser to terminal No. 1 on the aerial input panel. Connect the generator ground lead to terminal No. 3. Terminals 2 and 3 of the aerial input panel must be shorted with the connector link provided on the panel during the following adjustments.
2. Set the range switch in position No. 3 (extreme clockwise). Turn the signal generator and receiver dials to 20 M. C.
3. Now adjust compensator (20B) by turning the screw (clockwise) to the maximum capacity position, then slowly turn it counter-clockwise until a second maximum peak is reached on the output meter. The first peak from maximum capacity is the image signal and the receiver must not be adjusted to it. **NOTE:** In adjusting some receivers only one peak will be observed, therefore tune the compensator to maximum on this peak. If the above procedure is correctly performed, the image signal will be found at 19.060 M. C., by advancing the signal generator input, and turning the receiver dial to this frequency mark on the scale.
4. Leaving the signal generator and receiver dials at 20 M. C. the antenna and R. F. compensators (4B) and (16B) are now adjusted, by connecting a variable condenser (Philco Part No. 45-2325) across the oscillator compensator (20B) contact (first contact from the left side of the receiver facing rear underside view of the chassis) and ground. Now tune the added condenser until the second harmonic of the receiver oscillator beats against the signal from the generator, resulting in a maximum indication on the output meter. **NOTE:** It may be necessary to increase the signal generator output to obtain a signal of sufficient strength for reading on the output meter. Compensators (4B) and (16B) are now adjusted for maximum output. After these adjustments, remove the external condenser and readjust compensator (20B) as given in paragraph 3 above.

Tuning Range 2.3 to 7.4 M. C.

1. Turn the range switch to position No. 2 (middle range). Rotate the signal generator and receiver dials to 7.0 M. C. Then adjust compensator (20A) for maximum output.
2. Now turn the signal generator and receiver dials to 6 M. C. and adjust compensators (4A) Ant., and (16A) R. F. for maximum output.

Tuning Range 530 to 1720 K. C.

1. Turn the range switch to position No. 1 (Broadcast). Set the 088 signal generator indicator and the receiver dial to 1600 K. C.

Now adjust compensators (20) osc., (4) ant. and (16) R. F. for maximum output.

2. The low frequency end of this range is now adjusted as follows: Turn the signal generator and receiver dials to 580 K. C. Now tune compensator (19) for maximum output, then vary the tuning condenser of the receiver for maximum output about the 580 K. C. dial mark. Turn compensator (19) slightly to the right or left and vary the receiver turning condenser for maximum output. If the output reading increases, turn compensator (19) in the same direction a trifle more and again vary the tuning condenser for maximum output. This procedure of first setting the compensator, and then varying the tuning condenser, is continued until there is no further gain in the output reading. When a decrease in output is noted turn the compensator in the opposite direction.
3. Set the signal generator and receiver dials as given in Paragraph 1 above and adjust compensator (20) for maximum output.
4. Now turn the signal generator and receiver dials to 1500 K. C. and adjust compensators (4) ant. and (16) R. F. for maximum output.

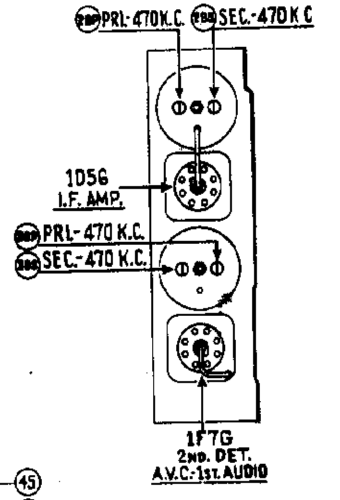

Fig. 2—I. F. Compensators, Top of Chassis

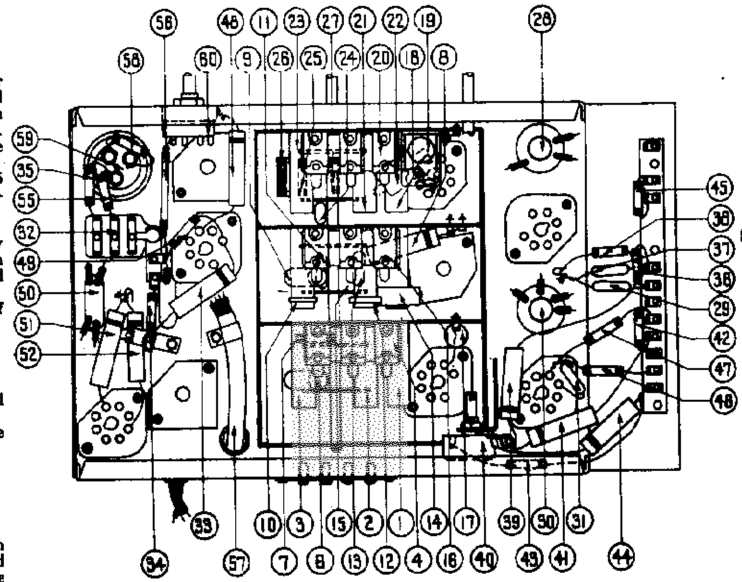

Fig. 4—Parts Location, Under Side of Chassis

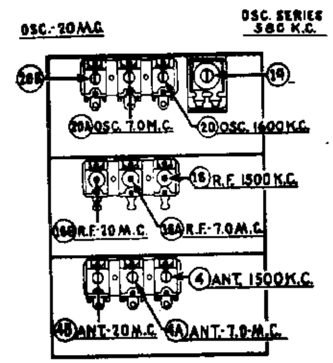

Fig. 3—R. F. Compensators, Under Side of Chassis

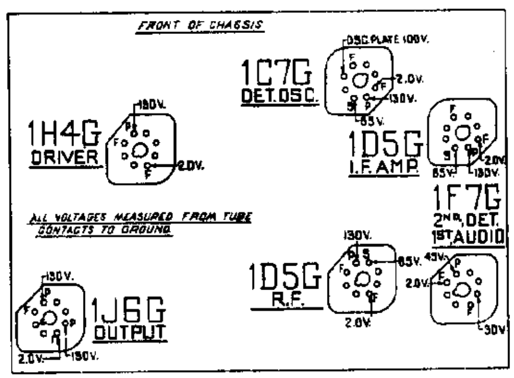

Fig. 1—Socket Voltages Underside of Chassis View

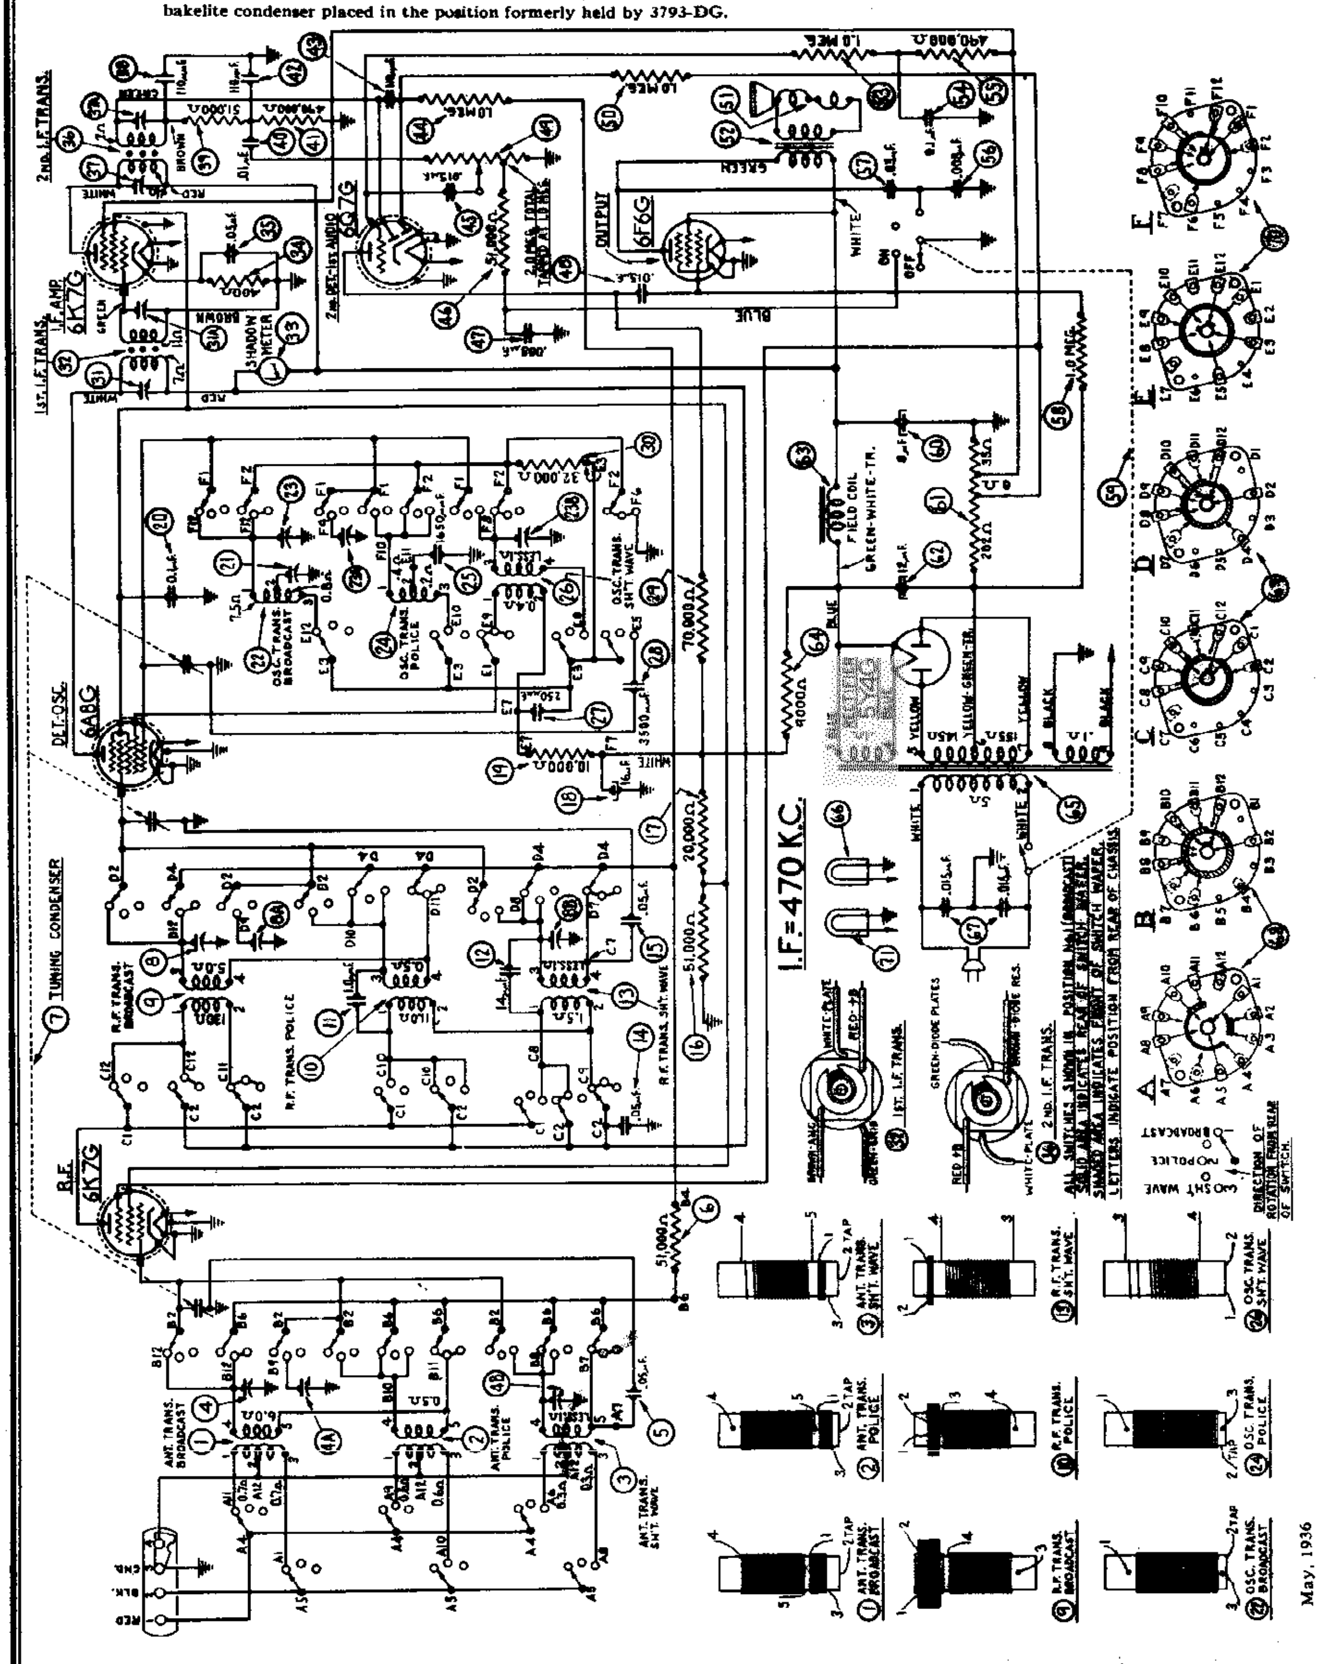
The voltages indicated by arrows were measured with a Philco 025 Circuit Tester which contains a voltmeter having a resistance of 1000 ohms per volt. Volume Control at minimum, range switch in broadcast position.

MODEL 37-630
Schematic, Coils
Change

PHILCO RADIO & TELEV. CORP.

Run 2.

While the circuit arrangement remains the same, the locations of the parts are slightly changed in this Run. Bakelite condenser ⑥ Part No. 3793-DG is removed from front and placed in the rear of the chassis. Tubular condenser ⑮ Part No. 30-4380 is replaced with a Part No. 8318-SU bakelite condenser placed in the position formerly held by 3793-DG.



MODEL 37-630

Alignment

PHILCO RADIO & TELEV. CORP.

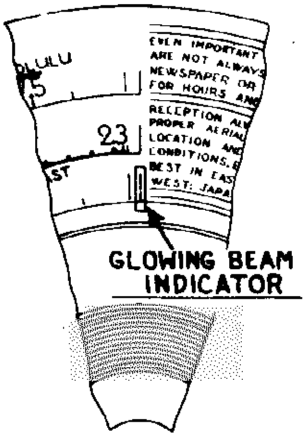

Fig. 2 Dial Calibration

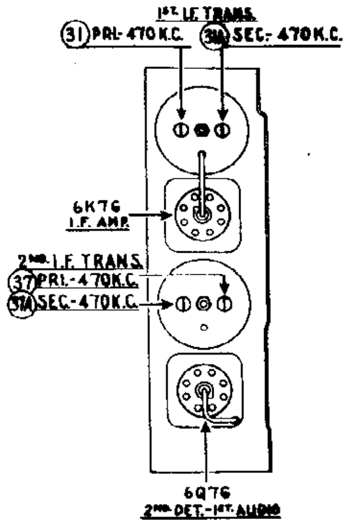

Fig. 3—Locations of I. F. Compensators

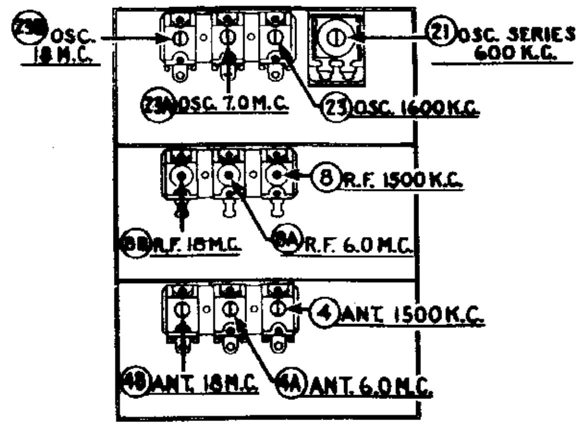

Fig. 4—Locations of R. F. Compensators

Alignment of the Compensators

The accurate adjustment of the various compensating condensers is vital to the proper functioning of this receiver. There are four compensating condensers in the I. F. Circuit, four in the Oscillator Circuit, three in the R. F. Amplifier Circuit and three in the Antenna Circuit. Incorrect adjustment will cause loss of sensitivity, unsatisfactory tone, and poor selectivity.

To accurately adjust this receiver, precision test equipment is necessary. A signal generator such as the PHILCO MODEL 088 SIGNAL GENERATOR, covering from 110 to 20,000 K. C. is recommended for adjusting the compensators at the various frequencies specified. A visual indication of the receiver output is also necessary to obtain correct adjustment of the compensators. PHILCO MODEL 025 CIRCUIT TESTER contains a sensitive output meter and is recommended for these adjustments.

Philco Fibre Handle Screw-driver No. 27-7059 completes the necessary equipment for these adjustments. The locations of the various compensators are shown in Figs. 3 and 4.

The following procedure must be observed in adjusting the compensators:—

Dial Calibration—In order to adjust this receiver correctly, the dial must be aligned to track properly with the tuning condenser. To do this, rotate the tuning condenser control to the extreme counter-clockwise position (maximum capacity). Loosen the screw of dial hub, then turn dial until the glowing indicator is centered on the first index line of dial scale (see Fig. 2). Now tighten the dial hub set screw in this position.

Shadow Meter Adjustment—Remove aerial and allow tubes to warm up. Then adjust shadow meter as follows:

1 Move the Shadow meter coil backwards and forwards, until the shadow is within one eighth of an inch of each side of the screen.
2 Remove the Rectifier tube from its socket, and rotate the shadow meter coil for minimum shadow width.
3 Replace the Rectifier tube. The shadow should then return to maximum width or within one-eighth of an inch of each side of the screen. If the shadow does not return to maximum width, operations 1 and 2 should be continued until it does.

Output Meter—The 025 Output Meter is connected to the plate and cathode terminals of the (6F6G) tube. Adjust the meter to use the (0-30) Volt Scale.

During the I. F. and R. F. adjustments, the signal generator output should be maintained at the lowest possible level that will give an indication on the output meter.

INTERMEDIATE FREQUENCY CIRCUIT

Frequency 470 K. C.

1 Connect the 088 Signal Generator output lead, through a .1 mfd. condenser, to the control grid of the 6A8G tube; and the ground connection of the output lead to the chassis.
2 Set the range switch in position No. 1 (Broadcast), then rotate the tuning condenser of the receiver to the maximum capacity position (counter-clockwise), and adjust the signal generator for 470 K. C.
3 Adjust compensators 37a 2nd I. F. Sec., 37 2nd I. F. Pri., 31a 1st I. F. Sec., and 31 1st I. F. Pri. for maximum reading on output meter.

RADIO FREQUENCY CIRCUIT

Tuning Range—7.3 to 22.0 M. C.

1 Remove the signal generator output lead from the grid of 6A8G tube, and connect it through a .1 mfd. condenser to terminal No. 1 on aerial input panel, and the generator ground lead to terminal No. 3, rear of chassis.
(a) Terminals 2 and 3 of aerial input panel must be connected with connector link provided on the panel, during these adjustments.
2 Set the tuning range switch in position No. 3 (Short Wave). Turn the signal generator and receiver dials to 18 M. C. and adjust compensators 23b Osc., 8b R. F. and 4b Ant. for maximum output. (See Note (a) below).
(a) The adjustment of the Radio Frequency compensator on the high frequency range causes a slight detuning of the oscillator circuit. In order to overcome this detuning effect, connect a variable condenser of approximately 350 mmfd., having a good vernier drive, across the oscillator section of the tuning condenser. Leaving the signal generator and receiver dials at 18 M. C., tune the added condenser so that the second harmonic of the receiver oscillator will beat against the signal from the 088 signal generator bringing in the signal. The antenna and R. F. compensators 4b and 8b should then be adjusted to give maximum output. Now remove the external condenser and turn compensator 23b to maximum capacity (clockwise) then without moving signal generator or receiver tuning condenser, back off compensator 23b (counter-clockwise) until a second peak is reached on the output meter. The first peak is caused by tuning to the image frequency signal and must not be used.

Tuning Range 2.3 to 7.4 M. C.

1 Turn the range switch to position No. 2 (police). Rotate the signal generator and receiver dials to 7.0 M. C. Then adjust compensator 23a for maximum output. Now turn the signal generator and receiver dials to 6.0 M. C. and adjust compensators 8a R. F. and 4a Ant. for maximum reading on the output meter.

Tuning Range 530 to 1720 K. C.

1 Set the range switch in position No. 1 (Broadcast). Set the 088 Signal Generator indicator at 800 K. C. and the receiver dial at 1600 K. C.
(a) In adjusting the receiver at 1600 K. C. the second harmonic of 800 K. C., to which the signal generator is tuned, is used. The second harmonic of 800 K. C. is 1600 K. C. Now adjust compensators 23 Osc., 8 R. F. and 4 Ant. for maximum reading on output meter.
2 The low frequency end of the range is now tuned by turning the signal generator and receiver dials to 600 K. C. and adjusting compensator 21 Osc. Series—(see Note (a) below)—for maximum reading on output meter.
(a) While compensator 21 is being adjusted, the tuning condenser must be rolled for maximum output. This is accomplished as follows:—First tune compensator 21 for maximum output. Then vary the tuning condenser for maximum output at 600 K. C. Now retune compensator 21, and again vary the tuning condenser back and forth at 600 K. C. for maximum output. This operation of first turning the compensator then the tuning condenser is continued until maximum output is obtained at the 600 K. C. frequency.
3 After the low frequency (600 K. C.) end of the range is adjusted, the 1600 K. C. end is readjusted, as given in Paragraph (1) above, to correct any variation that the low frequency series compensator may have caused in the alignment of the high frequency end.
4 Now turn the signal generator and receiver dials to 1500 K. C. and readjust compensators 4 Ant., and 8 R. F., for maximum output.

PHILCO RADIO & TELEV. CORP.

Electrical Specifications

Voltage Rating: 115 Volts A.C.
Frequency Rating: 50 to 60 cycles.
For 25 to 40 cycle operation the Power Transformer marked with asterisk in parts list is used.
Power Consumption: 65 Watts.
Types and Number of Tubes: 2 type 6K7G, R. F. and I. F. Amplifiers; 1 type 6A8G, Detector-Oscillator; 1 type 6Q7G, 2nd Detector, Automatic Volume Control and 1st Audio; 1 type 6F6G, Output; and 1 type 5Y4G Rectifier.
Undistorted Output: 3 watts.
Intermediate Frequency: 470 K. C.
Tuning Ranges: Three. Range 1.—530 to 1720 Kilocycles; Range 2.—2.3 to 7.4 Megacycles; Range 3.—7.35 to 22 Megacycles.
Speakers: X Cabinet—H24
T Cabinet—K38

Speaker Wiring

When replacing any part of the speaker, the hum bucking coil connections should be connected for minimum hum.

General Description

Model 37-630 is a 6 tube superheterodyne receiver for operation on alternating current, having three tuning ranges, covering standard broadcast and short-wave frequencies, and using the new Philco High-Efficiency self-centering glass tubes.

The circuit includes the Philco "Foreign Tuning System" controlled by the tuning range switch which provides maximum sensitivity and noise reduction, when used with the **Philco High Efficiency Aerial** supplied with the receiver. One stage of Radio Frequency amplification which greatly increases the signal to noise ratio, automatic bass compensation in the volume control circuit, shadow tuning and a separate diode circuit for automatic volume control are also incorporated in this receiver.

The red and black leads of the High-Efficiency Aerial "transmission line" are connected to terminals 1 and 2 respectively, of the terminal panel provided at the rear of the chassis. Connect the jumper on the terminal panel across terminals 3 and 4.

If a temporary aerial is used, the jumper should be across terminals 2 and 3. The aerial connects to terminal 1 and the ground to terminal 3.

A good ground connection is desirable in all installations. Make the ground connection from the nearest water or radiator pipe to terminal 3 on the terminal panel.

The chassis is constructed in three basic assembly units, concentrating each circuit in a single unit.

The Radio Frequency unit, located in the center of the chassis, contains a 6K7G tube which functions as a Radio Frequency Amplifier; a 6A8G tube, for the Detector-Oscillator circuit; individual Antenna, R. F. Amplifier and Oscillator coils for each tuning range; selector switch; compensating condensers for all coils; and other parts necessary for the associated circuits. The unit is separately mounted on rubber grommets, cushioning it from the main chassis.

The Intermediate Frequency unit, mounted on the right hand side of the chassis (facing front of set) consists of the Intermediate Frequency transformers, compensating condensers, a 6K7G for the I. F. Amplifier stage, and a 6Q7G tube as the second detector—automatic volume control and first audio stage. All voltages supplied to the I. F. and R. F. units are furnished from a terminal strip mounted in this unit.

The Power Pack and Audio Output circuits, together with the required voltage dividers and filter condensers are mounted in the power unit. This unit contains a 6F6G tube and a 5Y4G tube for the Power Output and Rectifier Circuits respectively, and the combined tone control and power switch.

Schematic Diagram, Fig. 5, is numbered, indicating all important parts. These numbers correspond with the parts layout shown in Fig. 6. In addition, the range switch wafers are shown on the schematic diagram. The contacts on each wafer are numbered and lettered to indicate their connection points in the schematic diagram, which are also lettered and numbered. The physical drawings of each coil used in the receiver are also shown on schematic diagram Fig. 5. The connections of these coils are numbered on the coil drawing and on the schematic diagram.

Fig. 1 shows the Voltage measurements taken from the bottom of the socket at each contact. In Fig. 2, the correct position of the dial indicator, for proper adjustment of the compensator condenser is shown. Fig. 3 and 4 are the locations of the I. F. and R. F. compensators respectively.

This receiver is used in cabinets type X code 121 and type T code 122. These instructions, however, will cover both types.

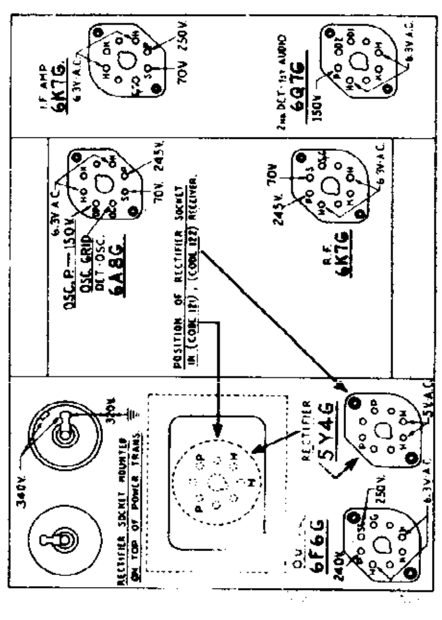

Fig. 1. Socket Voltages
Measured from Socket Contact to Ground
Underside of Chassis View

The voltages indicated by arrows were measured with a **Philco 025 Circuit Tester** which contains a voltmeter having a resistance of 1000 ohms per volt. Volume Control at minimum. Range Switch in broadcast position. Line voltage 115 A.C.

Alignment

Alignment of Compensators

The accurate adjustment of the various compensating condensers is vital to the proper functioning of this receiver. There are four compensating condensers in the I. F. Circuit, four in the Oscillator Circuit, three in the R. F. Amplifier Circuit and three in the Antenna Circuit. Incorrect adjustment will cause loss of sensitivity, unsatisfactory tone, and poor selectivity.

To accurately adjust this receiver, precision test equipment is necessary. A signal generator such as the PHILCO MODEL 088 SIGNAL GENERATOR, covering from 110 to 20,000 K. C. is recommended for adjusting the compensators at the various frequencies specified. A visual indication of the receiver output is also necessary to obtain correct adjustment of the compensators. PHILCO MODEL 025 CIRCUIT TESTER contains a sensitive output meter and is recommended for these adjustments.

Philco Fibre Handle Screw-driver No. 27-7059 completes the necessary equipment for these adjustments. The locations of the various compensators are shown in Figs. 6 and 7.

The following procedure must be observed in adjusting the compensators:

DIAL CALIBRATION—In order to adjust this receiver correctly, the dial must be aligned to track properly with the tuning condenser. To do this, rotate the tuning condenser control to the extreme counter-clockwise position (maximum capacity). Loosen the screw of dial hub, then turn dial until the glowing indicator is centered on the first index line of dial scale (see Fig. 5). Now tighten the dial hub set screw in this position.

SHADOW METER ADJUSTMENT—Remove aerial and allow tubes to warm up. Then adjust shadow meter as follows:

1—Move the Shadow meter coil backwards and forwards, until the shadow is within one-eighth of an inch of each side of the screen.

2—Remove the Rectifier tube from its socket, and rotate the shadow meter coil for minimum shadow width.

3—Replace the Rectifier tube. The shadow should then return to maximum width or within one-eighth of an inch of each side of the screen. If the shadow does not return to maximum width, operations 1 and 2 should be continued until it does.

OUTPUT METER—The 025 Output Meter is connected to the plate and cathode terminals of one (6F6G) tube. Adjust the meter to use the (0-30) Volt Scale.

During the I. F. and R. F. adjustments, the signal generator output should be maintained at the lowest possible level that will give an indication on the output meter.

INTERMEDIATE FREQUENCY CIRCUIT

Frequency 470 K. C.

1—Connect the 088 Signal Generator output lead, through a .1 mfd. condenser, to the control grid of the 6A8G tube; and the ground connection of the output lead to the chassis.

2—Set the range switch in position No. 1 (Broadcast), then rotate the tuning condenser of the receiver to the maximum capacity position (counter-clockwise), and adjust the signal generator for 470 K. C.

3—Adjust compensators (33)s 2nd I. F. Sec., (33)p 2nd I. F. Pri., (34)s 1st I. F. Sec., and (34)p 1st I. F. Pri. for maximum reading on output meter.

RADIO FREQUENCY CIRCUIT

Tuning Range—7.3 to 22.0 M. C.

1—Remove the signal generator output lead from the grid of 6A8G tube, and connect it through the .1 mfd. condenser to terminal No. 1 on aerial input panel, and the generator ground lead to terminal No. 3, rear of chassis.
(a) Terminals 2 and 3 of aerial input panel must be connected with connector link provided on the panel, during these adjustments.

2—Set the tuning range switch in position No. 3 (Short Wave). Turn the signal generator and receiver dials to 18 M. C. and adjust compensators (23)b Osc., (8)b R. F. and (4)b Ant. for maximum output (see note (a) below).
(a) The adjustment of the Radio Frequency compensator on the high frequency range causes a slight detuning of the oscillator circuit. In order to overcome this detuning effect, connect a variable condenser of approximately 350 mmfd., having a good vernier drive, across the oscillator section of the tuning condenser. Leaving the signal generator and receiver dials at 18 M. C., tune the added condenser so that the second harmonic of the receiver oscillator will beat against the signal from the 088 signal generator bringing in the signal. The antenna and R. F. compensator (4)b and (8)b should then be adjusted to give maximum output. Now remove the external condenser and turn compensator (23)b to maximum capacity (clockwise) then without moving signal generator or receiver tuning condenser, back off compensator (23)b (counter-clockwise) until a second peak is reached on the output meter. The first peak is caused by tuning to the image frequency signal and must not be used.

Tuning Range—2.3 to 7.4 M. C.

1—Turn the range switch to position No. 2 (police). Rotate the signal generator and receiver dials to 7.0 M. C. Then adjust compensator (23)a for maximum output. Now turn the signal generator and receiver dials to 6.0 M. C. and adjust compensators (8)a R. F. and (4)a Ant. for maximum reading on the output meter.

Tuning Range—530 to 1720 K. C.

1—Set the range switch in position No. 1 (Broadcast). Set the 088 Signal Generator indicator at 800 K. C. and the receiver dial at 1600 K. C.
(a) In adjusting the receiver at 1600 K. C. the second harmonic of 800 K. C., to which the signal generator is tuned, is used. The second harmonic of 800 K. C. is 1600 K. C. Now adjust compensators (23) Osc., (8) R. F. and (4) Ant. for maximum reading on output meter.

2—The low frequency end of the range is now tuned by turning the signal generator and receiver dials to 600 K. C. and adjusting compensator (21) Osc. series (see Note (a) below) for maximum reading on output meter.
(a) While compensator (21) is being adjusted, the tuning condenser must be rolled for maximum output. This is accomplished as follows: First tune compensator (21) for maximum output. Then vary the tuning condenser for maximum output at 600 K. C. Now retune compensator (21) and again vary the tuning condenser back and forth at 600 K. C. for maximum output. This operation of first turning the compensator then the tuning condenser is continued until maximum output is obtained at the 600 K. C. frequency.

3—After the low frequency (600 K. C.) end of the range is adjusted, the 1600 K. C. end is readjusted, as given in Paragraph (1) above, to correct any variation that the low frequency series compensator may have caused in the alignment of the high frequency end.

4—Now turn the signal generator and receiver dials to 1500 K. C. and readjust compensators (4) Ant., and (8) R. F., for maximum output.

MODEL 37-640
Voltage, Socket
Transformer Data
Notes

Model 37-640 is a 7 tube superheterodyne receiver for operation on alternating current, having three tuning ranges, covering standard broadcast and short-wave frequencies. The chassis is constructed in three basic assembly units, concentrating the R. F., I. F. and Audio Output circuits in individual units.

The circuit consists of the "PHILCO FOREIGN TUNING SYSTEM"—controlled by the range switch—providing maximum sensitivity and noise reduction, when used with the PHILCO HIGH EFFICIENCY AERIAL. One stage of radio frequency amplification which increases the signal to noise ratio, Automatic Bass Compensation in the volume control circuit, Shadow Tuning, a separate diode circuit for the Automatic Volume Control and a push-pull pentode audio output circuit are also incorporated in this receiver.

Aerial Connections

The Philco High Efficiency Aerial is recommended, for use with this receiver, to obtain maximum performance. A terminal panel is provided at the rear of the chassis for connecting the aerial. This panel contains four screw terminals and a connecting link.

When using the PHILCO HIGH EFFICIENCY AERIAL connect the red and black leads of the Aerial transmission line (lead-in) to terminals 1 and 2 respectively and the ground lead to terminal 3. The connector link should be across terminals 3 and 4.

If a temporary aerial and ground is used shift the connecting link to rest across terminals 2 and 3 and connect the aerial and ground to terminals 1 and 3 respectively.

REMOVING SWITCH AND COIL ASSEMBLIES FROM R. F. UNIT

Remove the center mounting screw on the rear of the R. F. unit. Then lift the rear of the unit and push forward until the rubber mounting grommet, on each side of the unit, clear the mounting slots. The unit is then lifted far enough from the chassis for removal of the two screws holding the selector switch indexing plate and shaft (front of the unit) then pull shaft straight out. Removal of the volume control shaft is also necessary.

IMPORTANT—When selector switch shaft is replaced, care should be taken to have all wafer rotors in the same position so that index projection on the end of shaft will slide freely into notched hole in wafer rotors. Never force shaft into rotors.

AERIAL SWITCH AND COIL ASSEMBLY. FIRST SECTION FROM REAR OF UNIT

a. Remove screw holding shield plate to unit base. This screw is located in the right hand corner of shield plate, facing rear underside of chassis.
b. Unsolder the leads connecting the range switch to the aerial panel and I. F. terminal panel; tubular condenser ⑤ to the tuning condenser stator plate and ground lead from assembly shield to unit frame— lift assembly straight out of unit.

R. F. AMPLIFIER ASSEMBLY, CENTER SECTION

a. Remove screw holding shield plate to unit base.
b. Unsolder the leads connecting the range switch to I. F. terminal panel and 6K7G plate socket contact, tubular condenser ⑮ to the tuning condenser housing, selector switch contact (D2) to the tuning condenser stator plates, tubular condenser ⑭ to shield ground lug and shield to R. F. unit base. The amplifier assembly may then be removed.

OSCILLATOR SWITCH AND COIL ASSEMBLY. THIRD SECTION FROM REAR OF UNIT

a. The oscillator assembly may now be removed by unscrewing the four screws holding shield to R. F. base. These screws are located on each side of the R. F. base.
b. Unsolder the leads connecting range switch to the 6K7G socket contacts and terminal panel in the I. F. unit, condenser ⑰ lead from tuning condenser housing and lead connecting selector switch to the tuning condenser stator plates. Then unsolder wires connecting selector switch to electrolytic condenser ⑯ and 6A8G socket contacts.
Parts are replaced by following the above procedure in the reverse order.

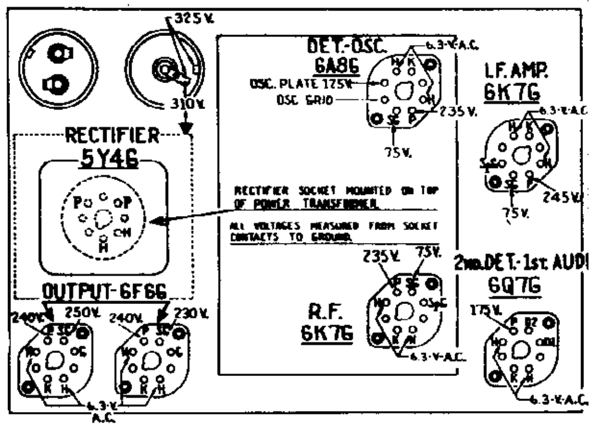

Fig. 1—Socket Voltages Measured from Underside of Chassis

The voltages indicated by arrows were measured with a Philco #2 Circuit Tester which contains a voltmeter having a resistance of 100 ohms per volt. Volume Control at minimum, range switch in broadcas position, line voltage 115 A. C.

Model 37-650

Electrical Specifications

Power Supply:

Voltage	Frequency Cycles	Consumption
115	50-60	110 watts
115	25-40	110 watts

Intermediate Frequency: 470 K. C.

Output: Undistorted 7 watts.

Philco Tubes: 6K7G—R. F. Amplifier; 6A8G—Oscillator and first detector; 6K7G—I. F. Amplifier; 6J5G—2nd Detector, A. V. C.; 6K5G—1st Audio; 2-6F6G—Output; 5Y4G—Rectifier.

Tuning Ranges: Range 1—530 to 1720 K. C.; Range 2—5.7 to 11.6 M. C.; Range 3—11.5 to 18.2 M. C.

Speakers: X Cabinet—H-26; B Cabinet—K-35.

MODEL 37-650

Alignment

PHILCO RADIO & TELEV. CORP.

Alignment of Compensators

The accurate adjustment of the various compensating condensers is vital to the proper functioning of this receiver. There are four compensating condensers in the I. F. Circuit, six in the Oscillator Circuit, five in the R. F. Amplifier Circuit and five in the Antenna Circuit. Incorrect adjustment will cause loss of sensitivity, unsatisfactory tone, and poor selectivity.

The locations of the various compensators are shown in Figs. 5 and 6.

The following procedure must be observed in adjusting the compensators:—

SHADOWMETER ADJUSTMENT

1. Remove the aerial and allow tubes to warm up. Then adjust shadowmeter as follows: Move the coil backward and forward until opposite edges of the shadow are ⅛ of an inch from each end of shadow screen, measuring along bottom edge. Adjustment of the shadowmeter light bracket may be necessary for perfect centering.
2. Remove the (5Y4G) rectifier tube from its socket and rotate coil until shadow reaches minimum width. This width is not to exceed ³⁄₁₆".
3. Replace the (5Y4G) rectifier tube. Shadow must not widen to more than ³⁄₁₆" or less than ⅛" from each side of screen. If these limits are not obtained readjust the shadowmeter as given in paragraphs 1 and 2 until they are reached.

OUTPUT METER— The 025 Output Meter is connected to the plate and cathode terminals of one of the (6F6G) tubes. Adjust the meter to use the (0-30) volt scale.

DIAL CALIBRATION—Rotate the tuning condenser control to the extreme counter-clockwise position (maximum capacity). Loosen the screw of dial hub, then turn dial until the glowing indicator is centered on the second index line of dial scale (see Fig. 4). Then tighten the dial hub set screw in this position.

INTERMEDIATE FREQUENCY CIRCUIT

Frequency 470 K. C.

1. Turn volume control to maximum volume position. Connect the 088 Signal Generator output through a .1 mfd. condenser, to the control grid of the 6A8G tube and the ground connection of the output lead to the chassis.
2. Set the range switch in position No. 1 (Broadcast), then rotate the tuning condenser of the receiver to the maximum capacity position (counter-clockwise) and adjust the signal generator for 470 K. C.
3. Adjust compensators (28S) 2nd I. F. Sec., (28P) 2nd I. F. Pri., (26S) 1st I. F. Sec. and (26P) 1st I. F. Pri. for maximum reading on the output meter.

RADIO FREQUENCY CIRCUIT

Tuning Range—7.3 to 18.0 M. C.

1. Remove the signal generator output lead from the grid of the 6A8G tube and connect it through the .1 mfd. condenser to terminal No. 1 on aerial input panel and the generator ground lead to terminal No. 3, rear of chassis. Terminals 2 and 3 must be connected with the shorting link provided on the panel during these adjustments.
2. Set the range switch in position No. 3. Turn the receiver and signal generator dials to 18 M. C. Now adjust compensator (16D) by turning the screw (clockwise) to the maximum capacity position. Then slowly turn it counter-clockwise until a second peak signal is reached on the output meter. The first peak from maximum capacity is the image signal and must not be used. NOTE: In some cases only one peak will be found, therefore, tune the compensator to this peak. If the above procedure is correctly performed, the image signal will be found at 17.060 M. C., by advancing signal generator input and turning receiver dial to this frequency mark on the dial.
3. The antenna and R. F. compensators (4C) and (10C) are now adjusted by connecting a variable condenser of approximately 350 mmfd.,—having a good vernier drive—across the oscillator compensator (16D) contact (first contact from left side of receiver facing rear underside view of chassis) and ground. Leaving the signal generator and receiver dials at 18 M. C., tune the added condenser until the second harmonic of the receiver oscillator beats against the signal from the generator, thereby giving an indication on the output meter. It may be necessary to increase the signal generator output to obtain a signal of sufficient strength for reading on the output meter. The antenna and R. F. compensators (4C) and (10C) should then be adjusted for maximum output. Then remove external condenser and readjust compensator (16D) as given in paragraph 2 above.
4. Turn signal generator and receiver dials to 12 M. C. and adjust compensators (16E), (10D), (4D) for maximum output.
5. Now turn signal generator and receiver dials to 18 M. C. and readjust compensators (16D), (10C) and (4C) as given in Paragraphs 2 and 3 above.

Tuning Range—5.7 to 11.6

1. Set range switch in position No. 2. Rotate signal generator and receiver dials to 11 M. C. Compensator (16B) is now adjusted as given in Paragraph 2, under tuning range 7.3 to 18 M. C. above. *Check image signal on the 10.06 dial mark.* The only difference in the two procedures is the frequency used.
2. Turn the signal generator to 11 M. C. Then connect a 350 mmfd. variable condenser from the oscillator compensator (16B) contact (third contact from left side of the receiver, facing rear underside view of chassis) and ground. Tune the added condenser, as given in Paragraph 3 under tuning range 7.3 to 18 M. C. Now adjust compensators (10A) and (4A) for maximum output. The only difference in the two procedures is in the connection of the variable condenser and the frequency used.
3. Readjust compensator (16B) as given in Paragraph 1 for maximum output.
4. Turn signal generator and receiver dials to 6 M. C. and adjust compensators (16C), (10B) and (4B) for maximum output.
5. After the 6 M. C. end of scale is adjusted, the high frequency end is readjusted as given in Paragraphs 1, 2 and 3 above.

Tuning Range—530 to 1720 K. C.

1. Turn signal generator and receiver dials to 1600 K. C.—If signal generator scale is not calibrated for 1600 K. C. the dial of the generator may be rotated to 800 K. C. and the second harmonic of this frequency (1600 K. C.) may be used for following adjustments. Compensators (16), (10) and (4) are now adjusted for maximum output.
2. Turn signal generator and receiver dials to 580 K. C. and adjust compensator (16A) for maximum output. This is accomplished as follows:
First tune compensator (16A) for maximum output. Then vary the tuning condenser for maximum output about the 580 K. C. scale mark. Now retune compensator (16A), and again vary the tuning condenser back and forth about 580 K. C. for maximum output. This operation of first tuning the compensator, then the tuning condenser is continued until maximum output is obtained on or about the 580 K. C. dial mark.
3. Turn signal generator and receiver dials to 1600 K. C. and readjust compensator (16) for maximum output.
4. Now rotate signal generator and receiver dials to 1500 K. C. and adjust compensators (10) and (4) for maximum output.

PHILCO RADIO & TELEV. CORP.

SERVICE DATA

DESCRIPTION

Model 37-650 is an 8 tube superheterodyne receiver for operation on alternating current. It has three tuning ranges, covering standard broadcast and short-wave frequencies. The chassis is constructed in four basic assembly units, concentrating the R. F., I. F., Audio and Power Circuits in individual units.

The circuit includes the **Philco Foreign Tuning System**—controlled by the range switch—providing maximum sensitivity and noise reduction, when used with the **Philco High Efficiency Aerial**; one stage of radio frequency amplification before the Detector-Oscillator tube; Automatic Bass Compensation in the Volume Control Circuit; Shadow Tuning; Automatic Volume Control, and a Push-Pull Pentode Output Circuit.

AERIAL CONNECTIONS

The red and black leads of the High-Efficiency Aerial "transmission line" are connected to terminals 1 and 2 respectively, of the terminal panel provided at the rear of the chassis. Connect the jumper on the terminal panel across terminals 3 and 4.

If a temporary aerial is used, the jumper should be across terminals 2 and 3. The aerial connects to terminal 1 and the ground lead to terminal 3. A good ground connection is desirable in all installations.

REPLACING DIAL

To replace the dial, remove the clamp holding the dial to the hub by turning clamp counter-clockwise, using the two holes provided on the clamp for this purpose.

REMOVING MASK ARM & LINK ASSEMBLY

First remove dial, then loosen set screw of dial hub and remove the hub and felt washer from the shaft. Now loosen screws holding indicator bracket and lens assembly, and move bracket forward about ½ inch. The assembly may now be removed by loosening set screw of range switch arm, then pull arm off of range switch shaft.

REMOVING SWITCH & COIL ASSEMBLIES OF R. F. UNIT

To replace any part in the switch and coil assemblies of the R. F. Unit, each assembly can be removed separately as follows:

First remove the tuning dial, mask and arm assembly. Remove the center mounting screw on the rear of the R. F. Unit. Then lift the rear of the unit and push forward until the rubber mounting grommets, on each side of the unit, clear the mounting slots. The unit is then lifted far enough from the chassis for removal of the two screws holding the selector switch indexing plate and shaft (front of unit). Then pull shaft straight out from the unit. Also, remove the volume control shaft by releasing the retaining clip, inside the chassis, from the shaft.

IMPORTANT—When selector switch shaft is replaced, care should be taken to have all wafer rotors in the same position, so that the key on the switch shaft will slide freely into the notched hole in each wafer rotor. *NEVER* force shaft into rotors.

Servicing Stages—It is necessary to unsolder some connecting leads in order to release the stage for servicing. If all the following connections are unfastened the stage will be entirely released. Ordinarily only one or two leads need be loosened in order to change coils, replace coupling condensers, or replace switch sections.

Antenna Stage Assembly—Rear Section of Unit

A. Remove screw holding shield plate to the unit base. This screw is located in the right hand corner of the shield plate, facing rear underside of the chassis.

B. Unsolder the wires at the I. F. and Aerial terminal panels which connect to the range switch, also wires from tuning condenser housing to tubular condenser (6); tuning condenser stator plate to selector switch contact (B3), and ground lead from assembly shield to unit frame. After disconnecting these wires assembly may be removed.

R. F. Stage Assembly—Middle Section

A. Remove screw (right side of assembly) holding shield plate to unit base.

B. Unsolder the two wires connecting the I. F. Unit to range switch contacts (C3) and (D12); also wires connecting tuning condenser housing to tubular condenser (13) and stator plates to selector switch contact (D3); selector switch contact (D2) to the grid of the 6A8G tube, and ground lead from shield to unit frame. Remove assembly from the unit.

Oscillator Stage Assembly—Front Section

A. The oscillator assembly may be removed by unscrewing the four screws holding shield to R. F. base. These screws are located on each side of the R. F. Unit.

B. Unsolder the wires connecting range switch contacts (E2) and (F2) to the 6A8G socket; tuning condenser stator plates to range switch contact (F3); mica condenser (19) to the tuning condenser housing; range switch to resistor (60) and (61), and ground lead to I. F. Unit. With these leads disconnect unit may be removed.

Replace the units by following the above procedure in the reverse order.

POWER TRANSFORMER DATA

Schematic Lead No.	A. C. Volts	Current	Circuit	Color	Resistance
1-2	120	—	Pri.	White	2.0 ohm

PHILCO RADIO & TELEV. CORP.

MODEL 37-660
Schematic
Coil Data

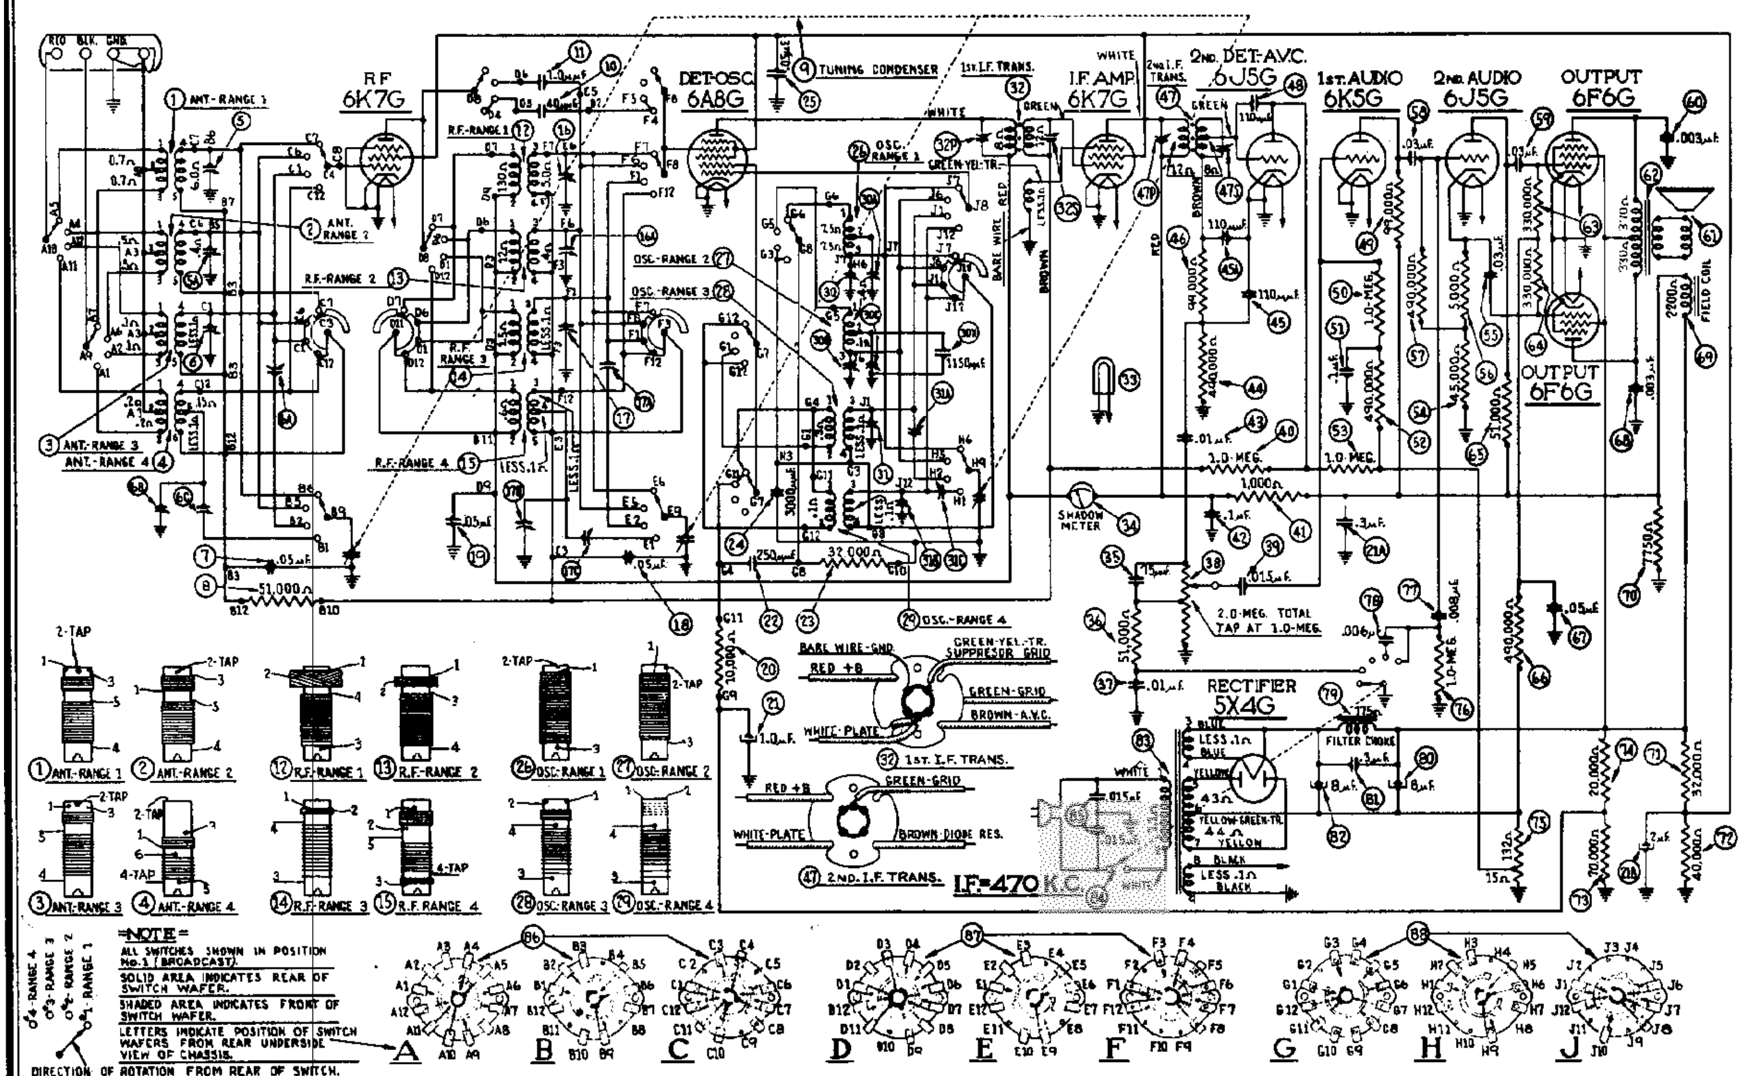

Fig. 2—Schematic Diagram

Model 37-660

July, 1936

Electrical Specifications

Power Supply: 115 V.
Frequency: 50-60 cycle.
For 25 to 40 cycle operation, use the Power transformer marked with asterisk in the parts list.
Consumption: 130 Watts.
Intermediate Frequency: 470 K. C.

Output: 10 Watts.
Philco Tubes: 6K7G—R.F. Amplifier; 6A8G—Oscillator and first detector; 6K7G—I.F. Amplifier; 6J5G—2nd detector, A.V.C.; 6K5G—1st Audio; 6J5G Phase Inverter; 2-6F6G—Output; 5Y4G—Rectifier.
Tuning Ranges: Range 1—530 to 1720 K. C.; Range 2—2.3 to 7.4 M. C.; Range 3—7.35 to 11.6 M. C.; Range 4—11.5 to 18.2 M. C.
Speakers: X cabinet—H-27; B cabinet—K-36.

MODEL 37-660 | PHILCO RADIO & TELEV. CORP. | Trimmers Alignment

The following procedure must be observed in adjusting the compensators:

DIAL CALIBRATION—In order to adjust this receiver correctly, the dial must be aligned to track properly with the tuning condenser. To do this rotate the tuning control to the extreme counter-clockwise position (maximum capacity). Loosen the set screw of the dial hub, then turn dial until the glowing indicator is centered between the first and second index lines of dial scale (see Fig. 4). Now tighten the dial hub set screw in this position.

SHADOW METER ADJUSTMENT—Remove aerial and allow tubes to warm up. Then adjust shadow meter as follows:

1. Move the shadow meter coil backwards and forwards, until the opposite edges of the shadow are 1/4 of an inch from each end of the shadow screen, measuring along the bottom edge of the screen. Adjustment of the shadow meter light bracket may be necessary for perfect centering.
2. Remove the rectifier tube from its socket, and rotate coil until shadow reaches minimum width. This width must not exceed 1/4 of an inch.
3. Replace the 5X4G rectifier tube in its socket. The shadow should then widen to not more than 1/4 inch or less than 1/16 inch from each side of the screen measuring along the bottom edge. If these limits are not obtained readjust the shadow meter as given in paragraphs 1 and 2 until they are reached.

OUTPUT METER—The 025 Output Meter is connected between the plate and cathode prongs of one of the 6F6G tubes. The meter is adjusted to use the (0-30) volt scale.

INTERMEDIATE FREQUENCY CIRCUIT

Frequency 470 K. C.

1. Connect the 088 Signal Generator output lead through a .1 mfd. condenser to the control grid of the 6A8G tube and the ground connection of the output lead to the chassis. Turn the Volume Control to maximum volume position.
2. Set the range switch in position No. 1 (Broadcast), then rotate the tuning condenser of the receiver to approximately 580 K. C. and adjust the signal generator for 470 K. C.
3. Adjust compensators 41s 2nd I.F. sec., 41p 2nd I.F. Pri., 32s 1st I.F. Sec. and 32p 1st I.F. Pri. for maximum reading on the output meter.

RADIO FREQUENCY CIRCUIT

Tuning Range—11.5 to 18.2 M. C.

1. Remove the signal generator output lead from the grid of the 6A8G tube and connect it with the .1 mfd. condenser to terminal No. 1 on aerial input panel and the generator ground lead to terminal No. 3, rear of chassis. Terminals 2 and 3 must be connected with the shorting link provided on the panel.
2. Set the range switch in position 4. Turn the receiver and signal generator dials to 18 M. C. Now adjust compensator 31b by turning the screw (clockwise) to the maximum capacity position, then slowly turning it (counter-clockwise) until a second peak signal is reached on the output meter. The first peak from maximum capacity is the image signal and must not be used. NOTE—In adjusting some receivers only one peak will be observed, therefore, tune the compensator to maximum on this peak. If the above procedure is correctly performed, the image signal will be found at 17.06 M. C., by advancing signal generator attenuator and turning receiver dial to this frequency mark on the dial.
3. The antenna and R.F. compensators 6b and 17b are now adjusted by connecting a variable condenser of approximately 350 mmfd.—having a good vernier drive—across the oscillator compensator 31b contact (first contact from left side of the receiver facing rear underside view of chassis) and ground. Leaving the signal generator and receiver dials at 18 M. C., tune the added condenser from the maximum capacity point until the second harmonic of the receiver oscillator beats against the signal from the generator thereby bringing in the signal. The antenna and R.F. compensators 6b and 17b are then adjusted for maximum output. Now remove the external condenser and readjust compensator 31b as given in paragraph 2 above.
4. Turn signal generator and receiver dials to 12 M. C. and adjust compensator 31c for maximum output. Then adjust compensators 17c and 6c for maximum output.
5. Now turn signal generator and receiver dials to 18 M. C. and readjust compensators 31b Osc., 6b Ant. and 17b R.F. as given in paragraphs 2 and 3 above.

Tuning Range (7.35) to (11.6) M. C.

1. Set range switch in position 3. Rotate signal generator and receiver dials to 11 M. C. Now adjust compensator 31 by turning the screw (clockwise) to the maximum capacity position, then slowly turn it (counter-clockwise) until a second peak signal is reached on the output meter. The first peak from maximum capacity is the image signal and must not be used. NOTE—In adjusting some receivers only one peak will be observed, therefore, tune the compensator to maximum on this peak. If the above procedure is correctly performed, the image signal will be found at 10.06 M. C. by advancing the signal generator attenuator and turning receiver dial to this frequency mark on the dial.
2. Using the 11 M. C. signal, compensators 17 R.F. and 6 Ant. are adjusted by using the procedure given in paragraph 3, under tuning range (11.5) to (18.2) M. C., with the exception, that the external condenser is connected from compensator 31 contact to ground. This contact is the third one from left side of the receiver facing rear underside view of chassis. Also use a 11 M. C. signal.
3. Readjust compensator 31 Osc. as given in paragraph 1 above.
4. Turn signal generator and receiver dial to 7.5 M. C. and adjust compensators 31a Osc. series 17a R.F. and 6a Ant. for maximum output.
5. Due to the slight interaction of the high and low frequency compensators of this range, compensators 31 osc., 17 R.F. and 6 Ant. are readjusted using procedure in paragraphs 1 and 2 above.

Tuning Range 2.3 to 7.4 M. C.

1. Set range switch in Position 2. Turn signal generator and receiver dials to 7.0 M. C. Now adjust compensators 30b Osc., 16a R.F. and 5a Ant. for maximum output.
2. Turn signal generator and receiver dials to 2.35 M. C. Compensator 30c is now adjusted for maximum as follows:

First tune compensator 30c for maximum output. Then vary the tuning condenser for maximum output about the 2.35 dial mark. Now retune compensator 30c, and again vary the tuning condensers back and forth about the 2.35 dial mark for maximum output. This operation of first tuning the compensator, then the tuning condenser is continued until maximum output is obtained at or about the 2.35 dial mark.

If the signal generator is not accurately calibrated the maximum point on the dial of the receiver may fall slightly above or below the dial mark.

3. Turn the signal generator and receiver dials to 7.0 M. C. and readjust compensator 30b for maximum output. Then turn signal generator and receiver dials to 6.0 M. C. and adjust compensators 16a R.F. and 5a Ant. for maximum output.

Tuning Range 530 to 1720 K. C.

1. Set range switch in position No. 1 (Broadcast). Rotate signal generator and receiver dials to 1600 K. C. Now adjust compensators 30 Osc., 16 R.F. and 5 Ant. for maximum output.
2. Tune signal generator and receiver dials to 580 K. C. Compensator 30a Osc. series is then adjusted for maximum output as given in paragraph 2 under tuning range 2.3 to 7.4 M. C., the only difference in the procedure being in the frequency used.
3. Readjust compensator 30 for maximum output, by turning signal generator and receiver dials to 1600 K. C.
4. Turn signal generator and receiver dials to 1500 K. C. and adjust compensators 16 R.F. and 5 Ant. for maximum output.

Alignment of Compensators

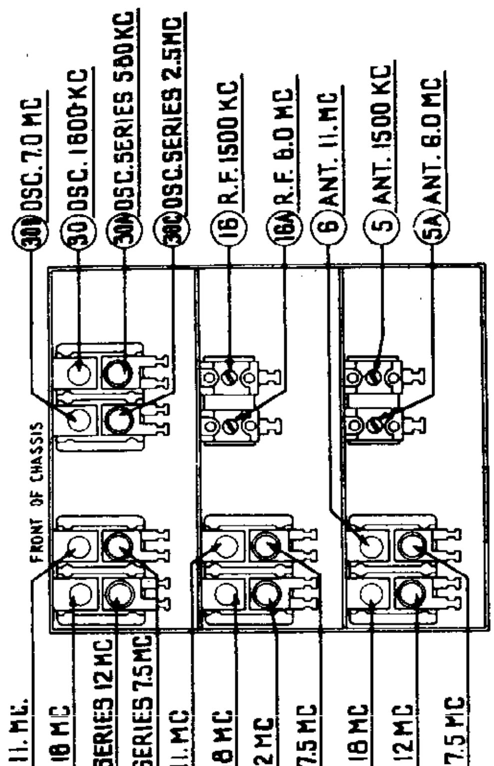

Fig. 6—Locations of R.F. Compensators Underside of Chassis

PHILCO RADIO & TELEV. CORP.

SERVICE DATA

Model 37-660 is a 9 tube superheterodyne receiver designed for operation on alternating current. It has four tuning ranges, covering standard broadcast and short-wave frequencies. The chassis is constructed in four basic assembly units, concentrating the R.F., I.F., Audio and Power circuits in individual units.

The circuit includes the PHILCO Foreign Tuning System—controlled by the range switch—providing maximum sensitivity and noise-reduction, when used with the Philco High-Efficiency Aerial; automatic bass compensation in the volume control circuit; shadow tuning; automatic volume control, and a push-pull pentode output circuit.

AERIAL CONNECTIONS

The red and black leads of the High-Efficiency Aerial "transmission line" are connected to terminals 1 and 2 respectively, of the terminal panel provided on the rear of the chassis. Connect the jumper on the terminal panel across terminals 3 and 4.

If a temporary aerial is used, the jumper should be across terminals 2 and 3. The aerial connects to terminal 1 and the ground lead to terminal 3. A good ground connection is desirable in all installations.

REPLACING DIAL

To replace the dial, remove the clamp holding the dial to the hub, by turning clamp counter-clockwise, using the two holes provided on the clamp for this purpose.

REMOVING MASK ARM & LINK ASSEMBLY

First remove dial, then loosen set screw of dial hub and remove the hub and felt washer from the shaft. Now loosen screws holding indicator bracket and lens assembly, and move bracket forward about ½ inch. The assembly may now be removed by loosening set screw of range switch arm, then pull arm off of range switch shaft.

REMOVING SWITCH & COIL ASSEMBLIES OF R.F. UNIT

To replace any part in the switch and coil assemblies of the R.F. Unit, each assembly can be removed separately as follows:

First remove the tuning dial, mask and arm assembly. Remove the center mounting screw on the rear of the R.F. Unit. Then lift the rear of the unit and push forward until the rubber mounting grommets, on each side of the unit, clear the mounting slots. The unit is then lifted far enough from the chassis for removal of the two screws holding the selector switch indexing plate and shaft (front of unit). Then pull shaft straight out from the unit. Also, remove the volume control shaft by releasing the retaining clip, inside the chassis, from the shaft.

IMPORTANT—When selector switch shaft is replaced, care should be taken to have all wafer rotors in the same position, so that the key on the switch shaft will slide freely into the notched hole in each wafer rotor. NEVER force shaft into rotors.

Servicing Stages—It is necessary to unsolder some connecting leads in order to release the stage for servicing. If all the following connections are unfastened the stage will be entirely released. Ordinarily only one or two leads need be loosened in order to change coils, replace coupling condensers, or replace switch sections.

ANTENNA ASSEMBLY—Rear Section

1. Unsolder the wires which connect the antenna panel and I.F. Unit to the range switch and assembly shield plate ground leads.
2. Unsolder the two leads from the gang condenser terminal panel which connect to the range switch. Also lead of tubular condenser (7) at the ground lug on the R.F. Unit.
3. Remove screw holding shield plate to the unit base. This screw is located in the right hand corner of the shield plate, facing the rear underside of the chassis. The assembly can then be removed.

R.F. ASSEMBLY—Middle Section

1. Unsolder the wires from the I.F. Unit and the 6K7G plate contact in R.F. Unit which connects to the range switch. Then remove ground leads of shield plate.
2. Unsolder the leads from the gang condenser terminal panels and the lead of tubular condenser (18) at the ground lug on R.F. Unit base.
3. Remove the screw holding shield plate to the unit base. This screw is located in the right hand corner of the shield plate facing the rear underside of the chassis. Then pull assembly straight out.

OSCILLATOR ASSEMBLY—Front Section

1. The oscillator assembly can be removed by unscrewing the two screws located on each side of the R.F. Unit.
2. Unsolder the wires connecting range switch to bakelite condenser (78) in the power unit, electrolytic condenser (21) in the R.F. Unit and OSC plate contact on the 6A8G socket.
3. Remove the leads from the gang condenser terminal panels and the lead of Mica condenser (24) at the ground lug on R.F. Unit base.

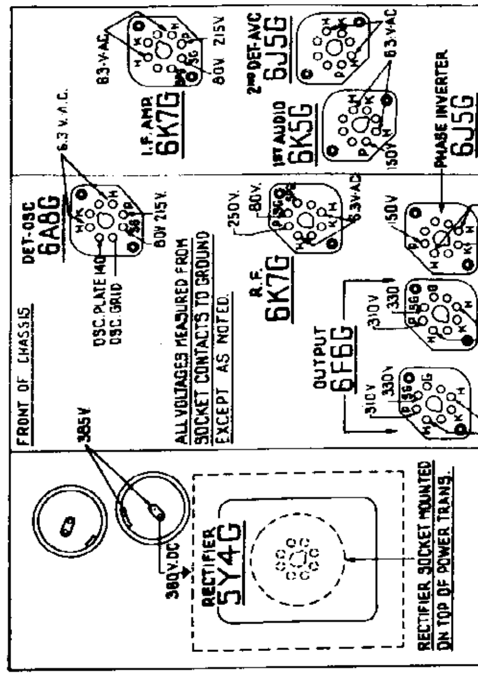

Fig. 1—Socket Voltages—Underside of Chassis View

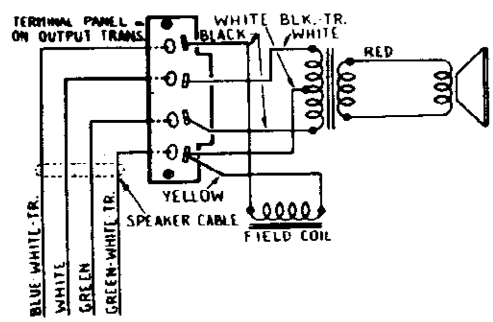
The voltages indicated by arrows were measured with a Philco 025 Circuit Tester which contains a voltmeter having a resistance of 1000 ohms per volt. Volume Control at minimum, range switch in broadcast position, line voltage 115 A. C.



Speaker Wiring for Types K-36 and H-27

MODEL 37-670
Schematic
Coil Data

PHILCO RADIO & TELEV. CORP.

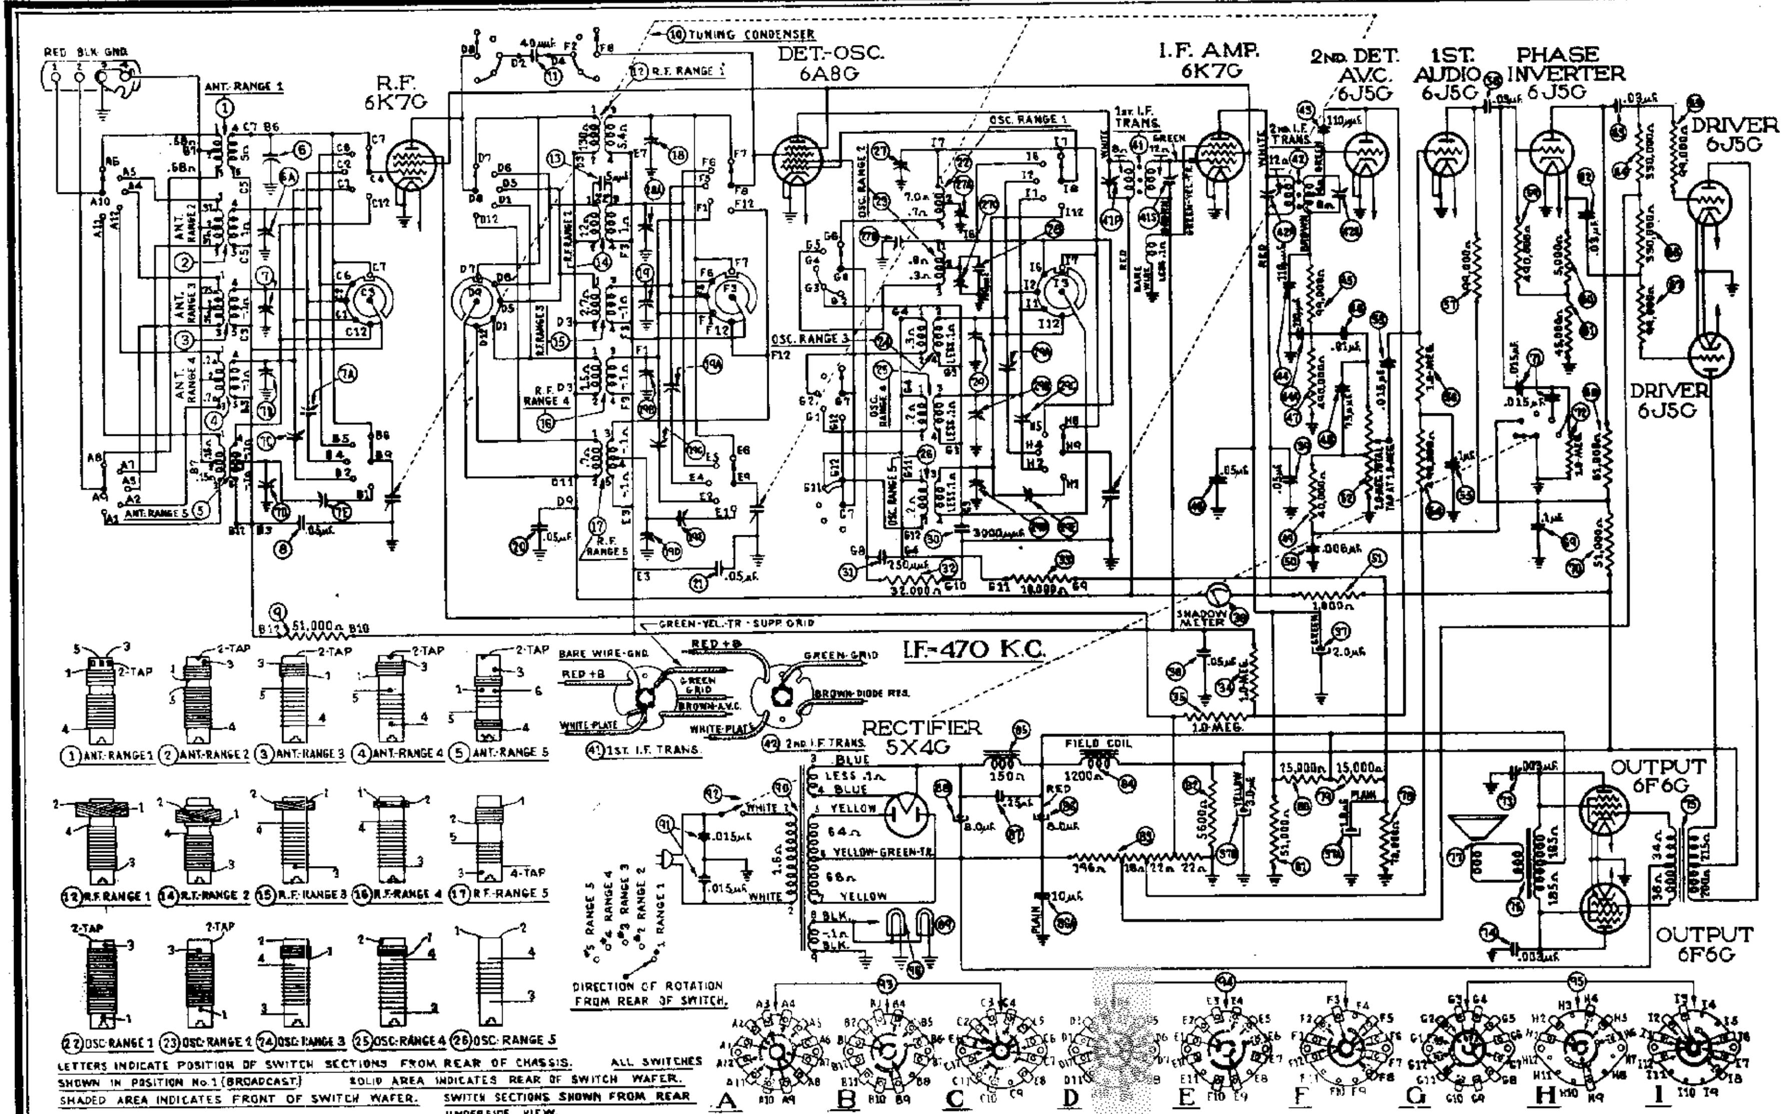

Fig. 3—Schematic Diagram 37-670

September, 1936

Electrical Specifications

POWER SUPPLY:

Voltage	Frequency	Power Consumption
115	50-60	130 watts
115	25-40	130 watts
220		

Power transformers for the different voltage and frequency ratings are listed in the Parts List, page 3.

Intermediate Frequency: 470 K. C.

Audio Output: 10 watts

Philco Tubes Used: 6K7G, R.F. Amplifier; 6A8G, Oscillator and First Detector; 6K7G, I.F. Amplifier; 6J5G, 2nd Detector, A.V.C.; 6J5G, First Audio; 6J5G, Phase Inverter; 2-6J5G, Push-Pull Drivers; 2-6F6G, Output; 5X4G, Rectifier.

Tuning Ranges: Five. Range 1—530-1600 K. C.; Range 2—1.58 to 4.75 M. C.; Range 3—4.7 to 7.4 M. C.; Range 4—7.35 to 11.6 M. C.; Range 5—11.5 to 18.2 M. C.

Speakers: "X" Cabinet, H-28; "B" Cabinet, K-37.

MODEL 37-670 Trimmers | PHILCO RADIO & TELEV. CORP. | Alignment Speaker Data

Alignment of Compensators

The locations of the various compensators are shown in Figs. 6 and 7.

The following procedure must be observed in adjusting the compensators:

DIAL CALIBRATION—In order to adjust this receiver correctly, the dial must be aligned to track properly with the tuning condenser. To do this rotate the tuning control to the extreme counter-clockwise position (maximum capacity). Loosen the set screw of the dial hub, then turn dial until the glowing indicator is centered on second index line of dial scale (see Fig. 5). Now tighten the dial hub set screw in this position.

SHADOW METER ADJUSTMENT—Remove aerial and allow tubes to warm up. Then adjust the shadow meter as follows:

1. Move the shadow meter coil backwards and forwards, until the opposite edges of the shadow are 1/8 of an inch from each end of the shadow screen, measuring along the bottom edge of the screen. Adjustment of the shadow meter light bracket may be necessary for perfect centering.
2. Remove the 5X4G rectifier tube from its socket and rotate coil until shadow reaches minimum width. This width must not exceed 3/16 of an inch.
3. Replace the 5X4G rectifier tube in its socket. The shadow should then widen until it is not more than 3/16 inch or less than 1/16 inch from each side of the screen, measuring along the bottom edge. If these limits are not obtained readjust the shadow meter as given in paragraphs 1 and 2 until they are reached.

OUTPUT METER—The 025 Output Meter is connected between the plate and cathode prongs of one of the (6F6G) tubes. The meter is adjusted to use the (0-30) volt scale.

INTERMEDIATE FREQUENCY CIRCUIT

Frequency 470 K. C.

1. Connect the 088 Signal Generator output lead through a .1 mfd. condenser to the control grid of the 6A8G tube, and the ground connection of the output lead to the chassis. Turn the Volume Control to maximum volume position.
2. Set the range switch in position No. 1 (Broadcast), then rotate the tuning condenser of the receiver to approximately 580 K. C. and adjust the signal generator for 470 K. C.
3. Adjust compensators (42S) 2nd I.F. Sec., (42P) 2nd I.F. Pri., (41S) 1st I.F. Sec., and (41P) 1st I.F. Pri. for maximum reading on the output meter.

RADIO FREQUENCY CIRCUIT

Tuning Range (11.5) to (18.2) M. C.

1. Remove the signal generator output lead from the grid of the 6A8G tube and connect it through the .1 mfd. condenser to terminal No. 1 on aerial input panel and the generator ground lead to terminal No. 3, rear of chassis. Terminals 2 and 3 must be connected by the shorting link provided on the panel.
2. Set the range switch in position No. 5. Turn the receiver and signal generator dials to 18 M. C. Now adjust compensator (29D) by turning the screw (clockwise) to the maximum capacity position, then slowly turning it (counter-clockwise) until a second peak signal is reached on the output meter. The first peak from maximum capacity is the image signal and must not be used. NOTE—In adjusting some receivers only one peak will be observed, therefore, tune the compensator to maximum on this peak. If the above procedure is correctly performed, the image signal will be found at 17.06 M. C. by advancing the signal generator attenuator and turning the receiver dial to this frequency mark on the dial.
3. The antenna and R.F. compensators (7D) and (19D) are now adjusted by connecting a variable condenser of approximately 350 mmfd.—Philco Part No. 45-2325 across the oscillator compensator (29D) (First contact from left side of the receiver facing rear underside of chassis) and ground. Leaving the signal generator and receiver dials at 18 M. C., tune the added condenser from the maximum capacity point until the second harmonic of the receiver oscillator beats against the signal from the generator thereby bringing in the signal. The antenna and R. F. compensators (7D) and (19D) are then adjusted for maximum output. Now remove the external condenser and readjust compensator (29D) as given in paragraph 2 above.
4. Turn signal generator and receiver dials to 12 M. C. and adjust compensator (29E) for maximum output. Then adjust compensators (19E) and (7E) for maximum output.
5. Now turn the signal generator and receiver dials to 18 M. C. and readjust compensators (29D) Osc., (7D) Ant. and (19D) R.F. as given in paragraphs 2 and 3 above.

Tuning Range (7.35) to (11.6) M. C.

1. Set range switch in position 4. Rotate signal generator and receiver dials to 11 M. C. Now adjust compensator (29B) by turning the screw (clockwise) to the maximum capacity position, then slowly turn it (counter-clockwise) until a second peak signal is reached on the output meter. The first peak from maximum capacity is the image signal and must not be used. NOTE—In adjusting some receivers only one peak will be observed, therefore, tune the compensator to maximum on this peak. If the above procedure is correctly performed, the image signal will be found at 10.06 M. C. by advancing the signal generator attenuator and turning receiver dial to this frequency mark on the dial.
2. Using the 11 M. C. signal, compensators (19B) R.F. and (7B) Ant. are adjusted by using the procedure given in paragraph 3, under tuning range (11.5) to (18.2) M. C. with the exception that the external condenser is connected across compensator (29B) (Third contact from left side of the receiver) and ground.
3. Remove the variable condenser and readjust compensator (29B) Osc. as given in paragraph 1 above.
4. Turn the signal generator and receiver dials to 7.5 M. C. and adjust compensators (29C) Osc. series, (19C) R.F. and (7C) Ant. for maximum output.
5. Due to the slight interaction of the high and low frequency compensators of this range, compensators (29B) Osc., (19B) R.F. and (7B) Ant. must be readjusted using the procedure in paragraphs 1 and 2 above.

Tuning Range (4.7) to (7.4) M. C.

1. Set range switch in Position 3. Turn signal generator and receiver dials to 7.0 M. C. Now adjust compensator (29) Osc., (19) R.F. and (7) Ant. for maximum output.
2. Turn the signal generator and receiver dials to 5.0 M.C. and adjust compensators (29A), (19A) and (7A) for maximum output.
3. Turn the signal generator and receiver dials to 7.0 M. C. and readjust compensators (29) Osc., (19) R.F. and (7) Ant. for maximum output.

Tuning Range (1.58) to (4.75) M. C.

1. Set the range switch in position 2. Turn the signal generator and receiver dials to 4.5 M. C
2. Now adjust compensators (27B) Osc., (18A) R.F. and (6A) Ant. for maximum output.
3. Rotate the signal generator and receiver dials to 1.7 M. C. Compensator (27C) Osc. series is now adjusted for maximum output as follows:

First tune compensator (27C) for maximum output, then vary the tuning condenser of the receiver for maximum output about the 1.7 M. C. dial mark. Now turn compensator (27C) slightly to the right or left and vary the receiver tuning condenser for maximum output. If the output reading increases, turn compensator (27C) in the same direction a trifle more, and again vary the tuning condenser for maximum output. If the output decreases, set the compensator in the opposite direction. This procedure of first setting the compensator and then varying the tuning condenser is continued until there is no further gain in output reading.

4. Turn signal generator and receiver dials to 4.5 M. C. and readjust compensators (27B), (18A) and (6A) as given in Paragraphs 1 and 2 above.

Tuning Range (530) to (1600) K. C.

1. Set range switch in position No. 1 (Broadcast). Rotate the signal generator and receiver dials to 1500 K. C. Now adjust compensators (27) Osc., (18) R.F. and (6) Ant. for maximum output.
2. Tune signal generator and receiver dials to 580 K. C. Compensator (27A) Osc. series is then adjusted for maximum output as given in paragraph 3 under tuning range (1.58) to (4.75) M. C., the only difference in the procedure being in the frequency used.
3. Readjust compensator (27) for maximum output, by turning the signal generator and receiver dials to 1500 K. C.
4. Turn the signal generator and receiver dials to 1400 K. C. and adjust compensators (18) R.F. and (6) Ant. for maximum output.

MODEL 37-670
Trimmers, Voltage
Socket, Data

SERVICE DATA

Model 37-670 is an 11 tube superheterodyne receiver designed for operation on alternating current. It has five tuning ranges, covering standard broadcast and short-wave frequencies. The chassis is constructed in four basic assembly units, concentrating the R.F., I.F., Audio and Power circuits in individual units.

The circuit includes the PHILCO Foreign Tuning System—controlled by the range switch—providing maximum sensitivity and noise-reduction, when used with the Philco High-Efficiency Aerial; automatic bass compensation in the volume control circuit; shadow tuning; automatic volume control, and a push-pull class "A" output circuit.

AERIAL CONNECTIONS

The red and black leads of the High-Efficiency Aerial "transmission line" are connected to terminals 1 and 2 respectively, of the terminal panel provided on the rear of the chassis. Connect the jumper on the terminal panel across terminals 3 and 4.

If a temporary aerial is used, the jumper should be across terminals 2 and 3. The aerial connects to terminal 1 and the ground lead to terminal 3. A good ground connection is desirable in all installations.

REPLACING DIAL

To replace the dial, remove the clamp holding the dial to the hub, by turning clamp counter-clockwise, using the two holes provided on the clamp for this purpose.

REMOVING MASK ARM & LINK ASSEMBLY

First remove dial, then loosen set screw of dial hub and remove the hub and felt washer from the shaft. Now loosen screws holding indicator bracket and lens assembly, and move bracket forward about ½ inch. The assembly may now be removed by loosening set screw of range switch arm, then pulling arm off of range switch shaft.

REMOVING SWITCH & COIL ASSEMBLIES OF R.F. UNIT

To replace any part in the switch and coil assemblies of the R.F. Unit, each assembly can be removed separately as follows:

First remove the tuning dial, mask and arm assembly. Remove the center mounting screw on the rear of the R.F. Unit. Then lift the rear of the unit and push forward until the rubber mounting grommets, on each side of the unit, clear the mounting slots. The unit is then lifted far enough from the chassis for removal of the two screws holding the selector switch indexing plate and shaft (front of unit). Then pull shaft straight out from the unit. Also, remove the volume control shaft by releasing the retaining clip, inside the chassis, from the shaft.

IMPORTANT—When selector switch shaft is replaced, care should be taken to have all wafer rotors in the same position, so that the key on the switch shaft will slide freely into the notched hole in each wafer rotor. **NEVER** force shaft into rotors.

Servicing Stages—It is necessary to unsolder some connecting leads in order to release the stage for servicing. If all the following connections are unfastened the stage will be entirely released. Ordinarily only one or two leads need be loosened in order to change coils, replace coupling condensers, or replace switch sections.

ANTENNA ASSEMBLY—Rear Section

1. Unsolder the wires which connect the antenna panel and I.F. Unit to the range switch, also the assembly shield ground leads.
2. Unsolder the two leads from the gang condenser terminal panel which connect to the range switch. Also the lead of tubular condenser (40) at the ground lug on the R.F. Unit.
3. Remove the screw holding the shield plate to the unit base. This screw is located in the right hand corner of the shield plate, facing the rear underside of the chassis. The assembly can then be removed.

R.F. ASSEMBLY—Middle Section

1. Unsolder the wires from the I.F. Unit and the 6K7G plate contact in R.F. Unit which connect to the range switch. Then remove ground leads of shield plate.
2. Unsolder the leads from the gang condenser terminal panels and the lead connecting D2 on the range switch to the 6K7G Plate Contact.
3. Remove the screw holding the shield plate to the unit base. This screw is located in the right hand corner of the shield plate facing the rear underside of the chassis. Then pull the assembly straight out.

OSCILLATOR ASSEMBLY—Front Section

1. Unscrew the two screws located on each side of the R.F. Unit.
2. Unsolder the wires connecting the range switch to resistors (81) and (78) in the power unit, electrolytic condenser (77) in the R.F. Unit and Osc. plate and grid contacts on the 6A8G socket.
3. Remove the leads from the gang condenser terminal panels and the lead of Mica condenser (30) at the ground lug on R.F. Unit base. With these leads disconnected lift oscillator section from unit.

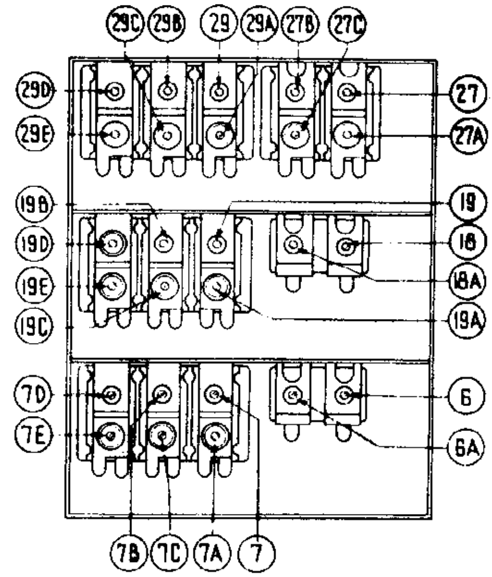

Fig. 7—R.F. Compensators Underside of Chassis

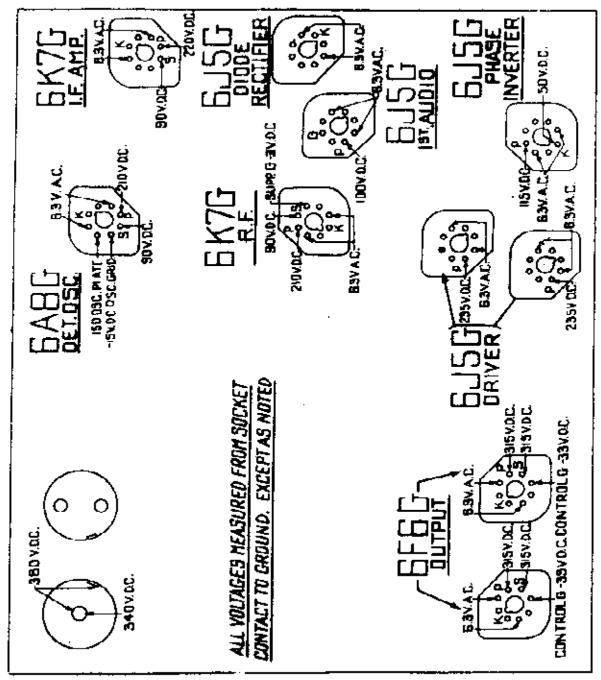

Fig. 2—Socket Voltages—Underside of Chassis View

The voltages indicated by arrows were measured with a voltmeter having a resistance of 1000 ohms per volt. Volume Control at minimum, range switch in broadcast position, line voltage 115 A.C.

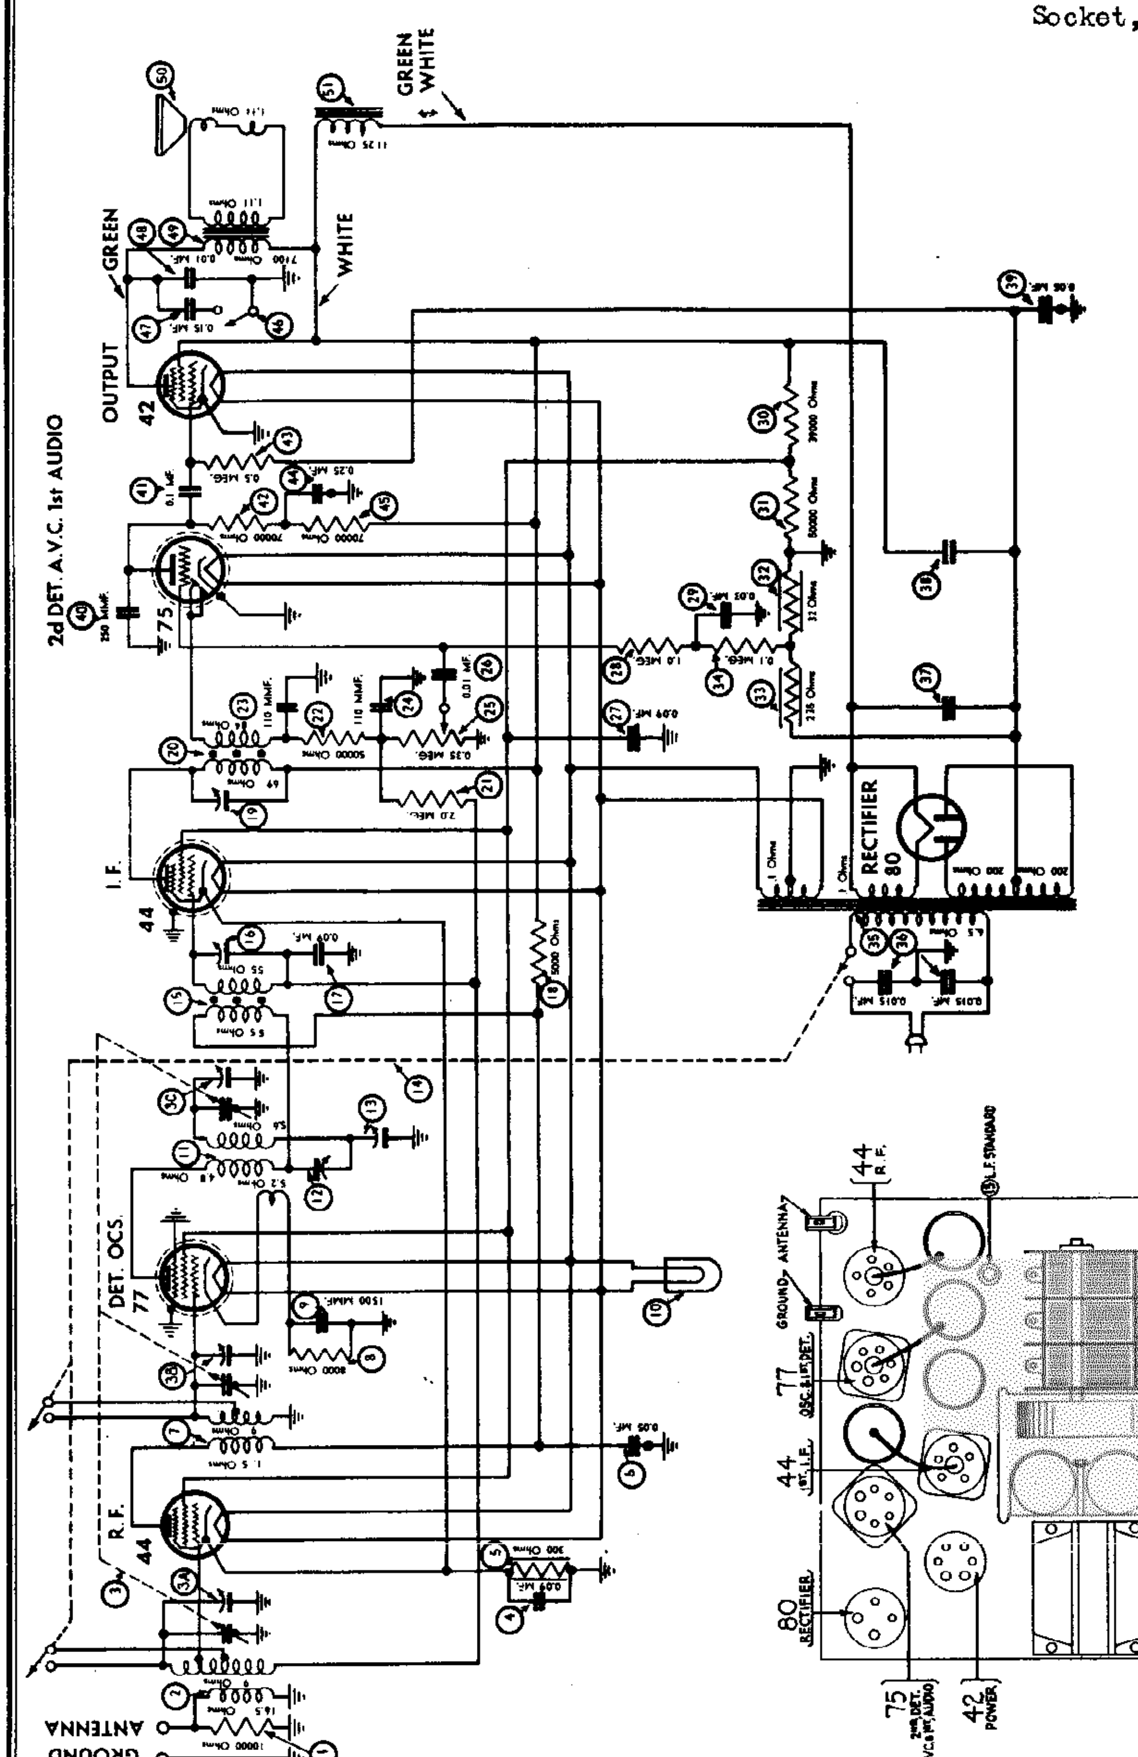
MODEL 89(Code 123)
Schematic
Socket,Trimmers



POWER SUPPLY: 115 volts, alternating current.
CURRENT CONSUMPTION: 60 watts.
SPEAKER: K-21.
TONE CONTROL: 2 point.
INTERMEDIATE FREQUENCY: 260 K. C.

BAND COVERAGE: Number one—550 to 1500 K. C.; number two—1.5 to 3.2 M. C.
NUMBER OF TUBES: Six.
NUMBER OF ACTUAL TUBE FUNCTIONS: Nine.

PHILCO RADIO & TELEV. CORP.

Model 89 (Code 123)

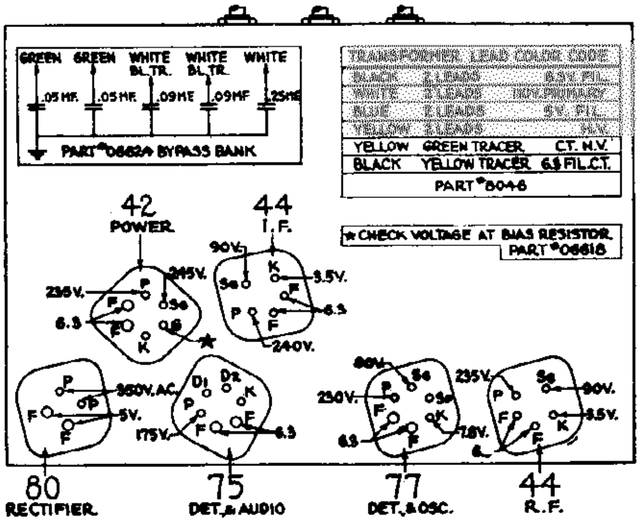

Fig. 1. Bottom View of Tube Sockets (Showing Voltages)

Description

The **PHILCO Model 89,** code 123, is of advanced design, incorporating a highly selective and very efficient R. F. Pre-amplifier, using the type 44 high mu tube.

The 1st detector and oscillator are combined in one tube, a type 77. The design of the oscillator circuit is such that changes in climatic conditions do not affect its stability. A single intermediate frequency stage designed around the high gain type 44 tube is used, insuring a maximum of power; a saving of two tubes is accomplished in the second detector unit by using a type 75 tube. This tube is a combination diode, triode; the diode functioning as a detector and automatic volume control and the triode as a separate audio amplifier.

The power or output stage uses a type 42 (6.3 fil.) pentode and is capable of delivering 3 watts undistorted output.

Adjusting Compensating Condensers

Adjustment of compensating condensers in the Model 89 requires an accurate signal generator covering the intermediate frequency as well as the standard broadcast range. The **PHILCO Model 088** or **024** can be used for this purpose.

Some instrument for measuring the output of the receiver while adjustments are being made is necessary. The **PHILCO 025 Circuit Tester** incorporates an output meter that is ideal for this purpose.

A **PHILCO No. 3164 Fibre Wrench** completes the equipment needed.

The location of the various compensating condensers is shown in Fig. 2 and Fig. 3. Connect the output meter to the plate and cathode terminals of the type 42 power tube, using the adapters provided with the "025" and set it for the 0-30 volt range.

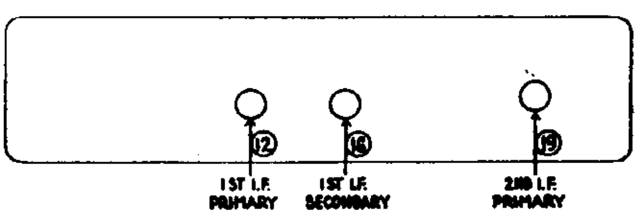

Fig. 3. I. F. Padder View from Rear of Chassis

I.F.—Set the signal generator at 260 K. C. and attach its antenna lead to the grid of the type 44 I.F. tube. Connect the ground lead of signal generator to the ground post of chassis. Turn the dial of the set to 540 K. C. and the volume control to the extreme right (maximum). Wave band switch in No. 1 position (left), tone control also in No. 1 position (left), adjust the signal generator attenuator for approximately ¼ scale reading on output meter. Using the fibre tuning wrench adjust condenser ⑲ (2nd I.F.) for maximum output meter reading. Remove the signal generator antenna lead from the grid of the 44 I.F. tube and connect it to the grid (removing grid clip), of the type 77, 1st detector and oscillator tube. Adjust the signal generator attenuator as before for ¼ scale output meter reading. With the fibre tuning wrench adjust condensers ⑭ and ⑫ (1st I.F.) for maximum output meter reading.

STANDARD (broadcast) and POLICE: Remove the antenna lead of the signal generator from the grid of the type 77 tube (replacing grid clip) and attach it to the antenna post on the chassis. Set the signal generator at 1500 K. C. and tune the set to 150 (1500 K. C.). Adjust signal generator attenuator as before for ¼ scale output meter reading. With the fibre tuning wrench adjust condensers ③A, ③B and ③C, for maximum output meter reading. Set the signal generator at 550 K. C. and tune the set to 55 (550 K. C.) adjust condenser ⑬ for maximum output meter reading. Readjust condenser ③C at 1500 K. C. During adjustments keep the output meter reading approximately ¼ scale to insure proper peaking of transformers.

PHILCO RADIO & TELEV. CORP.

Model 600

Specifications

TYPE CIRCUIT: Superheterodyne with pentode output.
POWER SUPPLY: 115 V., 60 cycle A.C.
TUBES USED: 1 type 6A7, Det. Osc., 1 type 77, 2nd Det., 1 type 41, Output, 1 type 80 Rectifier.
FREQUENCY RANGE: 530-1800 K.C.
INTERMEDIATE FREQUENCY: 460 K.C.
CURRENT CONSUMPTION: 45 watts.
SPEAKER: B-6.
POWER OUTPUT: ½ watt.

Adjusting Compensating Condensers

Adjustment of compensating condensers in Model 600 requires an accurate signal generator covering I.F., and standard-wave frequencies. The **PHILCO Model 088 All-Wave Signal Generator,** having a continuous range of from 100 to 20,000 K.C., is ideal for this purpose.

An output meter is also needed. **PHILCO Model 025 Circuit Tester** includes a high grade output meter.

Philco No. 3164 fibre wrench and No. 27-7059 fibre-handled screwdriver complete the equipment needed for making these adjustments. The locations of the various compensaters are shown in Fig. 4. Connect the output meter to the plate and cathode contacts of the type 41 power tube (using the adapters provided with the "025") and set it at the 0-30 volt range.

INTERMEDIATE FREQUENCY: Connect the 088 signal generator antenna lead to the grid of the 6A7 (removing grid clip) and the ground lead to the ground post or some part of the chassis. Adjust sensitivity control 28 approximately 1½ turns from tight (counter clockwise), then set the 088 signal generator at 460 K.C. and the attenuator for approximately ¼ scale reading on output meter. Adjust condensers 18 and 20 for maximum reading on output meter. Turn sensitivity control 28 in (clockwise) until a low hiss or click (oscillation) is heard. Then turn it out (counter clockwise) approximately ¼ turn.

STANDARD and POLICE: Remove the 088 signal generator antenna lead from the grid of the 6A7 (replacing grid clip) and connect it to the aerial post on the set. Turn the condenser gang all the way out (minimum capacity) and place a .006" (six thousandth inch) gauge between the stator and rotor plates. Turn the condenser gang in until the correct spacing (.006") is had between the rotor and stator plates. The pointer on the front of the cabinet should be set at 1800 K.C. to coincide with this condenser gang setting.

With the condenser gang set in this manner, set the 088 signal generator at 1800 K.C. and adjust condensers 5 and 11 for maximum reading on output meter.

Set the condenser gang and 088 signal generator at 600 K.C. and adjust condenser 16 for maximum output meter reading.

Care should be taken to adjust the 088 signal generator attenuator for approximately ¼ scale output meter reading for each stage before attempting to adjust compensators.

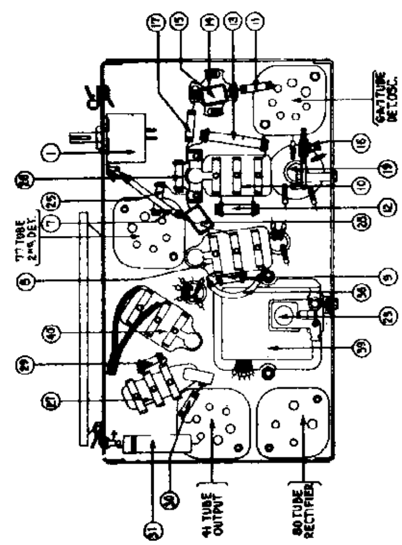

Fig. 3. Base View

Adjusting Compensating Condensers

Adjustment of compensating condensers in Model 602 requires an accurate signal generator covering I.F., and standard-wave frequencies. The **PHILCO Model 088 All-Wave Signal Generator,** having a continuous range of from 100 to 20,000 K.C., is ideal for this purpose.

An output meter is also needed. **PHILCO Model 025 Circuit Tester** includes a high grade output meter.

Philco No. 3164 fibre wrench and No. 27-7059 fibre-handled screwdriver complete the equipment needed for making these adjustments. The locations of the various compensating condensers are shown in Fig. 4. Connect the output meter to the plate and cathode contacts of the type 43 power tube (using the adapters provided with the "025") and set it at the 0-30 volt range.

INTERMEDIATE FREQUENCY: Turn the condenser gang all the way in (maximum capacity) and set the volume control of set at maximum (clockwise). Connect the 088 signal generator antenna lead to the grid of the 78 I.F. tube through a .00025 mf. condenser and the ground lead to the ground post of the set. Set the 088 signal generator attenuator for approximately ¼ scale reading on output meter. Adjust condensers ㉗ and ㉙ for maximum output meter reading.

Remove the 088 signal generator antenna lead from the grid of the 78 and connect it to the grid of the 6A7, adjust condensers ㉑ and ㉓ for maximum output meter reading.

WAVE TRAP: Connect the 088 signal generator antenna lead to the aerial post of set. Adjust condenser ①a for *minimum* output meter reading.

STANDARD and POLICE: Turn the condenser gang all the way out (minimum capacity) and place a .006" (six thousandth inch) gauge between the stator and rotor plates. Turn the condenser gang in until the correct spacing (.006") is had between the rotor and stator plates. The pointer on the front of the cabinet should be set at 1800 K.C. to coincide with this condenser gang setting.

With the condenser gang set in this manner, set the 088 signal generator at 1800 K.C. and adjust condensers ①a and ⑧a for maximum output meter reading.

Set the condenser gang and 088 signal generator at 600 K.C. and adjust condenser ⑧ for maximum output meter reading.

Care should be taken to adjust the 088 signal generator attenuator for approximately ¼ scale output meter reading for each stage before attempting to adjust compensators.

PHILCO RADIO & TELEV. CORP.

MODEL 604
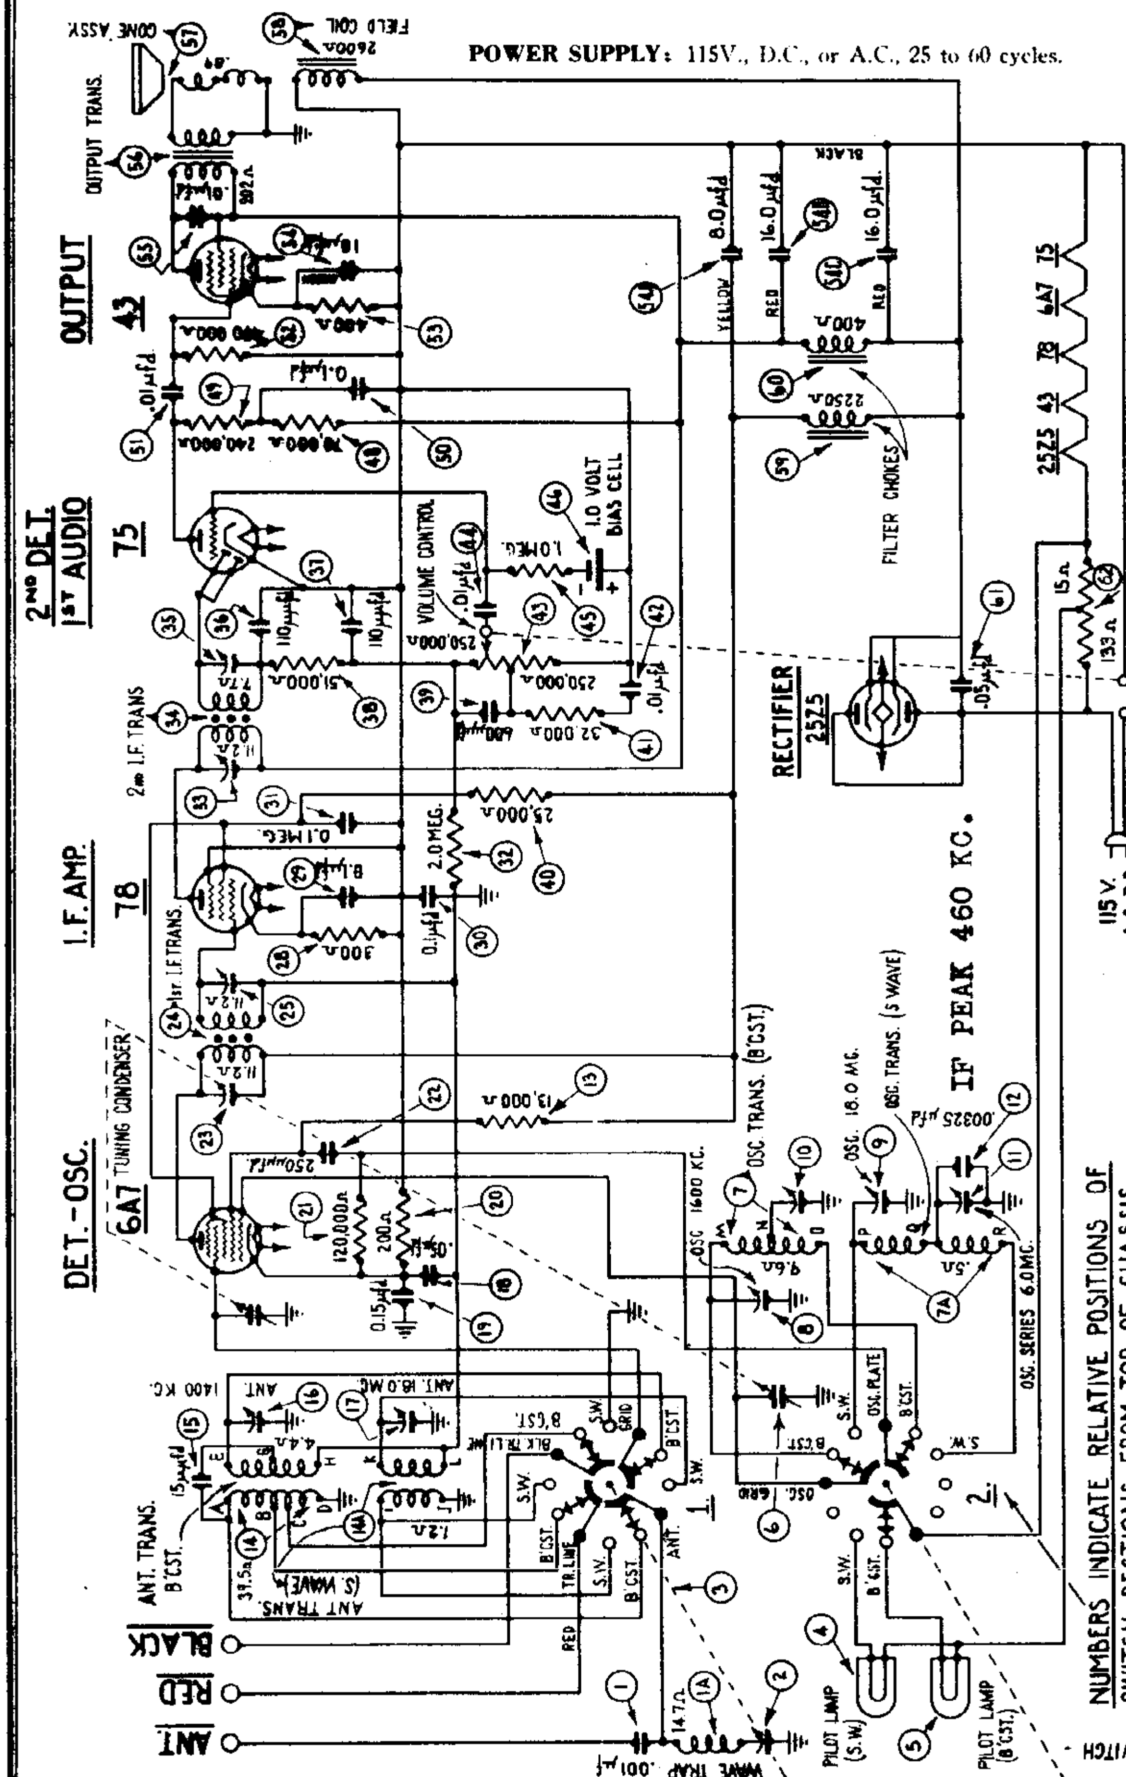
Schematic

POWER SUPPLY: 115V., D.C., or A.C., 25 to 60 cycles.



POWER CONSUMPTION: 50 watts.
PHILCO TUBES USED: 1 type 6A7, Det. Osc., 1 type 78 I.F. amplifier, 1 type 75, 2nd Det., 1st audio, 1 type 43 output, 1 type 25Z5 rectifier.
WAVE BANDS: Two: (1) Shortwave, (2) Standard and some Police.
FREQUENCY RANGE: Band (1) 6.0 to 18.0 M.C., Band (2) 530 to 1750 K.C.

SPEAKER: B5.
POWER OUTPUT: 3/4 Watt.

FIG. 5. Schematic Diagram of Model 604

PHILCO RADIO & TELEV. CORP.

Adjusting Compensating Condensers

Adjustment of compensating condensers in Model 604 requires an accurate signal generator covering I.F., and standard-wave frequencies. The **PHILCO Model 088 All-Wave Signal Generator,** having a continuous range of from 100 to 20,000 K.C., is ideal for this purpose.

An output meter is also needed. **PHILCO Model 025 Circuit Tester** includes a high grade output meter.

Philco No. 3164 fibre wrench and No. 27-7059 fibre-handled screwdriver complete the equipment needed for making these adjustments. The locations of the various compensating condensers are shown in Fig. 4. Connect the output meter to the plate and cathode contacts of the type 43 power tube (using the adapters provided with the "025") and set it at the 0-30 volt range.

INTERMEDIATE FREQUENCY: Turn the condenser gang all the way in (maximum capacity) and set the volume control of Receiver at maximum (clockwise). Connect the 088 signal generator antenna lead to the grid of the 78 I.F. tube through a .00025 mf. condenser and the ground lead to the chassis of the receiver. **Set the 088 signal generator** attenuator for approximately **¼ scale reading on output** meter. Adjust condensers ㉝ and ㉟ for maximum output meter reading.

Remove the 088 signal generator antenna lead from the grid of the 78 and connect it to the grid of the 6A7, adjust condensers ㉓ and ㉕ for maximum output meter reading.

WAVE TRAP: Connect the 088 signal generator antenna lead to the aerial post of receiver. Adjust condenser ② for *minimum* output meter reading.

SHORT WAVE: In adjusting the short wave or high frequency band, the det. compensator will have a tendency to "pull" or **change** the frequency of the oscillator. By shunting a padding or variable condenser (about .00025 Mf.) across the oscillator section of the gang (bottom section) and tuning it so that the second harmonic, instead of the fundamental, beats with the incoming signal, this "pull" can be minimized. The procedure for tuning this band is as follows:

Set the dial of the receiver at 18 megacycles (top scale) and the 088 dial at the same frequency. Turn wave band switch to position 1 (extreme right). Connect the shunt condenser to the oscillator section of the gang and tune it so that the second harmonic of the oscillator beats with the 18 M.C. signal from the 088. Next tune condenser ⑰ (antenna) for maximum reading of the output meter. Disconnect shunt condenser and tune condenser ⑨ (osc.) for correct dial calibration. The receiver, oscillator frequency, when correctly adjusted, will be higher than that of the incoming signal. In order to check this it should be possible to pick up the 18 M.C. 088 oscillator signal as an image signal by increasing the 088 output and tuning the receiver to approximately 17.1 M.C.

For the low frequency adjustment of this band, turn the dial to 6.0 M.C., set the signal generator at 6.0 M.C. and adjust condenser ⑪ (nut) for maximum output meter reading. Readjust condenser ⑨ at 18.0 M.C.

STANDARD AND POLICE: Turn wave band switch to position 2 (extreme left), set signal generator at 800 K.C. and dial of receiver at 1600 K.C. (using second harmonic of Signal Generator). Now adjust the oscillator and antenna "standard" condensers. These are ⑧ and ⑯ respectively. Turn dial of receiver and Signal Generator to 1400 K.C., and readjust condenser ⑯.

Turn the dial of receiver to 58, set signal generator at 580 K.C. and adjust condenser ⑩, (oscillator standard series), (screw) for maximum output meter reading.

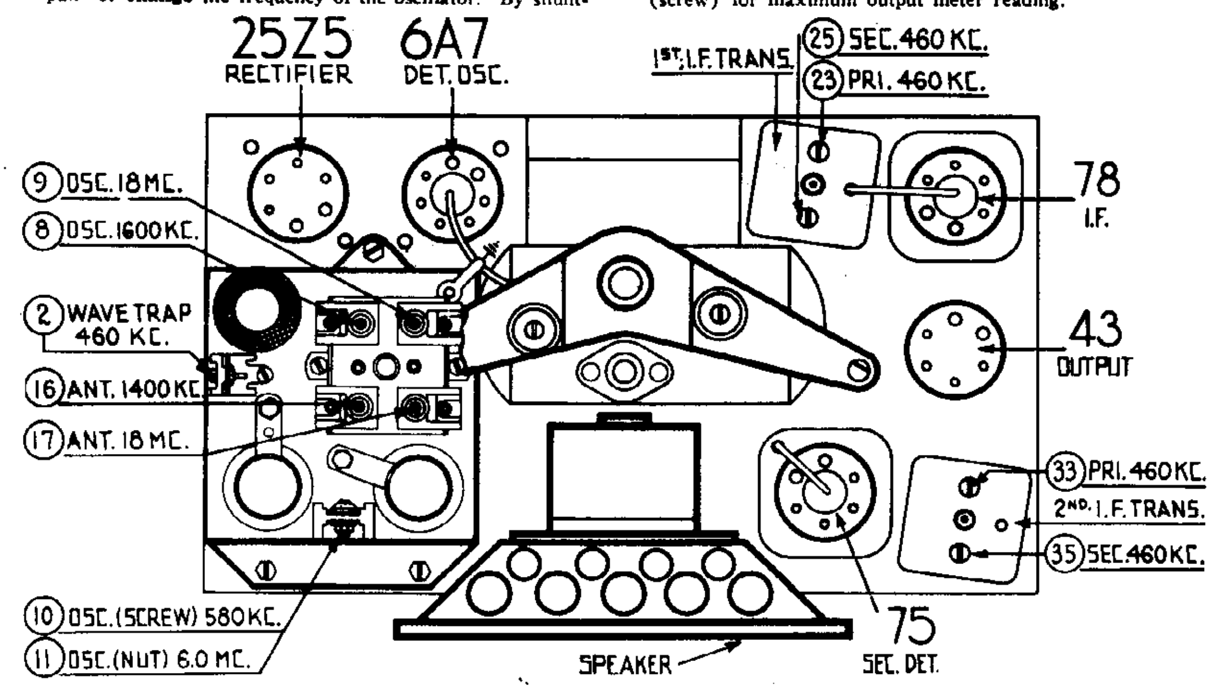

FIG. 4. Location of Compensating Condensers

The letters appearing on the terminals of the transformers below, correspond to those shown on the schematic diagram, Fig. 5.

Changes, Parts

PHILCO RADIO & TELEV. CORP.

Later 1935 Production Runs

This sheet supplements the regular bulletin No. 217 on the Philco 610 and also covers the Philco Radio-Phonograph 610PF. All circuit and part number changes up to date have been included.

Beginning with run No. 9 the grid bias arrangement for the 6A7 1st detector and 78 I.F. was changed. A fixed bias from the B.C. resistor is fed through the AVC circuit to the grids of these tubes.

Beginning with run No. 11 the oscillator circuit was changed to series feed to eliminate possibilities of failure at 6.0 mc.

Beginning with run No. 14 the dial mask assembly was changed to the glowing arrow wave band indicator type.

PHILCO RADIO & TELEV. CORP.

Later 1935 Production Runs

This sheet supplements the regular bulletin No. 218 on the Philco Model 620. All circuit and part number changes up to date have been included.

Beginning with run No. 7 the grid bias arrangement for the 78 R.F. and 6A7 1st detector was changed. A fixed bias from the B.C. resistor is fed through the AVC circuit to the grids of these tubes. The oscillator circuit was changed to series feed to eliminate possibilities of failure at 6.0 mc.

PARTS LIST

	Description	Part No.	Price List
1	Waveband Switch	42-1152	$1.75

Adjusting Compensating Condensers

Adjustment of compensating condensers in Model 624 requires an accurate signal generator covering I.F., standard-wave, police and short-wave frequencies. The **PHILCO Model 088 All-Wave Signal Generator,** having a continuous range of from 100 to 20,000 K.C., is ideal for this purpose.

An output meter is also needed. **PHILCO Model 025 Circuit Tester** includes a high grade output meter.

Philco No. 3164 fibre wrench and No. 27-7059 fibre-handled screwdriver complete the equipment needed for making these adjustments. The locations of the various compensating condensers are shown in Fig. 2. Connect the output meter to the plate and cathode contacts of the type 30 driver tube (using the adapters provided with the "025") and set it at the 0-30 volt range.

Set the signal generator at 460 K.C. with attenuator set at minimum, and attach its antenna lead to the grid cap of the 1A4 I.F. amplifier tube. Connect ground lead to ground terminal on set or some part of chassis. Set the dial at 55 and turn the waveband switch to position 3 (extreme left). Adjust the volume control of set to almost maximum (just before oscillator hiss becomes noticeable), and the 088 attenuator so that about one-fourth (¼) scale reading is had on the output meter. With a fibre screw-driver adjust condensers ㉗ and ㉙ (2nd I.F.) for maximum reading on output meter. Turn attenuator of signal generator to minimum and remove its antenna lead from the grid of the 1A4 I.F. tube. Place it on the grid of the 1C6, removing grid lead. Adjust 088 attenuator as before, then proceed to adjust condensers ㉔ and ㉖ (1st I.F.) for maximum output meter reading. Then remove the 088 oscillator lead and replace grid connection. Care should be taken to keep the output meter reading during adjustments at about one-fourth scale reading. This should be done by using the 088 attenuator control.

Connect the Signal Generator antenna and ground leads to the antenna and ground posts of the set. With the signal generator operating at 460 K.C. and the set controls adjusted as before for I.F. alignment, adjust wavetrap ① until a minimum reading is obtained on the output meter.

SHORT WAVE

In adjusting the short wave or high frequency band, the R.F. compensator will have a tendency to "pull" or change the frequency of the oscillator. By shunting a compensating or variable condenser (about .00025 Mf.) across the oscillator section of the gang (front section) and tuning it so that the second harmonic, instead of the fundamental, beats with the incoming signal, this "pull" can be minimized. The procedure for tuning this band is as follows:

Set the dial of the receiver at 18 megacycles (top scale) and the 088 dial at the same frequency. Turn wave band switch to position 1 (extreme right). Connect the shunt condenser to the oscillator section of the gang and tune it so that the second harmonic of the oscillator beats with the 18 M.C. signal from the 088. Next tune condenser ⑥ (antenna) for maximum reading of the output meter. Disconnect shunt condenser and tune condenser ⑯ (osc.) for correct dial calibration. The oscillator frequency, when correctly set, will be higher than that of the incoming signal and the image frequency lower. In order to check this it should be possible to tune the image at approximately 17.1 M.C. by increasing the input from the 088 oscillator.

For the low frequency adjustment of this band, turn the dial to 6.0 M.C., set the signal generator at 6.0 M.C. and adjust condenser ⑰ (nut) for maximum output meter reading. Readjust condenser ⑯ at 18.0 M.C.

STANDARD WAVE: Turn waveband switch to position 3 (standard broadcast), set signal generator at 1500 and dial of set at 150. Now adjust the oscillator and antenna "Standard" condensers for maximum output meter reading. These are ⑭ and ⑤, respectively.

Now turn the dial to 60, set signal generator at 600 and adjust condenser ⑲ (oscillator standard and police series) (screw) for maximum output meter reading.

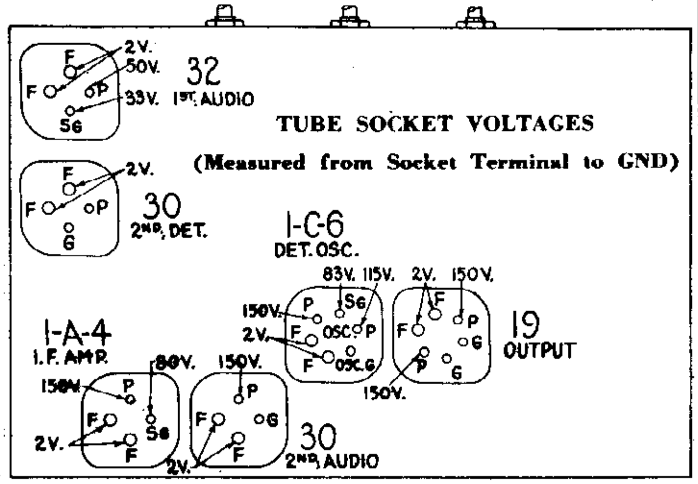

Fig. 1. Bottom View of Sockets, Showing Voltages

The voltages at the points indicated by the arrows above were obtained with a Philco type 025 Circuit Tester which contains a high resistance (1000 ohms per volt) voltmeter. Volume control at minimum, waveband switch at standard broadcast. KR-12 speaker.

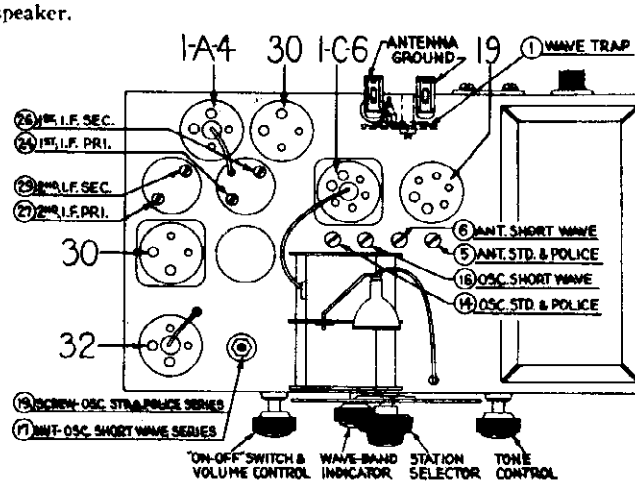

Fig. 2. Location of Compensating Condensers

Description

Philco Model 624 is a new type receiver designed to operate entirely from a 6-volt storage battery. Through a specially designed vibrator and power supply, the 6 volts from the storage battery is stepped up to the necessary "B" voltage for the plate and screen grid of the tubes. The correct filament voltages are obtained by using a series resistor arrangement.

TYPE CIRCUIT: Superheterodyne, with Class B output; built in connections for Philco all-wave aerial; aerial selector built into and operated by wave-band switch.

POWER SUPPLY: Battery operated; Model 624 uses a 6-volt 125-ampere-hour storage battery (Philco 110-R).

WAVE BANDS: Three—(1) Short Wave; (2) Police; (3) Standard.

COVERAGE OF EACH BAND: Band 1, 5700–18,000 K.C. (5.7 to 18.0 megacycles); Band 2, 2300–2500 K.C. (2.3–2.5 megacycles); Band 3, 530–1720 K.C.

TUNING DRIVE: Dual gear drive, ball bearing. 50 to 1 ratio for slow-speed tuning, 6 to 1 on main shaft.

TONE CONTROL: 2-Position.

INTERMEDIATE FREQUENCY: 460 K.C.

CURRENT CONSUMPTION: A battery, 1.5A.

SPEAKER: KR-12, Permanent Magnet Dynamic.

MODEL 625
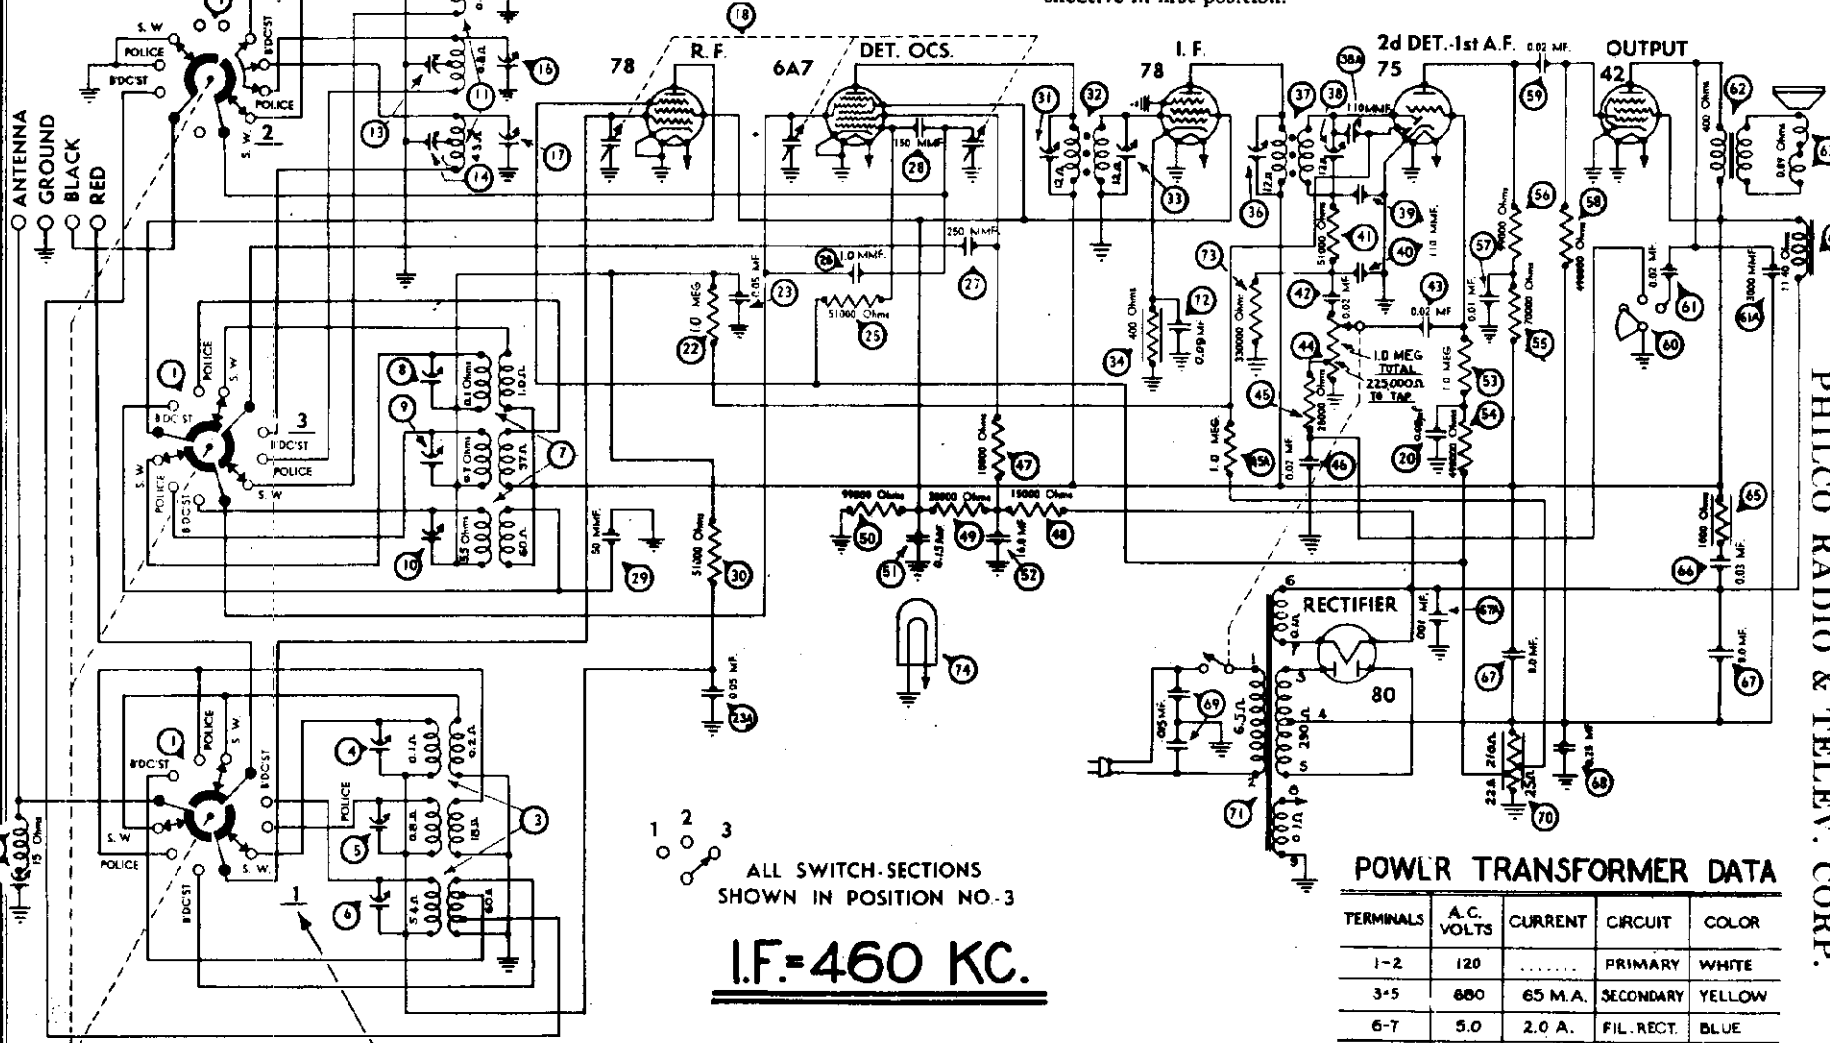
Schematic

Transformer Data

PHILCO RADIO & TELEV. CORP.

Intermediate Frequency: 460 K.C.
Power Consumption: 65 watts.

Tuning Drive: Two-speed gear drive, ball bearing. 50 to 1 ratio for slow-speed tuning.
Program Control: 3-position, with bass compensation effective in first position.



POWER TRANSFORMER DATA

TERMINALS	A.C. VOLTS	CURRENT	CIRCUIT	COLOR
1-2	120	....	PRIMARY	WHITE
3-5	680	65 M.A.	SECONDARY	YELLOW
6-7	5.0	2.0 A.	FIL. RECT.	BLUE
8-9	6.3	2.0 A.	FILAMENTS	BLACK
4	...	....	CENTER TAP OF 3-5	YELLOW, GREEN TRACER

Wave Bands: Three—(1) standard (with some Police); (2) Police, Aircraft and Amateur; (3) Short-wave.
Coverage of Each Band: Band 1, 540-1720 K.C.; Band 2, 1750 to 5800 K.C. (1.75-5.8 megacycles); Band 3, 5700-18000 K.C. (5.7 to 18.0 megacycles).

Fig. 3. Schematic Diagram of Model 625

Adjusting Compensating Condensers Model 625

The adjustment of the compensating condensers in Model 625 requires a signal generator covering the broadcast and police band, and also one capable of producing a signal at certain frequencies in the short wave band. Philco Model 088 All-wave signal generator is ideal for these requirements. Or you can use the Philco Model 024 or 048A instrument for the broadcast frequencies, and the Model 091 crystal controlled short wave signal generator for the "short-wave" frequencies. The location of all compensating condensers is shown in Fig. 2. An output meter is also needed, such as in Philco Model 025.

Adjustment of I. F.

1. Remove the antenna connection from the receiver, disconnect the grid clip from the first detector (type 6A7 tube), and connect the "ANT" output terminal of the broadcast signal generator to the grid cap of this tube; connect the "GND" terminal of the signal generator to the "GND" terminal of the receiver.

2. Connect the 0 to 80 volt range of the output meter in the Philco 048A or 025 unit to the plate and cathode of the output tube or to the two bottom prongs of the speaker plug.

3. Adjust the signal generator to a frequency of 460 K.C. Place the receiver in operation with the dial turned to the low frequency end of the standard broadcast band, wave band switch to extreme left (clockwise), and have the volume control adjusted near its maximum setting. Adjust the signal generator attenuator for approximately half-scale reading of the output meter.

4. The I.F. compensating condensers are located at the tops of the I.F. coil shields. The primary is adjusted by turning the screw in top and the secondary by the nut. Adjust condensers (24) and (23) (2d I.F. primary and secondary) for maximum reading in the output meter, and then condensers (22) and (21) (1st I.F. primary and secondary).

Adjustment of Wave-Trap

1. Connect the signal generator leads to the antenna and ground terminals of the receiver. Replace the grid clip on the 6A7 grid cap.

2. With the wave-band switch of the receiver still in the extreme left (standard band), (540-1720 K.C.), turn the station selector to 55.

3. With the signal generator in operation at 460 K.C., adjust the wave-trap (3) condenser until a MINIMUM reading is obtained on the output meter. The Philco fibre wrench, part No. 3164, is used for this adjustment. The wave-trap compensator is reached from rear of chassis.

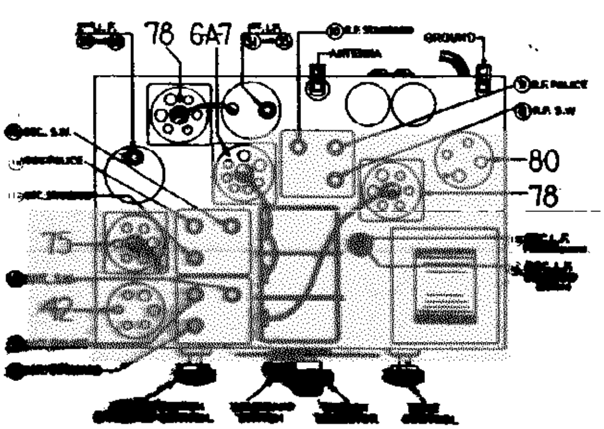


Fig. 2. Locations of Compensating Condensers

Adjustment of High and Low Frequency Compensators

1. With the wave-band switch still at Range No. 1 (broadcast band), set the dial at 1700 K.C. Set the signal generator at this frequency and adjust compensators (17), (6) and (10) for maximum output. These are the oscillator, antenna, and R.F. "standard" compensators respectively.

2. Tune the receiver and the signal generator to 600 K.C. and adjust compensator (14) (screw) for maximum output. This is the oscillator L.F. standard compensator.

3. Turn the wave-band switch to the second (middle) position. Set the dial at 3.6 M.C., at which point the fundamental of the 091 signal will be heard. If the Model 088 signal generator is being used, set it at 3.6 M.C. Adjust condensers (16), (5) and (9) in succession. These are the oscillator, antenna and R.F. police band adjustments.

4. Turn the tuning dial to 1.8 M.C., and set the signal generator (Model 024 or Model 088) at 1800 K.C. Adjust condenser (13) (Osc. L.F., police) (nut), to maximum signal.

5. Turn the wave-band switch to Band 3 (extreme right) and adjust the station selector to 18.0 megacycles. Set the signal generator at 18 M.C. By means of the Philco wrench, part No. 3164, adjust the oscillator S.W., antenna S.W. and R.F. S.W. compensators for maximum reading in the output meter. These are numbered (15), (4) and (8) respectively in figure No. 2.

Tube Socket Voltages
Measured to Ground

Tube	78 R.F.	6A7 Det. Osc.	78 I.F.	75 2d Det.	42 Output

Changes, Parts

PHILCO RADIO & TELEV. CORP.

Later 1935 Production Runs

This sheet supplements the regular bulletin No. 219 on the Philco 630 and also covers the Philco Radio-Phonograph 630PF. All circuit and part number changes up to date have been included.

Beginning with run No. 5 the grid bias arrangement for the 78 R.F. and 6A7 1st detector was changed. A fixed bias from the B.C. resistor is fed through the AVC circuit to the grids of these tubes.

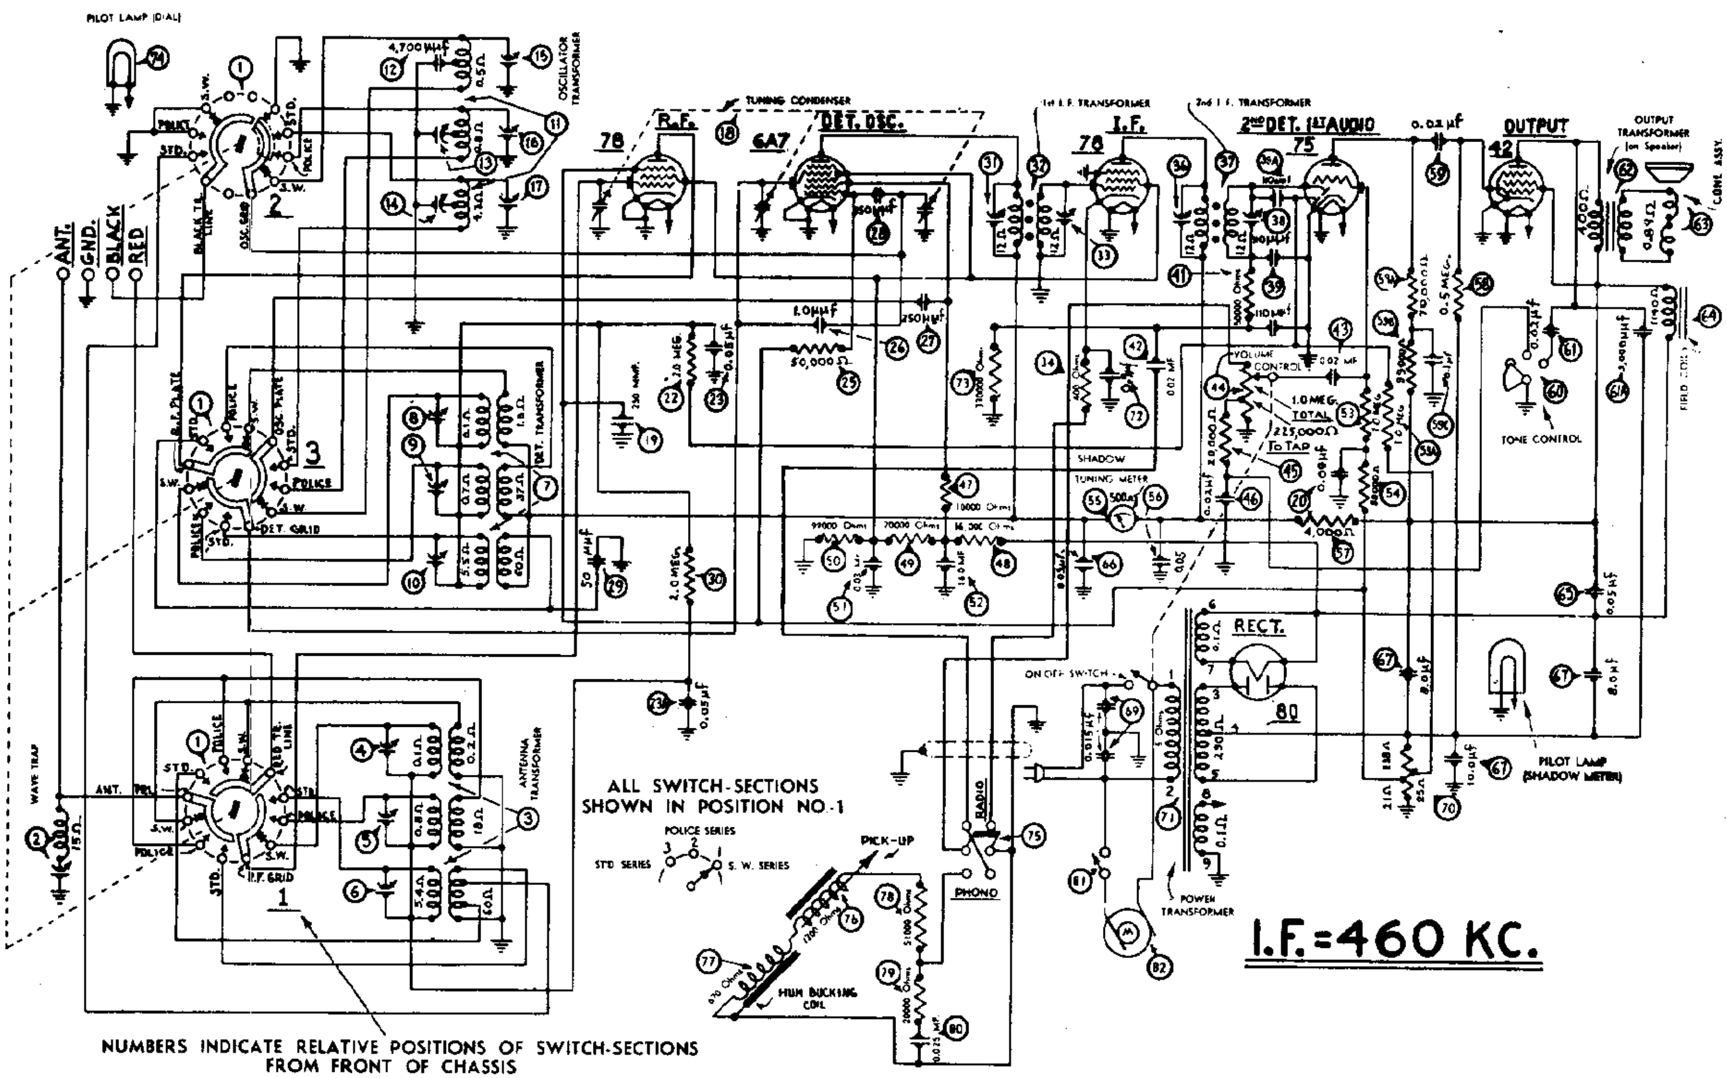
MODEL 635
Schematic

PHILCO RADIO & TELEV. CORP.



Type Circuit: Superheterodyne, with preselector R.F. amplifier, and pentode output (5 watts); built in connections for Philco All-wave aerial; aerial selector built into and operated by wave-band switch.

Power Supply: Alternating Current. Voltage and frequency as specified on chassis nameplate.

Tubes Used: 1 type 78, R.F.; 1 type 6A7, Detector-Oscillator; 1 type 78, I.F.; 1 type 75, 2d Detector and 1st A.F.; 1 type 42 Output; 1 type 80 Rectifier.

Wave Bands: Three—(1) Short Wave (with some Police); (2) Police, Aircraft and Amateur; (3) Standard.

Coverage of Each Band: Band 1, 540-1720 K.C.; Band 2, 1750 to 5800 K.C. (1.75-5.8 megacycles); Band 3, 5700-18000 K.C. (5.7 to 18.0 megacycles).

Tuning Drive: Two-speed gear drive, ball bearing. 50 to 1 ratio for slow-speed tuning.

Tone Control: 3-position, with bass compensation effective in first position.

Intermediate Frequency: 460 K.C.

Power Consumption: 70 watts.

MODEL 635 PHILCO RADIO & TELEV. CORP. Voltage, Alignment Transformer Data
Socket, Trimmers

Adjusting Compensating Condensers

The adjustment of the compensating condensers in Model 635 requires a signal generator covering the broadcast and police band, and also one capable of producing a signal at certain frequencies in the short wave band. Philco Model 088 All-wave signal generator is ideal for these requirements. Or you can use the Philco Model 024 or 048A instrument for the broadcast frequencies, and the Model 091 crystal controlled short wave signal generator for the "short wave" frequencies. The location of all compensating condensers is shown in Fig. 2. An output meter is also needed, such as in Philco Model 025

Adjustment of I. F.

1. Remove the antenna connection from the receiver, disconnect the grid clip from the first detector (type 6A7 tube), and connect the "ANT" output terminal of the broadcast signal generator to the grid cap of this tube; connect the "GND" terminal of the signal generator to the "GND" terminal of the receiver.
2. Connect the 0 to 30 volt range of the output meter in the Philco 048A or 025 unit to the plate and cathode of the output tube or to the two bottom prongs of the speaker plug.
3. Adjust the signal generator to a frequency of 460 K.C. Place the receiver in operation with the dial turned to the low frequency end of the standard broadcast band, wave band switch to extreme left (clockwise), and have the volume control adjusted near its maximum setting. Adjust the signal generator attenuator for approximately half-scale reading of the output meter.
4. The I.F. compensating condensers are located at the tops of the I.F. coil shields. The primary is adjusted by turning the screw in top and the secondary by the nut. Adjust condensers ([illegible]) and ([illegible]) (2d I.F. primary and secondary) for maximum reading in the output meter, and then condensers (31) and (33) (1st I.F. primary and secondary).

Adjustment of Wave-Trap

1. Connect the signal generator leads to the antenna and ground terminals of the receiver. Replace the grid clip on the 6A7 grid cap.
2. With the wave-band switch of the receiver still in the extreme left (standard band), (540-1720 K.C.), turn the station selector to 55.
3. With the signal generator in operation at 460 K.C., adjust the wave-trap (3) condenser until a MINIMUM reading is obtained on the output meter. The Philco fibre wrench, part No. 3164, is used for this adjustment. The wave-trap compensator is reached from rear of chassis.

Adjustment of High and Low Frequency Compensators

1. With the wave-band switch still at Range No. 3 (broadcast band), set the dial at 1700 K.C. Set the signal generator at this frequency and adjust compensators (17), (6) and (10) for maximum output. These are the oscillator, antenna, and R.F. "standard" compensators respectively.
2. Tune the receiver and the signal generator to 600 K.C. and adjust compensator (14) (screw) for maximum output. This is the oscillator L.F. standard compensator.
3. Turn the wave-band switch to the second (middle) position. Set the dial at 3.6 M.C. at which point the fundamental of the 091 signal will be heard. If the Model 088 Signal Generator is being used, set it at 3.6 M.C. Adjust condensers (16), (5) and (9) in succession. These are the oscillator, antenna and R.F. police band adjustments.
4. Turn the tuning dial to 1.8 M.C., and set the signal generator (Model 026 or Model 088) at 1800 K.C. Adjust condenser (13) (Osc. L.F., police) (nut), to maximum signal.
5. Turn the wave-band switch to Band 1 (extreme right) and adjust the station selector to 18.0 megacycles. Set the signal generator at 18 M.C. By means of the Philco wrench, part No. 3164, adjust the oscillator S.W., antenna S.W. and R.F. S.W. compensators for maximum reading in the output meter. These are numbered (15), (4) and (8) respectively in figure No. 2.

Adjusting Compensating Condensers

Adjustment of compensating condensers in Model 641 requires an accurate signal generator covering standard wave police, and shortwave frequencies. The **PHILCO Model 088 All-Wave Signal Generator,** having a continuous range of from 100 to 20000 K. C., is ideal for this purpose.

An output meter is also needed. **PHILCO Model 025 Circuit Tester** includes a high grade output meter.

Philco No. 3164 Fibre Wrench and **No. 27-7059 Fibre-Handled Screwdriver** complete the equipment needed for making these adjustments. The locations of the various compensating condensers are shown in Fig. 2. Connect the output meter to the plate contacts of the 43 output tubes (using the adapters provided with the "025") and set it at the 0-30 volt range.

I.F.—Connect the antenna lead from the No. 088 Signal Generator to the grid cap of the 78 I.F. amplifier (having removed the grid clip from the tube), and the ground lead to the ground post on the chassis. Set the Signal Generator No. 088 at 460 K. C., volume control of set full on, tone control counter-clockwise, wave band switch in No. 1 position, and condenser gang all the way in. Adjust the signal generator attenuator for approximately ¼ scale reading on the output meter, now adjust condensers [illegible] and [illegible] for maximum reading of the output meter. Remove the signal generator antenna lead from the grid cap (replacing grid clip) and connect to the 6A7 grid cap. Repeat procedure, this time tuning condensers 32 and 34 for maximum output reading. Care should be taken to keep the signal input from the signal generator low at all times to insure proper peaking of the transformers.

WAVE TRAP—Connect the Signal Generator antenna and ground-leads to the antenna and ground posts of the set. Replace the grid clip on the 6A7 tube cap. With the signal generator operating at 460 K. C. and the set controls adjusted as for I.F. adjustments, adjust wavetrap 1 until a minimum reading is obtained in the output meter.

SHORT WAVE—Turn wave band switch to extreme right (position 3) and set dial at 18.0 meg. Set Signal Generator at 18.0 meg. connect a shunt condenser across the oscillator section of the gang and tune the shunt for maximum output. Adjust condensers 4 and 15 for maximum output. Remove shunt condenser and adjust condenser [illegible] for correct calibration. Turn dial of set and signal generator to 6.0 meg. and adjust condenser 17 for maximum output. Repad condenser [illegible] on 18.0 meg.

STANDARD—Turn wave switch to Standard (position 1) and set dial at 1400 K. C. Set signal generator at 1400 K. C. adjust condensers 5, [illegible], [illegible] for maximum. Turn dial of set and signal generator to 580 K. C. and adjust condenser [illegible] for maximum output, retune condenser [illegible] at 1400 K. C.

POLICE BAND—Turn wave band switch to Police band (position 2), turn dial of set and signal generator to 2400 K. C. Adjust condensers 6 and [illegible] for maximum output.

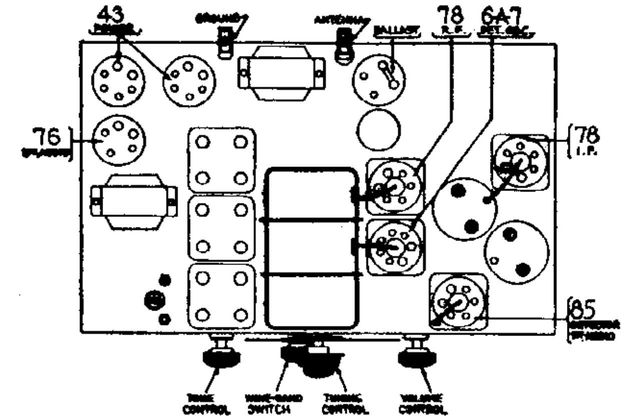

Fig. 1. Tube Sockets, top view

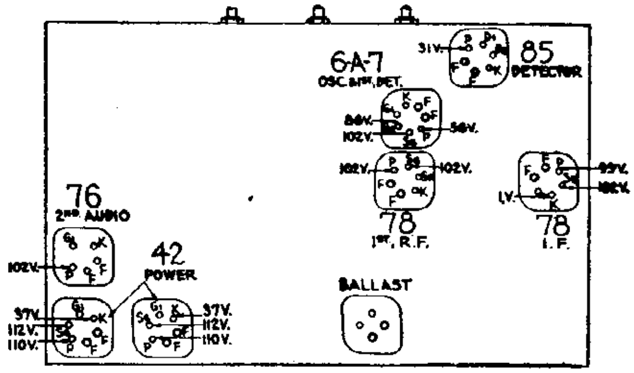

Fig. 2. Bottom View of Sockets with voltage measurements

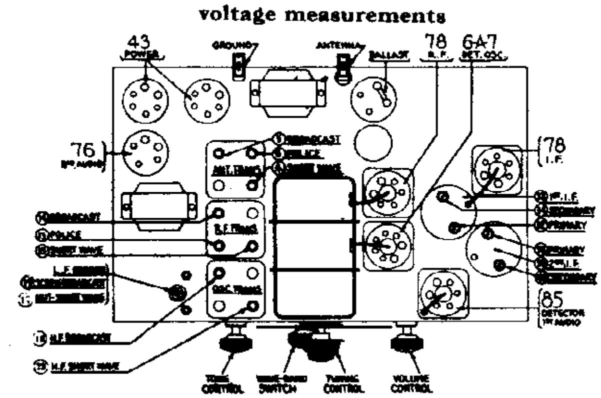

Fig. 5. Location of Compensating Condensers

TYPE CIRCUIT: Superheterodyne with preselector R. F. amplifier, and push-pull output (3 watts); built-in connections for Philco all-wave aerial; aerial selector built into and operated by wave band switch.

POWER CONSUMPTION: 40 watts.

SPEAKER: 641B—K-13; 641X—H-10.

COVERAGE OF EACH BAND: Standard (1), 530 to 1720 K. C.; Police (2), 2200 to 2600 K. C.; Shortwave (3), 5.8 to 18.0 Meg.

TUNING DRIVE: Dual Planetary, ball bearing, 80 to 1 ratio for slow speed tuning, 10 to 1 on main shaft.

TONE CONTROL: 3-position, base compensation effective in first position, second position (medium), third position (brilliant).

PHILCO RADIO & TELEV. CORP.

WAVE BANDS: Four—(1) Longwave (U. S. weather forecasts); (2) Standard; (3) Police; (4) Shortwave.
COVERAGE OF EACH BAND: Band 1, 150-390 K.C.; Band 2, 540-1730 K.C.; Band 3, 1.75 to 5.8 megacycles; Band 4, 5.8 to 18.0 megacycles.

TUNING DRIVE: Dual planetary, ball bearing, 80 to 1 ratio for slow speed tuning.
TONE CONTROL: 3-Position.
INTERMEDIATE FREQUENCY: 460 K.C.
CURRENT CONSUMPTION: "A" battery, .750 M.A.; "B" battery, 22 M.A.

Adjusting Compensating Condensers

Adjustment of compensating condensers in Model 643 requires an accurate signal generator covering long-wave, standard wave, police and short-wave frequencies.

The locations of the various compensating condensers are shown in Fig. 2. Connect the output meter to the plate and cathode contacts of the type 30 driver tube (using the adapters provided with the "025") and set it at the 0-30 volt range.

I.F.—Set the signal generator at 460 K.C. with attenuator set at minimum, and attach its antenna lead to the grid cap of the 34 I.F. amplifier tube (removing grid lead). Connect ground lead to ground terminal on set or some part of chassis. Set the dial at 55 and turn the waveband switch to position 2 (standard). Adjust the volume control of set to almost maximum (just before oscillator hiss becomes noticeable), and the 088 attenuator so that about one-fourth (¼) scale reading is had on the output meter. With a fibre screwdriver adjust condensers (44) and (45) (2nd I.F.) for maximum reading on output meter. Turn attenuator of signal generator to minimum and remove its antenna lead from the grid of the 34 I.F. tube, placing it on the grid of the 1C6. Adjust 088 attenuator as before then proceed to adjust condensers (40) and (41) (1st I.F.) for maximum reading. Then remove the 088 oscillator lead and replace grid connection. Care should be taken to keep the output meter reading during adjustments at about one-fourth scale reading. This should be done by using the 088 attenuator control.

WAVE TRAP—Connect the Signal Generator antenna and ground leads to the antenna and ground posts of the set. With the signal generator operating at 460 K.C. and the set controls adjusted as before for I.F. alignment, adjust wavetrap (1) until a minimum reading is obtained in the output meter.

SHORT WAVE—In adjusting the short wave or high frequency band, the R.F. compensator will have a tendency to "pull" or change the frequency of the oscillator. By shunting a padding or variable condenser across the oscillator section of the gang and tuning it so that the second harmonic, instead of the fundamental, beats with the incoming signal, this "pull" can be minimized. The procedure for tuning this band is as follows:

Set the dial of the receiver at 18 megacycles (top scale) and the 088 dial at the same frequency. Connect the shunt condenser to the oscillator section of the gang and tune it so that the second harmonic of the oscillator beats with the 18 M.C. signal from the 088. Next tune padders (22) and (8) (antenna and R.F.) for maximum reading of the output meter. Disconnect shunt condenser and tune padder (23) (osc.) for correct dial calibration. The oscillator frequency, when correctly set, will be higher than that of the incoming signal and the image frequency lower. In order to check this it should be possible to tune the image at approximately 17.1 M.C. by increasing the input from the 088 oscillator.

For the low frequency adjustment of this band, turn the dial to 6.0 M.C., set the signal generator at 6.0 M.C. and adjust condenser (20) for maximum reading. This compensator is underneath the chassis and reached from underneath.

POLICE BAND—Turn waveband switch to position 3 from left (police band); set dial at 5.5 and signal generator at 5500 K.C. Adjust condenser (25), (19) and (7) for maximum reading (osc., R.F. and Ant.). Turn dial to 1.8 and signal generator to 1800. Then adjust condenser (20) (nut) for maximum output reading.

STANDARD WAVE—Turn waveband switch to position 2 (standard broadcast), set signal generator at 1500 and dial of set at 150. Now adjust the oscillator, R.F., and antenna "Standard" condensers. These are (24), (18) and (6), respectively.

Now turn the dial to 60, set signal generator at 600 and adjust condenser (30)A (oscillator standard-series) (screw) for maximum reading.

LONG WAVE (Weather) BAND—Turn waveband switch to position 1 (left) (Longwave). Set dial at 35 and signal generator at 350 K.C. Adjust condensers (26), (17) and (5) (oscillator, R.F., and Antenna Longwave) for maximum reading.

Turn dial to 17, signal generator to 170 and adjust condenser (30)A (longwave series) for maximum reading.

In making these adjustments be sure that the signal level from the 088 is kept as low as possible. If the dial calibration is off, go over the low and high frequency padders in the oscillator circuit of each band until this is corrected.

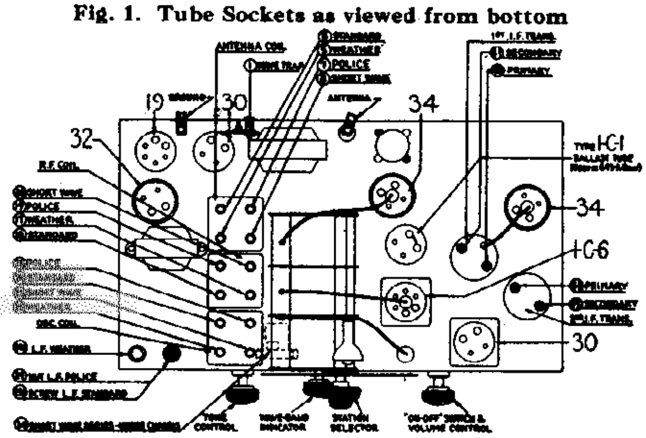

Fig. 2. Locations of Compensating Condensers

General Specifications

POWER SUPPLY: Battery operated Model 643 uses a 2-volt storage battery (Philco 172-R). Model 643-A uses dry A battery (Philco 41-8006). Both sets use a dry combination "B" and "C" battery unit (41-8061). This has a socket into which the plug on the battery cable attached to chassis is to be inserted.

TUBES USED: 1 type 34, pre-selector; 1 type 1C6, Detector-Oscillator; 1 type 34, I. F.; 1 type 30, 2nd Detector and A. V. C.; 1 type 32, 1st A. F.; 1 type 30, driver; 1 type 19 output. Model 643-A has also a ballast tube, type 1C1, to maintain constant filament voltage on all tubes. The socket for this tube exists in both 643 and 643-A chassis, but in the former, the type 1C1 tube is not used, and the filament contacts of the socket are shorted by a metal jumper.

ALL SWITCH-SECTIONS SHOWN IN POSITION NO.-1

TYPE CIRCUIT: Superheterodyne, with preselector R.F. amplifier, and push-pull pentode output (7 watts); built in connections for Philco All-wave aerial; aerial selector built into and operated by wave-band switch.

POWER SUPPLY: 115v., 60 cycle A.C.

COVERAGE OF EACH BAND: Band 1, 5.75–18 M.C.; Band 2, 1.75–5.8 M.C.; Band 3, 540–1750 K.C.

TUNING DRIVE: Dual planetary, ball bearing. 80 to 1 ratio for slow-speed tuning; glowing arrow wave band indicator.

INTERMEDIATE FREQUENCY: 460 K.C.

POWER CONSUMPTION: 85 watts.

SPEAKER: 645 Baby Grand Model—K31; Furniture Model—H21.

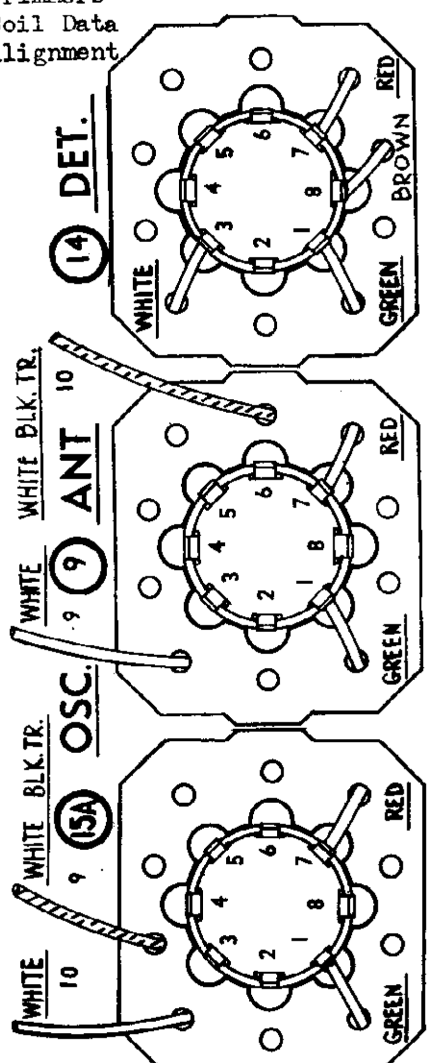

Fig. 1. R.F. Transformers

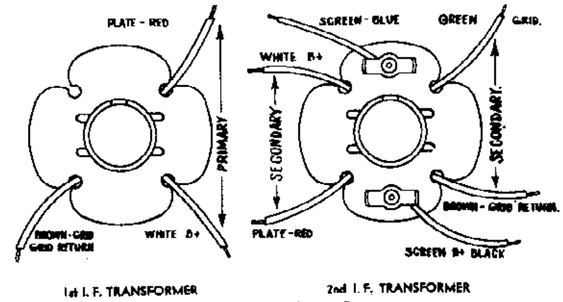

Fig. 2. I.F. Transformers

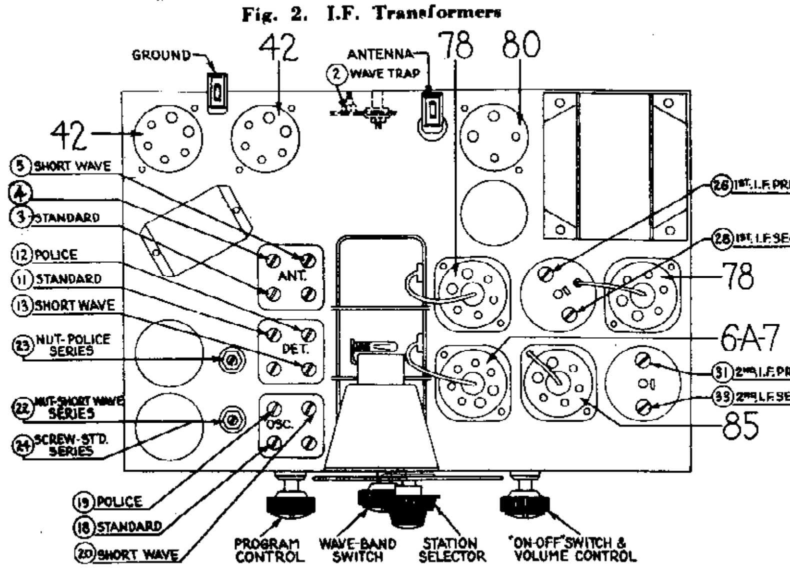

Fig. 4. Location of Compensating Condensers

Adjusting Compensating Condensers

The locations of the various compensating condensers are shown in Fig. 4. Connect the output meter to the plate contacts of the type 42 output tubes (using the adapters provided with the "025") and set it at the 0-30 volt range.

INTERMEDIATE FREQUENCY: Set the signal generator at 460 K.C. with attenuator set at minimum, connect a .001 mf. condenser in series with its antenna lead and attach it to the grid cap of the 78 I.F. amplifier tube. Connect ground lead to ground terminal on set. Set the dial at 55 and turn the waveband switch to position 3 (extreme left). Adjust the volume control of set to almost maximum, and the 088 attenuator so that about one-fourth (¼) scale reading is had on the output meter. With a fibre screwdriver adjust condensers 31 and 33 (2nd I.F.) for maximum reading on output meter. Turn attenuator of signal generator to minimum and remove its antenna lead from the grid of the 78 I.F. tube: place it on the grid of the 6A7. Adjust 088 attenuator as before, then proceed to adjust condensers 26 and 28 (1st I.F.) for maximum output meter reading. Then remove the 088 oscillator lead. Care should be taken to keep the output meter reading during adjustments at about one-fourth scale reading. This should be done by using the 088 attenuator control.

WAVE TRAP: Connect the Signal Generator antenna and ground leads to the antenna and ground posts of the set. With the signal generator operating at 460 K.C. and the set controls adjusted as before for I.F. alignment, adjust wave trap 2 until a minimum reading is obtained in the output meter.

SHORT WAVE: In adjusting the short wave or high frequency band, the det. compensator will have a tendency to "pull" or change the frequency of the oscillator. By shunting a padding or variable condenser (about .00025 Mf.) across the oscillator section of the gang (front section) and tuning it so that the second harmonic, instead of the fundamental, beats with the incoming signal, this "pull" can be minimized. The procedure for tuning this band is as follows:

Set the dial of the receiver at 18 megacycles (top scale) and the 088 dial at the same frequency. Turn wave band switch to position 1 (extreme right). Connect the shunt condenser to the oscillator section of the gang and tune it so that the second harmonic of the oscillator beats with the 18 M.C. signal from the 088. Next tune condensers 5 and 13 (antenna and det.) for maximum reading of the output meter. Disconnect shunt condenser and tune condenser 20 (osc.) for correct dial calibration. The oscillator frequency, when correctly set, will be higher than that of the incoming signal and the image frequency lower. In order to check this it should be possible to pick up the image at approximately 17.1 M.C. by increasing the input from the 088 oscillator.

For the low frequency adjustment of this band, turn the dial to 6.0 M.C., set the signal generator at 6.0 M.C. and adjust condenser 22 (nut) for maximum output meter reading. Readjust condenser 20 at 18.0 M.C.

POLICE: Turn wave band switch to position 2 (center), set signal generator at 5500 and dial of set at 5.5. Adjust condensers 19, 4 and 12 (osc., ant., and det.) for maximum output. Turn the set dial to 1.8 and the signal generator to 1800. Adjust condenser 23 (nut) (osc. series) for maximum output meter reading.

STANDARD WAVE: Turn waveband switch to position 3 (extreme left), set signal generator at 1500 and dial of set at 150. Now adjust the oscillator, antenna and det. "Standard" condensers. These are 18, 3 and 11 respectively. Turn the dial to 60, set signal generator at 600 and adjust condenser 24 (oscillator standard series), (screw) for maximum output meter reading.

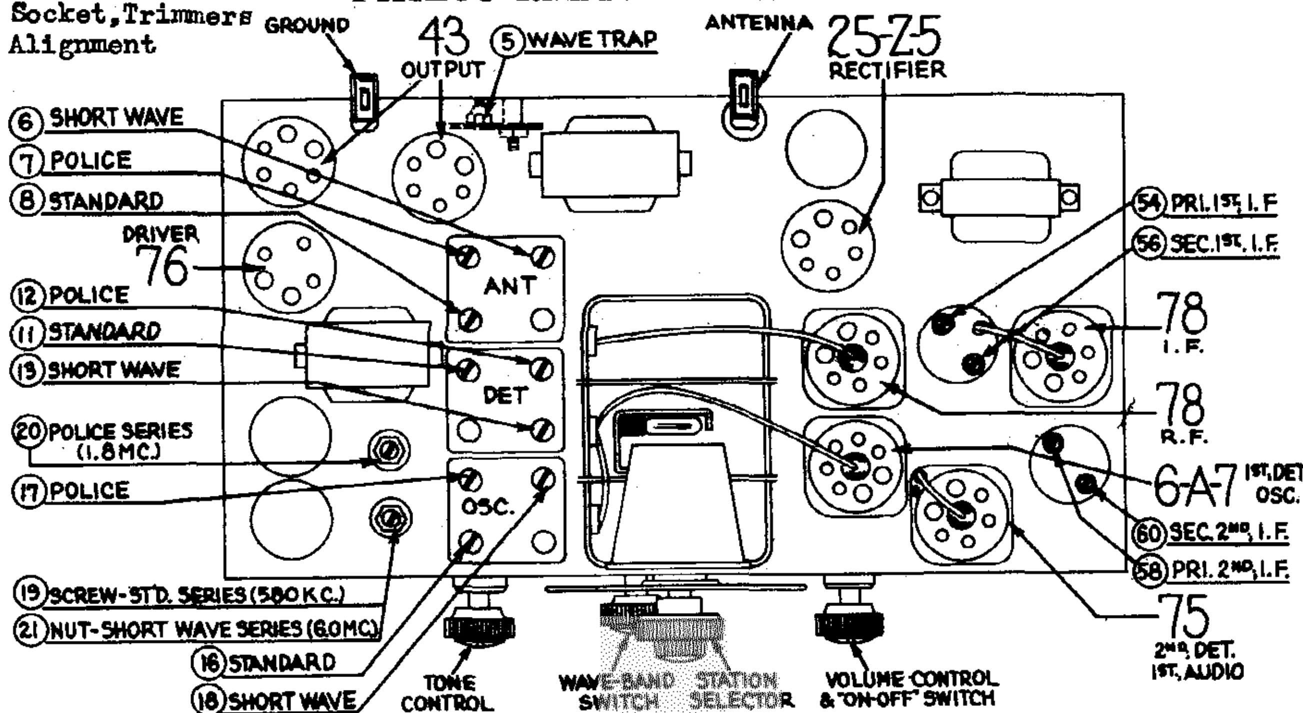

Fig. 4. Location of Compensating Condensers

Adjusting Compensating Condensers

Adjustment of compensating condensers in Model 651 requires an accurate signal generator covering I.F., standard-wave, police and short-wave frequencies. The **PHILCO Model 088 All-Wave Signal Generator,** *having a continuous* range of from 100 to 20,000 K.C., is ideal for this purpose.

An output meter is also needed. **PHILCO Model 025 Circuit Tester** includes a high grade output meter.

Philco No. 3164 fibre wrench and No. 27-7059 fibre-handled screwdriver complete the equipment needed for making these adjustments. The locations of the various compensating condensers are shown in Fig. 4. Connect the output meter to the plate contacts of the type 43 output tubes (using the adapters provided with the "025") and set it at the 0-30 volt range.

INTERMEDIATE FREQUENCY: Set the signal generator at 460 K.C. with attenuator set at minimum, connect a .001 mf. condenser in series with its antenna lead and attach it to the grid cap of the 78 I.F. amplifier tube. Connect ground lead to ground terminal on set. Set the dial at 55 and turn the waveband switch to position 3 (extreme left). Adjust the volume control of set to almost maximum, and the 088 attenuator so that about one-fourth (1/4) scale reading is had on the output meter. With a fibre screwdriver adjust condensers (58) and (60) *(2nd I.F.)* for maximum reading on output meter. Turn attenuator of signal generator to minimum and remove its antenna lead from the grid of the 78 I.F. tube; place it on the grid of the 6A7. Adjust 088 attenuator as before, then proceed to adjust condensers (54) and (56) (1st I.F.) for maximum output meter reading. Then remove the 088 oscillator lead. Care should be taken to keep the output meter reading during adjustments at about one-fourth scale reading. This should be done by using the 088 attenuator control.

WAVE TRAP: Connect the Signal Generator antenna and ground leads to the antenna and ground posts of the set. With the signal generator operating at 460 K.C. and the set controls adjusted as before for I.F. alignment, adjust wave trap (4) until a minimum reading is obtained in the output meter.

SHORT WAVE: In adjusting the short wave or high *frequency band, the det.* compensator will have a tendency to "pull" or **change** the frequency of the oscillator. By shunting a padding or variable condenser (about .00025 Mf.) across the oscillator section of the gang (front section) and tuning it so that the second harmonic, instead of the fundamental, beats with the incoming signal, this "pull" can be minimized. The procedure for tuning this band is as follows:

Set the dial of the receiver at 18 megacycles (top scale) and the 088 dial at the same frequency. Turn wave band switch to position 1 (extreme right). Connect the shunt condenser to the oscillator section of the gang and tune it so that the second harmonic of the oscillator beats with the 18 M.C. signal from the 088. Next tune condensers (6) and (13) (antenna and det.) for maximum reading of the output meter. Disconnect shunt condenser and tune condenser (18) (osc.) for correct dial calibration. The oscillator frequency, when correctly set, will be higher than that of the incoming signal and the image frequency lower. In order to check this it should be possible to pick up the image at approximately 17.1 M.C. by increasing the input from the 088 oscillator.

For the low frequency adjustment of this band, turn the dial to 6.0 M.C., set the signal generator at 6.0 M.C. and adjust condenser (21) (nut) for maximum output meter reading. Readjust condenser (18) at 18.0 M.C.

POLICE: Turn wave band switch to position 2 (center), set signal generator at 5500 and dial of set at 5.5. Adjust condensers (7), (12) and (17) (ant., det., and osc.) for maximum output. Turn the set dial to 1.8 and the signal generator to 1800. Adjust condenser (20) (osc. series) for maximum output meter reading.

STANDARD WAVE: Turn waveband switch to position 3 (extreme left), set signal generator at 1500 and dial of set at 150. Now adjust the oscillator, antenna and det. "Standard" condensers. These are (16), (11) and (8) respectively.

Now turn the dial to 60, set signal generator at 600 and adjust condenser (19) (oscillator standard series), (screw) for maximum output meter reading.

Parts List

PHILCO RADIO & TELEV. CORP.

MODEL 651
Voltage, Chassis

TUBE SOCKET VOLTAGES
(Measured from Tube Contact to B—)

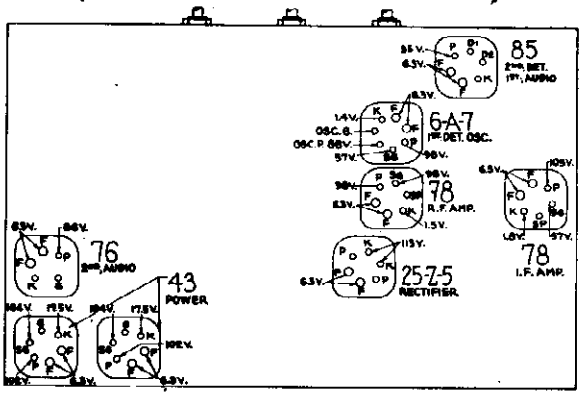

Fig. 3. Tubes as Viewed from Bottom

The voltages at the points indicated by the arrows above were obtained with a Philco type 025 Circuit Tester which contains a high resistance (1000 ohms per volt) voltmeter. Volume control at minimum, waveband switch at standard broadcast. KR-13 speaker.

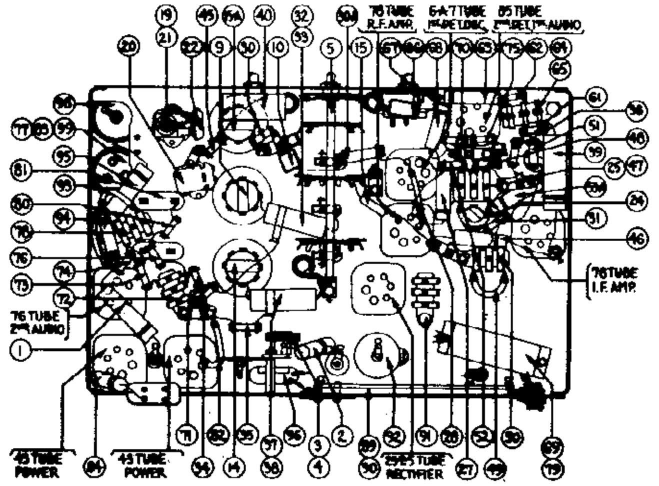

Fig. 6. Base View

NOTE: For Fig. 1. R.F. Transformers, For Fig. 2. I.F. Transformers, See MODEL 645.

Adjusting Compensating Condensers

Adjustment of compensating condensers in Model 655 requires an accurate signal generator covering I.F., standard-wave, police and short-wave frequencies. The **PHILCO Model 088 All-Wave Signal Generator,** having a continuous range of from 100 to 20,000 K.C., is ideal for this purpose.

An output meter is also needed. **PHILCO Model 025 Circuit Tester** includes a high grade output meter.

Philco No. 3164 fibre wrench and No. 27-7059 fibre-handled screwdriver complete the equipment needed for making these adjustments. The locations of the various compensating condensers are shown in Fig. 4. Connect the output meter to the plate contacts of the type 42 output tubes (using the adapters provided with the "025") and set it at the 0-30 volt range.

INTERMEDIATE FREQUENCY: Set the signal generator at 460 K.C. with attenuator set at minimum, connect a .001 mf. condenser in series with its antenna lead and attach it to the grid cap of the 78 I.F. amplifier tube. Connect ground lead to ground terminal on set. Set the dial at 55 and turn the waveband switch to position 3 (extreme left). Adjust the volume control of set to almost maximum, and the 088 attenuator so that about one-fourth (¼) scale reading is had on the output meter. With a fibre screwdriver adjust condensers (29) and (31) (2nd I.F.) for maximum reading on output meter. Turn attenuator of signal generator to minimum and remove its antenna lead from the grid of the 78 I.F. tube; place it on the grid of the 6A7. Adjust 088 attenuator as before, then proceed to adjust condensers (24) and (26) (1st I.F.) for maximum output meter reading. Then remove the 088 oscillator lead. Care should be taken to keep the output meter reading during adjustments at about one-fourth scale reading. This should be done by using the 088 attenuator control.

WAVE TRAP: Connect the Signal Generator antenna and ground leads to the antenna and ground posts of the set. With the signal generator operating at 460 K.C. and the set controls adjusted as before for I.F. alignment, adjust wave trap (2) until a minimum reading is obtained in the output meter.

SHORT WAVE: In adjusting the short wave or high frequency band, the det. compensator will have a tendency to "pull" or change the frequency of the oscillator. By shunting a padding or variable condenser (about .00025 Mf.) across the oscillator section of the gang (front section) and tuning it so that the second harmonic, instead of the fundamental, beats with the incoming signal, this "pull" can be minimized. The procedure for tuning this band is as follows:

Set the dial of the receiver at 18 megacycles (top scale) and the 088 dial at the same frequency. Turn wave band switch to position 1 (extreme right). Connect the shunt condenser to the oscillator section of the gang and tune it so that the second harmonic of the oscillator beats with the 18 M.C. signal from the 088. Next tune condensers (6) and (13) (antenna and det.) for maximum reading of the output meter. Disconnect shunt condenser and tune condenser (19) (osc.) for correct dial calibration. The set, oscillator frequency, when correctly adjusted, will be higher than that of the incoming signal. In order to check this it should be possible to pick up the 18 M.C. 088 oscillator signal as an image signal by increasing the 088 output and tuning the set to approximately 17.1 M.C.

For the low frequency adjustment of this band, turn the dial to 6.0 M.C., set the signal generator at 6.0 M.C. and adjust condenser (20) (nut) for maximum output meter reading. Readjust condenser (19) at 18.0 M.C.

POLICE: Turn wave band switch to position 2 (center), set signal generator at 5500 and dial of set at 5.5. Adjust condensers (18), (5) and (12) (osc., ant., and det.) for maximum output. Turn the set dial to 1.8 and the signal generator to 1800. Adjust condenser (21) (nut) (osc. series) for maximum output meter reading.

STANDARD WAVE: Turn waveband switch to position 3 (extreme left), set signal generator at 1500 and dial of set at 150. Now adjust the oscillator, antenna and det. "Standard" condensers. These are (17), (4) and (11) respectively.

Turn the dial to 60, set signal generator at 600 and adjust condenser (22) (oscillator standard series), (screw) for maximum output meter reading.

PHILCO RADIO & TELEV. CORP.

General Specifications

Type Circuit: Superheterodyne, with push-pull pentodes connected as triodes in output; output 10 watts; built in connections for Philco All-wave aerial; aerial selector built into and operated by wave-band switch.

Power Supply: Alternating Current. Voltage and frequency as specified on chassis nameplate.

Tubes Used: Ten (10) Total: 1 type 78 R.F., 1 type 77 1st detector, 1 type 76 oscillator, 2 type 78 I.F., 1 type 75 2nd detector 1st audio, 1 type 42 driver, 2 type 42 output, 1 type 80 rectifier.

Wave Bands: Four—(1) Shortwave; (2) Police and amateur; (3) Standard Broadcast; (4) Longwave (weather forecasts).

Frequency Ranges: Band (1)—5.7-18.0 Megacycles; Band (2)—1.75-5.8 Megacycles; Band (3)—540 to 1750 K.C.; Band (4)—150-390 K.C.

Program Control: 4 positions: (1) Mellow, (2) Brilliant, (3) Normal, (4) Noise reducing. Last two positions recommended for foreign short wave stations.

Tuning Meter: Shadow type tuning meter, mounted directly above scale.

Waveband Indicator: Glowing arrow on tuning scale shifts to proper scale when waveband switch is turned.

Automatic Volume Control: Fully effective on all stations.

Bass Compensation: Automatic: Effective on first two positions of program control, with volume control turned down.

Tuning Drive: Dual planetary, ball bearing. 80 to 1 ratio for slow-speed tuning, 10 to 1 on main knob.

Intermediate Frequency: 460 K.C.

Power Consumption: 90 watts.

Speaker: Type H-13.

Adjusting Compensating Condensers

Adjustment of compensating condensers in Model 665 requires an accurate signal generator covering long-wave, standard wave, police, and short-wave frequencies. The PHILCO Model 088 All-Wave Signal Generator, having a continuous range of from 100 to 20,000 K.C. (all fundamental frequencies) will be ideal for this purpose.

An output meter is also needed. PHILCO Model 025 Circuit Tester includes a high-grade output meter.

Philco No. 3164 fibre wrench and No. 27-7059 fibre handled screwdriver complete the equipment needed for making these adjustments. The locations of the various compensating condensers are shown in Fig. 2. Connect the output meter to the plate contacts of the output tubes (using the adapters provided with the "025") and set it at the 0-30 volt range.

I.F.—Set the Signal Generator at 460 K.C., and attach its antenna lead to the grid cap of the 77 1st detector tube (having removed the grid clip from the tube). Connect the ground terminal of the Signal Generator to the ground terminal of the set. Turn on the set, turn the waveband switch to standard broadcast (second position from left) and set dial at 60. Turn condenser (51) (2nd I.F. tertiary) all the way down before adjusting the other I.F. Compensators. Now with the fibre screwdriver, adjust condensers (57) and (55) (3rd I.F.), (52) and (49) (2nd I.F.), and then (42) and (40) (1st I.F.) until maximum reading is obtained in the output meter. Turn down the "attenuator" on the signal generator if the output meter needle goes off the scale. Now adjust condenser (51) (2nd I.F. tertiary) for maximum reading.

WAVE TRAP—Connect the Signal Generator antenna lead to the grid cap of the 78 R.F. tube. Replace the grid clip on the 77 tube cap. With the signal generator operating at 460 K.C. and the set controls adjusted as for I.F., adjust wavetrap (24) until the **minimum** reading is obtained in the output meter.

SHORTWAVE—Turn wave band switch to the shortwave position (extreme right). Set signal generator at 18 megacycles and dial of set at 18.0 (top scale). Now adjust the oscillator, Antenna, and R.F. shortwave compensators in turn, for maximum reading. These are (21), (13) and (7) respectively.

POLICE AND AMATEUR BAND—Turn the waveband switch to position 3 (from left). Set the dial and signal generator at 4.5 megacycles and adjust condensers (22), (12) and (6) respectively for maximum reading.

Set the signal generator at 1800 K.C. and turn the dial to 1.8. Adjust condenser (18) (nut), oscillator police series, to maximum reading.

STANDARD BROADCAST BAND—Turn the waveband switch to position 2 (from left). Set the dial and signal generator at 1500 K.C. and adjust condensers (29), (10) and (4) for maximum reading.

Set the dial and signal generator at 600 K.C. and adjust condenser (16) (screw), broadcast series, for maximum reading.

LONGWAVE BAND—Turn waveband switch to position 1 (left). Set the dial and signal generator at 340 K.C. and adjust condenser (28) (screw) to maximum. Then adjust (11) and (5) for maximum reading. Finally, set the dial and signal generator at 175 K.C. and adjust condenser (17) (nut) for maximum reading. This is the longwave series compensator.

Tube Socket and Power Transformer Voltages
Line Voltage 115

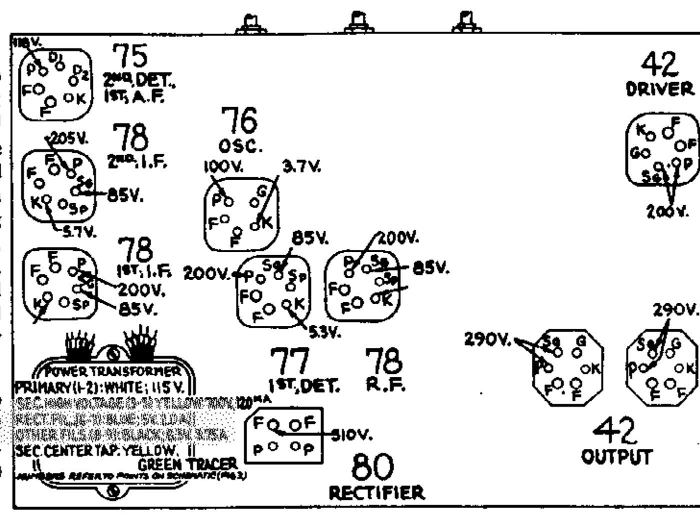

Fig. 1. Sockets as Viewed from Bottom

Socket voltages (measured to ground) obtained at points indicated by arrows. Above voltages were obtained by using a PHILCO type 025 Circuit Tester (or 048A All-purpose Tester), using test prods applied to sockets on underside of chassis. Volume control at minimum; dial at 60; waveband switch at standard broadcast (2d position from left). H-13 Speaker used.

MODEL 680
Chassis

PHILCO RADIO & TELEV. CORP.

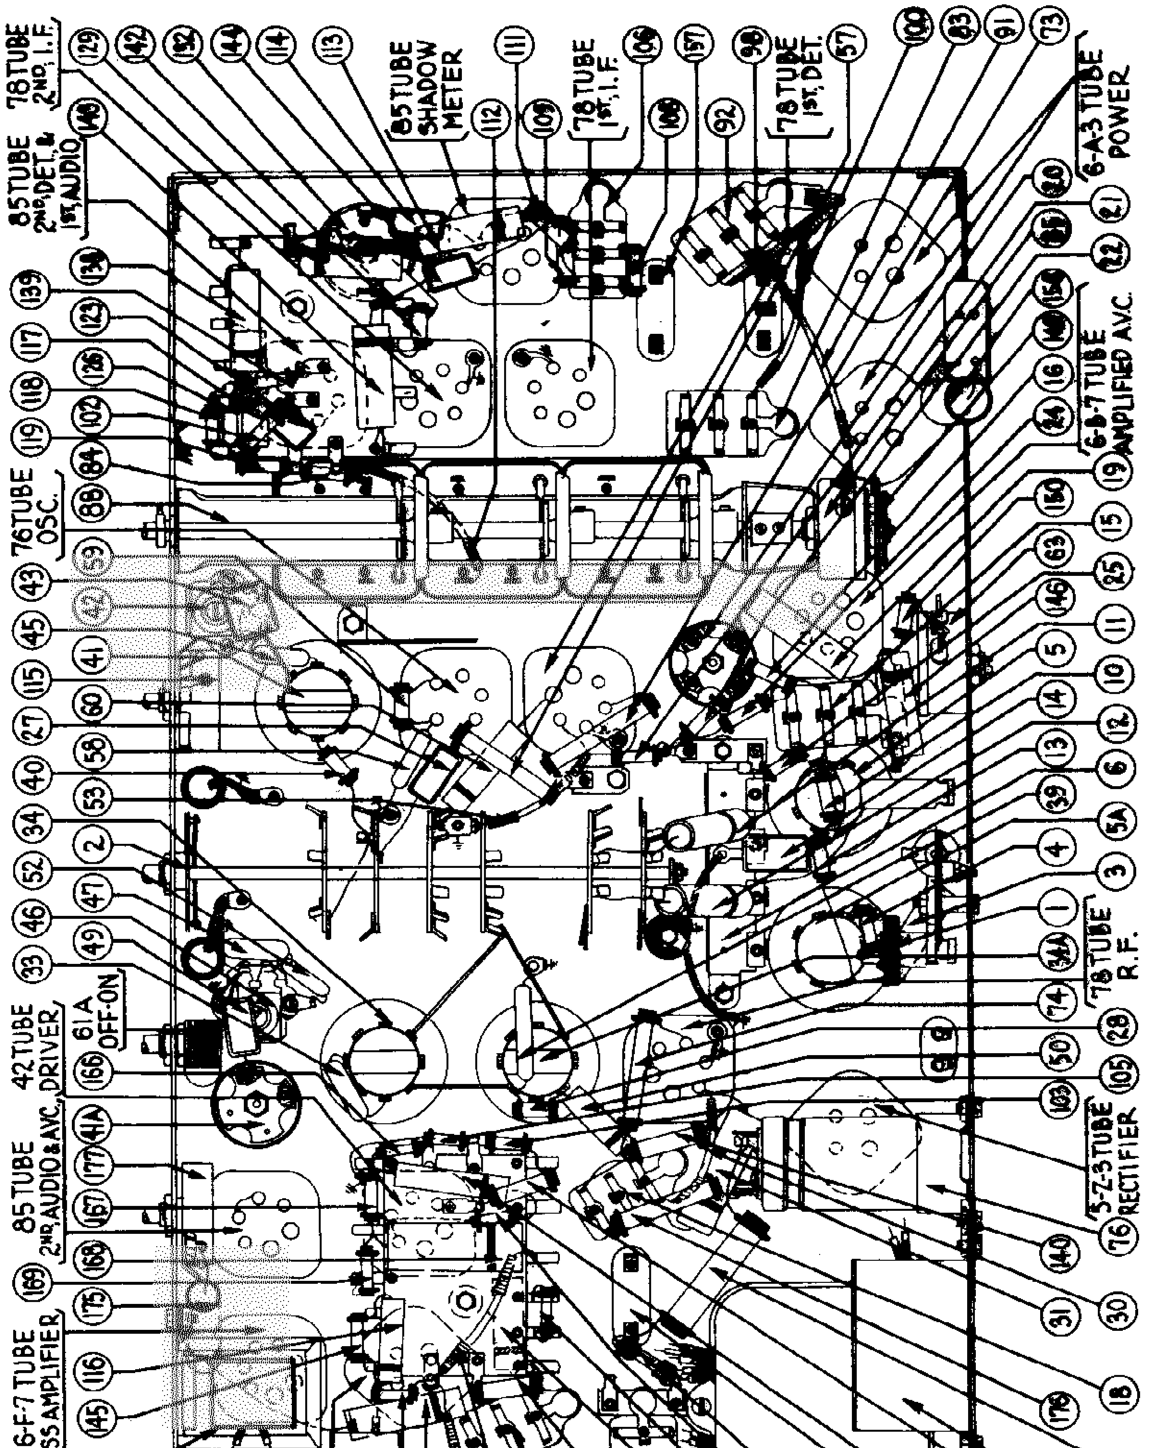

Fig. 3. Bottom View of Chassis

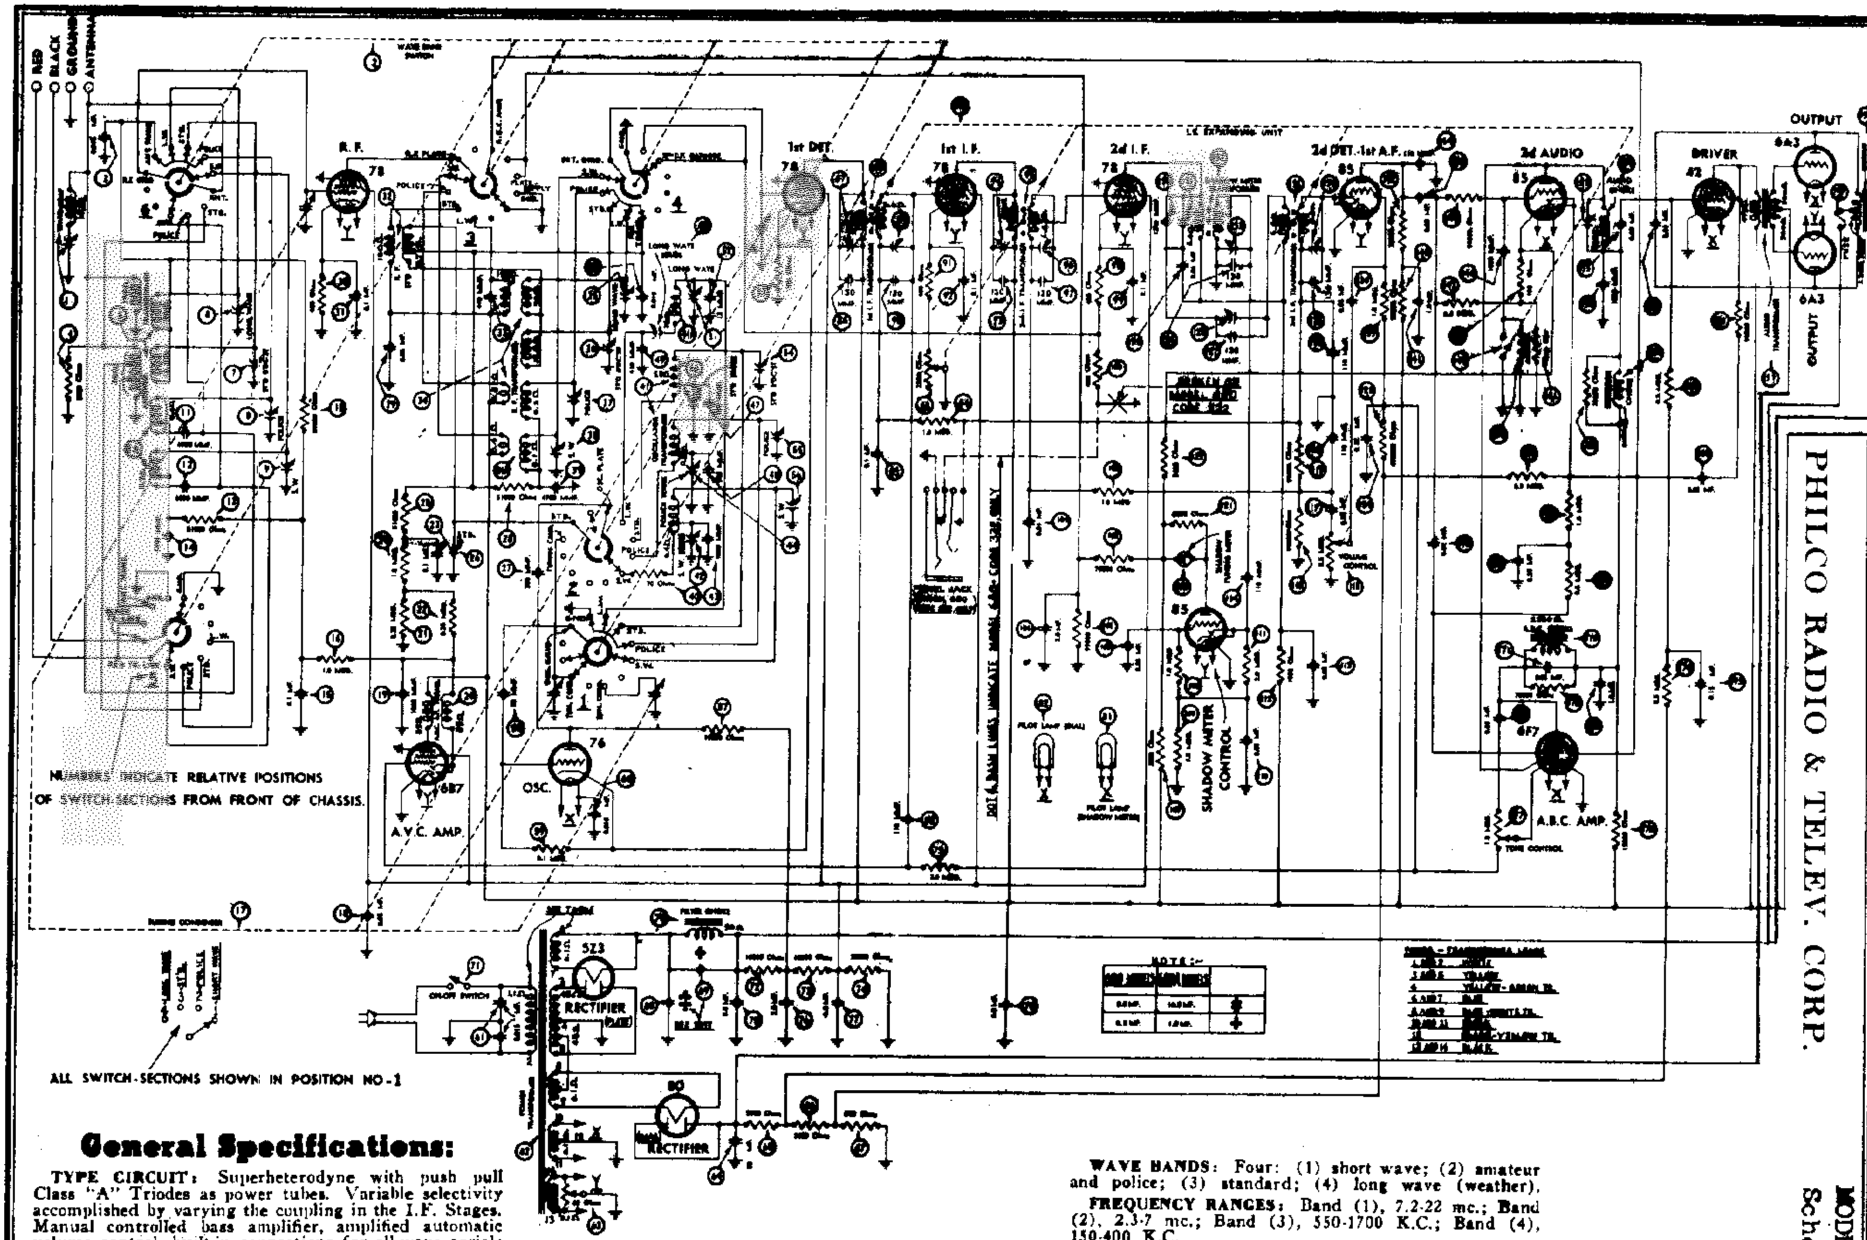
PHILCO RADIO & TELEV. CORP.



General Specifications:

TYPE CIRCUIT: Superheterodyne with push pull Class "A" Triodes as power tubes. Variable selectivity accomplished by varying the coupling in the I.F. Stages. Manual controlled bass amplifier, amplified automatic volume control, built-in connections for all-wave aerial; aerial selector built into and operated by wave band switch. Separate bias voltage supply for audio stages.

WAVE BANDS: Four: (1) short wave; (2) amateur and police; (3) standard; (4) long wave (weather).

FREQUENCY RANGES: Band (1), 7.2-22 mc.; Band (2), 2.3-7 mc.; Band (3), 550-1700 K.C.; Band (4), 150-400 K.C.

INTERMEDIATE FREQUENCY: 460 K.C.

MODEL 680
Socket, Voltage
Alignment

POWER SUPPLY: Alternating current, voltage and frequency as specified on name plate.
WAVE BAND INDICATOR: Glowing arrow on tuning scale shifts to proper scale when waveband switch is turned.
TUNING METER: Shadow type tuning meter mounted directly above scale and operated by a separate tube.
AUDIO OUTPUT: 20 watts undistorted output.
TUNING DRIVE: Dual Planetary, ball-bearing, 80 to 1 ratio for slow speed tuning. 10 to 1 normal.
POWER CONSUMPTION: 142 watts.
SPEAKER: U-10.

Adjusting Compensating Condensers

Adjustment of compensating condensers in Model 680 requires an accurate signal generator covering long-wave, standard wave, police, and short-wave frequencies. The **PHILCO Model 088 All-Wave Signal Generator**, having a continuous range of from 100 to 20,000 K.C. (all fundamental frequencies) will be ideal for this purpose.

An output meter is also needed. **PHILCO Model 025 Circuit Tester** includes a high-grade output meter.

PHILCO No. 3164 Fibre Wrench and **No. 27-7059 Fibre Handled Screwdriver** complete the equipment needed for making these adjustments. The locations of the various compensating condensers are shown in Fig. 2. Connect the output meter to the plate contacts of the output tubes (using the adapters provided with the "025") and set it at the 0-30 volt range.

Under no conditions attempt to adjust this receiver without these instruments.

Before attempting to adjust the I.F. stages, turn the condenser gang all the way in. The glowing arrow should then be between the two vertical lines at the extreme left of the low frequency calibrations. The Bass Control should be turned off (turn to left). The fidelity control in selective position (turn to left). Adjust the hum control (back of set) for minimum hum.

Attach the signal generator antenna lead to the grid of the 2nd I.F. 78 tube, and the ground lead to the ground post on set. Adjust the volume control of set to maximum (turn to right), tune the signal generator to 460 K.C., and adjust the attenuator of the signal generator for approximately ¼ scale output meter reading.

Turn condenser [illegible] (shadow meter compensator) approximately four turns to the left. Adjust condensers [illegible], [illegible], and [illegible] for maximum output meter reading. Adjust condenser [illegible] for minimum output meter reading.

Remove the signal generator antenna lead from the grid of the 2nd I.F., 78 tube and place it on the grid of the 1st I.F., 78 tube, again adjust the signal generator attenuator for approximately ¼ scale output meter reading and adjust condensers [illegible] and [illegible] for maximum output meter reading.

Remove the signal generator antenna lead from the grid of the 1st I.F., 78 tube and place it on the grid of the 1st detector, 78 tube. Regulate the signal generator attenuator as before for ¼ scale output meter reading. Adjust condensers [illegible] and [illegible] for maximum output meter reading.

Turn down the volume control of set and advance the signal generator attenuator until the shadow meter width decreases approximately fifty percent. Adjust condenser [illegible] for minimum shadow meter width.

Remove the signal generator antenna lead from the grid of 1st detector, 78 tube and couple it to the aerial post on the set through a 125 mmf. condenser. Turn the volume control of the set back to maximum (to right) and adjust the signal generator attenuator for approximately ½ scale output meter reading. Adjust the wave trap (condenser (D)) for minimum output meter reading.

Reconnect the signal generator antenna lead to the grid of the first detector 78 tube and adjust the signal generator attenuator for approximately ¼ scale output meter reading.

If the fidelity selectivity control is turned to the extreme right hand position, it will be found, upon varying the frequency of the signal generator, that two definite peaks will appear in the output meter reading—one at 452 K.C. and another at 468 K.C. These peaks in the output meter reading indicate peaks in the tuning curve. The amplitude of these peaks should be equal; that is, the same output meter reading should be obtained at both 452 K.C. and 468 K.C. Any variations in these two readings can be corrected by a slight readjustment of the shadow meter I.F. primary padder [illegible]. If the peak at 452 K.C. is higher than the one at 468 K.C., the primary padder will have to be turned out. If the reverse is true, the capacity of this padder must be increased. In any case, the voltmeter readings must be made equal by dividing the differences through readjustment.

R. F. and Oscillator Adjustments

SHORT WAVE

Turn the fidelity control back to the extreme left and the wave band switch to the extreme right (band 1). Connect the signal generator antenna lead to the aerial post on set through a two-meg resistor. Tune the set and signal generator to 18 mc. Turn the signal generator attenuator to maximum and adjust the volume control of set for ¼ scale reading on the output meter. Adjust condenser [illegible] for maximum output meter reading. Turn the dial of the set to approximately 17.1 mc. and check the image frequency.

Turn the dial of the set back to 18 mc. and connect a variable condenser (approximately 250 mmf.) across the oscillator section of the gang (2nd from front of chassis). Turn the variable shunt condenser in until the 18 mc. signal gives a reading on the output meter. Adjust condensers [illegible] and [illegible] for maximum output meter reading.

Removing the shunt condenser, turn the dial of the set and signal generator to 8 mc. and adjust condenser [illegible] for maximum output meter reading. Readjust condenser [illegible] with the set and signal generator tuned to 18 mc.

POLICE

Turn the wave band switch to position 2 and tune the set and signal generator to 6 mc. Adjust condensers (8), [illegible] and [illegible] for maximum output meter reading.

Turn the dial of the set and signal generator to 2.4 mc. and adjust condenser [illegible] for maximum output meter reading. Turn the dial of the set and signal generator back to 6 mc. and readjust condenser [illegible].

STANDARD

Turn the wave band switch to position 3 and tune the set and signal generator to 1500 K.C. and adjust condensers (7), [illegible], [illegible] and [illegible] for maximum output meter reading.

Turn the dial of the set and signal generator to 580 K.C., and remove the two meg. resistor from the antenna lead. Turn the volume control to maximum and adjust the signal generator attenuator for approximately ¼ scale output meter reading. Adjust condenser [illegible] for maximum output meter reading.

WEATHER

Turn the wave band switch to position 4, and tune the set and signal generator to 340 K.C. Adjust condensers [illegible], [illegible] and (61) for maximum output meter reading.

Turn the dial of the set and signal generator to 175 K.C. and adjust condenser [illegible] for maximum output meter reading. Readjust condenser (61) at 340 K.C.

Turn the wave band switch back to position (3) and tune the set and signal generator to 580 K.C. Adjust condenser [illegible] for maximum output meter reading. Tune the set and signal generator to 1500 K.C. and adjust condenser [illegible] for maximum output meter reading. Turn down (to left) the volume control and turn up (to right) the signal generator attenuator. Then adjust condenser [illegible] for maximum output meter reading.

Adjustment of 10 K. C. Filter

The 10 K.C. filter in the audio circuit will rarely require readjustment. As the proper adjustment of this padder ([illegible] on diagram) requires an accurately calibrated audio oscillator, it should be reset only in the event that it has been tampered with or in cases where it has become necessary to replace one of the elements of this filter.

Instructions covering an emergency adjustment of this filter can be obtained from your Philco distributor.

PHILCO RADIO & TELEV. CORP.

MODEL 680
Trimmers
Parts List

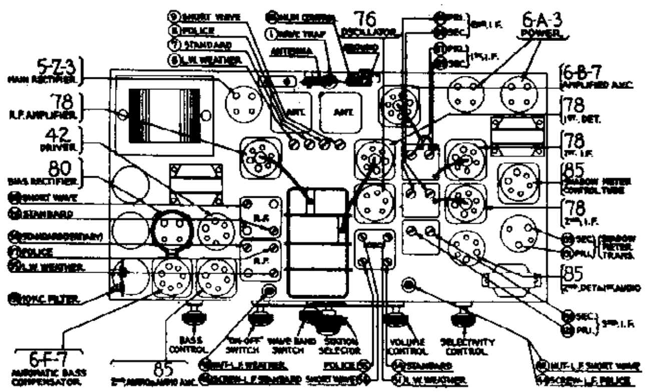

FIG. 2. Location of Compensating Condensers

TUBES USED: Fifteen (15) total: 1 type 78 R.F., 1 type 76 osc., 1 type 78, 1st det. and mixer, 2 type 78 I.F., 1 type 85, 2nd det. and 1st audio, 1 type 85, 2nd audio and audio A.V.C., 1 type 42 driver, 2 type 6A3 output, 1 type 6B7 amplified A.V.C., 1 type 6F7 automatic bass compensation, and bass amplifier, 1 type 85 shadow meter control, 1 type 80 fixed bias rectifier, 1 type 5Z3 main rectifier.

Replacement Parts for Model 680

Schematic No.	Part and Description	Part No.	List Price
1	Wave Trap	38-6850	$1.10
2	Wave Band Switch	42-1127	2.85
3	Condenser (0.015 mf.)	39-4358	.20
4	Resistor (5,000 ohms)	6096	.20
5	Antenna Transformer (Bdcst. 3 and 4)	32-1811	1.75
5a	Antenna Transformer (Bdcst. 1 and 2)	32-1812	1.10
6	Padder (Antenna Band 4)		
7	Padder (Antenna Band 3)	31-6047	.50
8	Padder (Antenna Band 2)		
9	Padder (Antenna Band 1)		
10	Resistor (51,000 ohms)	6098	.20
11	Condenser (6,000 mmf.)	30-4125	.20
12	Condenser (6,000 mmf.)	30-4125	.20
13	Resistor (51,000 ohms)	6098	.20
14	Condenser (4,700 mmf.)	30-1052	.55
15	Condenser (0.1 mf.)	4989-ODG	.40
16	Resistor (1.0 meg.)	33-1096	.20
17	Condenser Gang	31-1619	7.00
18	Condenser (0.05 mf.)	3615-ODG	.40
19	Condenser (1,000 mmf.)	30-4201	.20
20	I.F. Transformer (AVC)	32-1837	.70
21	Resistor (0.25 meg.)	6097	.20
22	Resistor (0.25 meg.)	6097	.20
23	Condenser (0.1 mf.)	Part of 15	....
24	Resistor (1.0 meg.)	33-1096	.20
25	Resistor (51,000 ohms)	6098	.20
26	Padder (R.F. Std.)	Part of 34a	....
27	Condenser (250 mmf.)	30-1032	.25

Notes

The coil windings terminate in leads instead of terminals or lugs. The color scheme of the leads is given in Figure 1.

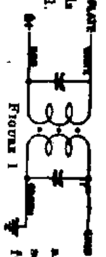

FIGURE 1

If replacements are ever necessary, replace the entire coil assembly, 32-2180 for the first I. F. stage and 32-2164 for the second I. F. stage. Neither the coil nor the padders will be furnished separately. Order only by the above numbers.

POLICE AUTO RADIO — MODELS 811PA, 811PB AND 811PV

There are two new types of Philco police auto radio Receivers, each designed to meet the special requirements of this particularly rigorous service: The Model 811PV, a variable tuning Police Receiver — and the Model 811P, a crystal controlled, fixed frequency Receiver, the DeLuxe Police Auto Radio.

HOUSING, PLATING, FINISH Both are single unit Receivers, housed in containers, 10¾ inches long by 7⅝ inches wide by 5-15/16 inches deep. The chassis, housing and covers are all steel and are plated to prevent rusting. They are given an exterior black wrinkle finish.

MOUNTING BRACKETS Hanger brackets riveted to the Receiver, hook on to a dash bracket which is permanently installed in the car, while a single bolt at the bottom fastens the Receiver securely to the dash. This makes the installation and removal of the Receiver a simple, rapid operation.

CONTROL SHAFTS, CONNECTIONS The volume control and (in case of 811PV) the tuning control couplers, the "A" battery and the antenna connectors are located on one end of the housing. The shafts are the rapid coupling type with the locking gland nut at the Receiver end. The "A" battery and antenna connections are quick detachable bayonet locking type, with the "A" fuse placed in the "A" lead.

CONDENSER MOUNTING The tuning condenser is mounted on live rubber. This prevents microphonic trouble from developing in the condenser and is a patented Philco feature.

CONDENSER DRIVE The condenser drive gear ratio (Model 811PV) is 16:1. This eliminates practically all back lash and due to the mechanism used, prevents the tuning condenser from detuning from vibration. This high gear ratio also makes accurate tuning much easier.

CONTROL UNIT The control unit for the Model 811PV is for installation on the edge of the instrument board. It contains the "On-Off" switch and the volume and tuning control knobs. The calibrated scale is illuminated. The Model 811P, fixed frequency Receiver, utilizes a single control knob, which is mounted on the instrument board. This controls the "On-Off" switch and the volume.

SUPERHETERODYNE RANGE 811PV DRIFT A superheterodyne circuit is used for the 811PV, also the 811P. The frequency coverage of the Model 811PV is from 1560 K.C. to 2600 K.C. continuously in one band. The oscillator and I.F. circuits are especially designed to reduce frequency drift to a minimum.

RANGE 811P The Model 811P, the fixed frequency Receiver, can be furnished adjusted for any one particular frequency within the limits of the regular police band, i. e., from 1680 K. C. to 1712 K. C. and from 2392 K. C. to 2490 K. C.

CRYSTAL CONTROL A crystal controlled oscillator circuit is employed in the Model 811P. The crystal control holds the oscillator on the required frequency and is responsible, in a large measure, for the greatly improved performance of this Receiver.

TUBE EQUIPMENT The tubes used in the 811P and 811PV are:

78 Tube — Tuned R. F. Amplifier with A. V. C.
6A7 Tube — First Detector — Oscillator with A. V. C.
78 Tube — I. F. Amplifier
75 Tube — Second Detector and "Q" Relay Stage.
75 Tube — First A. F. Amplifier with "Q" Control.
41 Tube — Power Output Stage
84 Tube — Full Wave Rectifier.

ANTENNAS Both Receivers employ antenna circuits that will track satisfactorily on any antenna capacity between 100 and 2500 mmf. This permits satisfactory operation on inserted metal top, door, spare wheel and other special types of antennas.

A. V. C. Both the R. F. stage and the first detector stage have full automatic volume control supplied by the diode detector.

"Q" CIRCUIT In addition to this, the Receivers also have a "Q" or carrier relay circuit. The function of this circuit is to completely silence the Receiver when tuned off carrier, or when the carrier goes off the air. The correct values of the resistor network have been determined and used for satisfactory city operation where it is desirable to exclude street car noises, etc. A switch is provided on the end of the Receiver housing, to open or close this circuit, since, when in remote sections of the territory, where the police transmitter signal might be very weak, slight additional sensitivity can be obtained with the "Q" circuit cut out. This "Q" circuit should not be confused with the conventional squelch circuit. The "Q" relay circuit operates on a carrier field strength equivalent to approximately 8 microvolts in the antenna. A carrier below this strength is almost always of insufficient strength to give satisfactory reception, especially in noisy locations.

DYNAMIC SPEAKER SPECIAL AUDIO A full-powered electro-dynamic speaker is used to give clarity of reproduction and better articulation. The audio and the speaker circuits are especially designed to give the best reproduction of the voice frequencies. The Receiver and speaker are capable of delivering considerably greater undistorted output than is normally required.

POWER SUPPLY The power supply is self contained and is not polarized. The Receiver can be installed in any car without reversing battery connections. Philco's Improved Full-wave Vibrator is used.

These models are without peer and are the best modern police Receivers obtainable. They represent the best designing, engineering and production skill in the industry.

ADJUSTMENTS — MODEL 811PV

The Model 811PV is a variable frequency Auto Radio Receiver with a frequency range of 1560 K. C. to 2600 K. C. The scale is calibrated only between 1575 K. C. and 1750 K. C., and between 2100 K. C. and 2500 K. C., since these are the conventional emergency police bands. The Model 811PV has an intermediate frequency of 260 K. C. and does not employ crystal control.

The Receiver must be set up for operation and the volume control set at maximum. The Receiver "Q" switch must be in the off position, cutting out the carrier relay circuit. Use a quality modulated oscillator or signal generator for the test signal, with an output meter connected across the output stage. The signal from the generator should be attenuated so that the output signal is just sufficient to actuate the output meter. The signal should not be strong enough to operate the automatic volume control.

The I. F. transformers are assembled complete with padding condensers.

Both the primary and the secondary padders are placed side by side in the top of the transformer shield can. The adjusting screws are accesible thru the holes in the top of the shield. (See Figure 1.)

I. F. STAGES — The signal generator must be set at exactly 260 K. C. and the generator lead connected to the grid cap of the 78 I. F. tube in series with a .1 mfd. condenser. Adjust the padders ⑤ and ⑥ on the second I. F. transformer for maximum output.

In a like manner, connect the signal generator lead to the grid caps of the 6A7 detector oscillator tube and adjust the padders on the first I. F. transformer.

R. F. — Connect a 2600 K. C. signal to the grid of the 78 R. F. amplifier tube in series with a .1 mfd. condenser. Set the tuning condenser at minimum capacity, using a strip of bond paper as a gauge under the heel of the rotor plates.

Adjust the first detector and oscillator padders ③ and ④ for maximum output.

Reset the signal generator for a 1600 K. C. signal. Tune in the signal and roll the variable condenser while adjusting the oscillator series padder ⑦.

Recheck the oscillator padder adjustment at 2600 K. C. Connect the signal generator to the Receiver antenna lead, using a 180 mmfd. condenser dummy antenna and adjust the antenna padder ① at 2600 K. C.

IMPORTANT — All adjustments should be repeated after the Receiver has been operated at 8 volts for approximately 8 hours.

I. F. TRANSFORMERS AND PADDERS

The I. F. transformers are assembled complete with padding condensers.

Both the primary and the secondary padders are placed side by side in the top of the transformer shield can. The adjusting screws are accessible thru the holes in the top of the shield. (See Figure 3.)

MODEL 811PA,811PB
Alignment

ADJUSTMENTS — MODELS 8 1 1 PA AND 8 1 1 PB

The fixed frequency Auto Radio Receivers are identical, except for the crystals used to obtain the various oscillator frequencies.

The Receivers, when used with the proper crystals, can be adjusted for any specified frequency between the limits of 1630 K. C. and 1712 K. C. (Model 811 PA) and 2382 K. C. and 2490 K. C. (Model 811 PB). Different crystals are used to obtain these frequencies. The crystal frequency, however, is no indication of the Receiver frequency adjustment.

FREQ. OF CRYSTAL	RECEIVER FREQ.	PART NO. CRYSTAL
1908 K. C.	1630-1634-1642 1650-1658-1666 K. C.	45-2194
1953 K. C.	1674-1682-1690 1698-1706-1712 K. C.	45-2195
2658 K. C.	2382-2390-2398 2406-2414 K. C.	45-2196
2696 K. C.	2422-2430-2442 2450 K. C.	45-2197
2784 K. C.	2458-2466-2474 2482-2490- K. C.	45-2198

The I. F. frequency used in each Receiver is the difference between the frequency of the crystal in the Receiver and the frequency of the transmitter, i. e.: the transmitter frequency is 2422 K. C., the crystal used is 2696 K. C., the difference is 274 K. C., which is the frequency to which the I. F. amplifier must be tuned.

The Receivers are carefully adjusted to the required frequency at the factory and ordinarily need no readjustments except when the transmitter frequency is changed. Then the Receiver must be padded while warm.

The Receiver must be set up for operation and the volume control set at maximum. The Receiver "Q" switch must be in the off position, cutting out the carrier relay circuit. Use a quality modulated oscillator or signal generator for the test signal, with an output meter connected across the output stage. The signal from the signal generator should be attenuated so that the output signal is just sufficient to actuate the output meter. The signal should not be strong enough to operate the automatic volume control.

I. F. STAGES — The signal generator must be set exactly on the predetermined frequency and the generator lead connected to the grid cap of the 78 I. F. tube in series with a .1 mfd. condenser. Adjust the padders 22, 24 on the second I. F. transformer for maximum output.

In a like manner, connect the signal generator lead to the grid cap of the 6A7 detector oscillator tube and adjust the padders 19 and 21 on the first I. F. transformer.

Check the adjustments of the second I. F. transformer and the first I. F. transformer.

R. F. — Tune the signal generator to the frequency of the transmitter and connect the output of the generator to the Receiver antenna lead, through a 200 mmfd. dummy antenna.

The variable condenser is locked in place with two set screws. Adjust these and tune the variable condenser to the input frequency. If the crystal oscillator circuit does not function at first, loosen the padder 13 on the oscillator section of the tuning condenser and also the series padder 17. If the oscillator output is low, it can be increased by adjusting the padder 13 for the higher frequencies and the padder 17 for the lower frequencies.

Adjust the R. F. and detector padders 6 and 10 for maximum output. If after adjusting, they are loose, back out the tuning condenser slightly — or if they are too tight, turn the condenser in slightly. Then readjust the padders.

On the Model 811PA (lower frequency band) adjust the series padder 17 for maximum output reading, and on the Model 811PB (higher frequency band) adjust the high frequency padder 13 The adjustment will not give a sharp peak, but it is possible to adjust for the maximum output. After this is obtained, back off the adjusting nut a half turn.

After completing these adjustments, recheck all the padders. This time, using a carefully calibrated signal generator, or better still, test tone from the police transmitter, connected to the Receiver antenna lead through a 200 mmfd. dummy antenna. Recheck the padders 6, 10, 13 and 17 on the gang condenser. Using the same signal, adjust the second I. F. and first I. F. padders for maximum output.

IMPORTANT — These adjustments should be repeated after the Receiver has been operated at 8 volts for approximately 8 hours.

DO NOT OPEN THE CRYSTAL HOLDER. If, for any reason whatever it has been opened, the crystal and plates should be very carefully cleaned with carbon tetrachloride. After cleaning, the crystal must not be touched by the fingers. Use a clean cloth for handling.

ANTENNA CONNECTIONS

NOTE:- Use "A" wiring when receiver is installed in a car having a top screen antenna, undercar antenna, spare wheel antenna or antenna having similarly low relative capacitance (50 μμf to 450 μμf).

Use "B" wiring when receiver is installed in a car having a metal insert top antenna, insulated door antenna, insulated trunk cover antenna or antenna having similarly high relative capacitance (450 μμf to 2500 μμf).

Notes, Parts List

PHILCO RADIO & TELEV. CORP.

NOTE: When receiver is installed in a car having top, under-car, spare wheel, or antenna's having similar lo-relative capacitance (50mmf.-450mmf.) use connector plug in "A". When installed in a car having a metal insert top, insulated door, insulated trunk cover, or antenna's having similarly hi-relative capacitance (450mmf.-2500mmf.) use condenser plug in "B".

MODEL 816
MODEL 817
Socket, Trimmers
Alignment

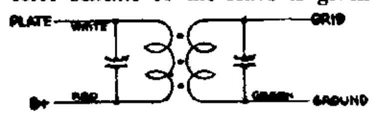
PHILCO RADIO & TELEV. CORP.

I. F. TRANSFORMERS AND PADDERS

The I. F. transformers are assembled complete with padding condensers.

Both the primary and the secondary padders are placed side by side in the top of the transformer shield can. The adjusting screws are accessible thru the holes in the top of the shield (See Figure).

The coil windings terminate in leads instead of terminals or lugs. The color scheme of the leads is given in Figure



If replacements are ever necessary, replace the entire coil assembly, 32-2026 for the first I. F. stage and 32-2027 for the second I. F. stage. Neither the coil nor the padders will be furnished separately. Order only by the above numbers.

MODEL 816 817 ADJUSTMENTS

All padding adjustments are carefully made at the factory and ordinarily no readjustments are necessary. However, when readjustments are required, the procedure given below must be followed in detail.

Equipment

Fully charged heavy duty storage battery or 6-volt power pack, 048A Philco Set Tester, 3164 Padding wrench, 27-7159 Padding screw driver.

General

OUTPUT METER—The output meter must be connected by means of an adapter to the plate of the type 41 output tube and to the Receiver chassis.

SIGNAL GENERATOR—With the Receiver and signal generator set up for operation at the prescribed frequency, turn the Receiver volume control on full and set the signal generator attenuator so that a half scale reading is obtained on the output meter. The signal in the speaker should be audible but not loud.

The shielding on the signal generator output lead must be connected to the Receiver housing.

Procedure

I. F.—Set the signal generator at exactly 260 K. C. Connect the generator lead to the grid cap of the 78 I. F. tube in series with a .1 mfd. condenser (without removing the grid cap).

Adjust the secondary screw padder 27 on the second I. F. transformer for maximum reading on the output meter. Then adjust the primary screw padder 25 for maximum reading. (See Figure for location of padders).

Remove the generator lead from the 78 tube.

Connect the generator lead to the grid cap of the 6A7 tube in series with a .1 mfd. condenser (without removing the grid cap). Adjust the secondary screw padder 24 on the first I. F. transformer for maximum reading on the output meter. Then adjust the primary screw padder 22 for maximum reading. (See Figure for location of padders).

HIGH FREQUENCY AND R. F.—After padding the first I. F. stage remove the generator lead from the 6A7 tube.

Set the signal generator at 1550 K. C. and then connect the generator lead to the grid cap of the 78 R. F. tube in series with a .1 mfd. condenser (without removing the grid cap).

Turn the tuning condenser plates out of mesh as far as they will go. With the tuning condenser in this position, adjust the high frequency padder 16 and the R. F. padder 11 until the maximum reading is obtained on the output meter. This is the true setting for 1550 K. C., 155 on the dial scale.

LOW FREQUENCY—Turn the tuning condenser plates in mesh to approximately 580 K. C., 58 on the dial scale and set the signal generator at 580 K. C. Roll the tuning condenser and adjust the low frequency padder screw 20 for maximum reading on the output meter.

HIGH FREQUENCY RE-ADJUSTMENT—Turn the tuning condenser plates out of mesh as far as they will go and set the signal generator at 1550 K. C. Then adjust the high frequency padder 16 again for maximum reading on the output meter.

Remove the generator lead from the 78 R.F. tube.

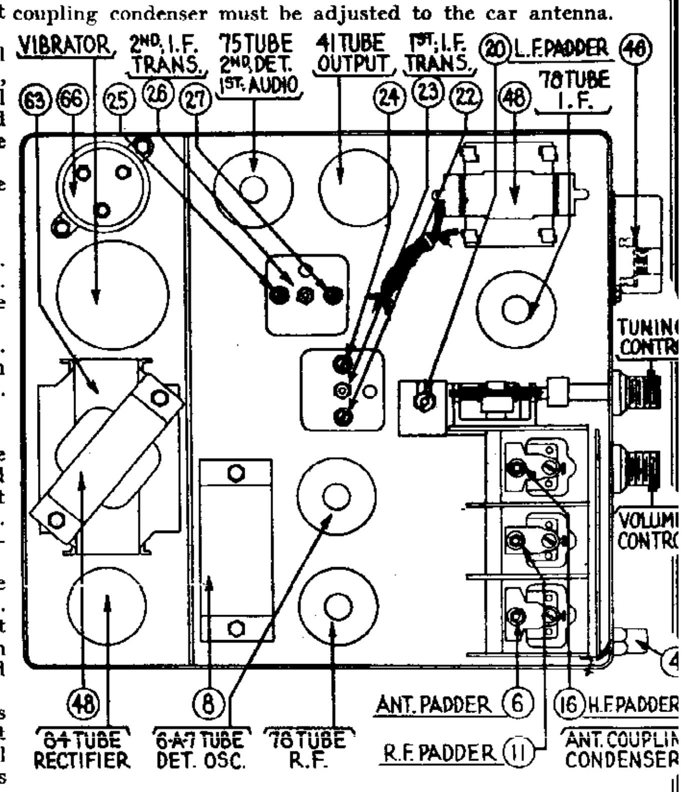
ANTENNA—Connect the generator lead to the antenna cable assembly (made up of Part No. L1915 loom, 1-27-7133 terminal and 40 inches of 16 strand No. 30 wire), using a 200 mmfd. condenser in series between the two leads. Place the connector plug in the antenna socket on the Receiver. Plug the cable into the antenna socket.

Turn the tuning condenser in mesh to 580 K. C., and adjust the signal generator at 580 K. C. Adjust the Antenna coupling condenser 4 for maximum reading.

Turn the tuning condenser to 1400 K. C. and set the generator at 1400 K. C. Adjust the padders 11 and 6 for the maximum reading on the output meter.

When the antenna stage adjustment is made with the Receiver installed in the car, the Receiver antenna lead must be connected to the car antenna in the usual manner. Connect the signal generator output lead to a wire placed near the car antenna but not connected to it.

When installing the radio in a car, follow the installation instructions carefully. The correct connector must be used in the antenna lead connector in the Receiver and the antenna coupling condenser must be adjusted to the car antenna.



The Model 817 Receiver is furnished with the new streamline "wide vision" control which can be installed on the edge of instrument board. This control unit is exceptionally attractive and is designed to blend harmoniously with the instrument boa of practically all cars. The circuit and layout of the Models 817B-817C and 817P Receivers are the same as the Model However, these Receivers are equipped with a special "customed" control unit which matches the instrument board fittings, is designed for installation in the space provided for radio control in the instrument board of the 1936 Buick, Chevrolet Pontiac cars.

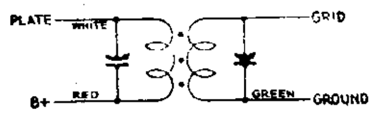
I. F. Transformers and Padders

The I. F. transformers are assembled complete with padding condensers.

Both the primary and the secondary padders are placed side by side in the top of the transformer shield can. The adjusting screws are accessible thru the holes in the top of the shield. (See Figure).

The coil windings terminate in leads instead of terminals or lugs. The color scheme of the leads is given in Figure



If replacements are ever necessary, replace the entire coil assembly, 32-2026 for the first I. F. stage and 32-2027 for the second I. F. stage. Neither the coil nor the padders will be furnished separately. Order only by the above numbers.

MODEL 818 818K ADJUSTMENTS

All padding adjustments are carefully made at the factory and ordinarily no readjustments are necessary. However, when readjustments are required, the procedure given below must be followed in detail.

Equipment

Fully charged heavy duty storage battery or 6-volt power pack, 048A Philco Set Tester, 3164 Padding wrench, 27-7159 Padding screw driver.

General

OUTPUT METER—The output meter must be connected by means of an adapter to the plate of the type 41 output tube and to the Receiver chassis.

SIGNAL GENERATOR—With the Receiver and signal generator set up for operation at the prescribed frequency, turn the Receiver volume control on full and set the signal generator attenuator so that a half scale reading is obtained on the output meter. The signal in the speaker should be audible but not loud.

The shielding on the signal generator output lead must be connected to the Receiver housing.

Procedure

I. F.—Set the signal generator at exactly 260 K. C. Connect the generator lead to the grid cap of the 78 I. F. tube in series with a .1 mfd. condenser (without removing the grid cap).

Adjust the secondary screw padder 39 on the second I. F. transformer for maximum reading on the output meter. Then adjust the primary screw padder 37 for maximum reading. (See Figure for location of padders).

Remove the generator lead from the 78 tube.

Connect the generator lead to the grid cap of the 6A7 tube in series with a .1 mfd. condenser (without removing the grid cap). Adjust the secondary screw padder 25 on the first I. F. transformer for maximum reading on the output meter. Then adjust the primary screw padder 23 for maximum reading. (See Figure for location of padders).

HIGH FREQUENCY AND R. F.—After padding the first I. F. stage remove the generator lead from the 6A7 tube.

Set the signal generator at 1550 K. C. and then connect the generator lead to the grid cap of the 78 R. F. tube in series with a .1 mfd. condenser (without removing the grid cap).

Turn the tuning condenser plates out of mesh as far as they will go. With the tuning condenser in this position, adjust the high frequency padder 16 and the R. F. padder 11 until the maximum reading is obtained on the output meter. This is the true setting for 1550 K. C., 155 on the dial scale.

LOW FREQUENCY—Turn the tuning condenser plates in mesh to approximately 580 K. C., 58 on the dial scale and set the signal generator at 580 K. C. Roll the tuning condenser and adjust the low frequency padder screw 20 for maximum reading on the output meter.

HIGH FREQUENCY RE-ADJUSTMENT—Turn the tuning condenser plates out of mesh as far as they will go and set the signal generator at 1550 K. C. Then adjust the high frequency padder 16 again for maximum reading on the output meter.

Remove the generator lead from the 78 R. F. tube.

ANTENNA—Connect the generator lead to the antenna cable assembly (made up of Part No. L1915 loom, 1-27-7133 terminal and 40 inches of 16 strand No. 30 wire), using a 200 mmfd. condenser in series between the two leads. Place the connector plug in the antenna socket on the Receiver. Plug the cable into the antenna socket.

Turn the tuning condenser in mesh to 580 K. C., and adjust the signal generator at 580 K. C. Adjust the Antenna coupling condenser 4 for maximum reading.

Turn the tuning condenser to 1400 K. C. and set the generator at 1400 K. C. Adjust the padders 11 and 6 for the maximum reading on the output meter.

When the antenna stage adjustment is made with the Receiver installed in the car, the Receiver antenna lead must be connected to the car antenna in the usual manner. The signal generator output lead should be connected to a wire placed near the car antenna but not connected to it.

When installing the radio in a car, follow the installation instructions carefully. The correct connector must be used in the antenna lead connector in the Receiver and the antenna coupling condenser must be adjusted to the car antenna.

Notes, Parts

PHILCO RADIO & TELEV. CORP.

NOTE: When receiver is installed in a car having top, under-car, spare wheel, or antenna's having similar lo-relative capacitance (50mmf.-450mmf.) use connector plug in "A". When installed in a car having a metal insert top, insulated door, insulated trunk cover, or antenna's having similarly hi-relative capacitance (450mmf.-2500mmf.) use condenser plug in "B".

PHILCO RADIO & TELEV. CORP.

I. F. TRANSFORMERS AND PADDERS

The I. F. transformers are assembled complete with padding condensers.

Both the primary and the secondary padders are placed side by side in the top of the transformer shield can. The adjusting screws are accessible thru the holes in the top of the shield. (See Figure 4).

The coil windings terminate in leads instead of terminals or lugs. The color scheme of the leads is given in Figure 3.

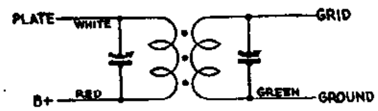

FIGURE 3

If replacements are ever necessary, replace the entire coil assembly, 32-2050 for the first I. F. stage and 32-2034 for the second I. F. stage. Neither the coil nor the padders will be furnished separately. Order only by the above numbers.

MODEL 819-819H ADJUSTMENTS

All padding adjustments are carefully made at the factory and ordinarily no readjustments are necessary. However, when readjustments are required, the procedure given below must be followed in detail.

Equipment

Fully charged heavy duty storage battery or 6-volt power pack, 048A Philco Set Tester, 3164 Padding wrench, 27-7159 Padding screw driver.

General

OUPTUT METER—The output meter must be connected by means of an adapter to the plate of the type 41 output tube and to the Receiver chassis.

SIGNAL GENERATOR—With the Receiver and signal generator set up for operation at the prescribed frequency, turn the Recevier volume control on full and set the signal generator attenuator so that a half scale reading is obtained on the output meter. The signal in the speaker should be audible but not loud.

The shielding on the signal generator output lead must be connected to the Receiver housing.

Procedure

I. F.—Set the signal generator at exactly 260 K. C. Connect the generator lead to the grid cap of the 78 I. F. tube (without removing the grid cap) in series with a .1 mfd. condenser.

Adjust the secondary screw padder (35) on the second I. F transformer for maximum reading on the output meter. Then adjust the primary screw padder (33) for maximum reading. (See Figure 4 for location of padders).

Remove the generator lead from the 78 tube.

Connect the generator lead to the grid cap of the 6A7 tube in series with a .1 mfd. condenser (without removing the grid cap). Adjust the secondary screw padder (24) on the first I. F. transformer for maximum reading on the output meter. Then adjust the primary screw padder (22) for maximum reading. (See Figure 4 for location of padders).

HIGH FREQUENCY AND R. F.—After padding the first I. F. stage remove the generator lead from the 6A7 tube.

Set the signal generator at 1550 K. C. and then connect the generator lead to the grid cap of the 78 R. F. tube in series with a .1 mfd. condenser (without removing the grid cap).

Turn the tuning condenser plates out of mesh as far as they will go. With the tuning condenser in this position, adjust the high frequency padder (18) and the R. F. padder (13) until the maximum reading is obtained on the output meter. This is the true setting for 1550 K. C., 155 on the dial scale.

LOW FREQUENCY—Turn the tuning condenser plates in mesh to approximately 580 K. C., 58 on the dial scale and set the signal generator at 580 K. C. Roll the tuning condenser and adjust the low frequency padder screw (17) for maximum reading on the output meter.

HIGH FREQUENCY RE-ADJUSTMENT—Turn the tuning condenser plates out of mesh as far as they will go and set the signal generator at 1550 K. C. Then adjust the high frequency padder (18) again for maximum reading on the output meter.

Remove the generator lead from the 78 RF tube.

ANTENNA—Connect the generator lead to the antenna cable assembly (made up of Part No. L1915 loom, 1-27-7133 terminal and 40 inches of 16 strand No. 30 wire), using a 200 mmfd. condenser in series between the two leads. Place the connector plug in the antenna socket on the Receiver. Plug the cable into the antenna socket.

Turn the tuning condenser in mesh to 580 K. C., and adjust the signal generator at 580 K. C. Adjust the Antenna coupling condenser (4) for maximum reading.

Turn the tuning condenser to 1400 K. C. and set the generator at 1400 K.C. Adjust the padders (13) and (6) for the maximum reading on the output meter.

When the antenna stage adjustment is made with the Receiver installed in the car, the Receiver antenna lead must be connected to the car antenna in the usual manner. The signal generator output lead should be connected to a wire placed near the car antenna but not connected to it.

When installing the radio in a car, follow the installation instructions carefully. The correct connector must be used in the antenna lead connector in the Receiver and the antenna coupling condenser must be adjusted to the car antenna.

Trimmers,Alignment

Alignment of the Compensators

To accurately adjust this receiver precision test equipment is necessary. The locations of the various compensators are shown in Figs. 5 and 6.

NOTE—The receiver should be allowed to heat for at least 15 minutes before adjusting the compensators.

OUTPUT METER

The 025 Output Meter is connected to the plate and cathode terminals of the 6F6G driver tube. Adjust the meter to use the (0-30) Volt Scale.

INTERMEDIATE FREQUENCY CIRCUIT

Frequency 470 K. C.

IMPORTANT — Before adjusting the compensators, calibrate tuning dial as given on Page 1.

1. Connect the 088 Signal Generator output lead in series with a .1 mfd. condenser to the grid of the 6K7G tube, 2nd I.F., and the ground connection of the output lead to the chassis.
2. Set the receiver volume control in the maximum position; tone control counter-clockwise; Magnetic Tuning Switch "Off" (counter-clockwise); range switch in position No. 1 (Broadcast); bass compensation switch on first tap from "off" position, and the receiver dial to approximately 580 K. C. Adjust the signal generator for 470 K. C.
3. Now adjust compensator (84P) for maximum output.
4. Remove the signal generator output lead with the .1 mfd. condenser from the 6K7G 2nd I.F. grid and connect them to the 6K7G, 1st I.F. grid.
5. Turn compensator (69T) clockwise until it is tight, then adjust compensators (68) and (69S) for maximum output. Now adjust compensator (69T) for maximum output. Caution: Do not adjust compensators (68) and (69S) unless compensator (69T) is turned to the extreme clockwise position.
6. Remove the signal generator output lead and condenser from the 6K7G, 1st I.F. tube and connect them to the grid of the 6L7G tube, 1st detector, and adjust compensators (64P) and (64S) for maximum output.

RADIO FREQUENCY CIRCUIT

Tuning Range 11.5-18.2 M. C.

1. The signal generator output lead with the .1 mfd. condenser, is connected to terminal No. 1 on the aerial input panel (rear of chassis) and the generator ground lead to terminal No. 3. Terminals 2 and 3 must be connected with the shorting link provided on the panel.
2. Set the magnetic tuning control in the "off" position. Set the range switch in position No. 5 (11.5 to 18.2 M. C.). Turn the receiver and signal generator dials to 18 M. C. and adjust the generator attenuator for a readable indication on the output meter. Now adjust compensator (44D) by turning the screw (clockwise) to the maximum capacity position, then slowly turn it counter-clockwise until a second maximum peak is reached on the output meter. The first peak from maximum capacity is the image signal and the receiver *must not* be adjusted to this signal. On some receivers, however, only one peak will be found, therefore, adjust compensator (44D) to this peak. If the above procedure is correctly performed, the image signal will be found at 17.06 M. C. by advancing the signal generator input, and turning the receiver dial to this frequency mark on the scale.
3. Leaving the signal generator and receiver dials at 18 M. C. the antenna and R. F. compensators (7D) and (25D) are now adjusted by connecting a variable condenser (Philco Part No. 45-2325) across the oscillator compensator (44D) contact (first contact from the left side of the receiver facing rear underside view of the chassis) and ground. Now tune the added condenser until the second harmonic of the receiver oscillator beats against the signal from the generator, resulting in a maximum indication on the output meter. Note: it may be necessary to increase the signal generator output to obtain a signal of sufficient strength for reading on the output meter. Compensators (7D) and (25D) are now adjusted for maximum output. After these adjustments, remove the external condenser and readjust compensator (44D) as given in paragraph 2 above.
4. Turn the signal generator and receiver dials to 12 M. C. and adjust compensators (44E), (25E) and (7E) for maximum output.
5. Readjust compensator (44D) as given in paragraph 2 above, for maximum output.
6. Readjust compensators (7D), (25D) and (44D) as given in paragraph 3 above. This readjustment is to correct any variation that the low frequency compensator may have caused in the high end of this range.

Tuning Range (7.35-11.6 M. C.)

1. Turn selector switch to Range 4. Set the signal generator and receiver dials to 11.0 M. C. Now adjust compensator (44B) for maximum output. Check for image at 10.06 M. C.
2. Leaving signal generator and receiver dial turned to 11.0 M. C., connect the external variable condenser across the oscillator compensator (44B) contact (third contact from left side of the receiver facing rear underside view of chassis) and ground. Tune the added condenser for maximum output, then adjust compensators (7B) and (25B) for maximum output. Remove the added condenser and adjust (44B) for maximum.
3. Turn the signal generator and receiver dials to 7.5 M. C. and adjust compensators (44C), (25C) and (7C) for maximum output.
4. Readjust compensator (44B) as given in paragraph 1 above.
5. Readjust compensators (7B), (25B) and (44B) as given in paragraph 2 above.

Tuning Range (4.7 to 7.4 M. C.)

1. Turn selector switch to range 3. Set the signal generator and receiver dials for 7.0 M. C. and adjust compensators (44), (25) and (7) for maximum output.
2. Rotate the signal generators and receiver dials to 5.0 M. C., then adjust compensators (44A), (25A) and (7A) for maximum output.
3. Readjust compensators (44), (25) and (7) on the 7.0 M. C. signal.

Tuning Range (1.58 to 4.75 M. C.)

1. Turn the selector switch to range 2. Set the signal generator and receiver dials to 4.5 M. C. Now adjust compensators (42B), (24A) and (6A) for maximum output.
2. Rotate the signal generator and receiver dials to 1.7 M. C. Compensator (42C) Osc. series is now adjusted for maximum output as follows: First tune compensator (42C) for maximum output, then vary the tuning condenser of the receiver for maximum output about the 1.7 M. C. dial mark. Now turn compensator (42C) slightly to the right or left and vary the receiver tuning condenser for maximum output. If the output reading increases, turn compensator (42C) in the same direction a trifle more, and again vary the tuning condenser for maximum output. If the output decreases, set the compensator in the opposite direction. This procedure of first setting the compensator and then varying the tuning condenser is continued until there is no further gain in output reading.
3. Readjust compensators (42B), (24A) and (6A) for maximum output as given in paragraph 1 above.

Tuning Range (530 to 1600 K. C.)

1. Set selector switch in range 1. Rotate the signal generator and receiver dial to 1500 K. C. Adjust compensators (42), (24) and (6) for maximum output.
2. Turn the signal generator and receiver dials to 580 K. C. Compensator (42A) Osc. series is now adjusted, using the same procedure as given in paragraph 2 under Tuning Range (1.58 to 4.75 M. C.). The only difference in the two adjustments is the frequency and compensator used.
3. Readjust compensator (42), on 1500 K. C. and compensators (24) and (6) on a 1400 K. C. signal.

ADJUSTMENT OF THE MAGNETIC TUNING CONTROL

1. Leaving the selector switch in position 1. Set the Magnetic tuning switch in the "out" position. Turn the signal generator and dial to 1000 K. C., then adjust the receiver dial for maximum output.

NOTE: It is very important to accurately adjust the receiver tuning condenser for peak output, also, adjust the signal generator attenuator to maximum output position.

2. Turn the (Magnetic Tuning Control) to the "on" position (clockwise). Compensator (84S) Sec. of magnetic tuning transformer is now adjusted for maximum output. If the indicator of the output meter goes off scale, turn the volume control of the receiver toward the miminum position until a readable indication is obtained.
3. The above adjustment is now checked for accuracy, by turning the magnetic tuning control "off". When this is done there should be no change in the tone of the received signal. If a change of tone or hiss develops, it indicates a shift in frequency and the adjustment must be made again.

PHILCO RADIO & TELEV. CORP.

Electrical Specifications

Type of Circuit: Superheterodyne with Magnetic Tuning; Spread-band dial; Philco Foreign Tuning System, and a class "A" Audio Output Circuit. Code 122 receiver has the Philco Automatic Dial tuning system.

Power Supply: 115 Volts A.C. 50 to 60 cycles or 25 to 40 cycle. Power transformer Part Numbers for the different voltage and frequency ranges are listed on Page 5.

Power Consumption: 155 Watts.

Intermediate Frequency: 470 K.C

Undistorted Output: 10 Watts. **Speaker:** U-15.

Tuning Ranges: Five—Range 1—530 to 1600 K.C.; Range 2—1.58 to 4.75 M.C.; Range 3—4.7 to 7.4 M.C.; Range 4—7.35 to 11.6 M.C.; Range 5—11.5 to 18.2 M.C.

Aerial Connections

To obtain the full advantage of the sensitivity of this receiver the Philco High Efficiency Aerial supplied with the receiver must be used. The connections for the aerial are as follows:

The red and black leads of the High-Efficiency Aerial "transmission line" are connected to terminals 1 and 2 respectively, of the terminal panel provided on the rear of the chassis. Connect the jumper on the terminal panel across terminals 3 and 4.

If a temporary aerial is used, the jumper should be across terminals 2 and 3. The aerial connects to terminal 1 and the ground lead to terminal 3. A good ground connection is desirable in all installations.

DIAL CALIBRATION

In order to adjust this receiver correctly the dial must be aligned to track properly with the tuning condenser. To do this proceed as follows:

1. Loosen the set screws on the shaft coupling of the tuning condenser. Then turn the tuning condenser until the plates are in the maximum capacity position. Now set the glowing beam indicator on the index line at the low frequency end of the broadcast band. With dial and tuning condenser in this position tighten set screws.
2. Turn the tuning condenser control until the indicator is on the first division from the index line.
3. With the dial in this position, loosen the shaft coupling set screws. Then turn the dial until the indicator is again on the index line. Tighten the set screws in this position.

NOTE: Be careful when turning the dial that the position of the tuning condenser is not disturbed.

REPLACING AUTOMATIC DIAL CONTROL SCREWS
Code 122

See Bulletin 258 for the procedure on removal of the Automatic Dial Control screws.

REPLACING THE DIAL OR MASK ARM ASSEMBLY
Code 122

To replace the dial or mask arm assembly, remove the chassis from the cabinet. Then remove the dial tuning knobs. Take off the control handle cover by removing the three screws holding it to the handle hub. When the metal cover is removed, two screws will be noted holding the control handle to the rotary hub. Remove the screws and detach the handle.

Now remove the five screws holding the dial escutcheon plate to the dial body and lift the escutcheon from the dial body. With these parts removed, the dial may be detached.

MASK ASSEMBLY—Code 122

With the dial removed, two fibre rings and one metal ring will be found around the outer side of the dial housing. Take off these rings and slip the mask from the housing.

SHADOWMETER ADJUSTMENT—Code 121

Remove aerial and allow tubes to warm up. Then adjust shadow meter as follows:

1. Move the shadow meter coil backwards and forwards, until the opposite edges of the shadow are 1/8 of an inch from end of the shadow screen, measuring along the bottom edge of the screen. Adjustment of the shadow meter light bracket may be necessary for perfect centering.
2. Remove the rectifier tube from its socket, and rotate coil until shadow reaches minimum width. This width must not exceed 3/32 of an inch.
3. Replace the 5X4G rectifier tube in its socket. The shadow should then widen to not more than 3/16 inch or less than 1/16 inch from each side of the screen measuring along the bottom edge. If these limits are not obtained readjust the shadow meter as given in paragraphs 1 and 2 until they are reached.

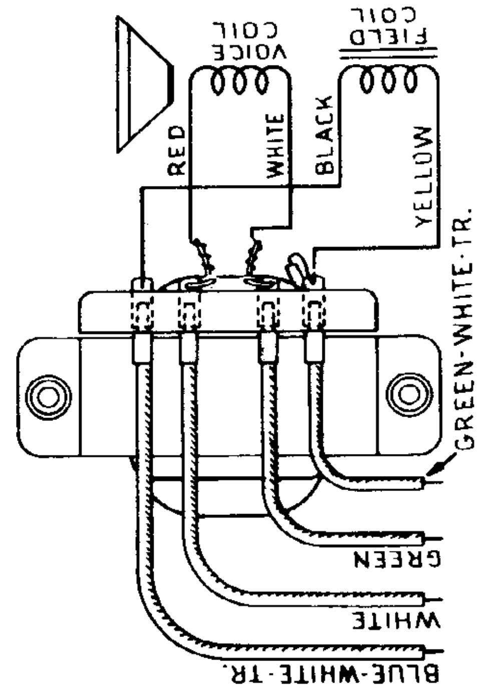

Fig. 2—U15 Speaker Wiring

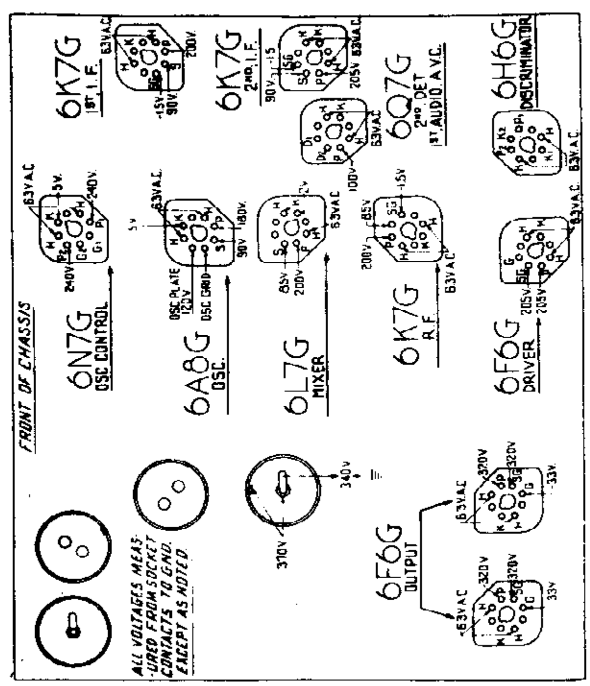

Fig. 1—Socket Voltages, Measured from Underside of Chassis

The voltages indicated by the arrows were measured with a voltmeter having a resistance of 1000 ohms per volt. Volume Control at minimum, range switch in broadcast position, line voltage 115 A.C.

MODEL P-1421
Packard
Socket, Trimmers
Alignment

PHILCO RADIO & TELEV. CORP.

I. F. TRANSFORMERS AND PADDERS

The I. F. transformers are assembled complete with padding condensers.

Both the primary and the secondary padders are placed side by side in the top of the transformer shield can. The adjusting screws are accessible thru the holes in the top of the shield. (See Figure 4).

The coil windings terminate in leads instead of terminals or lugs. The color scheme of the leads is given in Figure 3.

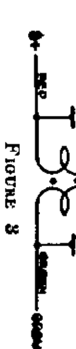

FIGURE 3

If replacements are ever necessary, replace the entire coil assembly, 32-2252 for the first I. F. stage and 32-2167 for the second I. F. stage. Neither the coil nor the padders will be furnished separately. Order only by the above numbers.

MODEL P-1421 ADJUSTMENTS

All padding adjustments are carefully made at the factory and ordinarily no readjustments are necessary. However, when readjustments are required, the procedure given below must be followed in detail.

Equipment

Fully charged heavy duty storage battery or 6-volt power pack, 048A Philco Set Tester, 3164 Padding wrench, 27-7159 Padding screw driver.

General

OUTPUT METER—The output meter must be connected by means of an adapter to the plate of the type 79 output tube and to the Receiver chassis.

SIGNAL GENERATOR—With the Receiver and signal generator set up for operation at the prescribed frequency, turn the Receiver volume control on full and set the signal generator attenuator so that a half scale reading is obtained on the output meter. The signal in the speaker should be audible but not loud.

The shielding on the signal generator output lead must be connected to the Receiver housing.

Procedure

I. F.—Set the signal generator at exactly 260 K. C. Connect the generator lead to the grid cap of the 78 I. F. tube in series with a .1 mfd. condenser (without removing the grid cap).

Adjust the secondary screw padder (27) on the second I. F. transformer for maximum reading on the output meter. Then adjust the primary screw padder (25) for maximum reading (See Figure 4 for location of padders).

Remove the generator lead from the 78 tube.

Connect the generator lead to the grid cap of the 6A7 tube in series with a .1 mfd. condenser (without removing the grid cap). Adjust the secondary screw padder (24) on the first I. F. transformer for maximum reading on the output meter. Then adjust the primary screw padder (22) for maximum reading. Readjust padders (25) and (27) with the generator lead connected to the type 6A7 tube. (See Figure 4 for location of padders).

HIGH FREQUENCY AND R. F.—After padding the first I. F. stage remove the generator lead from the 6A7 tube.

Set the signal generator at 1550 K. C. and then connect the generator lead to the grid cap of the 78 R. F. tube in series with a .1 mfd. condenser (without removing the grid cap).

Using a piece of paper approximately .006" thick as a gauge between the heel of the rotor plates and the stator plates, turn the rotor plates in mesh until they strike against the paper.

With the tuning condenser in this position, adjust the high frequency padder (16) and the R. F. padder (13) until the maximum reading is obtained on the output meter. This is the true setting for 1550 K. C., 155 on the dial scale.

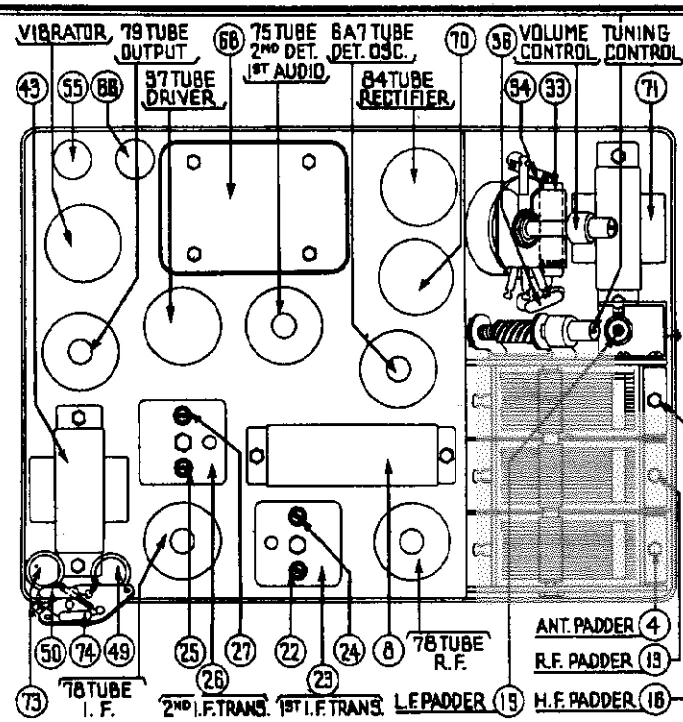

FIGURE 4

LOW FREQUENCY—Turn the tuning condenser plates in mesh to approximately 600 K. C., 60 on the dial scale and set the signal generator at 600 K. C. Roll the tuning condenser and adjust the low frequency padder screw (19) for maximum reading on the output meter.

HIGH FREQUENCY READJUSTMENT—Turn the tuning condenser plates out of mesh to 1550 K. C. and set the signal generator at 1550 K. C. Then adjust the high frequency padder (16) again for maximum reading on the output meter.

Remove the generator lead from the 78 R. F. tube.

ANTENNA — WHEN PADDING THE ANTENNA STAGE IT IS EXTREMELY IMPORTANT THAT THE PROPER DUMMY ANTENNA BE USED.

Connect the signal generator lead to the antenna lead on the Receiver using a 280 mmfd. condenser in series between the two leads.

Turn the tuning condenser to 1400 K. C. and set the generator at 1400 K. C. Adjust the padders (13) and (4) for the maximum reading on the output meter.

When the antenna stage adjustment is made with the Receiver installed in the car, the Receiver antenna lead must be connected to the car antenna in the usual manner. Connect the signal generator output lead to a wire placed near the car antenna but not connected to it.

				Nut (Rec. Mtg.)	W518A

The items marked with an asterisk are rarely required for service and in many cases will not be carried in stock by the local **service station.** In such cases it will be necessary to order these parts from Philco Transitone, Philadelphia or Chicago.

MODEL S-1431
Studebaker
Socket, Trimmers
Alignment

PHILCO RADIO & TELEV. CORP.

MODEL S-1431 ADJUSTMENTS

SIGNAL GENERATOR—With the Receiver and signal generator set up for operation at the prescribed frequency, turn the Receiver volume control on full and set the signal generator attenuator so that a half scale reading is obtained on the output meter. The signal in the speaker should be audible but not loud.

The shielding on the signal generator output lead must be connected to the Receiver housing.

Procedure

I. F.—Set the signal generator at exactly 260 K. C. Connect the generator lead to the grid cap of the 78 I. F. tube in series with a .1 mfd. condenser (without removing the grid cap).

Adjust the secondary screw padder 27 on the second I. F. transformer for maximum reading on the output meter. Then adjust the primary screw padder 25 for maximum reading. (See Figure 4 for location of padders).

Remove the generator lead from the 78 tube.

Connect the generator lead to the grid cap of the 6A7 tube in series with a .1 mfd. condenser (without removing the grid cap). Adjust the secondary screw padder 23 on the first I. F. transformer for maximum reading on the output meter. Then adjust the primary screw padder 21 for maximum reading. (See Figure 4 for location of padders).

HIGH FREQUENCY AND R. F.—After padding the first I. F. stage remove the generator lead from the 6A7 tube.

Set the signal generator at 1550 K. C. and then connect the generator lead to the grid cap of the 78 R. F. tube in series with a .1 mfd. condenser (without removing the grid cap).

Using a piece of paper approximately .006" thick as a gauge between the heel of the rotor plates and the stator plates, turn the rotor plates in mesh until they strike against the paper.

With the tuning condenser in this position, adjust the high frequency padder 15 and the R. F. padder 11 until the maximum reading is obtained on the output meter. This is the true setting for 1550 K. C., 155 on the dial scale.

LOW FREQUENCY—Turn the tuning condenser plates in mesh to approximately 600 K. C., 60 on the dial scale and set the signal generator at 600 K. C. Roll the tuning condenser and adjust the low frequency padder screw 18 for maximum reading on the output meter.

HIGH FREQUENCY READJUSTMENT—Turn the tuning condenser plates out of mesh to 1550 K. C. and set the signal generator at 1550 K. C. Then adjust the high frequency padder 15 again for maximum reading on the output meter.

Remove the generator lead from the 78 R. F. tube.

ANTENNA—When padding the antenna stage, it is extremely important that the proper dummy antenna be constructed and used.

Connect the signal generator lead to the antenna cable assembly (made up of Part No. L-2520 lead, and a 64 mmfd. condenser in series between the lead and the signal generator. Plug the cable into the ROOF ANTENNA CONNECTOR on the end of the Receiver.

Follow this padding procedure regardless of whether the Receiver is used with the Roof or Under-car antenna.

Turn the tuning condenser to 1400 K. C. and set the generator at 1400 K. C. Adjust the padders 11 and 6 for the maximum reading on the output meter.

When the antenna stage adjustment is made with the Receiver installed in the car, the Receiver antenna lead must be connected to the car antenna in the usual manner. Connect the signal generator output lead to a wire placed near the car antenna but not connected to it.

I. F. TRANSFORMERS AND PADDERS

The I. F. transformers are assembled complete with padding condensers.

Both the primary and the secondary padders are placed side by side in the top of the transformer shield can. The adjusting screws are accessible thru the holes in the top of the shield. (See Figure 4).

The coil windings terminate in leads instead of terminals or lugs. The color scheme of the leads is given in Figure 8.

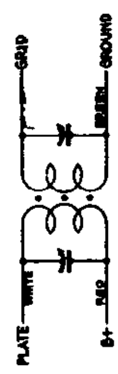

FIGURE 8

If replacements are ever necessary, replace the entire coil assembly, 82-2286 for the first I. F. stage and 82-2167 for the second I. F. stage. Neither the coil nor the padders will be furnished separately. Order only by the above numbers.

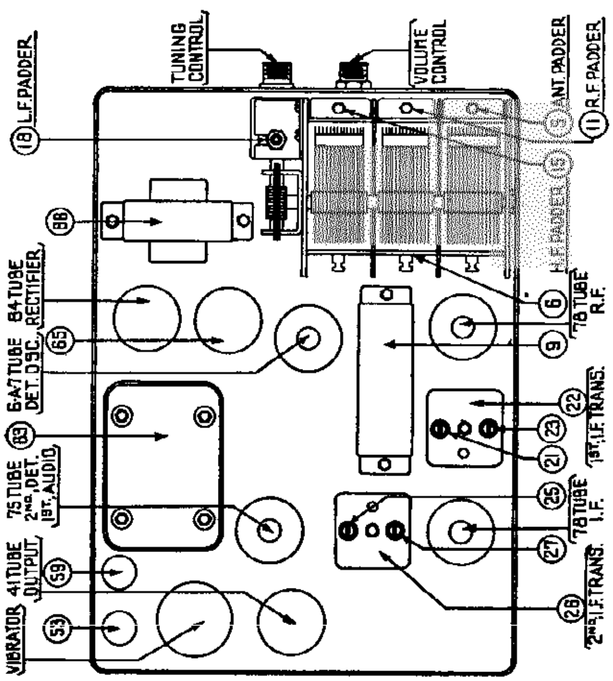

FIGURE 4

OUTPUT METER—The output meter must be connected by means of an adapter to the plate of the type 41 output tube and to the Receiver chassis.

CHANGES IN MODELS

Since Publication of Each Service Bulletin

Grouped under each model and arranged according to date . . . All models included . . . August 1st to December 31st, 1935.

The second column on each page gives the "Run Number" of the set at the time of the change (where this information was available from our records). The Run Number is stamped on the top of the chassis with a rubber stamp and is the lefthand number in the rectangle.

The Code Number of the set is given on the chassis name plate or name label (at rear of chassis).

MODEL 29

Approximate Date of Change	Run No.	CHANGES
11-1-35		No. 44 on base view of Fig. 4 should be 45. No. 45 next to 44 on base view of Fig. 4 should be 44.

MODEL 54

9-1-35 | 14

	Old Part No.	New Part
Condenser 39	3793-AG	3793-AM
Condenser 40	3615-BF	3615-BY
Condenser 41	8035-F	8035-T

MODEL 60

Approximate Date of Change	Run No.	CHANGES
10-1-35	11	Tube Shield and Tube Shield Base Nos. 28-2726 and 28-2725 for the 6A7 Tube will no longer be necessary.

	Old Part No.	New Part No.
Resistor 30	5872 (½ watt) 2 meg.	33-1025 (¼ watt)
Resistor 31	4409 (½ watt) 1 meg.	33-1096 (¼ watt)
Resistor 32	4411 (½ watt) 99,000 ohms	6099 (¼ watt)
Resistor 34, 38	5385 (½ watt) 70,000 ohms	33-1115 (¼ watt)

MODEL 116 (Code 121 and 122)

Approximate Date of Change	Run No.	CHANGES
8-1-35	..	Adjustment of high frequency end of broadcast band should be made at 1500 K. C. (1.5 M. C. on the Philco 088 scale) instead of 1600 K. C.
	5	There will be an addition of resistor and condenser assembly. Replace Condenser No. 6287DU 66 with 6287-ODU. The latter is impregnated with the new high melting point wax.

Remove	No. on Schematic Code 121	No. on Schematic Code 122	Install
30-4336 (.00125 mfd.)	66	66	33-6978
5837 (1000 ohms)	68	61	
33-1114 (8000 ohms)	69	68	
30-1028 (.003 mfd.)	70	69	7301

9-1-35	9	This change made to eliminate frequency drift.

	Old Part No.	New Part No.
2nd I. F. Transformer 50	32-1784	32-1865

	3	Code 122 only

	Old Part No.	New Part No.
Condenser 60	30-2011	30-2069
Insulator	27-7195	27-7194

MODEL 116 (Code 121 and 122)

Approximate Date of Change	Run No.	CHANGES
11-1-35	..	Code 122
	..	The grid lead from the 6A3 power tube near the front of the chassis is changed to run over to and parallel with the end of the chassis down as far as condenser 63 then over to the input transformer. Change made to prevent audio oscillation.

Code 121, Run No. 9 Code 122, Run No. 11

Part	Schematic No.	Removed

12-1-35

Code 121, Run No. 12

Code 122, Run No. 10

		Old Part	New Part
Input Transformer	63	32-7447	32-7057

Change 104 Resistor (10,000 ohm) to 60a

September Change Notices indicated a change in the 2nd I. F. Transformer 50. The Part No. of the new Transformer is 32-1865 and the corresponding Compensating Condenser Part No. is 31-6067.

MODEL 116X and 116B

Approximate Date of Change	Run No.	CHANGES
8-1-35	..	Add bezel frame gasket No. 27-7973. Remove Rubber Bumper No. 27-4150 to prevent microphonics. Remove Bezel Light Guard No. 27-8001 on Codes 121 and 122.

MODEL 610

Approximate Date of Change	Run No.	CHANGES
8-1-35	7	Tube Shield and Tube Shield Base on the 6A7 tube will not be necessary. Remove Part No. 28-2726 and 28-2725.
10-1-35	8	Part No. 6096 (5000 ohms) 8 Resistor and Part No. 33-1206 (20 ohms) 9 Resistor will not be used. In eliminating Resistor 9, shunt a wire across the terminals from which it is disconnected.
11-1-35	..	Reverse numbers 41 and 59 shown in Figure 8.

MODELS 610B, 610F, 611F PHILCO RADIO & TELEV. CORP.
611(121), 620, 620(121), 623 Changes

MODEL 610F

Approximate Date of Change	Run No.	CHANGES
8-1-35	..	Remove 27-7981 Bezel Glass Gasket and install 27-8036. Add Bezel Frame Gasket, Part No. 27-7972 to 610-F.

MODEL 610B

8-1-35	..	Add Part No. 27-7971 Bezel Frame Gasket.

MODEL 611-F

9-1-35	..	Remove bezel glass gasket, Part No. 27-7981, and install Part No. 27-8036.

MODEL 611 (Code 121)

9-1-35	2	The new condensers are impregnated with the high melting point wax.

	Old Part	New Part
Condenser	8035-DU	8035-ODU
Condenser	3793-SU	3793-OSU
Condenser	6287-DU	6287-ODU
Condenser	3903-SU	3908-OSU
Condenser	4989-FU	4989-OFU
Condenser	4989-DU	4989-ODU
Condenser	3615-SU	3615-OSU
Tone Control	30-4345	30-4377

10-1-35	2	

	Old Part	New Part
Resistor	4287 (1 watt) 51,000 ohms	4518 (½ watt)
Condenser	30-1055 .00225 mfd. mica	30-1042

Resistor Part No. 33-1001 (5000 ohm) no longer necessary.

12-1-35	4	The Oscillator Circuit was changed to series feed. The Oscillator Plate is disconnected from the lead connecting Condenser (9) and Resistor (41) and connected to the top of the lower primary winding. The bottom end of this primary is disconnected from Condenser (15) and (19) and connected to the lead, connecting Condenser (8) and Resistor (41). The lead from Resistor (18) to the top of the primary is changed so that it connects to the bottom of the secondary. Resistor (40) is removed from the circuit. Resistor (18) is changed so that it connects from the 6A7 cathode to the switch side of Condenser (9). Resistor (19) is removed. The following are necessary part changes:

Part	Schematic No.	Remove Old Part No.	Add New Part No.
Resistor		33-1128 (120,000 ohm)	
Osc. Transformer		32-1831	32-1973
Resistor		33-1206 (20 ohm)	

The Dial Mask Assembly was changed to the Glowing Arrow Wave Band Indicator Type.

Part	Schematic No.	Remove Old Part No.	Add New Part No.
Tuning Condenser	(5)	31-1528	31-1740
Glowing Arrow Mask			27-5167
Glowing Arrow Screen			27-5166
Mask Arm			29-3274
Link			29-3285
Coupling			29-3586
Screen Brcket			31-1751
Hub and Set Screw Assy.		31-1550	31-1724

MODEL 620 (Code 121)

8-1-35		Add the following parts: 1 No. 27-7972 Bezel Frame Gasket. 1 No. 27-8036 Bezel Glass Gasket Remove No. 27-7981 Bezel Glass Gasket MODEL 620 B Add No. 27-7971 Bezel Frame Gasket
10-1-35	5	

	Old Part	New Part
Resistor	5237 (½ watt) 1,000 ohms	33-1028 (¼ watt)
Resistor	5385 (½ watt) 70,000 ohms	33-1115 (¼ watt)
Resistor	4411 (½ watt) 99,000 ohms	6099 (¼ watt)

MODEL 620 (Code 121)—

Approximate Date of Change	Run No.	CHANGES
11-1-35	5	A condenser, Part No. 30-4310 (.001 mf.) was connected from the center terminal of condenser to the ground terminal of condenser. Tube Shield, Part No. 28-2726 and Tube Shield Base, Part No. 28-2725, for 6A7 tube no longer necessary.

MODEL 620

12-1-35	9	

	Schematic No.	Old Part No.	New Part No.
Ant. Transformer	(5)	32-1609	32-1867
Det. Transformer	(7)	32-1636	32-1868
Osc. Transformer	(11)	32-1637	32-1869

MODEL 623

9-1-35	..	Remove pilot light reflector No. 28-2979 and replace with reflector No. 28-3237. Change made to increase light intensity through dial scale.

	Old Part	New Part
Input Transformer	32-7454	32-7480

10-1-35	4	Change made to increase sensitivity.

	Old Part	New Part
1st I. F. Transformer	32-1793 34 I. F. Tube	32-1671 1A4 Tube

	8	Connect bottom terminal (ordinarily grounded) to positive terminal of filament supply.

	Old Part	New Part
Volume Control	33-5115	33-5142

11-1-35	6	10,000 ohm Resistor, part (4), Part No. 33-1000, no longer necessary.
12-1-35	..	The Dial Mask Assembly was changed to the Glowing Arrow Wave Band Indicator Type.

Part	Schematic No.	Old Part No.	New Part No.
Wave Switch	(3)	42-1112	42-1155

Glowing Arrow Screen			27-5166
Mask Arm			29-3274
Link			29-3285
Coupling			29-3586
Screen Bracket			31-1751
Hub Assembly		31-1550	31-1724

	9	The Oscillator Circuit was changed to series feed.

Part	Remove Old Part No.	Schematic No.	Add New Part No.
Condenser	30-1033 (.00015 mf.)		30-1049 (.0006 mf.)
Resistor	6097 (490,000 ohm)		
Resistor	33-1013 (25,000 ohm)		
Oscillator Trans.	32-1831		32-1973
Resistor	33-1206 (20 ohm)	(9)	
Condenser	6359 (.006 mf.)		30-1031 (.00011 mf.)

MODEL 623 (Continued)

Approximate Date of Change	Run No.	CHANGES
..	9	**S. W. SECTION OF OSC. TRANSFORMER** Condenser [illegible] and Resistor [illegible] were removed and the wires connected to the ends of these parts were connected together. The wires between the police tap at the left of Switch Section No. 2 and the joint in the wire just above that was broken and Condenser No. 30-1049 inserted. The connection between the bottom (S. W.) primary and secondary of the Oscillator Transformer was broken and condensers (14) and (15) connected between the bottom of the secondary and ground. Resistor [illegible] removed. The lead connected to the top of the primary disconnected and brought down to the bottom of the secondary. Resistor (8) also removed. A lead from the bottom of the primary was connected to the lead running from Condenser (9) to Resistor [illegible]. The oscillator plate wire was disconnected from this lead and brought down to the top of the primary. **BROADCAST AND POLICE SECTION OF OSC. TRANSFORMER** Resistor (17) was disconnected from the bottom of the upper section of the Osc. Transformer and connected to the switch side of the Condenser (8).

MODEL 623-B and 623-F

9-1-35	..	Remove bezel glass gasket, Part No. 27-7981, and replace with Part No. 27-8036.

Model 630 (Code 121)

10-1-35	4	

	Old Part		New Part
Resistor [illegible]	33-1040 (½ watt)	4,000 ohms	33-1031 (¼ watt)
Resistor [illegible]	6650 (½ watt)	20,000 ohms	6649 (1 watt)

11-1-35	7	Remove Shadowmeter Shunt Resistor [illegible], Part No. 33-1040 (4,000 ohms).

Part	Schematic No.	Old Part	New Part
Shadowmeter	[illegible]	45-2086	45-2083

MODEL 630

Schematic No.		Old Part No.	New Part No.
Ant. Transformer	(3)	32-1699	32-1867
Det. Transformer	(7)	32-1636	32-1868
Osc. Transformer	[illegible]	32-1637	32-1869

MODEL 640 (Code 121)

		Replace Resistor [illegible], Part No. 6650 (20,000 ohms) with Part No. 33-1177.
8-1-35	6	Replace speaker plug socket, No. 27-6033 with No. 27-6043.
	4	Replace 1st I. F. Transformer, Part No. 32-1835 with No. 32-1917 to prevent microphonics. Remove rubber bumper, No. 27-4150 to prevent microphonics. Remove Bezel Light Guard No. 27-8001. Part [illegible] on base view in bulletin should be 2nd I. F. Part [illegible], 1st I. F. Replace Bezel Glass Gasket No. 27-7981 with No. 27-8036. Add No. 27-7972 Bezel Frame Gasket.
11-1-35	9	

Part	Schematic No.	Old Part	New Part
Tuning Condenser	[illegible]	31-1556	31-1671

Run No. 10

Shadow Meter	[illegible]	45-2080	45-2083
Resistor	[illegible]	33-1040	Removed

MODEL 640-B

Approximate Date of Change	Run No.	CHANGES
9-1-35	..	Uses K31 instead of K21 Speaker.

MODEL 641

9-1-35	..	Connect an 8,000 ohm resistor, Part No. 33-1114, across shadow meter.
10-1-35	..	**Corrections in Replacement Parts List** Part [illegible] .015 mf. Condenser is part of (64-A). Part [illegible] should be .03 mf. and the correct Part Number is 30-4025. Part [illegible] should be 3615-DG. Referring to bottom view of chassis, condenser marked [illegible] should be [illegible] and condenser [illegible] changed to [illegible]. Capacity of sections in [illegible] is (.05 — .2 — .75 — .09 — .25). Part Number of B-C Resistor is 33-3214. List Price 25c. Price of No. 27-4226 Waveband Knob, List 10c.
11-1-35	..	

Part	Old Part	New Part
Bezel Assembly	40-5722	40-5724

12-1-35	2	A .00011 Mf. Condenser, Part No. 30-1031 is connected from the plate of the 85 Detector Tube to the Cathode Circuit.

MODEL 642

		Old Part	New Part
9-1-35	Tone Control [illegible]	30-4316	30-4332

12-1-35	2	The Dial and Mask Assembly were changed to the Glowing Arrow Wave Band Indicator Type.

Part	Schematic No.	Old Part No.	New Part No.
Tuning Condenser	[illegible]	31-1626	31-1741
Hub and Set Screw Assembly		31-1550	31-1724
Mask Assembly			27-5137
Glowing Arrow Screen			27-5166
Screen Bracket			31-1760
Glowing Arrow Mask			27-5167
Mask Arm			29-3274
Link			29-3285
Coupling			29-3586
Pilot Lamp Assembly		38-7002	
Wave Switch	(2)	42-1107	42-1152

MODEL 643

9-1-35	..	Filament current reads (point) .750MA., it should read 750MA. Part No. 33-5119 [illegible] in Model 643, Bulletin No. 226, listed at $1.10 changed to $1.45.
12-1-35	..	Change Chassis Mounting Washer (rubber) listed as 27-4021 to 27-4201. Pilot Lamp [illegible], Part No. 5816, should be Part No. 34-2065.
11-1-35	3	

Part	Schematic No.	Old Part	New Part
Condenser	[illegible]	6959 (.006 mf.)	30-1031 (.00011 mf.)

These changes made to reduce hum.

MODEL 660

Approximate Date of Change	Run No.	CHANGES
9-1-35	8	Remove rubber bumper, Part No. 31-1706, (to prevent microphonics). B. C. Resistors [illegible], Part No. 33-2020, in Bulletin No. 223, should be 33-3020. Compensating Condenser No. [illegible] in Fig. 2 is labelled "standard," it should be "police"; also Condenser No. [illegible] is labelled "police" and shoud be "standard."

Part	Old Part	New Part
Tone Control (Code 121)	30-4343	30-4378
2nd I. F. Transformer [illegible]	32-1734	32-1865
Tone Control (Code 122)	30-4351	30-4379

Approximate Date of Change	Run No.	CHANGES
11-1-35	..	Shadow meter shunt resistor (2000 ohms) Part [illegible], Part No. 6984, removed. Reverse Numbers [illegible] and [illegible] shown in Fig. 2.

Part	Schematic No.		Old Part	New Part
Condenser	5	[illegible]	30-4123 (.05 mf.)	30-4170 (.1 mf.)
Tuning Condenser	3	[illegible]	31-1706	31-1683
Dial Hub Assembly			31-1575	31-1724

Approximate Date of Change	Run No.	CHANGES
12-1-35	..	September Change Notices indicated a change of the 2nd I. F. Transformer [illegible]. The Part Number of the new Transformer is 32-1865 and the corresponding Compensating Condenser Number is 31-6067.

MODEL 680 (Code 122)

Approximate Date of Change	Run No.	CHANGES
11-1-35	4	240,000 ohm resistor. Part No. 33-1097, added, connected from wiper arm (center terminal) to bottom terminal of bass control. The correct Part Number (163) on Parts List is 30-4113. Part No. of Large (H Type) Acoustic Clarifier is 36-1158.
12-1-35	5	Shadow Meter (120), Part No. 45-2088 is replaced with No. 45-2083. Shunt Resistor (121), Part No. 7352 (6,000 ohms) removed.
	6	Sensitivity Control (85), Part No. 33-5124 is replaced with Part No. 33-5144. The correct number and price for Input Transformer (157) is 32-7447 at $3.00.

U-7 SPEAKER

9-1-35	..	The correct cone assembly number for the type U-7 speaker is 36-3381.

CORRECTIONS IN 1936 PHILCO PARTS CATALOG

Tubular Paper Condenser 30-4346 should be 30-4336, working voltage, 1000.

Tubular Condenser Kit (page 13), Part No. 45-1109 should be 45-1139.

Tuning Condenser 31-1039 should be 31-1106, list $5.30.

Tuning Condenser 31-1006 should be 31-1005, list $4.00.

Potentiometer, Part No. 33-5511 should be 33-5111.

I. F. Amplifier Kit, Part No. 38-6685 should be 38-7453, list $6.15.

I. F. Amplifier Kit complete should be Part No. 40-5814, list $8.81.

Headphones only should be Part No. 45-2098 instead of 8303.

Filter Choke (in short-wave section) should be Part No. 5643 instead of 5468.

Power Amplifier Output Transformer 32-7055 should be 32-7255, list $15.00 instead of $4.50.

Heavy Duty Resistor, Part No. 33-3134 should be 33-3176.

Heavy Duty Resistor, Part No. 33-3135 should be 33-3175.

Knobs, Part No. 24-4051 should be 27-4051.

Cones, replacement for K-13 and K-17 speakers should be 36-3159, list $0.80 instead of 02996 (list $0.90).

Field Coil, S-15 Speaker should be 36-3519 instead of 36-3579.

Dial Drive Assemblies
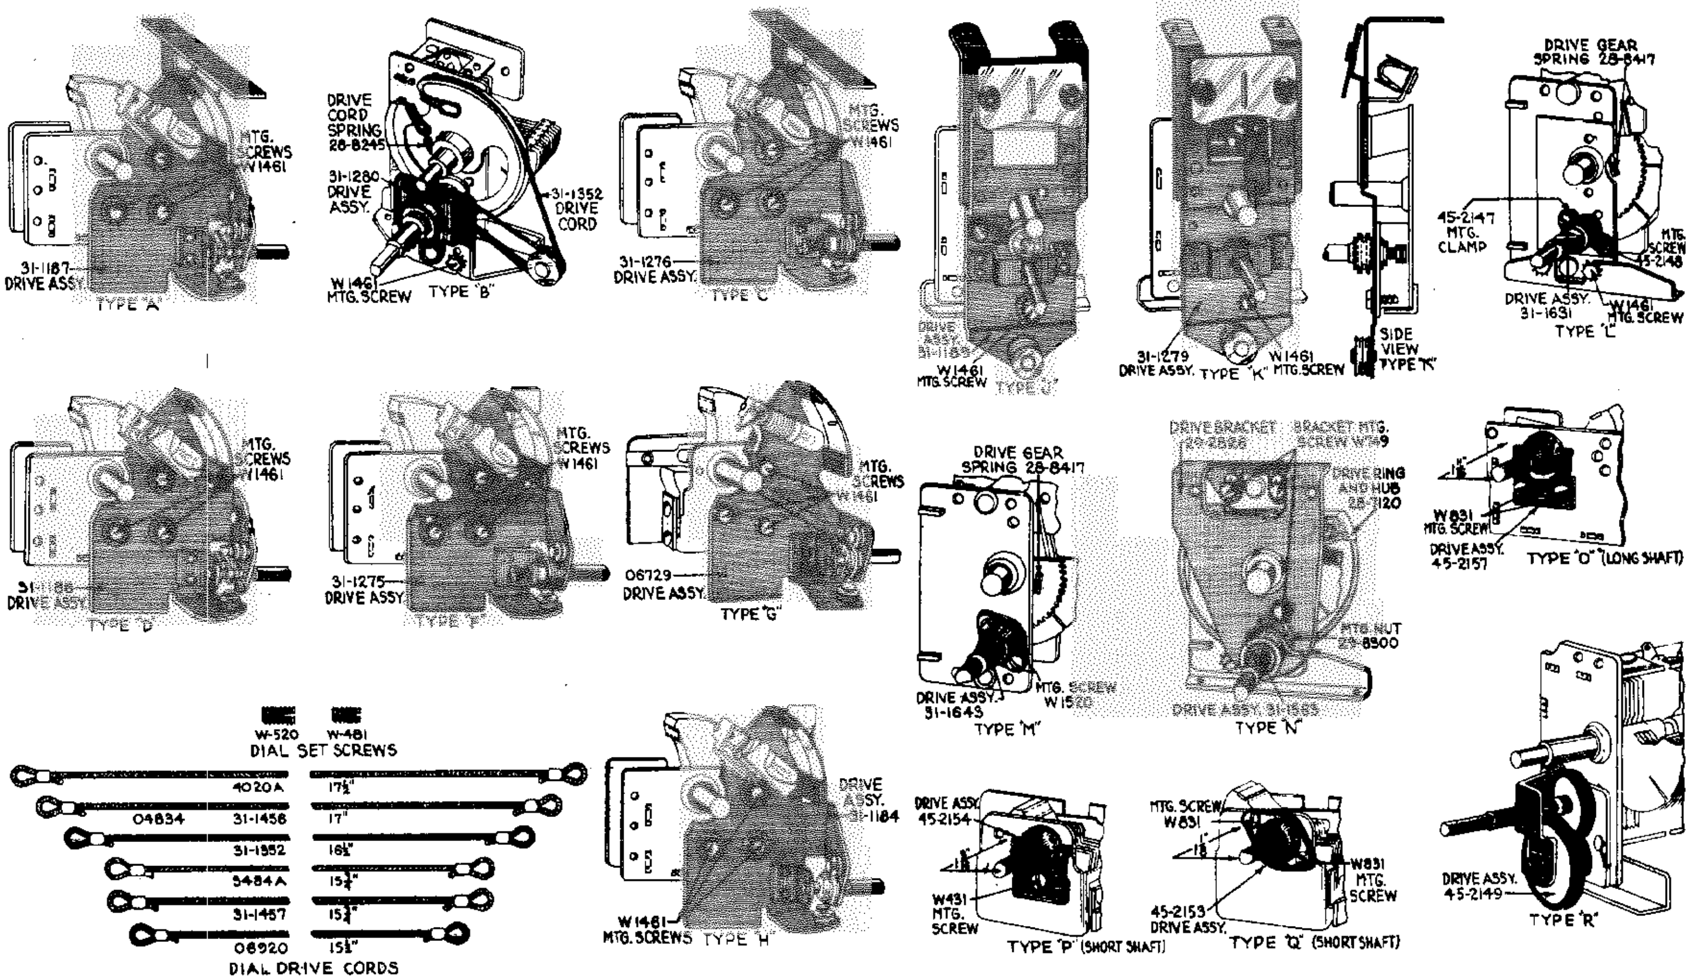
Details, Notes

PHILCO RADIO & TELEV. CORP.

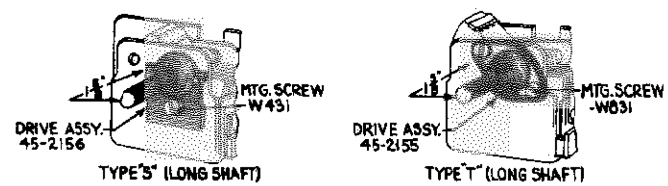


Here is complete information on dial drives for all Philco Models. This bulletin also contains a list of other miscellaneous parts such as dials, dial set screws, mounting screws and drive cords.

Illustrations of the various types of drives are provided to facilitate selecting the correct replacement assembly for models on which more than one type drive was used. These illustrations are listed by letters in the third column of the table.

To use this bulletin correctly, first locate the model number of the set being repaired. It will be found in the first column. If the model has more than one type drive, it will be listed more than once. Next, follow across to the third column for the number of the illustration. If no illustration is shown, use the assembly number in the fourth column. If an illustration is indicated, refer to pages 2 and 3, and use the assembly number of the drive that is identical to the drive assembly being repaired.

We recommend the replacement of the entire drive assembly in all cases if it is defective. This will insure a smooth working dial, plus long life.

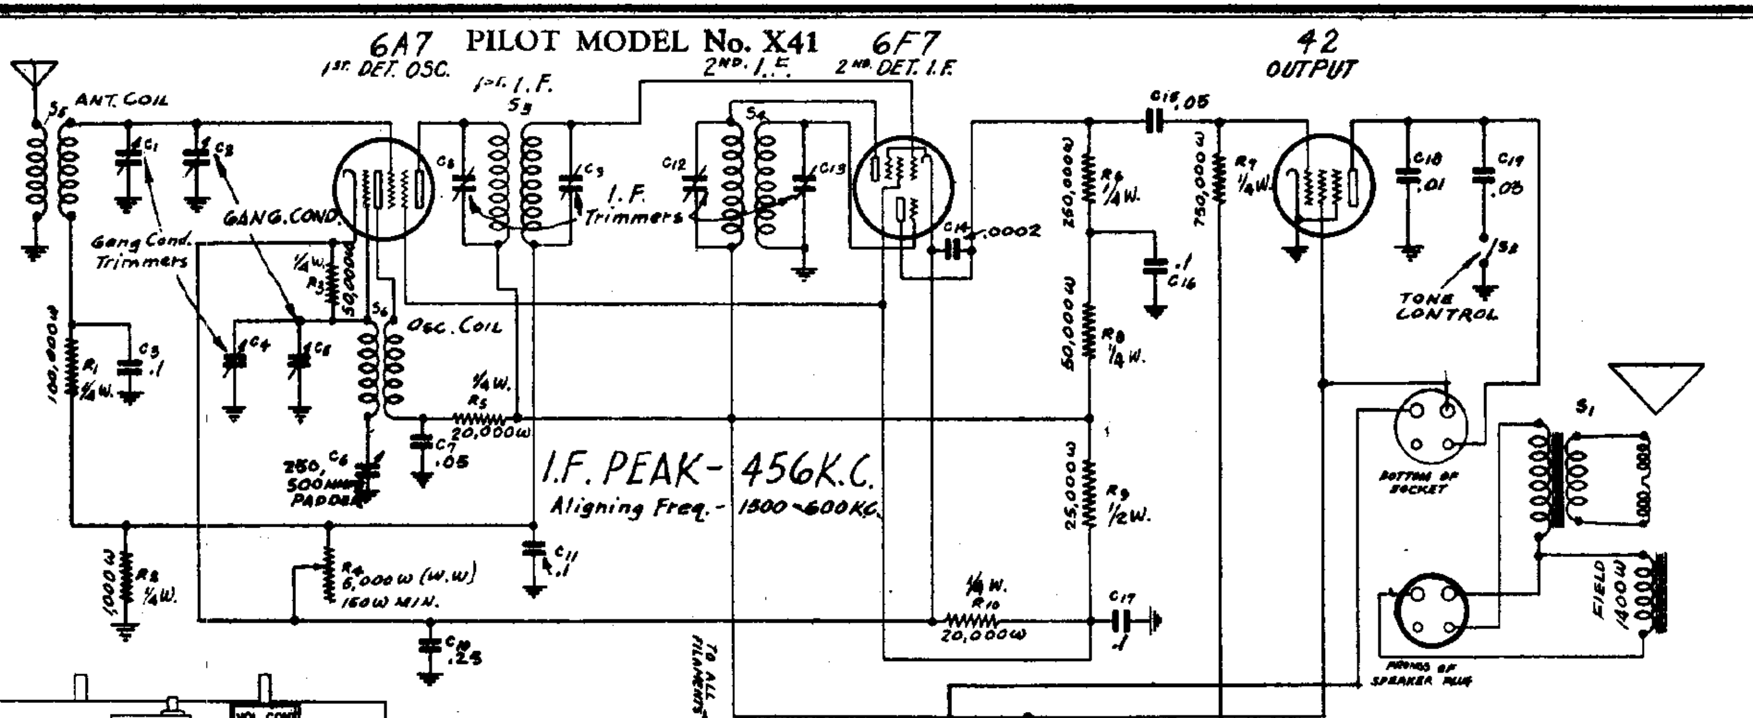


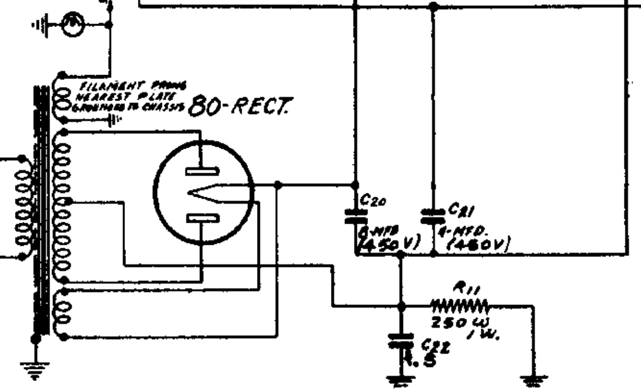
Socket, Trimmers Alignment

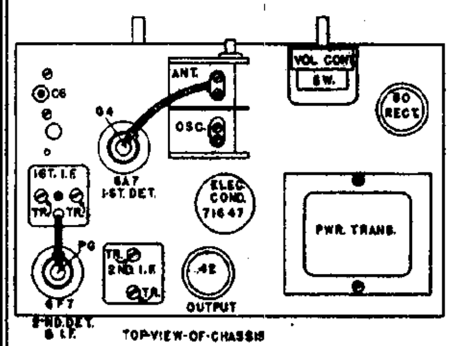
PILOT RADIO CORP.

MODEL X-41
Schematic, Voltage

PILOT MODEL No. X41







VOLTAGES MEASURED AT TUBE SOCKETS

	Det. Osc. 6A7	Audio Output 42	Amp. Det. 6F7	Rectifier 80
PLATE	220	210	220	335 Volts D.C. from Filament to transformer center tap.
SCREEN	66	237	66	
CATHODE	18	*16	18	
FILAMENT	6.3	6.3	6.3	4.9

Speaker field volts—85 volts.
Anode grid of 6A7—150 volts.
Triode plate of 6F7—95 volts.
Plate and screen voltages measured to cathode.
Cathode voltages measured to chassis frame.

*Measured across 250 ohm resistor, R-11.
Measurements made with voltmeter of 1,000 ohms per volt.

I. F. ALIGNMENT: When aligning the intermediate Frequency Amplifier, the external oscillator must be set at 456 kc. The tuning condenser should be set at maximum capacity. Connect the antenna lead of the external oscillator to the control grid of the type 6F7 tube in the I. F. Amplifier stage through a 0.1 mfd. fixed condenser. Connect the ground lead of the external oscillator to the receiver ground clip. The I. F. alignment capacitors are located at the top of the shielded I. F. Transformers. Rotate the adjusting screw of each capacitor on I. F. Unit No. 2 slowly until maximum output is noted. On completion of this operation, remove the external oscillator leads from the type 6F7 I. F. Amplifier tube and connect it in the same manner to the control grid at the top of the type 6A7 tube.

Now rotate each adjustment screw on I. F. Unit No. 1 for maximum output. During these operations, use the least possible input to prevent broadening of the resonance peaks.

In order to obtain the most accurate realignment of the I. F. Amplifier, it is essential to repeat the alignment process in both I. F. units with the external oscillator leads connected across the control grid of the 6A7 tube.

BROADCAST ALIGNMENT: After the I. F. Amplifier is completely realigned, connect the external oscillator leads to the receiver antenna and ground leads, this time with a .0002 mfd. condenser in the antenna lead. Adjust the tuning control pointer at the 1500 kc. mark. Adjust the broadcast band oscillator trimmer to maximum response. Adjust the signal section trimmer in the same manner.

Next adjust the 600 kc. padder condenser. Set the external oscillator at 600 kc. Rotate the receiver tuning control until resonance is indicated. Then rock the tuning control back and forth about this resonance position, and at the same time adjust the padder condenser for the highest resonance peak.

Now repeat the 1500 kc. trimmer adjustment, following in every detail the procedure previously described.

SERVICE INFORMATION
MODELS 213, 215

REMOVAL OF CHASSIS FROM CABINET:

To remove the chassis from the cabinet proceed as follows:

Be certain that the line cord is removed from the power outlet socket.

Remove the "slip-on" knobs and felt washers from the controls on the front panel.

Remove the speaker plug from the socket at the rear of the chassis.

Remove the four mounting screws, located underneath the cabinet.

REALIGNMENT: Should the receiver require re-alignment, the outlined procedure below should be followed. For best results an external modulated oscillator with adequate frequency range, and a visual output meter, should be used.

Before connecting the chassis to the power line, reconnect the speaker cable in its socket at the rear of the chassis.

The location of the R. F. alignment trimmer condensers is on the side of the band switch. The trimmers in the lowest row are those for aligning Band 1. Those in the second row from the bottom are for Band 2. Those in the third row up are for the Broadcast. In the Model 215 there is an additional row of trimmers located immediately above those for the Broadcast.

The padder condenser is located under the rear section of the band switch. In the Model 215 an additional padder for the Longwave range is located at the right of the Broadcast padder. Access to the padder condenser is made through a hole provided in the rear of the chassis frame.

I. F. ALIGNMENT: When aligning the Intermediate Frequency Amplifier, the external oscillator must be set at 456 kc. The Band Selector Switch should be in the position marked "Broadcast", and the tuning condenser should be set at maximum capacity. Connect the "antenna" lead of the external oscillator to the control grid of the type 6K7 tube in the I. F. Amplifier stage through a .1 mfd. fixed condenser. Connect the "ground" lead of the external oscillator to the receiver ground lead. The I. F. alignment capacitors are located at the side of the shielded I. F. Transformers. Rotate the adjusting screw of each capacitor on I. F. Unit No. 2 slowly until maximum output is noted. On completion of this operation, remove the external oscillator lead from the type 6K7 I. F. amplifier tube and connect it in the same manner to the control grid at the top of the type 6A8 tube.

Now rotate each adjustment screw on I. F. Unit No. 1 for maximum output. During these operations, use the least possible input to prevent broadening of the resonance peaks.

In order to obtain the most accurate realignment of the I. F. amplifier, it is essential to repeat the alignment process in both I. F. Units.

BROADCAST ALIGNMENT: After the I. F. amplifier is completely realigned, connect the external oscillator leads to the receiver antenna and ground leads. Set the Band Selector Switch in the "Broadcast" position and place the tuning control pointer at the 1500 kc. mark. Adjust the broadcast band oscillator trimmer.

Next adjust the interstage alignment trimmer for maximum response. Finally adjust the antenna section trimmer in the same manner.

Next adjust the 600 kc. padder condenser, located in the lower rear section of the band switch, under the chassis. Set the external oscillator at 600 kc. Rotate the receiver tuning control until resonance is indicated. Then rock the tuning control back and forth about this resonance position, and at the same time adjust the padder condenser for the highest resonance peak.

Now repeat the 1500 kc. trimmer adjustment, following in every detail the procedure previously described.

ALIGNMENT OF THE SHORT WAVE-BANDS: The procedure in aligning the short wave-bands is identical with that for the broadcast with the exception of the adjustment of the padder condenser. The alignment frequencies are as follows:

Band 2: 50 Meters (6,000 kc.)
Band 1: 16.6 Meters—(18,000 kc.)

When aligning Band 2, set the Band Selector Switch in the position marked "Band 2". Set the tuning control pointer at the 50 meters. Adjust the oscillator alignment capacitor on Band 2 for maximum output. Next adjust the interstage and antenna section alignment capacitors for maximum output.

To align Band 1, set the Band Selector Switch in the position marked "Band 1". Set the tuning control pointer at the 16.6 meter mark. Set the external oscillator at 16.6 meters. Adjust the oscillator section alignment capacitor on Band 1 for maximum output.

Proceed next to align the interstage section of Band 1. In doing this, it is essential to rock the tuning control back and forth about the resonance position and at the same time to adjust the trimmer for the highest resonance peak. Next align the antenna section for maximum sensitivity.

NOTE.

The above alignment positions refer to the Model 213 only, which is calibrated in frequency. The alignment points for the Model 215, which is calibrated in meters only, is as follows:

Longwave	Align at 750 meters.
	Pad at 2,000 meters.
Broadcast	Align at 200 meters.
	Pad at 500 meters.
Band 2	Align at 49 meters.
Band 1	Align at 17 meters.

REMOVAL OF BAND SELECTOR SWITCH ASSEMBLY: Should it be necessary to remove the switch assembly, this is easily done by removing the supporting screws. Before doing this, however, it is essential to unsolder the leads between the switch and the chassis.

It is advisable to realign the receiver after reinstalling the switch assembly.

CAUTION: When making repairs on the receiver, use only ROSIN CORE SOLDER. NEVER USE SOLDERING PASTE OR ACID FLUXES OF ANY TYPE.

RECEIVER DESCRIPTION

Operating Voltages—115, 125, 150, 220, 240 volts, Alternating Current.
Frequency Rating —50 to 60 cycles.
Power Consumption—70 Watts.
Circuit —One stage of Tuned Radio Frequency amplification for all frequencies, electron-coupled oscillator-modulator, diode detector, class "A" pentode output stage, automatic volume control.
Wavelength Range—From 550 meters to 16 meters (545 kc. to 18,800 kc.).
Undistorted power output—3 watts.
Intermediate Frequency—456 kc.
Tube Functions —Type 6K7: R. F. amplifier for all bands.
Type 6A8: Electron emission control oscillator-detector.
Type 6K7: I. F. amplifier.

VOLTAGES

The D. C. voltages measured at the tube sockets of the set should be read with a high resistance voltmeter of at least 1000 ohms per volt.

	R. F. Type 6K7	Osc. Det. Type 6A8	I. F. Type 6K7	Diode Det. Type 6H6	Aud. Driv. Type 6J7	Pow. Pent. Type 6F6	Rectifier Type 5Z4

** Measured through resistor.
All plate, screen and cathode voltages measured to ground.

MODELS 108, 109
SERVICE INFORMATION

I. F. ALIGNMENT: When aligning the Intermediate Frequency Amplifier, the external oscillator must be set at 456 kc. The Band Switch should be in the position marked "Broadcast," and the tuning condenser should be set at maximum capacity. Connect the "antenna" lead of the external oscillator to the control grid of the type 6D6 tube in the I. F. Amplifier stage through a .002 mfd. fixed condenser. Connect the "ground" lead of the external oscillator to the receiver ground lead. The I. F. alignment capacitors are located at the top of the shielded I. F. Transformers. Rotate the adjusting screw of each capacitor on I. F. Unit No. 2 slowly until maximum output is noted. On completion of this operation, remove the external oscillator leads from the type 6D6 I. F. Amplifier tube and connect it in the same manner to the control grid at the top of the type 6A7 tube.

Now rotate each adjustment screw on I. F. Unit No. 1 for maximum output. During these operations, use the least possible input to prevent broadening of the resonance peaks.

In order to obtain the most accurate realignment of the I. F. Amplifier, it is essential to repeat the alignment process in both I. F. units with the external oscillator leads connected across the control grid of the 6A7 tube.

BROADCAST ALIGNMENT: After the I. F. amplifier is completely realigned, connect the external oscillator leads to the receiver antenna and ground leads. Set the Band Switch in the "Broadcast" position and place the tuning control pointer at the 1400 kc. mark. Adjust the broadcast band oscillator trimmer to maximum response. Adjust the signal section trimmer in the same manner.

Next adjust the 600 kc. padder condenser. Set the external oscillator at 600 kc. Rotate the receiver tuning control until resonance is indicated. Then rock the tuning control back and forth about this resonance position, and at the same time adjust the padder condenser for the highest resonance peak.

Now repeat the 1400 kc. trimmer adjustment, following in every detail the procedure previously described.

ALIGNMENT OF THE SHORT-WAVE BANDS: The procedure in aligning the short wave-bands is identical with that for the broadcast with the exception of the adjustment of the padder condenser. The alignment frequency is;

16.8 Meters—(17,800 kc.)

Turn the Band Switch to the short wave position. Tune the external oscillator to 16.8 meters. Tune the receiver so that the dial pointer is in a position coincident with the 16.8 meter indication on the dial scale. Adjust the short wave oscillator trimmer for maximum response. Next adjust the signal circuit trimmer for maximum resonance. Repeat all adjustments to assure correct alignment, rocking the gang condenser to right or left for maximum gain.

THE HIGH BAND ALIGNMENT: Procedure in the Model 105 is similar to the Broadcast section of that receiver. Align at 376 k.c. Adjust the padder at 160 k.c.

Should it be necessary to remove the band switch assembly, it is advisable to realign the receiver after reinstalling.

CATHODE	2.6	2.25	2.6	.5	12.5	120**
FILAMENT	6.3	6.3	6.3	6.3	25	25

NOTE: The D.C. voltages measured at the tube sockets of the set should be read with a high resistance voltmeter of at least 1,000 ohms per volt.

All voltages measured to chassis.
Speaker field voltage 118 volts.
Anode Grid of 6A7 81 volts.
* Measured through Plate Resistor.
** Cathode to chassis.

NOTE: These measurements should be made with the volume control turned to the right, and with the tuning adjusted at "No signal" position on dial.

Power Consumption .... 50 Watts
Line Volts .... 110-125 volts A.C.-D.C.
I. F. Frequency .... 456 Kc.
Power Output .... 1 Watt

REALIGNMENT: Should the receiver require realignment, the outlined procedure below should be followed. In the schematic wiring diagram the location and function of the various alignment capacitors are clearly illustrated. For best results an external modulated oscillator with adequate frequency range, and a visual output meter should be used.

Before connecting the chassis to the power line, reconnect the speaker cable in its socket at the top of the chassis.

I. F. ALIGNMENT: When aligning the Intermediate Frequency Amplifier, the external oscillator must be set at 456 kc. The Band Selector Switch should be in the position marked "Broadcast", and the tuning condenser should be set at maximum capacity. Connect the "antenna" lead of the external oscillator to the control grid of the type 6D6 tube in the I. F. Amplifier stage through a .1 mfd. fixed condenser. Connect the "ground" lead of the external oscillator to the receiver chassis. The I. F. alignment capacitors are located at the side of the shielded I. F. Transformers. Rotate the adjusting screw of each capacitor on I. F. Unit No. 2 slowly until maximum output is noted. On completion of this operation, remove the external oscillator lead from the type 6D6 I. F. amplifier tube and connect it in the same manner to the control grid at the top of the type 6A7 tube.

Now rotate each adjustment screw on I. F. Unit No. 1 for maximum output. During these operations, use the least possible input to prevent broadening of the resonance peaks.

In order to obtain the most accurate realignment of the I. F. Amplifier, it is essential to repeat the alignment process in both I. F. Units, with the external oscillator connected to the 6A7 tube.

BROADCAST ALIGNMENT: After the I. F. Amplifier is completely realigned, connect the external oscillator leads to the receiver antenna and ground this time with a 200 mmf. condenser in the antenna lead. Set the Band Selector Switch in the "Broadcast" position and place the tuning control pointer at the 1500 kc. mark. Adjust the broadcast band oscillator trimmer to maximum response.

Next adjust the interstage alignment trimmer for maximum response. Finally adjust the antenna section trimmer in the same manner.

Next adjust the 600 kc. padder condenser, located on the top of the oscillator coil. Set the external oscillator at 600 kc. Rotate the receiver tuning control until resonance is indicated. Then rock the tuning control back and forth about this resonance position, and at the same time adjust the padder condenser for the highest response.

Now repeat the 1500 kc. trimmer adjustment, following in every detail the procedure previously described.

ALIGNMENT OF THE SHORT WAVE BAND: The procedure in aligning the short wave band is identical with that for the broadcast with the exception of the adjustment of the padder condenser. The alignment frequency is 16.8 Meters—(17,800 kc.).

Turn the Band Switch to the right. Tune the external oscillator to 16.8 meters. Tune the receiver so that the dial pointer is in a position coincidental with the 16.8 meter indication on the dial scale. Adjust the short wave oscillator trimmer for maximum response. Next adjust the signal circuit trimmer for maximum resonance. Repeat all adjustments to assure correct alignment, rocking the gang condenser to right or left for maximum gain.

THE HIGH BAND ALIGNMENT: Procedure in the Model 125 is similar to the Broadcast section of that receiver. Align at 375 kc. Adjust the padder at 160 kc.

Should it be necessary to remove any part of the band switch assembly, it is advisable to realign the receiver after reinstalling.

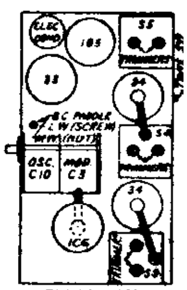
*Anode grid of 1C6 is 125 V.



Batteries Required: One Eveready Air Cell or 2.2-volt storage battery, three 45-volt B batteries, one 22½-volt C battery, and one 4½-volt C battery.

Tubes: Two 34's, one 1C6, one 33, one 1B5.

Wavelength Range: 16-52 m. and 178-550 m. or 18,800-5,700 kc. and 1,680-545 kc.

Undistorted Power Output: .7 watt.

I. F. Alignment Frequency: 456 kc.

Circuit: Short wave and broadcast superheterodyne.

Output: Class A pentode amplifier.

Air Cell Life: When operating a Pilot 153, the No. A-600 Air Cell will have a total operating life of approximately 1,000 hours.

REALIGNMENT: Should the receiver require realignment, the procedure outlined below should be followed. In the service information sheet, the location and function of the various alignment capacitors are clearly illustrated. For best results an external modulated oscillator with adequate frequency range, and a visual output meter, should be used.

Before connecting the chassis to the power line, reconnect the speaker cable in its socket at the rear of the speaker.

I. F. ALIGNMENT: When aligning the Intermediate Frequency Amplifier, the external oscillator must be set at 456 kc. The Band Switch should be in the position marked "Broadcast", and the tuning condenser should be set at maximum capacity. When aligning the receiver on all positions, the volume control and the tone control should be turned to the maximum clockwise position. Connect the antenna lead of the external oscillator to the control grid of the 34 tube in the 2nd I. F. Amplifier through .1 mfd. fixed condenser. Connect the ground lead of the external oscillator to the receiver ground lead. The I. F. alignment trimmers are located at the top of the shielded I. F. Transformers. Rotate the adjusting screw of each capacitor on I. F. Unit No. 3 slowly until maximum output is noted. On completion of this operation, remove the external oscillator lead from the 34 2nd I. F. amplifier tube and connect it in the same manner to the control grid of the 34 1st I. F. amplifier tube. Now rotate each adjustment screw on I. F. Unit No. 2 for maximum output. Following this, connect the external oscillator leads to the control grid of the 1C6 tube. Adjust each trimmer on the I. F. Unit No. 1 for maximum gain.

During these operations, use the least possible input to prevent broadening of the resonance peaks.

In order to obtain the most accurate realignment of the I. F. amplifier, it is essential to repeat the alignment process in all I. F. Units, with the external oscillator leads connected across the control grid of the 1C6 tube.

BROADCAST ALIGNMENT: After the I.F. amplifier is completely realigned, connect the external oscillator leads to the receiver antenna and ground leads with a .0002 mfd. condenser in the antenna lead. Set the Band Switch in the "Broadcast" position and place the tuning control pointer at the 1400 kc. mark. Adjust the broadcast band oscillator trimmer to maximum response. Adjust the signal section trimmer in the same manner.

Next adjust the 600 kc. padder condenser. Set the external oscillator at 600 kc. Rotate the receiver tuning control until resonance is indicated. Then rock the tuning control back and forth about this resonance position, and at the same time adjust the padder condenser for the highest resonance peak.

Now repeat the 1400 kc. trimmer adjustment, following in every detail the procedure previously described.

ALIGNMENT OF THE SHORT-WAVE BAND: The procedure in aligning the short-wave bands is identical with that for the broadcast with the exception of the adjustment of the padder condenser. Insert a 400-ohm non-inductive resistor in the signal generator antenna lead. The alignment frequency is 16.8 meters—(17,800 kc.)

Turn the Band Switch to the right. Tune the external oscillator to 16.8 meters. Tune the receiver so that the dial pointer is in a position coincidental with the 16.8 meter indication on the dial scale. Adjust the short wave oscillator trimmer for maximum response. Next adjust the signal circuit trimmer for maximum resonance. Repeat all adjustments to assure correct alignment, rocking the gang condenser to right or left for maximum gain.

THE LONG WAVE ALIGNMENT: Procedure in the Model 155 is similar to the Broadcast section of that receiver. Align at 375 kc. Adjust the padder at 160 kc.

Should it be necessary to remove the band switch assembly, it is advisable to realign the receiver after reinstalling.

Cathode	2.8	2.8	2.5	13	116
Screen	50	95	—	95	—
Heater	6.3	6.3	6.3	25	25

*Voltage measured through plate resistor.
Speaker field voltage, 115 volts.
Anode grid of 6A7, 95 volts.

REALIGNMENT: Should the receiver require realignment, the outlined procedure below should be followed. In the service information sheet, the location and function of the various alignment capacitors are clearly illustrated. For best results an external modulated oscillator with adequate frequency range, and a visual output meter, should be used.

Before connecting the chassis to the power line, reconnect the speaker cable in its socket at the rear of the speaker.

I. F. ALIGNMENT: When aligning the Intermediate Frequency Amplifier, the external oscillator must be set at 456 kc. The Band Switch should be in the position marked "Broadcast", and the tuning condenser should be set at maximum capacity. Connect the "antenna" lead of the external oscillator to the control grid of the type 6D6 tube in the I.F. Amplifier stage through a .1 mfd. fixed condenser. Connect the "ground" lead of the external oscillator to the receiver ground lead. The I.F. alignment capacitors are located at the top of the shielded I.F. Transformers. Rotate the adjusting screw of each capacitor on I.F. Unit No. 2 slowly until maximum output is noted. On completion of this operation, remove the external oscillator leads from the type 6D6 I.F. Amplifier tube and connect it in the same manner to the control grid at the top of the type 6A7 tube.

Now rotate each adjustment screw on I.F. Unit No. 1 for maximum output. During these operations, use the least possible input to prevent broadening of the resonance peaks.

In order to obtain the most accurate realignment of the I.F. Amplifier, it is essential to repeat the alignment process in both I.F. units with the external oscillator leads connected across the control grid of the 6A7 tube.

BROADCAST ALIGNMENT: After the I.F. amplifier is completely realigned, connect the external oscillator leads to the receiver antenna and ground leads with a .0002 mfd. condenser in the antenna lead. Set the Band Switch in the "Broadcast" position and place the tuning control pointer at the 1400 kc. mark. Adjust the broadcast band oscillator trimmer to maximum response. Adjust the signal section trimmer in the same manner.

Next adjust the 600 kc. padder condenser. Set the external oscillator at 600 kc. Rotate the receiver tuning control until resonance is indicated. Then rock the tuning control back and forth about this resonance position, and at the same time adjust the padder condenser for the highest resonance peak.

Now repeat the 1400 kc. trimmer adjustment, following in every detail the procedure previously described.

SHORT-WAVE ALIGNMENT: The procedure in aligning the short-wave bands is identical with that for the broadcast with the exception of the adjustment of the padder condenser. The alignment frequency is 16.8 Meters—(17,800 kc.) Turn the Band Switch to the right. Tune the external oscillator to 16.8 meters. Tune the receiver so that the dial pointer is in a position coincidental with the 16.8 meter indication on the dial scale. Adjust the short wave oscillator trimmer for maximum response. Next adjust the signal circuit trimmer for maximum resonance. Repeat all adjustments to assure correct alignment, rocking the gang condenser to right or left for maximum gain.

THE LONG WAVE ALIGNMENT: Procedure in the Model 205 is similar to the Broadcast section of that receiver. Align at 375 kc. Adjust the padder at 160 kc.

Should it be necessary to remove the band switch assembly, it is advisable to realign the receiver after reinstalling.

PILOT MODELS 193 AND 195

AC MODELS 193 and 195

(MODEL 195 IS SOLD OUTSIDE THE U. S. A. ONLY)

I. F. ALIGNMENT: When aligning the Intermediate Frequency Amplifier, the external oscillator must be set at 456 kc. The Band Switch should be in the position marked "Broadcast," and the tuning condenser should be set at maximum capacity. Connect the "antenna" lead of the external oscillator to the control grid of the type 6K7 tube in the I. F. Amplifier stage through a .1 mfd. fixed condenser. Connect the "ground" lead of the external oscillator to the receiver ground lead. The I. F. alignment capacitors are located at the top of the shielded I. F. Transformers. Rotate the adjusting screw of each capacitor on I. F. Unit No. 2 slowly until maximum output is noted. On completion of this operation, remove the external oscillator leads from the type 6K7 I. F. Amplifier tube and connect it in the same manner to the control grid at the top of the type 6A8 tube.

Now rotate each adjustment screw on I. F. Unit No. 1 for maximum output. During these operations, use the least possible input to prevent broadening of the resonance peaks.

In order to obtain the most accurate realignment of the I. F. Amplifier, it is essential to repeat the alignment process in both I. F. units with the external oscillator leads connected across the control grid of the 6A8 tube.

WAVE TRAP ADJUSTMENT: With the oscillator still set at 456 kc., connect the oscillator to the antenna and ground. Then adjust the wave trap condenser to minimum deflection on the output meter.

BROADCAST ALIGNMENT: After the I. F. Amplifier is completely realigned, connect the external oscillator leads to the receiver antenna and ground leads, through a .0002 mfd. condenser. Set the Band Switch in the "Broadcast" position and place the tuning control pointer at the 1500 kc. mark. Adjust the broadcast band oscillator trimmer to maximum response. Adjust the signal section trimmer in the same manner.

Next adjust the 600 kc. padder condenser. Set the external oscillator at 600 kc. Rotate the receiver tuning control until resonance is indicated. Then rock the tuning control back and forth about this resonance position, and at the same time adjust the padder condenser for the highest resonance peak.

Now repeat the 1500 kc. trimmer adjustment, following in every detail the procedure previously described.

ALIGNMENT OF THE SHORT-WAVE BANDS: The procedure in aligning the short-wave bands is identical with that for the broadcast with the exception of the adjustment of the padder condenser which is of fixed value and requires no adjustment. The alignment frequency is 16.6 Meters—(18,000 kc.)

Turn the Band Switch to the right. Tune the external oscillator to 16.6 meters. Tune the receiver so that the dial pointer is in a position coincidental with the 16.6 meter indication on the dial scale. Adjust the short wave oscillator trimmer for maximum response. Next adjust the signal circuit trimmer for maximum resonance. Repeat all adjustments to assure correct alignment, rocking the gang condenser to right or left for maximum gain.

Model 193 is aligned in the same manner at 6,000 kc. with the switch in Band 2 position.

LONG WAVE ALIGNMENT: Procedure in the Model 195 is similar to the Broadcast section of that receiver. Align at 375 kc. Adjust the padder at 160 kc.

Should it be necessary to remove the band switch assembly, it is advisable to realign the receiver after reinstalling.

Frequency Rating —50 to 60 cycles.
Power Consumption—60 Watts.
Tubes —1 type 6A8, 1 type 6K7, 1 type 6Q7, 1 type 6F6, 1 type 5W4.
Undistorted power output—3 watts.
Intermediate Frequency—456 kc.

VOLTAGES

The D. C. Voltages measured at the tube sockets of the set should be read with a high resistance voltmeter of at least 1000 ohms per volt.

	OSC. DET. Type 6A8	I. F. Type 6K7	DIODE DET. Type 6Q7	POWER PENTODE Type 6F6	RECTIFIER Type 5W4
Plate	230	230	105*	205	***
Cathode	4.	3.	1.5	**	
Screen	85	85	6.3	230	
Filament	6.3	6.3	6.3	6.3	

*Voltages measured through 250,000 ohm resistor.

Speaker field voltage 90 volts. All plate voltages measured to cathode. All screen voltages measured to cathode. All cathode voltages measured to chassis frame.

****Grid bias voltage for No. 42 tube obtained across R-16 (250 ohms resistor).**

*****Filament to chassis ground 315 volts D. C.**

~~Anode grid of 6A7 to cathode—195 volts.~~

Models 253 and 255 All-Wave,

(MODEL 255 IS SOLD IN THE EUROPEAN AREA ONLY)

The location of the R. F. alignment trimmer condensers is on the side of the band switch. The trimmers in the lowest row are those for aligning Band 1. Those in the second row from the bottom are for Band 2. Those in the third row up are for the Broadcast. In the Model 255 there is an additional row of trimmers located immediately above those for the Broadcast.

The padder condenser is located under the rear section of the band switch. In the Model 255 an additional padder for the long wave range is located at the right of the Broadcast padder. Access to the padder condenser is made through a hole provided in the rear of the chassis frame.

I. F. ALIGNMENT: When aligning the Intermediate Frequency Amplifier, the external oscillator must be set at 456 kc. The Band Selector Switch should be in the position marked "Broadcast", and the tuning condenser should be set at maximum capacity. Connect the "antenna" lead of the external oscillator to the control grid of the type 6D6 tube in the I. F. Amplifier stage through a 1 mfd. fixed condenser. Connect the "ground" lead of the external oscillator to the receiver ground lead. The I. F. alignment capacitors are located at the side of the shielded I. F. Transformers. Rotate the adjusting screw of each capacitor on I. F. Unit No. 2 slowly until maximum output is noted. On completion of this operation, remove the external oscillator lead from the type 6D6 I. F. amplifier tube and connect it in the same manner to the control grid at the top of the type 6A7 tube.

Now rotate each adjustment screw on I. F. Unit No. 1 for maximum output. During these operations, use the least possible input to prevent broadening of the resonance peaks.

In order to obtain the most accurate realignment of the I. F. amplifier, it is essential to repeat the alignment process in both I. F. Units with the external oscillator leads connected across the control grid of the 6A7 tube.

BROADCAST ALIGNMENT:

See Models 193 & 195

ALIGNMENT OF THE SHORT WAVE-BANDS:— The procedure in aligning the short wave-bands is identical with that for the broadcast with the exception of the adjustment of the padder condenser. The alignment frequencies are as follows:

Band 2: 50 Meters—(6,000 kc.)
Band 1: 16.6 Meters—(18,000 kc.)

A 400 ohm resistor should be used in series with the antenna lead in place of the condenser used on Broadcast.

When aligning Band 2, set the Band Selector Switch in the position marked "Band 2." Set the tuning control pointer at 50 meters. Adjust the oscillator alignment capacitor on Band 2 for maximum output. Next adjust the interstage and antenna section alignment capacitors for maximum output.

To align Band 1, set the Band Selector Switch in the position marked "Band 1". Set the tuning control pointer at the 16.6 meter mark. Set the external oscillator at 16.6 meters. Adjust the oscillator section alignment capacitor on Band 1 for maximum output.

Proceed next to align the interstage section of Band 1. In doing this, it is essential to rock the tuning control back and forth about the resonance position and at the same time to adjust the trimmer for the highest resonance peak. Next align the antenna section for maximum sensitivity.

LONG WAVE MODEL 255

The above alignment positions refer to the Model 253 only, which is calibrated in frequency. The alignment points for the Model 255, which is calibrated in meters only, is as follows:

High Band	Align at 750 meters.	
	Pad at 2,000 meters.	
Broadcast	Align at 200 meters.	
	Pad at 500 meters.	
Band 2	Align at 49 meters.	
Band 1	Align at 17 meters.	

The Model No. 253 is an all wave superheterodyne receiver with a frequency range extending from 18,800 kc. to 545 kc. (16 meters to 550 meters). The Model No. 255 is similar to the Model No. 253 but has an additional long wave range embracing the wavelengths from 750 meters to 2000 meters (400 kc. to 150 kc.)

This receiver is designed to operate entirely from a six volt storage battery. A 100-ampere-hour battery is recommended. Connections to the battery are made by means of the RED and the BLACK rubber covered leads. A large clip is attached to each lead. Connect the RED lead to the POSITIVE terminal of the battery. Connect the BLACK lead to the NEGATIVE terminal.

CAUTION: BE CERTAIN OF THE POLARITY OF THE BATTERY BEFORE CONNECTING THE RECEIVER TO IT, OR SERIOUS DAMAGE TO THE RECEIVER MAY RESULT.

(MODEL 295 IS SOLD OUTSIDE THE U. S. A. ONLY)

REMOVAL OF CHASSIS FROM CABINET:

To remove the chassis from the cabinet proceed as follows:

Be certain that the line cord is removed from the power outlet socket.

Remove the "slip-on" knobs and felt washers from the controls and loosen the set screw on the tuning knob.

Remove the speaker plug from the socket at the rear of the chassis.

Remove the four mounting screws, located underneath the cabinet.

Remove the tuning beam plug from the socket at the front of the chassis.

REALIGNMENT: Should the receiver require re-alignment, the procedure outlined below should be followed. For best results an external modulated oscillator with adequate frequency range, and a visual output meter, should be used.

Before connecting the chassis to the power line, reconnect the speaker cable in its socket at the rear of the chassis.

The location of the R. F. alignment trimmer condensers is on the side of the band switch. The trimmers in the lowest row are those for aligning Band 1. Those in the second row from the bottom are for Band 2. Those in the third row up are for the Broadcast. In the Model 295 there is an additional row of trimmers located immediately above those for the Broadcast.

The padder condenser is located under the rear section of the band switch. In the Model 295 an additional padder for the long wave range is located at the right of the Broadcast padder. Access to the padder condenser is made through a hole provided in the rear of the chassis frame.

I. F. ALIGNMENT: When aligning the Intermediate Frequency Amplifier, the external oscillator must be set at 456 kc. The Band Selector Switch should be in the position marked "Broadcast", and the tuning condenser should be set at maximum capacity. Connect the "antenna" lead of the external oscillator to the control grid of the type 6K7 tube in the I. F. Amplifier stage through a .1 mfd. fixed condenser. Connect the "ground" lead of the external oscillator to the receiver ground lead. The I. F. alignment capacitors are located at the side of the shielded I. F. Transformers. Rotate the adjusting screw of each capacitor on I. F. Unit No. 2 slowly until maximum output is noted. On completion of this operation, remove the external oscillator lead from the type 6K7 I. F. amplifier tube and connect it in the same manner to the control grid at the top of the type 6A8 tube.

Now rotate each adjustment screw on I. F. Unit No. 1 for maximum output. During these operations, use the least possible input to prevent broadening of the resonance peaks.

In order to obtain the most accurate realignment of the I. F. amplifier, it is essential to repeat the alignment process in both I. F. Units.

BROADCAST ALIGNMENT: After the I. F. amplifier is completely realigned, connect the external oscillator leads to the receiver antenna and ground leads. Insert a 200 mmf. condenser in series with the antenna lead. Set the Band Selector Switch in the "Broadcast" position and place the tuning control pointer at the 1500 kc. mark. Adjust the broadcast band oscillator trimmer.

Next adjust the interstage alignment trimmer for maximum response. Finally adjust the antenna section trimmer in the same manner.

Next adjust the 600 kc. padder condenser, located in the lower rear section of the band switch, under the chassis. Set the external oscillator at 600 kc. Rotate the receiver tuning control until resonance is indicated. Then rock the tuning control back and forth about this resonance position, and at the same time adjust the padder condenser for the highest resonance peak.

Now repeat the 1500 kc. trimmer adjustment, following in every detail the procedure previously described.

ALIGNMENT OF THE SHORT WAVE-BANDS:— The procedure in aligning the short wave-bands is identical with that for the broadcast with the exception of the adjustment of the padder condenser. Insert a 400 ohm non-inductive resistor in series with the antenna lead. The alignment frequencies are as follows:

Band 2: 50 Meters—(6,000 kc.)
Band 1: 16.6 Meters—(18,000 kc.)

When aligning Band 2, set the Band Selector Switch in the position marked "Band 2". Set the tuning control pointer at 50 meters. Adjust the oscillator alignment capacitor on Band 2 for maximum output. Next adjust the interstage and antenna section alignment capacitors for maximum output.

To align Band 1, set the Band Selector Switch in the position marked "Band 1". Set the tuning control pointer at the 16.6 meter mark. Set the external oscillator at 16.6 meters. Adjust the oscillator section alignment capacitor on Band 1 for maximum output.

Proceed next to align the interstage section of Band 1. In doing this, it is essential to rock the tuning control back and forth about the resonance position and at the same time to adjust the trimmer for the highest resonance peak. Next align the antenna section for maximum sensitivity.

LONG WAVE MODEL 295

The above alignment positions refer to the Model 293 only, which is calibrated in frequency. The alignment points for the Model 295, which is calibrated in meters only, is as follows:

Long Wave	Align at 750 meters.
	Pad at 2,000 meters.
Broadcast	Align at 200 meters.
	Pad at 500 meters.
Band 2	Align at 49 meters.
Band 1	Align at 17 meters.

The Long Wave alignment procedure is similar to that for the Broadcast. A 200 mmf. condenser should be used in series with the antenna lead in aligning this band.

REMOVAL OF BAND SELECTOR SWITCH ASSEMBLY: Should it be necessary to remove the switch assembly, this is easily done by removing the supporting screws. Before doing this, however, it is essential to unsolder the leads between the switch and the chassis.

It is advisable to realign the receiver after reinstalling the switch assembly.

CAUTION: When making repairs on the receiver, use only ROSIN CORE SOLDER. NEVER USE SOLDERING PASTE OR ACID FLUXES OF ANY TYPE.

PILOT MODELS 304 AND 305

MODEL 305 IS SOLD OUTSIDE THE U. S. A. ONLY)

Undistorted power output—4 watts.
I. F.—456 kc.

Type of Circuit — All wave Superheterodyne with TRF stage on all bands, A. V. C., Class "A" push pull parallel power output stage.

VOLTAGES

The D. C. Voltages measured at the tube sockets of the set should be read with a high resistance voltmeter of at least 1,000 ohms per volt.

	R.F. 6K7	Osc. & 1st Det. 6A8		I.F. 6K7	2nd Det. & Amp. 6R7	Pwr. Pent. 25A6	Pwr. Pent. 25A6	Pwr. Pent. 25A6	Pwr. Pent. 25A6	Rect. 25Z6	Rect. 25Z6	T.B. 6E5
Plate	91	80	88	83	73	80	80	80	80	—	—	*6
Screen	91	—	49	80	—	90	90	90	90	—	—	—
Cathode	0	0	0	0	0	12.5	12.5	12.5	12.5	99	99	—
Filament	6.3	6.5	—	6.3	6.3	26	26	26	26	26	26	6.3

Speaker field—99 Volts. Tuning Beam—Target 90 volts to ground.

A 6E5 tuning beam should be plugged into the tuning beam socket on the chassis, whenever the receiver is operated outside the cabinet.

* Measured through 1 megohm.

I. F. ALIGNMENT: When aligning the Intermediate Frequency Amplifier, the external oscillator must be set at 456 kc. The Band Switch should be in the position marked "Broadcast", and the tuning condenser should be set at maximum capacity. When aligning the receiver on all positions, the volume control and the tone control should be turned to the maximum clockwise position. Connect the antenna lead of the external oscillator to the control grid of the 6K7 tube in the I. F. Amplifier through a .1 mfd. fixed condenser. Connect the ground lead of the external oscillator to the chassis. The I. F. alignment trimmers are located at the top of the shielded I. F. Transformers. Rotate the adjusting screw of each capacitor on I. F. Unit No. 2 slowly until maximum output is noted. Following this, connect the external oscillator leads to the control grid of the 6A8 tube. Adjust each trimmer on I. F. Unit No. 1 for maximum gain.

During these operations, use the least possible input to prevent broadening of the resonance peaks.

In order to obtain the most accurate realignment of the I. F. amplifier, it is essential to repeat the alignment process in all I. F. Units, with the external oscillator leads connected to the control grid of the 6A8 tube.

BROADCAST ALIGNMENT: After the I. F. amplifier is completely realigned, connect the external oscillator leads to the receiver antenna and ground leads through a .0002 mfd. condenser. Leave the Band Switch in the "Broadcast" position and place the tuning control pointer at the 1500 kc. mark. Tune the external oscillator to 1500 kc. Adjust the broadcast band oscillator trimmer to maximum response.

Next adjust the interstage alignment trimmer for maximum response. Finally adjust the antenna section trimmer in the same manner.

Next adjust the 600 kc. padder condenser, located in the lower rear partition of the band switch, under the chassis. Set the external oscillator at 600 kc. Rotate the receiver tuning control to the resonance position, and at the same time adjust the padder condenser for the highest peak.

Now repeat the 1500 kc. trimmer adjustment, following in every detail the procedure previously described.

The alignment frequencies are as follows:

Band 5—150 and 375 kc.—2000 and 800 m.
Band 4—600 and 1500 kc.—500 and 200 m.
Band 3—69.7 meters— 4,300 kc.
Band 2—27.2 meters—11,000 kc.
Band 1—13.6 meters—22,000 kc.

When aligning Band 3, set the Band Switch in the position marked Band 3. Rotate the tuning condenser to the 4300 kc. indication on the dial scale. Set the external oscillator at 4300 kc. Adjust the Band 3 oscillator trimmer for maximum sensitivity. Next adjust the interstage and antenna trimmer condensers for maximum sensitivity. Check the overall sensitivity of the band at several points along the dial scale.

Align Band 2 in a similar manner using a 400-ohm non-inductive resistor in place of the .0002 mfd. condenser. The alignment frequency is 11,000 kc. (27.2 meters).

The alignment of Band 1 requires greater care due to the higher frequencies covered by this band. The tracking characteristic of Band 1 of this receiver differs from that of the other bands, in that the 1st detector and T.R.F. circuits resonate on the high frequency side of the oscillator. This condition applies only to Band 1. The alignment frequency is 22,000 kc. or 13.6 meters. Set the external oscillator at 22,000 kc. Rotate the tuning condenser of the receiver until the dial pointer is co-incidental with the 22,000 kc. indication on the dial scale. Adjust the oscillator trimmer condenser for maximum sensitivity. Proceed next to align the interstage section. In doing this it is essential to rock the tuning control back and forth about the resonance position and at the same time to adjust the trimmer for the highest resonant peak. Next align the antenna section for minimum sensitivity.

Part No. 71786-6-36

THE LONG WAVE ALIGNMENT procedure in the Model 305 is similar to that of the broadcast. Turn the Band Switch to the Long Wave position. The alignment frequency is 375 kc. Adjust the padder condenser at 150 kc. Use a .0002 mfd. condenser in the antenna lead from the external oscillator.

Pilot engineers recommend the doublet antenna. When using a doublet, connect one lead-in wire to the blue lead at the rear of the set, and the other one to the yellow lead. Next, connect the black lead to the ground.

If you use an ordinary single-wire antenna, connect the antenna to the blue lead on the set. Then connect the yellow and black leads together, and to the ground.

PHONOGRAPH PICK-UP: A jack is provided at the rear of the chassis for plugging in an electric phonograph pick-up, in order that records can be reproduced by the loudspeaker, through the high-quality amplifier with which this set is equipped. The pick-up should be of the high-impedance type.

EXTRA SPEAKER: At the rear of the chassis there is a socket for plugging in an extra speaker, which can be located in the kitchen, in one of your up-stairs rooms, or down cellar in the game room. This will give you the equivalent of an extra radio, at the small expense of the extra speaker. We recommend a permanent magnet dynamic speaker of 10,000 ohms. These speakers operate without any field exciting current.

PILOT MODELS 393 AND 395

MODEL 393 IS SOLD OUTSIDE THE U. S. A. ONLY

The location of the R. F. alignment trimmer condensers is at the right end of the chassis underneath the deck.

I. F. ALIGNMENT: When aligning the Intermediate Frequency Amplifier, the external oscillator must be set at 456 kc. The Band Selector Switch should be in the position marked "Broadcast", and the tuning condenser should be set at maximum capacity. Connect the "antenna" lead of the external oscillator to the control grid of the type 6K7 tube in the I. F. Amplifier stage through a .1 mfd. fixed condenser. Connect the "ground" lead of the external oscillator to the receiver ground lead. The I. F. alignment capacitors are located at the side of the shielded I. F. Transformers. Rotate the adjusting screw of each capacitor on I. F. Unit No. 2 slowly until maximum output is noted. On completion of this operation, remove the external oscillator lead from the type 6K7 I. F. amplifier tube and connect it in the same manner to the control grid at the top of the type 6A8 tube.

Now rotate each adjustment screw on I. F. Unit No. 1 for maximum output. During these operations, use the least possible input to prevent broadening of the resonance peaks.

In order to obtain the most accurate realignment of the I. F. amplifier, it is essential to repeat the alignment process in both I. F. Units.

BROADCAST ALIGNMENT: After the I. F. amplifier is completely realigned, connect the external oscillator leads to the receiver antenna and ground leads. Insert a 200 mmf. condenser in series with the antenna lead. Set the Band Selector Switch in the "Broadcast" position and place the tuning control pointer at the 1500 kc. mark. Adjust the broadcast band oscillator trimmer.

Next adjust the interstage alignment trimmer for maximum response. Finally adjust the antenna section trimmer in the same manner.

Next adjust the 600 kc. padder condenser, located on the top of the oscillator coil. Set the external oscillator at 600 kc. Rotate the receiver tuning control until resonance is indicated. Then rock the tuning control back and forth about this resonance position, and at the same time adjust the padder condenser for the highest resonance peak.

Now repeat the 1500 kc. trimmer adjustment, following in every detail the procedure previously described.

ALIGNMENT OF THE SHORT WAVE-BANDS—The procedure in aligning the short wave-bands is identical with that for the broadcast with the exception of the adjustment of the padder condenser. Insert a 400 ohm non-inductive resistor in series with the antenna lead. The alignment frequencies are as follows:

Band 2: 50 Meters—(6,000 kc.)
Band 1: 16.6 Meters—(18,000 kc.)

When aligning Band 2, set the Band Selector Switch in the position marked "Band 2". Set the tuning control pointer at 50 meters. Adjust the oscillator alignment capacitor on Band 2 for maximum output. Next adjust the interstage and antenna section alignment capacitors for maximum output.

To align Band 1, set the Band Selector Switch in the position marked "Band 1". Set the tuning control pointer at the 16.6 meter mark. Set the external oscillator at 16.6 meters. Adjust the oscillator section alignment capacitor on Band 1 for maximum output.

Proceed next to align the interstage section of Band 1. In doing this, it is essential to rock the tuning control back and forth about the resonance position and at the same time to adjust the trimmer for the highest resonance peak. Next align the antenna section for maximum sensitivity.

LONG WAVE MODEL 395

The above alignment positions refer to the Model 393 only, which is calibrated in frequency. The alignment points for the Model 395, which is calibrated in meters only, is as follows:

Long Wave	Align at 750 meters. Pad at 2,000 meters.
Broadcast	Align at 200 meters. Pad at 500 meters.
Band 2	Align at 49 meters.
Band 1	Align at 17 meters.

The Long Wave alignment procedure is similar to that for the Broadcast. A 200 mmf. condenser should be used in series with the antenna lead in aligning this band.

For Phonograph Pickup & Extra Speaker Data See Models 304 & 305

Pilot engineers recommend the doublet antenna. To connect this set to a doublet, first remove the link across the D and G terminals at the rear of the chassis. Then connect one wire of the doublet lead to post A, and the other wire to post D.

If you use a single-wire antenna, leave the link across D and G. Connect the lead-in to A, and the ground wire to either D or G.

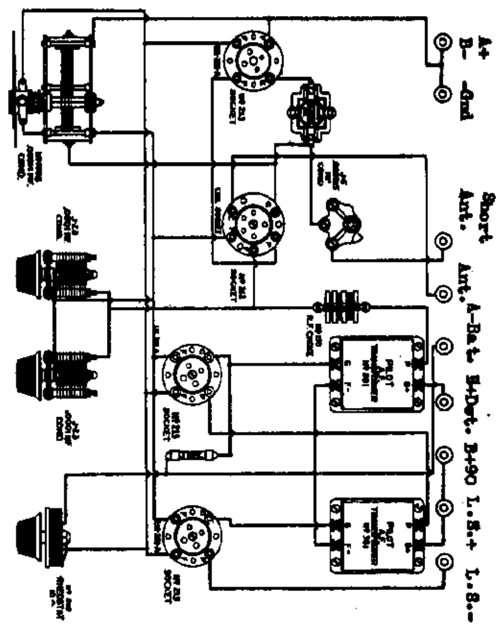
APRIL 1928

PILOT WASP

10,000 MILE SHORT WAVE RECEIVER, TYPE 3-SW
17 TO 500 METERS

ASSEMBLY NOTES: Front panel 7x14 inches, base panel 7x13 inches. Mount base panel with No. 35 PILOT brackets, with top of base panel 1½ inches above bottom of front panel. Make all lines as short as possible.

To control regeneration on short waves, put upper midget condenser at zero, and adjust with lower midget. Use same method on broadcast waves, but put upper midget at full capacity. Use PILOT plug-in coil as follows: Red ring, 20-meter band; Orange ring, 40-meter band; Yellow ring, 80-meter band; Green ring, 160-meter band; Blue ring, broadcast band.



PILOT RADIO CORP.

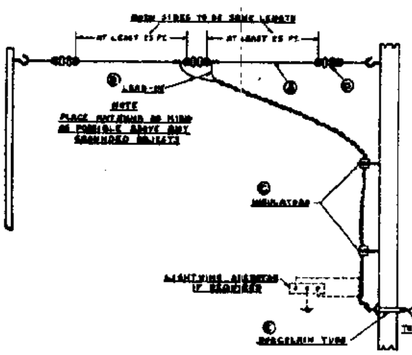
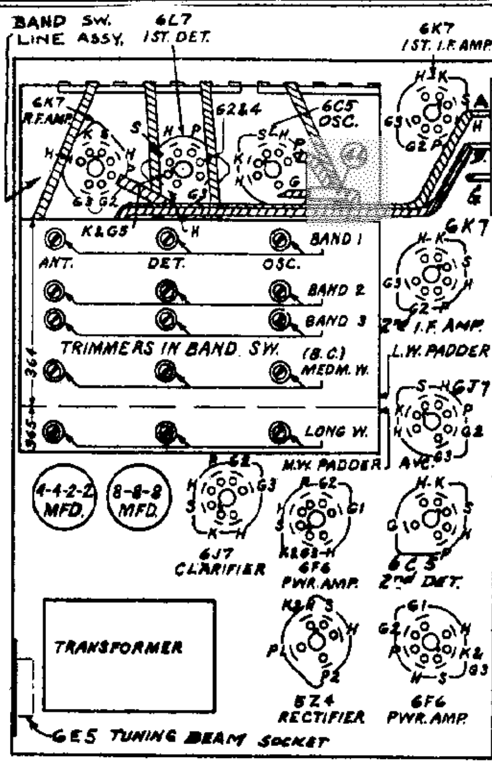
ALL-WAVE ANTENNA SYSTEM





WIRING TO BAND SWITCH & ARRANGEMENT OF SOCKET TERMINALS.

RECEIVER DESCRIPTION

Operating Voltages—115, 125, 150, 220, 240 Volts—Alternating Current 50-60 Cycles.
Power Consumption 125 Watts.
Wavelength range —From 13 to 565 meters (23,000 kc. to 530 kc.)
Undistorted power output—8 Watts.
I. F. —456 kc.
Type of Circuit —All wave Superheterodyne with TRF stage on all bands, A. V. C., Class "A" push pull power output stage.

I. F. ALIGNMENT: When aligning the Intermediate Frequency Amplifier, the external oscillator must be set at 456 kc. The Band Switch should be in the position marked "Broadcast", and the tuning condenser should be set at maximum capacity. When aligning the receiver on all positions, the volume control and the tone control should be turned to the maximum clockwise position. Connect the antenna lead of the external oscillator to the control grid of the 6K7 tube in the 2nd I. F. Amplifier through a .1 mfd. fixed condenser. Connect the ground lead of the external oscillator to the receiver ground lead. The I. F. alignment trimmers are located at the top of the shielded I. F. Transformers. Rotate the adjusting screw of each capacitor on I. F. Unit No. 3 slowly until maximum output is noted. On completion of this operation, remove the external oscillator lead from the 6K7 2nd I. F. amplifier tube and connect it in the same manner to the control grid of the 6K7 1st I. F. amplifier tube. Now rotate each adjustment screw on I. F. Unit No. 2 for maximum output. Following this, connect the external oscillator leads to the control grid of the 6L7 tube. Adjust each trimmer on the I. F. Unit No. 1 for maximum gain.

During these operations, use the least possible input to prevent broadening of the resonance peaks.

In order to obtain the most accurate realignment of the I. F. amplifier, it is essential to repeat the alignment process in all I. F. Units, with the external oscillator leads connected across the control grid of the 6L7 tube.

BROADCAST ALIGNMENT: After the I. F. amplifier is completely realigned, connect the external oscillator leads to the receiver antenna and ground leads through a .0002 mfd. condenser. Set the Band Switch in the "Broadcast" position and place the tuning control pointer at the 1500 kc. mark. Tune the external oscillator to 1500 kc. Adjust the broadcast band oscillator trimmer to maximum response.

Next adjust the interstage alignment trimmer for maximum response. Finally adjust the antenna section trimmer in the same manner.

Next adjust the 570 kc. padder condenser, located in the lower rear section of the band switch, under the chassis. Set the external oscillator at 570 kc. Rotate the receiver tuning control to the resonance position, and at the same time adjust the padder condenser for the highest peak.

Now repeat the 1500 kc. trimmer adjustment, following in every detail the procedure previously described.

The alignment frequencies are as follows:
Band 3—69.73 meters— 4,300 kc.
Band 2—26.07 meters—11,500 kc.
Band 1—13. meters—23,000 kc.

When aligning Band 3, set the Band Switch in the position marked Band 3. Rotate the tuning condenser to the 4300 kc. indication on the dial scale. Set the external oscillator at 4300 kc. Adjust the Band 3 oscillator trimmer for maximum sensitivity. Next adjust the interstage and antenna trimmer condensers for maximum sensitivity. Check the overall sensitivity of the band at several points along the dial scale.

Align Band 2 in a similar manner using a 400-ohm non-inductive resistor in place of the .0002 mfd. condenser. The alignment frequency is 11,500 kc. (26.07 meters).

The alignment of Band 1 requires greater care due to the higher frequencies covered by this band. The tracking characteristic of Band 1 of this receiver differs from that of the other bands, in that the 1st detector and T.R.F. circuits resonate on the high frequency side of the oscillator. This condition applies only to Band 1. The alignment frequency is 23000 kc. or 13 meters. Set the external oscillator at 13 meters. Rotate the tuning condenser of the receiver until the dial pointer is co-incidental with the 13 meter indication on the dial scale. Adjust the oscillator trimmer condenser for maximum sensitivity. Proceed next to align the interstage section. In doing this it is essential to rock the tuning control back and forth about the resonance position and at the same time to adjust the trimmer for the highest resonant peak. Next align the antenna section for maximum sensitivity.

THE LONG WAVE ALIGNMENT procedure in the Model 365 is similar to that of the broadcast. Turn the Band Switch to the Long Wave position. The alignment frequency is 380 kc. Adjust the padder condenser at 150 kc. Use a .0002 mfd. condenser in the antenna lead from the external oscillator.

SERVICE INFORMATION

REALIGNMENT: Should the receiver require alignment, the outlined procedure below should be followed. In the service information sheet, the location and function of the various alignment capacitors are clearly illustrated. For best results, an external modulated oscillator with adequate frequency range and a visual output meter, should be used.

Before connecting the chassis to the power line, reconnect the speaker cable in its socket at the rear of the chassis, and reinsert the tuning beam cable plug in the socket at the front of the chassis.

VOLTAGES

Volume Control—Turn to right during measurements. Speaker field—104 Volts.
Tuning Beam—Target 200 Volts to ground.

The D. C. Voltages measured at the tube sockets of the set should be read with a high resistance voltmeter of at least 1,000 ohms per volt.

Resistance Measurement

The resistance values shown between Radiotron socket contacts, grid caps, resistors, terminals, and receiver chassis ground, on Figure 4, have been carefully selected so as to facilitate a rapid continuity check of the circuits. The use of this diagram in conjunction with the Schematic Circuit Diagram, Figure 1, and Chassis Wiring Diagram, Figure 2, will permit the location of certain troubles which might otherwise be difficult to ascertain. Each value as specified should hold within $\pm 20\%$. Variations in excess of this limit will usually be indicative of trouble in circuit under test. Resistance values were measured with the Radiotrons in sockets; tuning condenser in full mesh, and volume control set at maximum except where otherwise noted. In all cases of measuring the resistance between points of the circuit and ground, it will be necessary to connect the negative terminal of the resistance meter to chassis-ground. If the polarity of the resistance meter is not known, it may be readily ascertained by connecting a d-c voltmeter of indicated polarity across the terminals of the device.

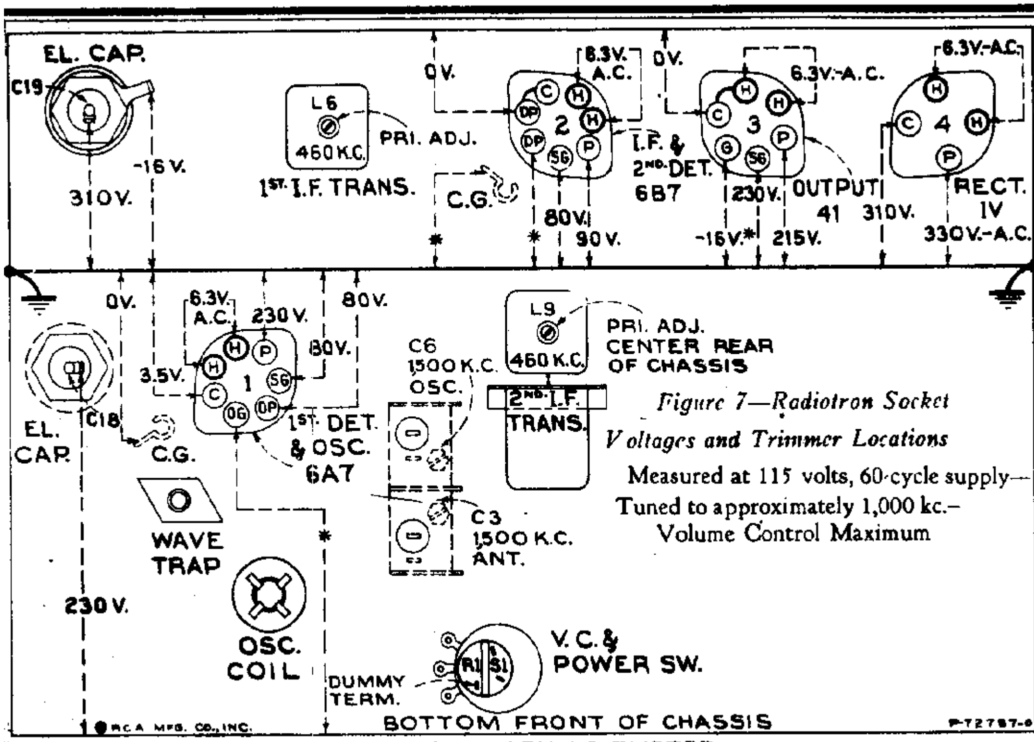

Figure 7—Radiotron Socket Voltages and Trimmer Locations
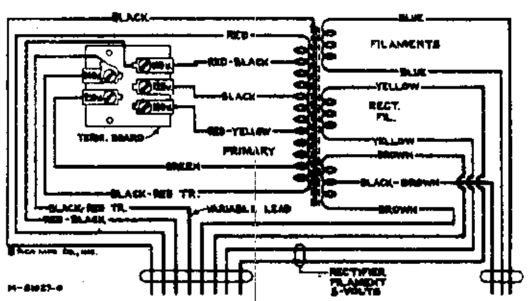
Measured at 115 volts, 60-cycle supply—
Tuned to approximately 1,000 kc.—
Volume Control Maximum

* CANNOT BE MEASURED WITH ORDINARY VOLTMETER.

Radiotron Socket Voltages

The voltage values indicated from the Radiotron socket contacts, grid caps, resistors, and terminals to receiver chassis ground on Figure 7 will assist in locating cause for faulty operation. Each value as specified should hold within $\pm 20\%$ when the receiver is normally operative at its rated line voltage. Variations in excess of this limit will usually be indicative of trouble in the basic circuits. These voltages were measured with receiver tuned to approximately 1,000 kc., no signal being received and volume control set at maximum. To duplicate the conditions under which the voltages were measured requires a 1,000-ohm-per-volt d-c meter, having ranges of 10, 50, 250, and 500 volts. Use the nearest range above the voltage to be measured. A-C voltages were measured with a corresponding a-c meter.



Primary Resistance - 23.6 ohms Total
Secondary Resistance - 180 ohms Total

Figure 5—Universal Transformer

RCA MFG. CO., INC.

MODEL 4T
Circuit Data, Alignment, Parts List

GENERAL FEATURES

This model contains a four-tube chassis mounted in a table-type cabinet. The superheterodyne circuit is used, incorporating such features of design as automatic volume control, magnetite core adjusted i-f transformers, diode detection, reflexed audio system, electrodynamic speaker, and improved antenna wavetrap. The frequency range extends from 540 to 1,720 kc. which covers the regular broadcast band and includes police calls in the 1,500 to 1,720 kc. portion of the range.

CIRCUIT DESCRIPTION

Four Radiotrons are associated in combination with a superheterodyne circuit. Two of the Radiotrons are applied so as to obtain plural functions. The first tube, an RCA-6A7 pentagrid converter tube, is employed as a combination first detector and oscillator. The second tube, an RCA-6B7, performs the functions of i-f amplification, diode detection, audio amplification, and automatic volume control. A power-amplifier pentode, RCA-41, is used in the output stage.

Half-wave rectification is used in the power supply stage. The speaker field winding serves as a reactor in the filter circuit.

The radio-frequency and intermediate-frequency stages are intercoupled by means of transformers. The antenna transformer couples directly into the first detector, having its secondary tuned by one section (front) of the two-gang tuning condenser. The oscillator system is tuned by the second (rear) section of the condenser. Adjustable magnetite-core trimmers are provided for adjusting the inductance of the windings of the input i-f transformer (primary and secondary) and the output transformer (primary) so as to resonate at 460 kc. with the fixed capacitors shunting these respective coils. The i-f signal originating in the first-detector circuit is transferred to the control grid of the RCA-6B7, amplified in the pentode section, coupled back to the diode section of this same tube where it is rectified before passing through resistor R-4. A fraction of the audio component developed across resistor R-4 appears across resistor R-6 from whence it is transferred to the control grid of the Radiotron 6B7 through winding L-7; L-7 and capacitor C-10 offering low and high reactance respectively to audio frequencies. The amplified audio signal, in the plate circuit of the RCA-6B7, developed across resistor R-5 is coupled to the control grid of the power-output tube for final amplification. The output of this stage is coupled to the loudspeaker through the output transformer T-4. The d-c signal component, of the diode rectified current, developed across R-4, increases the bias of the RCA-6B7, thereby reducing its gain and giving A.V.C. action.

SERVICE DATA

NOTE: Oscillation may occur in receiver if external ground connection is not used.

The various diagrams of this booklet contain such information as will be needed to locate causes for defective operation if such develops. The values of resistors, capacitors, coils, etc., are indicated adjacent to the symbols signifying these parts on the diagrams.

Identification titles, such as R-3, L-2, C-1, etc., are provided for reference between the illustrations and the Replacement Parts List. The coils, reactors, and transformer windings are rated in terms of their d-c resistance only. Ratings of less than one ohm are generally omitted.

ALIGNMENT PROCEDURE

There are two alignment trimmers provided in the antenna coil and oscillator coil tuned circuits. The i-f transformer adjustments are made by means of three screws attached to molded magnetite cores.

All of the adjustable circuits of this receiver have been properly aligned at the factory to give correct performance and their settings should remain intact indefinitely when the receiver is used under ordinary conditions. However, necessity for re-adjustment may occasionally occur from continued extremes of temperature, climate, tampering or purported alteration for services, or after repairs have been made to the r-f or i-f tuned circuits. Improper alignment usually causes the impairment of sensitivity, selectivity, and tone quality. Such conditions will usually exist simultaneously.

In re-adjusting the tuned circuits, it is important to apply a definite procedure, and to use adequate and reliable test equipment. A standard test oscillator such as the RCA Stock No. 9595 will be required as the source of the signal at the specified alignment frequencies. Visual indication of the receiver output during alignment is also necessary to accurately show when the correct point of adjustment is reached. The RCA Stock No. 4317 Neon Output Indicator is especially suitable for this use.

The following procedure should be observed in adjusting the various trimming capacitors and molded magnetite cores:

I-F Core Adjustments

The three adjustment screws (one on top and one on bottom of first i-f transformer and one on bottom of second i-f transformer) are located as shown by Figures 5 and 7. Each circuit must be aligned to a basic frequency of 460 kc. To do this, attach the output indicator across the loudspeaker voice coil or across the output transformer primary. Connect the output of the test oscillator to the RCA-6A7 control grid, the ground of the test oscillator being connected to the receiver ground terminal. Adjust the test oscillator to 460 kc. Advance the receiver tuning control to a point within its range where no interference is encountered either from local broadcast stations or local oscillator. Set the volume control to its maximum position. Increase the output of the test oscillator until a slight indication is apparent on the output indicator. Adjust the bottom screw of the second i-f transformer to produce maximum (peak) indicated receiver output. Then adjust the two screws of the first i-f transformer for maximum (peak) receiver output as shown by the indicating device.

During these adjustments, regulate the test oscillator output so the indication is always as low as possible. By doing so, broadness of tuning, due to A.V.C. action, will be avoided. It is advisable to repeat the adjustment of all i-f screws to assure that the interaction between them has not disturbed the original adjustment.

Wave-Trap Adjustment

Attach the output of the test oscillator to the black antenna lead through a 300-ohm resistor, the ground connection of the test oscillator remaining the same. Leave the test oscillator adjusted to 460 kc. as before. Turn the rotor plates of the two-gang tuning condenser completely out of mesh. Then adjust the wave-trap trimmer to the point which causes maximum suppression of the 460 kc. signal.

R-F Trimmer Adjustments

Calibrate the tuning dial by first loosening its set screw and then rotating dial until the extreme end calibration mark (beyond 55 on dial) is in alignment with the dial shadow-indicator while the two-gang tuning condenser plates are in full mesh. Re-tighten set screw.

The output meter should be left connected to the output system. The connections for the test oscillator remain the same as for "Wave-trap adjustment."

Adjust the test oscillator to 1,500 kc. and set the receiver tuning control to a dial reading of 1,500 kc. Leave the volume control at its maximum position. Regulate the output of the test oscillator until a slight indication is perceptible at the receiver output. Then adjust the two trimming capacitors C-6 and C-5 of the oscillator and antenna coils, Figure 3, so that each produces maximum (peak) receiver output.

MODELS T4-8A, T4-9A
Voltage, Socket, Data
Parts List

RCA MFG. CO., INC.

These instruments are similar to Models T 4-8 and T 4-9 except for several circuit modifications. The major differences include:—rearrangement of wave-trap circuit, removal of oscillator low frequency trimmer, replacement of the RCA-6F7 with an RCA-6B7, and reflexing of the i-f stage for additional audio amplification. The intermediate frequency remains at 460 kc. The antenna and oscillator coils are to be aligned only at 1400 kc. Refer to T 4-8 and T 4-9. Service Notes for loudspeaker data, power ratings and specifications.

MODELS 4X,4X3,4X4
Circuit Data
Alignment,Parts

RCA MFG. CO., INC.

General Features

Each model contains a four-tube chassis mounted in a table-type cabinet. The superheterodyne type of circuit is used, with such features of design as magnetite core adjusted i-f transformers, improved core adjusted antenna wave-trap, illumination of full-vision dial scale, resistance-coupled audio system, and an electrodynamic loudspeaker. The tuning range covers from 540 to 1,720 kc which includes the standard-broadcast and one police band.

Circuit Arrangement

The conventional superheterodyne type of circuit, consisting of a combined first-detector—oscillator stage, a combined i-f amplifier and second detector stage, an audio power-output stage, and a half-wave rectifier stage, is used.

Tuned Circuits

The antenna and oscillator coils are tuned by a variable two-section gang condenser having trimming capacitors in shunt with each section. A wave-trap is employed and is connected in series with the antenna to reduce undesirable signals in the range of the i-f amplifier. It is tuned to 460 kc by means of a screw attached to the molded magnetite core.

The intermediate-frequency amplifier system consists of the pentode section of the RCA-6F7 in a transformer-coupled circuit. This stage operates at a basic frequency of 460 kc. Adjustable mangetite cores are provided for adjusting the inductance of the first i-f transformer primary and secondary, and the second i-f transformer secondary windings to 460 kc.

Second Detector and Audio System

The second-detector circuit uses the triode-portion of the RCA-6F7 in a conventional three-element power-detector circuit. The output of this stage is resistance-capacitance coupled to an RCA-43 power-output tube which, in turn, is transformer-coupled to the dynamic speaker.

Rectifier

The plate, grid, cathode, and the loudspeaker field voltages required for the operation of this receiver are supplied by the RCA-25Z5 tube operating as a half-wave rectifier.

SERVICE DATA

Alignment Procedure

There are two alignment trimmers provided in the antenna-coil and oscillator-coil tuned circuits. The i-f transformer adjustments are made by means of three screws attached to molded magnetite cores. The wave-trap is likewise adjusted by a screw attached to its molded core. Re-adjustment may occasionally occur from continued extremes of climate, tampering, purported alteration for services, or after repairs have been made to the r-f or i-f tuned circuits. Improper alignment usually causes the impairment of sensitivity, selectivity, and tone quality. Such conditions will usually exist simultaneously.

In re-adjusting the tuned circuits, it is important to apply a definite procedure and to use adequate and reliable test equipment. A standard test oscillator, such as the RCA Stock No. 9595, will be required as the source of the signal at the specified alignment frequencies. Visual indication of the receiver output during alignment is also necessary to accurately show when the correct point of adjustment is reached. The RCA Stock No. 4317 Neon Output Indicator is especially suitable for this use.

The procedure outlined below should be followed in adjusting the various trimming capacitors and molded magnetite cores:

I-F Core Adjustments

The three adjustment screws (one on top and one on bottom of first i-f transformer and one on bottom of second i-f transformer) are located as shown by figures 2 and 4. Each circuit must be aligned to a basic frequency of 460 kc. To do this, attach the output indicator across the loudspeaker voice coil. Connect the output of the test oscillator through a .05-mfd. capacitor to the RCA-6A7 control grid, the ground of the test oscillator being connected to the receiver chassis. Set the test oscillator to 460 kc. Advance the receiver volume control to its full-on position and adjust the receiver tuning control to a point within its range where no interference is encountered either from broadcast stations or the heterodyne oscillator. Increase the output of the test oscillator until a slight indication is apparent on the output indicator.

Adjust the bottom core screw of the second i-f transformer to produce maximum (peak) indicated receiver output. Then adjust the two core screws of the first i-f transformer for maximum (peak) receiver output as shown by the indicating device.

It is advisable to repeat the adjustment of all i-f core screws to assure that the inter-action between them has not disturbed the original adjustment.

Wave-Trap Adjustment

Attach the output of the test oscillator to the "Antenna terminal" (see wave-trap, top view chassis, figure 2) through an 80-mmfd. capacitor, the ground connection of the test oscillator and receiver chassis being connected as before. Receiver "Antenna wire" should be reeled up for this and the following r-f adjustments.

Leave the test oscillator adjusted to 460 kc as before. Then adjust the wave-trap trimmer to the point which causes maximum suppression of the 460 kc signal.

R-F Trimmer Adjustments

Since the dial is mounted on the cabinet, it will be necessary to perform the operations, in sequence, as follows:

Place the receiver in its cabinet. Set the gang tuning condenser to its maximum capacity (full-mesh) position and place the tuning knob on the gang tuning condenser shaft. Tighten the knob set screw with the dial pointer set to the low-frequency calibration line beyond 550 kc (beyond "55" on the dial). Turn the tuning knob until the dial pointer indicates 1,500 kc. Remove the tuning knob from shaft and receiver from cabinet, being careful not to disturb the setting of the gang condenser.

With the test oscillator and output indicator connected as specified under "Wave-trap adjustment" and receiver volume control in its maximum position, tune the test oscillator to 1,500 kc and regulate its output to produce a suitable indication on the output indicator. Adjust the oscillator and antenna trimmers C8 and C4 for maximum (peak) output.

Loudspeaker

Centering of the loudspeaker voice coil is made in the usual manner with three narrow paper feelers after first removing the front paper dust cover. This may be removed either permanently by cutting it away with a sharp knife, or by softening its cement with a very light application of acetone using care not to allow the acetone to flow down into the air gap. The dust cover may be cemented back in place with ambroid upon completion of adjustment.

Radiotron Socket Voltages

The voltage values indicated from the Radiotron socket contacts, grid caps, resistors, and terminals to receiver chassis ground, on figure 4, will assist in locating cause for faulty operation. Each value as specified should hold within ±20% when the receiver is normally operative at its rated line voltage. Variations in excess of this limit will usually be indicative of trouble in the basic circuits. These voltages were measured with set tuned to approximately 550 kc, no signal being received, and volume control set to maximum. To duplicate the conditions under which the voltages were measured requires a 1,000-ohm-per-volt d-c meter, having ranges of 10, 50, and 250 volts. Use nearest range above voltage to be measured. A-c voltages were measured with a corresponding a-c meter.

Resistance Measurements

The resistance values shown between Radiotron socket contacts, grid caps, resistors, terminals, and receiver chassis ground, on figure 3, have been carefully selected so as to facilitate a rapid check of the circuit for defective parts, bad joints, etc. The use of this diagram in conjunction with the Schematic Circuit Diagram, figure 1, and the Chassis Wiring Diagram, figure 2, will permit the location of certain troubles which would otherwise be difficult to ascertain. Each value as specified should hold within ±20%. Variations in excess of this limit will usually be indicative of trouble in the basic circuits. Resistance values were measured with the Radiotrons in sockets, power supply disconnected, tuning condenser in full-mesh, and volume control set at maximum except where otherwise noted. In all cases of measuring the resistance between points of the circuit and ground, it will be necessary to connect the negative (–) terminal of the resistance meter to the chassis ground. If the polarity of the resistance meter is not known, it may be readily ascertained by connecting a d-c voltmeter of indicated polarity across the terminals of the device.

Radiotron Socket Voltages

Operating conditions of the basic circuits of this instrument may be determined by measuring the voltages applied to the tube elements. Figure 5 shows the voltage values from the socket contacts to ground and appearing across the heater contacts (H-H). Each value as specified should hold within ±20% when this instrument is normally operative, with all tubes intact and rated voltage applied. Variations in excess of this limit will usually be indicative of trouble.

The voltages given on this diagram are actual measured voltages, and are obtained with the voltmeter load in the circuit.

To fulfill the conditions under which the d-c voltages were measured requires a 1,000-ohm-per-volt d-c voltmeter having ranges of 10, 50, 250, and 500 volts. Voltages below 10 volts should be measured on the 10-volt scale; between 10 and 50 on the 50-volt scale; between 50 and 250 on the 250-volt scale; and above 250 on the 500-volt scale.

For meters of the 1,000-ohm-per-volt type, but ranges other than above, use the nearest ranges to those specified. If the range is higher the voltage may be higher, if the range is lower the voltage may be lower; either condition depending on the percentage of circuit current drawn by the meter.

RCA MFG. CO., INC.

General Description

Model 5M is a single-unit receiver containing the radio chassis, power conversion system, and loudspeaker all in one housing. A convenient three-contact loudspeaker receptacle installed on the chassis case permits the addition of a remote dynamic loudspeaker if desired.

Engineering features incorporated in this instrument are: The inclusion of ignition suppression means within the circuits of the receiver, reduction of power line modulation in antenna circuit, improved high-gain molded core antenna coil; permeability tuned intermediate frequency transformers; continuously variable high-frequency tone control; and a "plug-in" type of synchronous rectifier-vibrator for obtaining high-voltage supply. Correct arrangement of parts, adequate shielding, and the ingenious insertion of filters at proper points in the circuit insure minimum disturbances from apparatus associated with the electrical circuits of the automobile and from adjacent power lines.

This receiver is housed in a substantial metal case. Removable covers permit ready access to the under and top sides of the chassis. Flexible shafts interconnect the operating head to the controlled devices within the receiver housing. The unit is adaptable for mounting on either the left-hand or the right-hand side of the firewall as local conditions demand.

Circuit Arrangement

The schematic and wiring layouts of the electrical circuit are shown in Figures 1 and 2, respectively. From these diagrams it may be seen that five Radiotrons are incorporated in the basic superheterodyne circuit. In sequence, there is an r-f stage, a dual first-detector-oscillator stage, a single i-f stage, a second-detector-audio-amplifier-a.v.c. stage, and a pentode power output stage. The power supply system contains a mechanical interrupter and rectifier. The following circuit features are of particular importance:

Noise Filter—Reduction of ignition interference and similar disturbances are brought about by filter arrangements in the antenna input circuit and the "A" battery input lead. This antenna filter, L-1, C-1, and C-2, is a "low-pass" type, having an acceptance band below 1,600 kc. The inductance L-2 is for the purpose of shunting out power line hum pickup.

Tuned Circuits—There are seven resonant circuits in the radio frequency end of the receiver. The r-f, first-detector, and oscillator grid circuits are tuned by a three-gang tuning condenser. The remaining tuned circuits consist of the primary and secondary windings of the i-f transformers which resonate with fixed condensers and are tuned by molded cores to a nominal frequency of 260 kilocycles.

Detection—Detection takes place as the result of the rectifying action of one of the diodes of the RCA-6B7 tube, the current being developed through resistors R-9 and R-10. The audio and d-c components of the detected signal are selected from the manual volume control resistor (R-10) by its movable arm, and applied to the control grid of the RCA-6B7; amplification results and the signal passes on to the power output stage. The d-c applied to the grid prevents overload as the volume control is advanced.

A.V.C.—The a.v.c. diode of the RCA-6B7 tube is coupled through capacitor C-21 to the primary of the second i-f transformer. Due to the rectifying action of this diode, a current is developed through resistor R-14. The d-c voltage drop in this resistor is used for automatically regulating the control grid bias of the r-f, first detector, and i-f stages, the voltage being applied through a suitable filter network. Due to the fact that the a.v.c. diode returns through resistor R-14 to a point which is 12 volts negative with respect to its cathode, the a.v.c. action is delayed until the input signal reaches a predetermined level. This gives more uniform output for widely varying signal strengths into the antenna.

Audio System—As mentioned under "Detection" the audio component of the detected signal is selected from the manual volume control and applied to the control grid of the RCA-6B7 tube. The plate circuit of this tube is connected through capacitor C-28 to the control grid of the pentode power output tube, RCA-42. This tube is coupled through the output transformer T-2 to the loudspeaker.

SERVICE DATA

NOTE: Certain models of 1936 automobiles are equipped with "high-capacitance type" (400 mmfd. or greater) built-in antennas. The 1936 models of Dodge, De Soto, and Chrysler are examples of automobiles so equipped. Installation of receiver in automobiles with such "high-capacity" antennas necessitates the following modification of the antenna circuit of the receiver to suit the characteristics of the antenna installation:

Remove the tubular paper-covered capacitor C-3 (.01 mfd.), Figure 2, and replace with the small molded type capacitor (500 mmfd.) furnished with Escutcheon Kit for respective model of automobile.

The various diagrams of this booklet contain such information as will be needed to locate causes for defective operation when such develops. The ratings of the resistors, capacitors, coils, etc., are indicated adjacent to the symbols signifying these parts on the diagrams. Identification titles, such as R-3, L-2, C-1, etc., are provided for reference between the illustrations and the Replacement Parts List. The coils, reactors, and transformer windings are rated in terms of their d-c resistances only. Ratings of less than one ohm are generally omitted.

Alignment Procedure

There are four alignment trimmers provided in the antenna, coil, detector coil, and oscillator coil tuned circuits. The i-f transformer adjustments are made by means of four screws attached to molded cores.

NOTE: The antenna coil has a molded core which is adjusted at the factory for the correct inductance. This adjustment should not be disturbed.

All of the adjustable circuits of this receiver have been properly aligned at the factory to give correct performance and their settings should remain intact indefinitely when the receiver is used under ordinary conditions. However, necessity for re-adjustment may occasionally occur from continued extremes of climate, tampering, purported alteration for service purposes, or after repairs have been made to the r-f or i-f tuned circuits. Improper alignment usually causes the receiver to be insensitive, non-selective, and subnormal in respect to tone quality. Such indications will usually exist simultaneously.

In re-adjusting the tuned circuits, it is important to apply a definite procedure and to use adequate and reliable test equipment. A standard test oscillator, such as the RCA Stock No. 9595, will be required as the source of signal at the specified alignment frequencies. Means for indication of the receiver output during alignment is also necessary to accurately show when the correct point of adjustment is reached. Two indication methods are applicable—one requires use of the cathode-ray oscillograph, and the other requires a voltmeter or glow type indicator. The cathode-ray alignment method is advantageous in that the indication provided is in the form of a wave image which represents the resonance characteristics of the circuits being tuned. This type of alignment is possible through use of apparatus such as the RCA Stock No. 9558 Frequency Modulator and the RCA Stock No. 9545 Cathode-Ray Oscillograph. Alignment by the output meter method should be indicated by an instrument such as the RCA Stock No. 4317 Neon Glow Indicator. The two procedures are outlined as follows:

CATHODE-RAY ALIGNMENT

Attach the cathode-ray oscillograph vertical input terminals to the second detector output, with the "Hi" connected to the junction of the two resistors, R-9 and R-10, and the "0" connected to the receiver chassis. Advance the vertical amplifier gain control of the oscillograph to full-on, allowing it to remain at such position for all adjustments. Turn the vertical "A" amplifier to "On." Set the oscillograph power switch to "On" and adjust the intensity and focusing controls to give a sharply defined spot on the screen. Interconnect the frequency modulator impulse generator terminals to the oscillograph "Ext. Sync." terminals, as shown by Figure 4.

I-F Adjustments

(a) Connect the output of the test oscillator to the control grip cap of the i-f tube (RCA-6K7) through a 0.25 mfd. capacitor and connect the ground of the oscillator to the receiver chassis. Tune the oscillator to 260 kc., place its modulation switch to "On" and its output range switch to "Hi." The frequency modulator must not be connected to the oscillator for the preliminary adjustments.

(b) Set the cathode-ray oscillograph horizontal "B" amplifier to "Timing" and the synchronizing switch (timing) to "Int." Place the synchronizing input and frequency controls to about their mid-positions. Turn the range switch to its No. 1 position.

(c) Increase the output of the oscillator until a deflection is noticeable on the oscillograph screen. The figure obtained represents several waves of the detected signal, the amplitude of which may be observed as an indication of output. Cause the wave image formed (400-cycle waves) to be spread completely across the screen by advancing the horizontal "B" gain control. The image should be synchronized and made to remain motionless by adjustment of the synchronizing input and frequency controls.

(d) Adjust the two screws (attached to molded cores) of the second i-f transformer, one on top and one on bottom, to produce maximum vertical deflection of the oscillographic wave which is present on the screen. This adjustment places the transformer in exact resonance with the 260 kc. signal.

(e) The sweeping operation should follow using the frequency modulator. Shift the oscillograph synchronizing switch to "Ext.", change its range switch to No. 2 position and set the frequency control to its mid-position. Place the frequency modulator in operation, with its sweep range switch in the "Lo" position. Interconnect the test oscillator and frequency modulator with the special shielded patch cord provided. Turn the oscillator modulation switch to "Off."

(f) Increase the frequency of the test oscillator by slowly turning its tuning control until two separate, distinct, and similar waves appear on the screen. These waves will be identical in shape, but will be totally disconnected and appearing in reversed positions. They will have a common base line which is discontinuous. Adjust the frequency and synchronizing input controls of the oscillograph to get the proper waves and to make them remain motionless on the screen. Continue increasing the oscillator frequency until the forward and reverse curves move together and overlap, with their highest points exactly coincident. This condition will obtain at an oscillator setting of approximately 360 kc.

(g) With the images established as in (f), re-adjust the two screws on the second i-f transformer so that they cause the curves on the oscillograph screen to become exactly coincident throughout their lengths and have maximum amplitude.

(h) Without altering the adjustments of the apparatus, shift the output connections of the oscillator to the input of the i-f system, i. e., between the first detector (RCA-6A8) control grid and ground. Regulate its output so that the amplitude of the oscillographic image is approximately the same as used above for adjustment (g) of the second i-f transformer.

(i) The two first i-f transformer adjustment screws, one on top and one on bottom, should then be adjusted so that they cause the forward and reverse curves to become coincident throughout their lengths and have maximum amplitude. The composite wave obtained in this manner represents the resonance characteristic of the total i-f system. Lack of symmetry or irregularity of the resultant image will indicate the presence of a defect in the i-f system.

R-F Adjustments

NOTE: Before making r-f adjustments, it may be advisable to replace the bottom cover to eliminate vibrator interference.

(a) Adjust the dial pointer on the remote control head by the following procedure: Rotate tuning knob to its extreme clockwise position irrespective of location of pointer on dial. Now turn the pointer adjusting screw in the center of the back of the control unit until the pointer is at the end calibration mark beyond the 55 on dial scale.

(b) Attach the output of the test oscillator to the receiver input, i. e., between the antenna and ground terminals, with a 175 mmfd. capacitor in series with antenna lead.

NOTE: For r-f alignment of receivers in which the tubular paper condenser C-3 (.01 mfd.) has been replaced by the small molded condenser, 500 mmfd. (change easily identified by reference to Figure 2 and bottom of chassis), use a .001 mfd. capacitor instead of the 175 mmfd. capacitor in series with the antenna lead and test oscillator.

There should be a shunt capacitor of 50 or 60 mmfd. from the antenna lead at the receiver to ground. Accurately tune the oscillator to 1,400 kc. The oscillograph should be left connected to the second detector output circuit as for the above i-f adjustments. Return the synchronizing switch to its "Int." position and turn the range switch to its No. 1 position.

(c) Tune the receiver to a dial reading of 1,400 kc. Then regulate the oscillator output so as to increase the amplitude of the waves on the oscillograph screen to a conveniently observable size. The several waves of detected signal, as appearing on the screen, should be synchronized by operation of the synchronizing and frequency controls. Trimmers, C-13, C-9, and C-4, of the oscillator, detector, and antenna coils should then be adjusted so that each causes maximum vertical deflection (amplitude) of the images.

(d) The oscillator modulation should then be turned to "Off" and the frequency modulator placed in operation, connected to the oscillator with the shielded patch cord. Change the oscillograph synchronizing switch to "Ext.", set its range switch to its No. 2 position and the frequency control slightly above its mid-position.

(e) Increase the frequency of the test oscillator gradually, until the point is reached where the two similar, distinct, and separate wave images appear on the screen and become coincident at their highest points. This will occur at an oscillator setting of approximately 1,500 kc. These waves should be synchronized on the oscillograph screen by careful re-adjustment of the synchronizing and frequency controls. Re-adjust trimmers, C-13, C-9, and C-4, to produce complete coincidence at maximum amplitude of the two waves.

(f) Disconnect the frequency modulator from the oscillator. Place the modulation switch of the oscillator to "On" and tune the oscillator to 600 kc. Set the synchronizing switch of the oscillograph to "Int." and turn the range switch to No. 1 position.

(g) Tune the receiver station selector control so as to pick up the 600 kc. signal, disregarding the dial reading at which it is best received.

(h) Change the oscillograph synchronizing switch to "Ext." and place the oscillator modulation switch to "Off." Interconnect the frequency modulator and oscillator with the special shielded patch cord. Return the range control of the oscillograph to its No. 2 position and set the frequency control slightly above its mid-position.

(i) Shift the test oscillator to its 200-400 kc. range and tune it to the point at which the forward and reverse waves show on the oscillograph screen. This condition will obtain at an oscillator setting of approximately 230 kc. The signal obtained from the oscillator for this adjustment will be the third harmonic of 200 kc. An increase in the oscillator output may be necessary. The trimmer C-12 should then be adjusted to the point which produces maximum amplitude of the oscillographic images. It will not be necessary to rock the tuning control for this adjustment, inasmuch as the frequency modulator is varying the signal in an equivalent manner.

(j) Retune trimmers C-13, C-9, and C-4 as in (c), (d), and (e) to correct for any change in high-frequency alignment which may have been caused by the adjustment of C-12.

After the receiver has been replaced in the car, it may be necessary to make a final correction of the dial pointer by tuning in a station of known frequency and adjusting the pointer by means of the slotted screw head on the rear of the control head.

OUTPUT METER ALIGNMENT

Place the receiver in operation with its two covers removed. Attach the output indicator across the loudspeaker voice coil circuit or across the output transformer primary. Advance the receiver volume control to its maximum position, letting it remain in such position for all adjustments. For each adjusting operation, regulate the test oscillator output control so that the signal level is as low as possible and still observable at the receiver output. Use of such small signal will obviate broadness of tuning which would otherwise result from a.v.c. action on a stronger one.

I-F Adjustments

(a) Connect the output of the test oscillator to the control grid cap of the i-f tube (RCA-6K7) through a 0.25 mfd. capacitor and connect the ground of the oscillator to the receiver chassis. Adjust the frequency of the oscillator to 260 kc. Tune the receiver to a point where no interference is received from the heterodyne oscillator or local stations.

(b) Adjust the two screws (attached to molded cores) of the second i-f transformer, one on top and one on bottom, until maximum output is produced by the indicating device.

(c) Remove the oscillator from the i-f tube input and connect it between the control grid cap of the first detector tube (RCA-6A8) and chassis ground, using the 0.25 mfd. capacitor as previously. Allow its tuning to remain at 260 kc. Tune the receiver to avoid interference as in (a).

(d) Adjust the two screws of the first i-f transformer for maximum (peak) receiver output. The indication for this adjustment will be broad, due to the "flat-top" characteristic of the i-f system. The two screws should, therefore, be very carefully adjusted so that the indicator remains fixed at maximum as the oscillator is shifted through a range 2 kc. above and below its normal setting of 260 kc. An irregular double-peaked indication is to be avoided

R-F Adjustments

NOTE: Before making r-f adjustments, it may be advisable to replace the bottom cover to eliminate vibrator interference.

(a) Adjust the dial pointer on the remote control head by the following procedure. Rotate tuning knob to its extreme clockwise position irrespective of location of pointer on dial. Now turn the pointer adjusting screw in the center of the back of the control unit until the pointer is at the end calibration mark beyond the 55 on dial scale.

(b) Connect the output of the test oscillator to the antenna-ground terminals of the receiver with a 175 mmfd. capacitor in series with the antenna lead.

NOTE: For r-f alignment of receivers in which the tubular paper condenser C-3 (.01 mfd.) has been replaced by the small molded condenser, 500 mmfd. (change easily identified by reference to Figure 2 and bottom of chassis), use a .001 mfd. capacitor instead of the 175 mmfd. capacitor in series with the antenna lead and test oscillator.

There should be a shunt capacitor of 50 or 60 mmfd. from the antenna lead at the receiver to ground. Tune the oscillator to 1,400 kc. Allow the output indicator to remain attached to the receiver output.

(c) Tune the receiver so that the dial reading is 1,400 kc. Then adjust the oscillator, detector, and antenna coil trimmers, C-13, C-9, and C-4 respectively, tuning each to the point producing maximum indicated receiver output.

(d) Shift the oscillator frequency to 600 kc. and tune the receiver to pick up this signal, disregarding the dial reading at which it is best received. The oscillator series trimmer, C-12, should then be adjusted, simultaneously rocking the receiver tuning control backward and forward through the signal until maximum (peak) receiver output results from the combined operations. The adjustment of C-13, C-9, and C-4 should be repeated as in (c) to correct for any change in its alignment due to the adjustment of C-12.

Final Tuning Dial Adjustment

Final adjustment of the dial pointer may be made during operation after the receiver is installed in automobile. To do this tune in a station of known frequency (say 760 kc.—approximately 76 on dial) as accurately as possible. Now reset the dial pointer to exactly 76 on the dial by means of the adjusting screw at center rear of operating head.

Interrupter

The mechanical interrupter used in the power system is constructed with a plug-in base, so as to be easily removed from the receiver. Its adjustments have been correctly set during manufacture by means of special equipment. In cases of faulty operation of the interrupter, a renewal should be made.

The symmetrical plug-in base on this device permits the unit to be placed in its socket so as to give correct output voltage polarity on an automobile with either a positive or negative "A" ground. For installation with positive "A" ground, insert vibrator so positive (+) symbol is nearest label on vibrator compartment partition; for negative "A" ground, insert with negative (−) symbol nearest label.

Radiotrons

Deterioration of tubes and their approach to failure is usually evidenced by noisy or intermittent operation, loss of sensitivity and distorted tone quality. When suspected as faulty, the tubes should be removed from the receiver and checked with standard tube testing apparatus. It is not feasible to test the tubes while in the receiver, due to measurement inaccuracies which would result from the effects of the circuits.

Tuning Condenser Drive

Smooth control should be obtained over the entire tuning range of the variable condenser. If irregularity is present, check the action of the gear mechanism for binding or backlash at every point within the tuning range. A bind may be due to improper mesh between the worm gear and the large gears on the condenser shaft. To correct such a condition, loosen the three screws holding the gear plate and adjust the mesh of the gears to a position which gives smooth operation. Gear backlash is prevented by the small compression spring between the two large gears on the rotor shaft.

Receiver Housing

The screws holding the receiver chassis to the case must all be in place and tightly installed, inasmuch as they appreciably affect the ground resistance of the assembly and will consequently have a bearing on the amount of ignition noise received.

Volume Control and Power Switch

This adjustment is made by turning the small control knob fully clockwise and then fully counterclockwise. This places the friction clutch mechanism on the volume control in proper alignment.

General Features

This receiver is of the superheterodyne type and has many distinctive features. Its design includes magnetite core adjusted i-f transformers and wave trap, aural compensated volume control, tone control, resistance coupled audio system, phonograph terminal board, band selective illumination of dial scales, and an 8-inch dust-proof electrodynamic loudspeaker.

Tuning is continuous through the "Standard broadcast" and "Short wave" bands (including 49 meters).

The "Short wave" position of this extensive range also includes channels assigned for police, amateur, and aviation communication. Trimming adjustments are located at accessible points. Their number is reduced to the least that is consistent with efficient operation. The tuning dial ratio of ten to one permits ease of tuning, especially in the "Short wave" band.

Circuit Arrangement

The first detector and oscillator functions are accomplished in a single tube, an RCA-6A7. The input of this tube is coupled to the antenna through a tuned transformer. A shunt (magnetite core adjusted) wave trap is connected across the primary of this transformer to prevent signals of intermediate frequency (460 kc.) from being introduced into the first stage as interference. The two-section gang condenser, which tunes the antenna transformer secondary and the heterodyne oscillator coil, has adjustable trimmers for obtaining exact alignment. Each of these coils is tapped so that the range switch increases the range of tuning by decreasing the amount of inductance.

The intermediate frequency stage is coupled to the RCA-6A7 and to the RCA-75 by means of tuned transformers. These transformers resonate with fixed capacitors and are adjusted by molded magnetite cores to tune to 460 kc.

The modulated signal as obtained from the output of the i-f system is detected by one of the diodes of the RCA-75 tube. Audio frequency secured by this process is passed on to the control grid of this same tube for amplification before final reproduction. The d-c voltage, which results from detection of the signal, is used for automatic volume control. This voltage, which develops across resistor R7, is applied as automatic control grid bias to the first detector and i-f tubes through a suitable resistance filter. Minimum operating bias for the RCA-6A7 and RCA-6D6 tubes is developed across resistors R19 and R20 respectively.

Manual volume control is effected by means of an acoustically tapered potentiometer connected as a variable coupling element between the output of the second detector and the first audio control grid. After amplification by the RCA-75, the audio signal is transmitted by resistance-capacitance coupling to the input of the RCA-42 power output stage, which, in turn, is transformer-coupled to the dynamic speaker. High-frequency tone control is provided by means of a shunt capacitor across the plate circuit of the output tube, which may be cut in or out of the circuit with a control switch S3.

The power supply system consists of an RCA-80 rectifier tube which is supplied from an efficiently designed power transformer and which works into a suitable filter. The various potentials required for the plate, screen, control grid, and cathode circuits are obtained from the output of the filter. The electrodynamic loudspeaker field coil is used as a filter reactor.

SERVICE DATA

The various diagrams of this booklet contain such information as will be needed to isolate causes for defective operation if such develops. The ratings of the resistors, capacitors, coils, etc., are indicated adjacent to the symbols signifying these parts on the diagrams. Identification titles, such as R3, L2, C1, etc., are provided for reference between the illustrations and the Replacement Parts List. The coils, reactors, and transformer windings are rated in terms of their d-c resistances only. Ratings of less than one ohm are generally omitted.

Alignment Procedure

There are three alignment trimmers provided in the antenna transformer and oscillator coil tuned circuits. The i-f transformer adjustments are made by means of screws attached to molded magnetite cores. All of these circuits have been accurately adjusted during manufacture and should remain properly aligned unless affected by abnormal conditions or altered during servicing. Loss of sensitivity, improper tone quality, and poor selectivity are the usual indications of improper alignment.

The correct performance of this receiver can only be obtained when the aligning has been done with adequate and reliable apparatus. The manufacturer of this receiver has available, for sale through its distributors and dealers, a complete assortment of such service equipment as may be needed for the alignment operation.

A test oscillator, such as the RCA Stock No. 9595, is required as a source of the specified alignment frequencies. Visual indication of receiver output during the adjustment is necessary and should be accomplished by the use of an indicator such as the RCA Stock No. 4317 Neon Output Indicator.

The procedure outlined below should be followed in adjusting the various trimmer capacitors and molded cores:

I-F Core Adjustments

The four adjustment screws (attached to molded magnetite cores) of the two i-f transformers (one on top and one on bottom of each i-f transformer) are located as shown by figures 3 and 7. Each circuit must be aligned to a basic frequency of 460 kc. To do this, attach the output indicator across the loudspeaker voice coil or across the output transformer primary.

Connect the output of the test oscillator to the control grid of the RCA-6A7 through a .05 mfd. capacitor. Connect the test oscillator ground terminal to the ground terminal of the receiver chassis. Range selector should be in "Short wave" position. Tune the oscillator to 460 kc. Advance the receiver volume control to its full-on position and adjust the receiver tuning control to a point, within its range, where no interference is encountered either from local broadcast stations or from the heterodyne oscillator. Increase the output of the test oscillator until a slight indication is present on the output indicator. Adjust the two magnetite core screws of the second i-f transformer to produce maximum (peak) indicated receiver output. Then, adjust the two magnetite core screws of the first i-f transformer for maximum (peak) receiver output as shown by the indicating device. During these adjustments, regulate the test oscillator output so that the indication is always as low as possible. By doing so, broadness of tuning due to a.v.c. action will be avoided. It is advisable to repeat the adjustment of all i-f magnetite core screws to assure that the interaction between them has not disturbed the original adjustment.

Wave-Trap Adjustment

Attach the output of the test oscillator to the receiver "Antenna" terminal through a 200 mmfd. (important) capacitor. The ground connections remain connected together. Leave the test oscillator adjusted to 460 kc. and range selector in "Short wave" position as before. Then adjust the wave-trap screw to the point which causes maximum suppression of the 460 kc. signal.

R-F Trimmer Adjustments

Calibrate the tuning dial by setting the pointer to a horizontal position (53 on "Standard broadcast" scale) with the two-gang tuning condenser in full mesh. The output indicator should be left connected to the system. Connections for the test oscillator remain the same as for "Wave-trap adjustment." Adjust the test oscillator to 1,700 kc. and set the receiver tuning control to a dial reading of 1,700 kc. Leave the volume control of the receiver at its maximum position. Make sure that the range selector is at its broadcast position. Regulate the output of the test oscillator until a slight indication is perceptible at the receiver output. Then adjust the two trimmers, C6 and C3, of the oscillator and antenna transformer coils (mounted on the variable condenser) so that each produces maximum (peak) receiver output. After this maximum has been accurately obtained, shift the test oscillator to 600 kc. Tune the receiver to pick up this signal, disregarding the dial reading at which it is best received. Then, adjust the receiver oscillator series trimmer, C8, simultaneously rocking the tuning control backward and forward through the signal until maximum receiver output results from these combined operations. The adjustment at 1,700 kc. should then be repeated to correct for any change which may have been caused by the oscillator series trimmer adjustment.

Phonograph Attachment

A terminal board is provided for connecting a phonograph into the audio amplifying circuit. Typical methods of connecting a low-impedance pick-up, or the RCA Victor Models R-93, R-93-2, and R-93S phonographs are shown on the schematic diagram (figure 1).

Loudspeaker

Centering of the loudspeaker voice coil is made in the usual manner with three narrow paper feelers after first removing the front paper dust cover. This may be removed either permanently by cutting it away with a sharp knife, or by softening its cement with a very light application of acetone using care not to allow the acetone to flow down into the air gap. The dust cover may be cemented back in place with ambroid upon completion of adjustment.

Resistance Measurement

The resistance values shown between Radiotron socket contacts, grid caps, resistors, terminals, and receiver chassis ground, on figure 4, have been carefully selected so as to facilitate a rapid continuity check of the circuits. The use of this diagram in conjunction with the Schematic Circuit Diagram, figure 1, and Chassis Wiring Diagram, figure 2, will permit the location of certain troubles which might otherwise be difficult to ascertain. Each value as specified should hold within ±20%. Variations in excess of this limit will usually be indicative of trouble in circuit under test. Resistance values were measured with the Radiotrons in sockets; tuning condenser in full mesh, and volume control set at maximum except where otherwise noted. In all cases of measuring the resistance between points of the circuit and ground, it will be necessary to connect the negative terminal of the resistance meter to chassis-ground. If the polarity of the resistance meter is not known, it may be readily ascertained by connecting a d-c voltmeter of indicated polarity across the terminals of the device.

Radiotron Socket Voltages

The voltage values indicated from the Radiotron socket contacts, grid caps, resistors, and terminals to receiver chassis ground on figure 7 will assist in locating cause for faulty operation. Each value as specified should hold within ±20% when the receiver is normally operative at its rated line voltage. Variations in excess of this limit will usually be indicative of trouble in the basic circuits. These voltages were measured with receiver tuned to approximately 1,000 kc., no signal being received and volume control set at minimum. To duplicate the conditions under which the voltages were measured requires a 1,000 ohm-per-volt d-c meter, having ranges of 10, 50, 250, and 500 volts. Use the nearest range above the voltage to be measured. A-C voltages were measured with a corresponding a-c meter.

RCA MFG. CO., INC.

Circuit Arrangement

The conventional superheterodyne type of circuit, consisting of a combined first-detector–oscillator stage, a single i-f stage, a diode-detector-automatic-volume-control stage, an audio voltage amplifier stage, an audio power output stage, and a half-wave rectifier power supply stage, is used.

Tuned Circuits

The antenna coil system consists of two series-connected primary and two series-connected secondary windings to provide the two ranges of tuning. The oscillator coil is similarly wound on a single form.

A range selector switch, consisting of S2, S3, S4, and S5, is used to connect the various sections of these coil systems and to illuminate the proper dial scale for the band in operation. The coils are tuned by a variable two-section gang condenser having trimming capacitors in shunt with each section. A series trimming capacitor is also associated with the "Standard broadcast" oscillator coil.

The intermediate frequency amplifier system consists of an RCA-78 in a transformer coupled circuit. This stage operates at a basic frequency of 460 kc. Adjustable magnetite cores are provided for adjusting inductance of the input i-f transformer (primary and secondary) and the output transformer (primary) windings.

Detector and A. V. C.

The modulated signal, as obtained from the output of the i-f stage is detected by one of the diodes in the RCA-75 tube. The audio frequency component, secured by this process, is transferred from the movable arm of the volume control R6 through coupling capacitor C17 to the control grid of the RCA-75 for voltage amplification. The d-c voltage which results from detection of the signal is used for automatic volume control. This voltage which develops across resistor R6 is applied as automatic control grid bias to the first-detector and i-f tube through a suitable resistance filter circuit.

Audio System

The audio frequency component, mentioned under "Detection and a.v.c.," transferred to the control grid of the RCA-75, is amplified in the tube and then coupled to the control grid of the power output tube RCA-43 through capacitor C20. The output of the power amplifier is transformer coupled into the dynamic loudspeaker.

Rectifier

The plate, grid, cathode and the loudspeaker field voltages required for the operation of this receiver are supplied by the RCA-25Z5 tube operating as a half-wave rectifier.

SERVICE DATA

Caution: *Certain tests (e. g. alignment and voltage measurement) require operation of receiver with the chassis removed from the cabinet. To permit such operation on models using interlock switch, it will be necessary to hold the interlock switch (see figure 5) closed either by inserting a screwdriver, rod, or pencil through the small interlock hole at rear of chassis, or by temporarily unhooking the interlock tension spring and pushing the interlock bar towards the front of the chassis.* ***Avoid external grounding of receiver or associated equipment*** *since the power supply is connected to the receiver chassis. Carelessness may cause serious damage to equipment.* ***Replace interlock tension spring upon completion of test.***

Alignment Procedure

There are three alignment trimmers provided in the antenna coil and oscillator coil tuned circuits. The i-f transformer adjustments are made by means of three screws attached to molded magnetite cores. Re-adjustment may occasionally occur from continued extremes of climate, tampering, purported alteration for services, or after repairs have been made to the r-f or i-f tuned circuits. Improper alignment usually causes the impairment of sensitivity, selectivity, and tone quality. Such conditions will usually exist simultaneously.

In re-adjusting the tuned circuits, it is important to apply a definite procedure and to use adequate and reliable test equipment. A standard test oscillator, such as the RCA Stock No. 9595 will be required as the source of the signal at the specified alignment frequencies. Visual indication of the receiver output during alignment is also necessary to accurately show when the correct point of adjustment is reached. The RCA Stock No. 4317 Neon Output Indicator is especially suitable for this use.

The procedure outlined below should be followed in adjusting the various trimming capacitors and molded magnetite cores.

I-F Core Adjustments

The three adjustment screws (one on top and one on bottom of first i-f transformer and one on bottom of second i-f transformer) are located as shown by figures 2 and 5. Each circuit must be aligned to a basic frequency of 460 kc. To do this attach the output indicator across the loudspeaker voice coil or across the output transformer primary. Connect the output of the test oscillator through a .05 mfd. capacitor to the RCA-6A7 control grid, the ground of the test oscillator being connected to the receiver chassis through a .05 mfd. capacitor. Set the test oscillator to 460 kc. Set the range selector to "Short-wave" position. Advance the receiver volume control to its full-on position and adjust the receiver tuning control to a point within its range where no interference is encountered either from local broadcast stations or heterodyne oscillator. Increase the output of the test oscillator until a slight indication is apparent on the output indicator.

Adjust the bottom core screw of the second i-f transformer to produce maximum (peak) indicated receiver output. Then adjust the two core screws of the first i-f transformer for maximum (peak) receiver output as shown by the indicating device.

During these adjustments regulate the test oscillator output so the indication is always as low as possible. By doing so, broadness of tuning due to a.v.c. action will be avoided. It is advisable to repeat the adjustment of all i-f core screws to assure that the interaction between them has not disturbed the original adjustment.

Wave-Trap Adjustment

Attach the output of the test oscillator to the "Antenna Terminal" (see wave-trap, top view chassis, figure 2) through an 80 mmfd. capacitor, the ground connection of the test oscillator and receiver chassis being connected through capacitor as before. Receiver "Antenna Wire" should be coiled up for this and the following r-f adjustments.

Leave the test oscillator adjusted to 460 kc. and range selector in "Short wave" position as before. Then adjust the wave-trap trimmer to the point which causes maximum suppression of the 460 kc. signal.

R-F Trimmer Adjustments

Roughly calibrate the tuning dial by setting the pointer to the bottom horizontal line at the low frequency end of the broadcast scale with the two-gang tuning condenser at its maximum capacity. The output indicator should be left connected to the output system. The connections for the test oscillator remain the same as for "Wave-trap" adjustment. Volume control should be in maximum position. Make sure range selector is set to "Standard broadcast."

Set oscillator and antenna trimming capacitors C11 and C5, respectively, to a position near minimum capacitance (plates near out). Adjust the test oscillator to 1,700 kc.

Tune the receiver to pick up this signal (near 1,700 kc. on dial) for maximum response disregarding dial reading. Always keep test oscillator output as low as is possible and still obtain visual indication. Adjust trimming capacitors C11 and C5 so that each produces maximum (peak) receiver output, re-adjusting receiver tuning slightly if necessary, but using the minimum trimming capacitance possible to obtain peaks. Adjust the dial pointer (without disturbing gang tuning condenser) to a dial reading of 1,700 kc. Shift the test oscillator to 600 kc. Tune the receiver to receive the signal disregarding the dial reading at which it is best received. Then adjust the oscillator series capacitor, C8, simultaneously rocking the tuning control backward and forward through the signal until maximum receiver output results from these combined operations. The adjustment at 1,700 kc. should then be repeated to correct for any change which may have been caused by the oscillator series trimming capacitor adjustment.

Loudspeaker

Centering of the loudspeaker voice coil is made in the usual manner with three narrow paper feelers after first removing the front paper dust cover. This may be removed either permanently by cutting it away with a sharp knife, or by softening its cement with a very light application of acetone using care not to allow the acetone to flow down into the air gap. The dust cover may be cemented back in place with ambroid upon completion of adjustment.

Radiotron Socket Voltages

The voltage values indicated from the Radiotron socket contacts, grid caps, resistors and terminals to receiver chassis ground on figure 5 will assist in locating cause for faulty operation. Each value as specified should hold within ± 20% when the receiver is normally operative at its rated line voltage. Variations in excess of this limit will usually be indicative of trouble in the basic circuits. These voltages were measured with set tuned to approximately 1,000 kc. ("Standard broadcast" range); no signal being received and volume control setting optional. To duplicate the conditions under which the voltages were measured requires a 1,000-ohm-per-volt d-c meter, having ranges of 10, 50 and 250 volts. Use nearest range above voltage to be measured. A-C voltages were measured with a corresponding a-c meter.

REPLACEMENT PARTS

Stock No.	Description	List Price
11400	Band—Tube shield rubber band—Package of 5	$0.10
12118	Cap—Grid contact cap—Package of 5	.15

Drive Mechanism

RCA MFG. CO., INC.

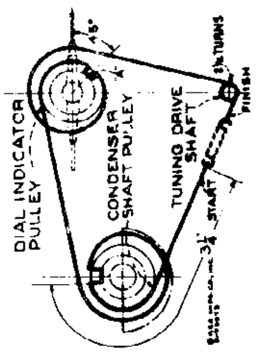

Figure 3—Tuning Drive Cord Mechanism

Rear view of drive assembly showing threading of drive cord with variable condenser plates in full mesh. To perform this operation, unsolder the four leads (connected between antenna coil and range selector switch) from the range selector switch, unsolder antenna lead-in wire from wave-trap terminal, unsolder lead from rear section of gang tuning condenser, and remove the four screws which secure the tuning drive frame to the chassis proper. This frame with gang tuning condenser still attached may now be easily removed for the threading operation. The relative position of the parts and method of threading are shown on the above diagram. In case the cord is too long for proper tension, it may be effectively shortened by first releasing finish end of cord, inserting a match or other shim under the cord at point "A" and then re-hooking the end of the cord to the tension spring. Replace drive assembly and re-solder leads.

Resistance Measurements

The resistance values shown between Radiotron socket contacts, grid caps, resistors, terminals, and receiver chassis ground, on figure 4 have been carefully selected so as to facilitate a rapid check of the circuit for defective parts, bad joints, etc. The use of this diagram in conjunction with the Schematic Circuit Diagram, figure 1, and the Chassis Wiring Diagram, figure 2, will permit the location of certain troubles which would otherwise be difficult to ascertain. Each value as specified should hold within ±20%. Variations in excess of this limit will usually be indicative of trouble in the basic circuits. Resistance values were measured with the Radiotrons in sockets, power supply disconnected, tuning condenser in full mesh, and volume control set at maximum except where otherwise noted. In all cases of measuring the resistance between points of the circuit and ground, it will be necessary to connect the negative (−) terminal of the resistance meter to the chassis ground. If the polarity of the resistance meter is not known, it may be readily ascertained by connecting a d-c voltmeter of indicated polarity across the terminals of the device.

Circuit Arrangement

Tuned Circuits

The antenna coil system consists of two series-connected primary and two series-connected secondary windings to provide the two ranges of tuning. The oscillator coil is similarly wound on a single form. A multi-pole range selector switch, consisting of S2, S3, S4, and S5, is used to connect the various sections of these coil systems and to illuminate the proper tuning dial scale for the band in operation. The coils are tuned by a variable two-section gang condenser having trimming capacitors in shunt with each section. A series trimming capacitor is also associated with the "Standard broadcast" oscillator coil.

The intermediate frequency amplifier system consists of an RCA-78 in a transformer coupled circuit. This stage operates at a basic frequency of 460 kc. Adjustable magnetite cores are provided for adjusting inductance of the input i-f transformer (primary and secondary) and the output transformer (primary) windings.

Detector and A.V.C.

The modulated signal, as obtained from the output of the i-f stage, is detected by one of the diodes in the RCA-75 tube. The audio frequency component, secured by this process, is transferred from the movable arm of the volume control R8 through coupling capacitor C20 to the control grid of the RCA-75 for voltage amplification. The d-c voltage which results from detection of the signal is used for automatic volume control. This voltage which develops across resistor R8 is applied as automatic control grid bias to the first-detector and i-f tube through a suitable resistance filter circuit.

Audio System

The audio frequency component, mentioned under "Detection and A.V.C.," transferred to the control grid of the RCA-75, is amplified in the tube and then coupled to the control grid of the power output tube RCA-41 through capacitor C23. The output of the power amplifier is transformer coupled into the dynamic loudspeaker. A single "Bias Cell," see figures 1 and 2, is used for supplying bias voltage to the control grid of the RCA-75 tube.

Rectifier

The plate, grid, cathode, and loudspeaker field voltages required for the operation of this receiver are supplied by the RCA-12Z3 tube operating as a half-wave rectifier.

SERVICE DATA

CAUTION: Certain tests (e.g. alignment and voltage measurement) require operation of receiver with chassis removed from cabinet. Avoid external grounding of receiver chassis or associated equipment since the power supply is now connected to receiver chassis through the speaker field. Carelessness may cause serious damage to equipment.

Alignment Procedure

There are three alignment trimmers provided in the antenna coil and oscillator coil tuned circuits. The i-f transformer adjustments are made by means of three screws attached to molded magnetite cores.

Improper alignment usually causes the impairment of sensitivity, selectivity, and tone quality. Such conditions will usually exist simultaneously.

In re-adjusting the tuned circuits, it is important to apply a definite procedure and to use adequate and reliable test equipment. A standard test oscillator, such as the RCA Stock No. 9595 will be required as the source of the signal at the specified alignment frequencies. Visual indication of the receiver output during alignment is also necessary to accurately show when the correct point of adjustment is reached. The RCA Stock No. 4317 Neon Output Indicator is especially suitable for this use.

The procedure outlined below should be followed in adjusting the various trimming capacitors and molded magnetite cores.

I-F Core Adjustments

The three adjustment screws (one on top and one on bottom of first i-f transformer and one on bottom of second i-f transformer) are located as shown by figures 2 and 6. Each circuit must be aligned to a basic frequency of 460 kc. To do this attach the output indicator across the loudspeaker voice coil or across the output transformer primary. Connect the output of the test oscillator through a .05 mfd. capacitor to the RCA-6A7 control grid, the ground of the test oscillator being connected to the receiver external yellow ground lead. Set the test oscillator to 460 kc. Place the range selector in "Short wave" position. Advance the receiver volume control to its full-on position and adjust the receiver tuning control to a point within its range where no interference is encountered either from local broadcast stations or heterodyne oscillator. Increase the output of the test oscillator until a slight indication is apparent on the output indicator.

Adjust the bottom magnetite core screw of the second i-f transformer to produce maximum (peak) indicated receiver output. Then adjust the two magnetite core screws of the first i-f transformer for maximum (peak) receiver output as shown by the indicating device.

During these adjustments regulate the test oscillator output so the indication is always as low as possible. By doing so, broadness of tuning due to A.V.C. action will be avoided. It is advisable to repeat the adjustment of all i-f magnetite core screws to assure that the interaction between them has not disturbed the original adjustment.

Wave-Trap Adjustment

Attach the output of the test oscillator to the black antenna lead through a 200 mmfd. capacitor, the ground connection of the test oscillator and receiver being connected as before.

Leave the test oscillator adjusted to 460 kc., and range selector in "Short wave" position as before. Then adjust the wave-trap trimmer to the point which causes maximum suppression of the 460 kc. signal.

R-F Trimmer Adjustments

Roughly calibrate the tuning dial by setting the pointer to the bottom horizontal line at the low frequency end of the broadcast scale with the two-gang tuning condenser at its maximum capacity. The output indicator should be left connected to the output system. The connections for the test oscillator remain the same as for "Wave-trap" adjustment. Volume control should be in maximum position.

Set range selector to "Standard broadcast" position.

Set oscillator and antenna trimming capacitors C12 and C6, respectively, to a position near minimum capacitance (plates near out). Adjust the test oscillator to 1,700 kc.

Tune the receiver to pick up this signal (near 1,700 kc. on dial) for maximum response disregarding dial reading. Always keep test oscillator output as low as is possible and still obtain visual indication. Adjust trimming capacitors C12 and C6 so that each produces maximum (peak) receiver output, re-adjusting receiver tuning slightly if necessary, but using the minimum trimming capacitance possible to obtain peaks. Adjust the dial pointer (without disturbing gang tuning condenser) to a dial reading of 1,700 kc. Shift the test oscillator to 600 kc. Tune the receiver to receive the signal disregarding the dial reading at which it is best received. Then adjust the oscillator series capacitor, C8, simultaneously rocking the tuning control backward and forward through the signal until maximum receiver output results from these combined operations. The adjustment at 1,700 kc. should then be repeated to correct for any change which may have been caused by the oscillator series trimming capacitor adjustment.

Loudspeaker

Centering of the loudspeaker voice coil is made in the usual manner with three narrow paper feelers after first removing the front paper dust cover. This may be removed either permanently by cutting it away with a sharp knife, or by softening its cement with a very light application of acetone using care not to allow the acetone to flow down into the air gap. The dust cover may be cemented back in place with ambroid upon completion of adjustment.

Radiotron Socket Voltages

Note: Two voltage values are shown for some readings. The higher value shown in parenthesis with asterisk (*) indicates operating conditions without voltmeter loading. [illegible]

CAUTION: [illegible]

Radiotron Socket Voltages

Operating conditions of the basic circuits of this instrument may be determined by measuring the voltages applied to the tube elements. Figure 5 shows the voltage values from the socket contacts to ground and appearing across the heater contacts (H-H). Each value as specified should hold within ±20% when this instrument is normally operative with all tubes intact and rated voltage applied. Variations in excess of this limit will usually be indicative of trouble.

The voltages given on this diagram are actual measured voltages, and are obtained with the voltmeter load in the circuit.

To fulfill the conditions under which the d-c voltages were measured requires a 1,000-ohm-per-volt d-c voltmeter having ranges of 10, 50, 250, and 500 volts. Voltages below 10 volts should be measured on the 10-volt scale; between 10 and 50 on the 50-volt scale; between 50 and 250 on the 250-volt scale; and above 250 on the 500-volt scale.

MODELS 6M, 6M2
Chassis Wiring

RCA MFG. CO., INC.

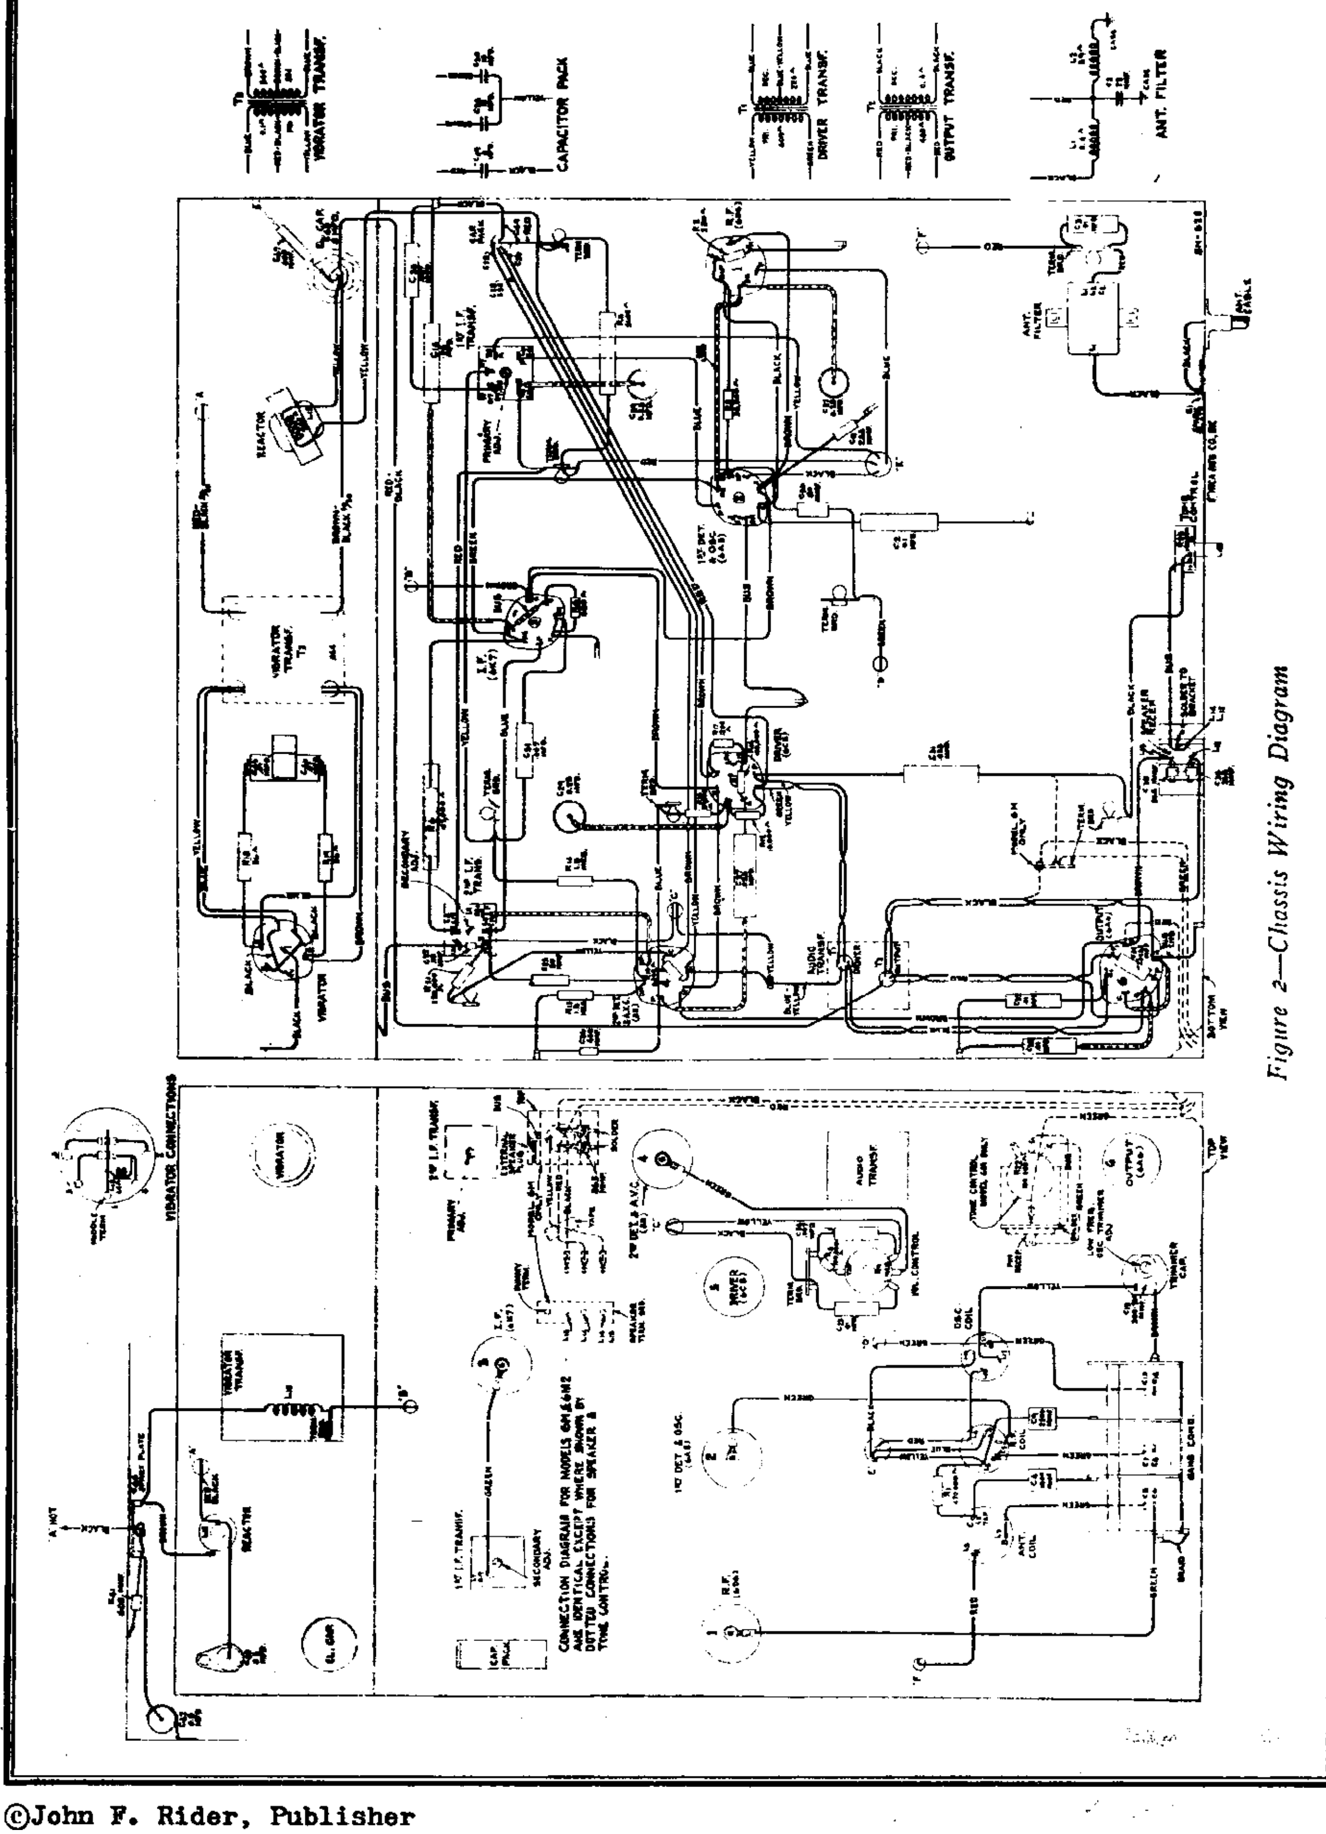

Figure 2—Chassis Wiring Diagram

RCA MFG. CO., INC.

General Description

These two automobile receivers represent the results of thorough development, design, and substantial manufacture. Noteworthy technical improvements have been applied in achieving marked advantages of installation, operation, and efficiency of performance.

Model 6M is a single-unit receiver containing the radio chassis, power conversion system, and loudspeaker all in one housing. A convenient three-contact loudspeaker receptacle installed on the chassis case permits the addition of a remote dynamic loudspeaker if desired.

Model 6M2 is a double-unit receiver utilizing a chassis and its power conversion equipment similar to the Model 6M, assembled together in one case, with its loudspeaker mounted individually in a separate cylindrical housing.

Engineering features incorporated in these instruments are: The inclusion of ignition suppression means within the circuits of the receiver; reduction of power line modulation in antenna circuit; improved high-gain molded core antenna coil; permeability tuned intermediate frequency transformers; continuously variable high-frequency tone control; and a "plug-in" type of synchronous rectifier-vibrator for obtaining high-voltage supply.

Correct arrangement of parts, adequate shielding, and the ingenious insertion of filters at proper points in the circuit insure minimum disturbances from apparatus associated with the electrical circuits of the automobile and from outside sources.

Both receivers are compactly housed in substantial metal cases. Removable covers permit ready access to the under and top sides of the chassis. Flexible shafts interconnect the operating head to the controlled devices within the receiver housing. These units are adaptable for mounting on either the right-hand or the left-hand side of the engine firewall as local conditions demand.

Circuit Arrangement

The schematic and wiring layouts of the electrical circuit are shown in Figures 1 and 2 respectively. From these diagrams it may be seen that six Radiotrons are incorporated in the basic superheterodyne circuit. In sequence, there is an r-f stage, a dual first detector—oscillator stage, a single i-f stage, a second detector—audio amplifier—a.v.c. stage, a driver stage, and a class "B" output stage. The power supply system contains a mechanical interrupter and rectifier. The following circuit features are of particular importance:

Noise Filter—Reduction of ignition interference and similar disturbances are brought about by filter arrangements in the antenna input circuit and the "A" battery input lead. This antenna filter, L-1, C-1, and C-2, is a "low-pass" type, having an acceptance band below 1,600 kc. The inductance L-2 is for the purpose of shunting out power line hum pickup.

Tuned Circuits—There are seven resonant circuits in the radio frequency end of the receiver. The r-f, first detector, and oscillator grid circuits are tuned by a three-gang tuning condenser. The remaining tuned circuits consist of the primary and secondary windings of the i-f transformers, which resonate with fixed condensers and are tuned by molded cores to a nominal frequency of 260 kilocycles.

Detection—Detection takes place as a result of the rectifying action of one of the diodes of the RCA-85 tube, the current being developed through resistors R-20 and R-21. The audio component of this current is coupled through capacitor C-23 to the one megohm volume control R-9. The arm of this volume control is connected to the grid of the RCA-85 tube, thus giving a means of continuously varying the voltage input to the audio amplifier.

A.V.C.—The a.v.c. diode of the RCA-85 tube is coupled through capacitor C-25 to the primary of the second i-f transformer. Due to the rectifying action of this diode, a current is developed through resistor R-13. The d-c voltage drop in this resistor is used for automatically regulating the control grid bias of the r-f, first detector, and i-f stages, the voltage being applied through a suitable filter network. Due to the fact that the a.v.c. diode returns through resistor R-13 to a point which is 15 volts negative with respect to its cathode, the a.v.c. action is delayed until the input signal reaches a predetermined level. This gives more uniform output for widely varying signal strengths into the antenna.

Audio System—As mentioned under "Detection", the audio component of the detected signal is selected from the manual volume control and applied to the control grid of the RCA-85 tube. The plate circuit of this tube is connected through capacitor C-27 to the control grid of the driver tube, an RCA-6C5. The plate circuit of the driver tube is coupled through the driver transformer T-1 to the control grids of the class "B" output tube, RCA-6A6. This tube is coupled through the output transformer T-2 to the loudspeaker.

SERVICE DATA

NOTE: Certain models of 1936 automobiles are equipped with "high-capacitance type" (400 mmfd. or greater) built-in antennas. The 1936 models of Dodge, De Soto, and Chrysler are examples of automobiles so equipped. Installation of receivers in automobiles with such "high-capacity" antennas necessitates the following modification of the antenna circuit of the receiver to suit the characteristics of the antenna installation:

Remove the tubular paper-covered capacitor C-3 (.01 mfd.). Figure 2, and replace with the small molded type capacitor (500 mmfd.) furnished with Escutcheon Kit for respective model of automobile.

Alignment Procedure

There are four alignment trimmers provided in the antenna coil, detector coil, and oscillator coil tuned circuits. The i-f transformer adjustments are made by means of four screws attached to molded cores.

NOTE: The antenna coil has a molded core which is adjusted at the factory for the correct inductance. This adjustment should not be disturbed.

In readjusting the tuned circuits, it is important to apply a definite procedure and to use adequate and reliable test equipment. A standard test oscillator, such as the RCA Stock No. 9595, will be required as the source of signal at the specified alignment frequencies. Means for indication of the receiver output during alignment is also necessary to accurately shown when the correct point of adjustment is reached. Two indication methods are applicable—one requires use of the cathode-ray oscillograph, and the other requires a voltmeter or glow-type indicator. The cathode-ray alignment method is advantageous in that the indication provided is in the form of a wave image which represents the resonance characteristics of the circuits being tuned. This type of alignment is possible through use of apparatus such as the RCA Stock No. 9558 Frequency Modulator and the RCA Stock No. 9545 Cathode-Ray Oscillograph. Alignment by the output meter method should be indicated by an instrument such as the RCA Stock No. 4317 Neon Glow Indicator. The two procedures are outlined as follows:

CATHODE-RAY ALIGNMENT

Attach the cathode-ray oscillograph vertical input terminals to the second detector output, with the "Hi" connected to the junction of the two resistors, R-20 and R-21, and the "0" connected to the receiver chassis. Advance the vertical amplifier gain control of the oscillograph to full-on, allowing it to remain at such position for all adjustments. Turn the vertical "A" amplifier to "On." Set the oscillograph power switch to "On" and adjust the intensity and focusing controls to give a sharply defined spot on the screen. Interconnect the frequency modulator impulse generator terminals to the oscillograph "Ext. Sync." terminals, as shown by Figure 4.

I-F Adjustments

(a) Connect the output of the test oscillator to the control grid cap of the i-f tube (RCA-6K7) through a 0.25 mfd. capacitor and connect the ground of the oscillator to the receiver chassis. Tune the oscillator to 260 kc., place its modulation switch to "On" and its output range switch to "Hi." The frequency modulator must not be connected to the oscillator for the preliminary adjustments.

(b) Set the cathode-ray oscillograph horizontal "B" amplifier to "Timing" and the synchronizing switch (timing) to "Int." Place the synchronizing input and frequency controls to about their mid-positions. Turn the range switch to its No. 1 position.

(c) Increase the output of the oscillator until a deflection is noticeable on the oscillograph screen. The figure obtained represents several waves of the detected signal, the amplitude of which may be observed as an indication of output. Cause the wave image formed (400-cycle waves) to be spread completely across the screen by advancing the horizontal "B" gain control. The image should be synchronized and made to remain motionless by adjustment of the synchronizing input and frequency controls.

(d) Adjust the two screws (attached to molded cores) of the second i-f transformer, one on top and one on bottom, to produce maximum vertical deflection of the oscillographic wave which is present on the screen. This adjustment places the transformer in exact resonance with the 260 kc. signal.

(e) The sweeping operation should follow using the frequency modulator. Shift the oscillograph synchronizing switch to "Ext.", change its range switch to No. 2 position and set the frequency control to its mid-position. Place the frequency modulator in operation, with its sweep range switch in the "Lo" position. Interconnect the test oscillator and frequency modulator with the special shielded patch cord provided. Turn the oscillator modulation switch to "Off."

(f) Increase the frequency of the test oscillator by slowly turning its tuning control until two separate, distinct, and similar waves appear on the screen. These waves will be identical in shape, but will be totally disconnected and appearing in reversed positions. They will have a common base line, which is discontinuous. Adjust the frequency and synchronizing input controls of the oscillograph to get the proper waves and to make them remain motionless on the screen. Continue increasing the oscillator frequency until the forward and reverse curves move together and overlap, with their highest points exactly coincident. This condition will obtain at an oscillator setting of approximately 530 kc.

(g) With the images established as in (f), readjust the two screws on the second i-f transformer so that they cause the curves on the oscillograph screen to become exactly coincident throughout their lengths and have maximum amplitude.

(h) Without altering the adjustments of the apparatus, shift the output connections of the oscillator to the input of the i-f system, i. e., between the first detector (RCA-6A8) control grid and ground. Regulate its output so that the amplitude of the oscillographic image is approximately the same as used above for adjustment (g) of the second i-f transformer.

(i) The two first i-f transformer adjustment screws, one on top and one on bottom, should then be adjusted so that they cause the forward and reverse curves to become coincident throughout their lengths and have maximum amplitude. The composite wave obtained in this manner represents the resonance characteristic of the total i-f system. Lack of symmetry or irregularity of the resultant image will indicate the presence of a defect in the i-f system.

R-F Adjustments

NOTE: Before making r-f adjustments, it may be advisable to replace the bottom cover to eliminate vibrator interference.

(a) Adjust the dial pointer on the remote control head by the following procedure. Rotate tuning knob to its extreme clockwise position irrespective of location of pointer on dial. Now turn the pointer adjusting screw in the center of the back of the control unit until the pointer is at the end calibration mark below the 55 on dial scale.

(b) Attach the output of the test oscillator to the receiver input, i. e., between the antenna and ground terminals, with a 175 mmfd. capacitor in series with antenna lead.

NOTE: For r-f alignment of receivers in which the tubular paper condenser C-3 (.01 mfd.) has been replaced by the small molded condenser 500 mmfd. (change easily identified by reference to Figure 2 and bottom of chassis), use a .001 mfd. capacitor instead of the 175 mmfd. capacitor in series with the antenna lead and test oscillator.

There should be a shunt capacitor of 50 or 60 mmfd. from the antenna lead at the receiver to ground. Accurately tune the oscillator to 1,400 kc. The oscillograph should be left connected to the second detector output circuit as for the above i-f adjustments. Return the synchronizing switch to its "Int." position and turn the range switch to its No. 1 position.

(c) Tune the receiver to a dial reading of 1,400 kc. Then regulate the oscillator output so as to increase the amplitude of the waves on the oscillograph screen to a conveniently observable size. The several waves of detected signal, as appearing on the screen, should be synchronized by operation of the synchronizing and frequency controls. Trimmers, C-13, C-8, and C-5, of the oscillator, detector, and antenna coils should then be adjusted so that each causes maximum vertical deflection (amplitude) of the images.

(d) The oscillator modulation should then be turned to "Off" and the frequency modulator placed in operation, connected to the oscillator with the shielded patch cord. Change the oscillograph synchronizing switch to "Ext.", set its range switch to its No. 2 position and the frequency control slightly above its mid-position.

(e) Increase the frequency of the test oscillator gradually, until the point is reached where the two similar, distinct, and separate wave images appear on the screen and become coincident at their highest points. This will occur at an oscillator setting of approximately 1,500 kc. These waves should be synchronized on the oscillograph screen by careful readjustment of the synchronizing and frequency controls. Readjust trimmers, C-13, C-8, and C-5, to produce complete coincidence at maximum amplitude of the two waves.

(f) Disconnect the frequency modulator from the oscillator. Place the modulation switch of the oscillator to "On" and tune the oscillator to 600 kc. Set the synchronizing switch of the oscillograph to "Int." and turn the range switch to No. 1 position.

(g) Tune the receiver station selector control so as to pick up the 600 kc. signal, disregarding the dial reading at which it is best received.

(h) Change the oscillograph synchronizing switch to "Ext." and place the oscillator modulation switch to "Off." Interconnect the frequency modulator and oscillator with the special shielded patch cord. Return the range control of the oscillograph to its No. 2 position and set the frequency control slightly above its mid-position.

(i) Shift the test oscillator to its 200-400 kc. range and tune it to the point at which the forward and reverse waves show on the oscillograph screen. This condition will obtain at an oscillator setting of approximately 230 kc. The signal obtained from the oscillator for this adjustment will be the third harmonic of 200 kc. An increase in the oscillator output may be necessary. The trimmer C-15 should then be adjusted to the point which produces maximum amplitude of the oscillographic images. It will not be necessary to rock the tuning control for this adjustment, inasmuch as the frequency modulator is varying the signal in an equivalent manner.

(j) Retune trimmers C-13, C-8, and C-5 as in (c), (d), and (e) to correct for any change in high-frequency alignment which may have been caused by the adjustment of C-15.

OUTPUT METER ALIGNMENT

Place the receiver in operation with its two covers removed. Attach the output indicator across the loudspeaker voice coil circuit or across the output transformer primary. Advance the receiver volume control to its maximum position, letting it remain in such position for all adjustments. For each adjusting operation, regulate the test oscillator output control so that the signal level is as low as possible and still observable at the receiver output. Use of such small signal will obviate broadness of tuning which would otherwise result from a.v.c. action on a stronger one.

I-F Adjustments

(a) Connect the output of the test oscillator to the control grid cap of the i-f tube (RCA-6K7) through a 0.25 mfd. capacitor and connect the ground of the oscillator to the receiver chassis. Adjust the frequency of the oscillator to 260 kc. Tune the receiver to a point where no interference is received from the heterodyne oscillator or local stations.

(b) Adjust the two screws (attached to molded cores) of the second i-f transformer, one on top and one on bottom, until maximum output is produced by the indicating device.

(c) Remove the oscillator from the i-f tube input and connect it between the control grid cap of the first detector tube (RCA-6A8) and chassis ground, using the 0.25 mfd. capacitor as previously. Allow its tuning to remain at 260 kc. Tune the receiver to avoid interference as in (a).

(d) Adjust the two screws of the first i-f transformer for maximum (peak) receiver output. The indication for this adjustment will be broad due to the "flat-top" characteristic of the i-f system. The two screws should, therefore, be very carefully adjusted so that the indicator remains fixed at maximum as the oscillator is shifted through a range 2 kc. above and below its normal setting of 260 kc. An irregular double-peaked indication is to be avoided.

R-F Adjustments

NOTE: Before making r-f adjustments, it may be advisable to replace the bottom cover to eliminate vibrator interference.

(a) Adjust the dial pointer on the remote control head by the following procedure. Rotate tuning knob to its extreme clockwise position irrespective of location of pointer on dial. Now turn the pointer adjusting screw in the center of the back of the control unit until the pointer is at the end calibration mark below the 55 on dial scale.

(b) Connect the output of the test oscillator to the antenna-ground terminals of the receiver with a 175 mmfd. capacitor in series with the antenna lead.

NOTE: For r-f alignment of receivers in which the tubular paper condenser C-3 (.01 mfd.) has been replaced by the small molded condenser 500 mmfd. (change easily identified by reference to Figure 2 and bottom of chassis), use a .001 mfd. capacitor instead of the 175 mmfd. capacitor in series with the antenna lead and test oscillator.

There should be a shunt capacitor of 50 or 60 mmfd. from the antenna lead at the receiver to ground. Tune the oscillator to 1,400 kc. Allow the output indicator to remain attached to the receiver output.

(c) Tune the receiver so that the dial reading is 1,400 kc. Then adjust the oscillator, detector, and antenna coil trimmers, C-13, C-8, and C-5 respectively, tuning each to the point producing maximum indicated receiver output.

(d) Shift the oscillator frequency to 600 kc. and tune the receiver to pick up this signal, disregarding the dial reading at which it is best received. The oscillator series trimmer, C-15, should then be adjusted, simultaneously rocking the receiver tuning control backward and forward through the signal until maximum (peak) receiver output results from the combined operations. The adjustment of C-13, C-8 and C-5 should be repeated as in (c) to correct for any change in its alignment due to the adjustment of C-15.

	MISCELLANEOUS ASSEMBLIES	
4287	Body—Antenna cable female connector body—Package of 10	.40
4289	Body—"A" lead fuse connector body—Package of 10	.35
12810	Button—Plug button for receiver housing (used on 6M only)	.16
12444	Cable—Shielded antenna cable approx. 8 in. long, complete with female-section of connector	.38
12473	Cable—Shielded antenna lead-in cable, approx. 31 in. long, complete with 2 male connections of connector	1.12
4288	Cap—Male connector cap for "A" lead or antenna cable—Package of 10	.36
5025	Capacitor—Generator capacitor	.40
4293	Capacitor—Ammeter capacitor	.60
11418	Capacitor—.5 Mfd.—(C42)	.50
4291	Clip—"A" lead ammeter clip—Package of 10	.70
12457	Cover—Receiver housing top cover (used on 6M only)	.65
12458	Cover—Receiver housing bottom cover assembly (used on 6M only)	.60
12461	Cover—Receiver case bottom cover (used in 6M2 only)	.60
12462	Cover—Receiver case top cover (used in 6M2 only)	.62
12535	Fastener—Receiver housing top cover fastener—Package of 10	.30
4286	Ferrule—Antenna cabl eor "A" lead connector ferrule and bushing—Package of 10	.38
5028	Fuse—"A" lead fuse—15 amp.—Package of 5	.40
12448	Grille—Speaker grille assembly (used on 6M only)	$0.85
12456	Housing—Receiver housing complete (used on 6M only)	4.80
12460	Housing—Receiver case complete (used on 6M2 only)	4.58
4290	Insulator—Fuse connector insulator—Package of 10	.85
4323	Knob—Tone control knob (used on 6M only)—Package of 5	.70
4132	Knob—Tone control knob (used on 6M2 only)—Package of 5	.55
12443	Lead—"A" lead (set end), approx. 8 in. long, complete with male section of connector	.26
12506	Plate—Name plate and mounting screws (used in 6M only)	.28
12507	Plate—Name plate and mounting screws (used in 6M2 only)	.28
12508	Plate—RCA monogram and rivets (used on 6M2 only)	.28
12609	Ring—Rubber ring for speaker mounting (used on 6M2 only)	.28
12459	Screw—Speaker mounting screw assembly, consisting of 1 screw, 1 nut, and 1 lockwasher to mount speaker in case (used on 6M only)—Package of 4	.20
12533	Screw—Self-tapping slotted hex. head, ¼ in. long, used in receiver housing—Package of 10	.16
4393	Screw—Set screw for tone control knob Stock No. 4132 (used on 6M2 only)—Package of 10	.25
12248	Socket—3-contact socket and bracket assembly for reproducer cable	.20
12502	Socket—Pin socket and bracket assembly for tone control lead	.30
4284	Spring—Antenna cable connector spring—Package of 10	.30
12446	Stud—Receiver mounting stud assembly, comprising 1 stud, 1 washer, 1 lockwasher and 1 nut	.20
12254	Stud—Speaker mounting stud assembly, comprising 1 stud, 1 spacer, 1 washer and 2 nuts (used in 6M2 only)	.24
5024	Suppressor—Distributor suppressor	.38
12249	Tone Control—(R22)	.85
4285	Washer—Antenna cable connector insulating washer—Package of 10	.22

The prices quoted above are subject to change without notice.

Tuning Condenser Drive

Smooth control should be obtained over the entire tuning range of the variable condenser. If irregularity is present, check the action of the gear mechanism for binding or backlash at every point within the tuning range. A bind may be due to improper mesh between the worm gear and the large gears on the condenser shaft. To correct such a condition, loosen the three screws holding the gear plate and adjust the mesh of the gears to a position which gives smooth operation. Gear backlash is prevented by the small compression spring between the two large gears on the rotor shaft.

Interrupter

The mechanical interrupter used in the power system is constructed with a plug-in base, so as to be easily removed from the receiver. Its adjustments have been correctly set during manufacture by means of special equipment. In cases of faulty operation of the interrupter, a renewal should be made.

The symmetrical plug-in base on this device permits the unit to be placed in its socket so as to give correct output voltage polarity on an automobile with either a positive or negative "A" ground. For installation with positive "A" ground, insert vibrator so positive (+) symbol is nearest label on vibrator compartment partition; for negative "A" ground, insert with negative (-) symbol nearest label.

Radiotrons

Deterioration of tubes and their approach to failure is usually evidenced by noisy or intermittent operation, loss of sensitivity, and distorted tone quality. When suspected as faulty, the tubes should be removed from the receiver and checked with standard tube testing apparatus. It is not feasible to test the tubes while in the receiver, due to measurement inaccuracies which would result from the effects of the circuits.

Receiver Housing

The screws holding the receiver chassis to the case must all be in place and tightly installed, inasmuch as they appreciably affect the ground resistance of the assembly and will consequently have a bearing on the amount of ignition noise received.

Final Tuning Dial Adjustment

Final adjustment of the dial pointer may be made during operation after the receiver is installed in automobile. To do this, tune in a station of known frequency (say 760 kc.—approximately 76 on dial) as accurately as possible. Now reset the dial pointer to exactly 76 on the dial by means of the adjusting screw at enter rear of operating head.

Volume Control and Power Switch

This adjustment is made by turning the small control knob fully clockwise and then fully counter-clockwise. This places the friction clutch mechanism on the volume control in proper alignment.

General Features

These receivers employ the same type chassis. The table models 6BT and 6BT6 each employ an eight-inch, dust-proof, permanent-magnet, dynamic loudspeaker while the console Models 6BK and 6BK6 each employ a twelve-inch, dust-proof, permanent-magnet, dynamic loudspeaker. Models 6BT and 6BK obtain their plate supply from "B" batteries and their filament supply from either a 2½-volt Air-cell or a 2-volt storage battery. Models 6BT6 and 6BK6 obtain their plate supply from a compact, vibrator power-supply unit, which, in turn, is operated from a 6-volt storage battery. One cell (2 volts) of this same storage battery is used to supply filament voltage to the Radiotrons. The vibrator is of the "plug-in" type which permits ready removal or replacement. Models 6BT and 6BK have a pilot-lamp switch combined with the main power switch so that the pilot lamp may be turned off, after the receiver is tuned in, to conserve battery current.

The circuit used in these receivers is of the superheterodyne type with such design features as magnetite core adjusted i-f transformers, improved core-adjusted antenna, wave-trap, high-frequency tone control, automatic volume control, phonograph terminal board, new edge-lighted dial, plunger-type air trimming capacitors, and built-in antenna coupler.

SERVICE DATA

The first-detector and oscillator functions are combined in the RCA-1C6 tube. The input of this tube is coupled to the antenna through a tuned r-f transformer. A series wave-trap, tuned by means of an adjustable magnetic core, is connected from antenna to ground to prevent signals of intermediate frequency (460 kc) from being introduced into the first stage as interference. [illegible]

means of the synchronous vibrator. The complete unit is acoustically shielded to prevent noise. The vibrator-power-unit chassis should be insulated from the receiver chassis, when removed for service, to avoid vibrator buzz. The vibrator unit has been carefully adjusted by means of special equipment to ensure quiet operation over an extensive period of life. No adjustments should be attempted on a vibrator suspected of being in a defective condition, but a renewal installed. The plug-in arrangement affords easy removal or replacement.

A 6-volt storage battery supplies power for the vibrator and for the tube filaments. Four connections are required to the 6-volt battery. The + 6-volt (black) lead and the + 4-volt (blue) lead supply filament voltage to the receiver, while the + 4-volt (red) lead and − volt (yellow) lead supply voltage to the vibrator power unit. The two 4-volt leads (blue and red) should make separate connections to the same battery strap to avoid against vibrator buzz which might otherwise result if these two leads are joined together or touch each other. The 7½-volt C battery is located on the top-side of the receiver chassis and securely held in place by a metal cover (see figure 3). The four bias cells are located underneath the receiver chassis (see figures 2 and 3).

CIRCUIT ARRANGEMENT

The schematic and wiring layouts of the electrical circuit are shown in Figures 2 and 3, respectively. From these diagrams it may be seen that six Radiotrons are incorporated in the basic Superheterodyne circuit. In sequence, there is an r-f stage, a dual first detector-oscillator stage, a single i-f stage, a second detector audio amplifier-a.v.c. stage, and a pentode output stage. The power supply system contains a mechanical interrupter and an RCA-84 rectifier Radiotron. The following circuit features are of particular importance:

[illegible] interference and [illegible] filter arrangement [illegible]. This filter is a "band-pass" type, having an acceptance band between 540 kc. and 1600 kc., and sharply defined cut-off below and above these two limits. Primary to secondary capacity coupling in the first r-f transformer has been minimized to further suppress interference.

Tuned Circuits—There are seven resonant circuits in the radio frequency end of the receiver. The r-f, first detector and oscillator grid circuits are tuned by a three-gang tuning condenser. The remaining tuned circuits consist of the primary and secondary windings of the i-f transformers which are resonated by trimmers to a nominal frequency of 260 kilocycles.

Detection-A.V.C.—Detection takes place as a result of the rectifying action of the diodes of the RCA-6B7 tube and develops a current through resistors R-7 and R-17. The d-c voltage drop in the resistors R-7 and R-17 due to the detected signal is used for automatically regulating the control grid bias of the r-f and first detector stages. The amplification of these stages thus becomes dependent upon the signal's strength. This process (a.v.c.) compensates for fading signals and re[illegible] direction, [illegible]. A smaller [illegible] detection is [illegible]7 and carried to the control grid of the i-f stage. This voltage likewise furnishes automatic volume control.

Audio System—The audio and d-c components of the detected signal are selected from the manual volume control resistor (R-17) by its movable arm and are applied to the control grid of the RCA-6B7. The d-c applied to this grid increases the bias as the a-f is increased and prevents overload as the volume control is advanced. By virtue of an effect of a high series resistance in the screen grid circuit, the cut-off of the operating characteristic is extended as the control grid bias is increased, thereby preventing distortion. After amplification by the 6B7, the audio signal is transmitted to the output stage and thence to the loudspeaker for final reproduction.

Power—The heaters of all tubes are supplied directly from the battery of the car through efficient filters within the receiver housing. High voltage d-c plate and bias supply is obtained from the six volt battery by use of a mechanical interrupter and a tube rectifier. The interrupter is adapted for convenient removability by having its base constructed for "plug in" mounting.

Grounding—The wiring of the receiver chassis is so arranged that sensitive circuits are grounded at points predetermined by careful test. This procedure reduces noise induction caused by interference circulating in the receiver case. Several of the circuits are grouped and grounded at a single point to further eliminate such trouble. The resistance of the chassis, the receiver housing and the shielded cable has been kept as low as possible in order to minimize ignition noise.

SERVICE DATA

Regular maintenance will insure proper operation of this receiver over an extensive period of life. It should therefore receive the same routine inspections and adjustments as are accorded the mechanical and electrical systems of the car. The following service information suggests procedure to be applied in locating and repairing faults which may develop and affect the operation of the receiver.

Defects External To Receiver

Interference—Failure or disconnection of spark suppressing capacitors at gas gauge, temperature indicator, and generator will allow the ignition interference produced at such points to be radiated and picked up by the receiver. Defects [illegible] only affect operation of the [illegible] interference as well. The system should therefore be thoroughly checked and repaired if necessary. The three pairs of bonding fingers attached to the floor boards which contact the transmission control cover, and the bonding strip from muffler front bracket to chassis frame side member for noise reduction, may develop loose connections and cause intermittent noise level in the receiver. In checking the receiver for noisy operation, it is also wise to make sure that interference is not being caused by disturbing electrical devices which are not part of but are in vicinity of the car.

Battery—Corroded terminals at the storage battery will usually result in low voltage at the receiver and consequent low sensitivity. Noise may also be generated by this condition. Battery conditions will be reflected in the motor operation as well as that of the radio.

Antenna—Vibration may occasionally cause the antenna connections to become loose or broken. These should be carefully checked and repaired if necessary. Corrosion due to weather is also deleterious at these points. Each connection should be thoroughly cleaned to assure solid contact at all times. The grounding point of the antenna lead should be at the front, left, running board bracket. This point of connection should not be changed, since its position on the car is very critical in regard to interference. The ground connection to the case of the receiver should be kept a secure connection to the frame of the car at all times, if loose, it may cause intermittent operation of the receiver, loss of sensitivity or will produce noisy symptoms.

Defects Within Receiver

Total Inoperation—Failure to operate may be due to one or more causes. When a receiver is found in such condition, its parts should be checked as follows:

(a) FUSE—May be burned out or making poor contact. In case of burnout, replace with a fuse of equivalent rating. If second fuse fails, remove receiver from car and investigate condition of interrupter and receiver circuits.

(b) TUBES—Dismount the receiver and remove top cover. Check to see that all tubes are correctly placed in their proper sockets. One or more tubes may be defective. To determine their condition, remove them from the receiver and test with standard tube-testing equipment. If such equipment is unavailable, substitute the tubes with others known to be in good condition. It is not advisable to test the tubes while in the receiver due to measurement errors which would result from the associated circuits.

(c) INTERRUPTER—Improper operation of the power supply interrupter is usually evidenced by reception of "sputtering noise." To check, remove the antenna connection and advance the receiver volume control (engine off). An increase in noise will usually indicate that the interrupter is in poor condition. Further investigation should be made by substitution of the interrupter with one known to be in good condition. No adjustments should be attempted on this unit. The operation of the interrupter and the associated rectifier system may also be proved normal by [illegible]

(d) [illegible] should be made to [illegible] speaker voice coil [illegible] that of the cable [illegible] and speaker. Battery [illegible] to the equipment, [illegible] Figure 6 gives the [illegible] obtained on a receiver [illegible] tion. Deviations from [illegible] be as much as ± 20% [illegible] the receiver is appreciably affected. The absence or erratic reading of one or more of the voltages will indicate a fault in the particular circuit under test; in which case, each transformer, resistor, capacitor, choke and conductor of the circuit should be individually checked for open circuit, short circuit and grounding. Reference to the diagram Figure 2 will give the values of the circuit elements and their schematic relations. Figure 3 illustrates the physical locations of the parts and the color coding of the wiring. Defective parts [illegible]

Int[illegible] be [illegible] such [illegible] or within a tube. Ex[illegible] definite method of tracing [illegible]. A connection which is inter[illegible] disclosed by regular test methods [illegible] the complete system of wiring should be carefully inspected and checked to assure that it is secure. Intermittent or distorted reception may occasionally be caused by a partially defective resistor, capacitor, or winding. This type of defect is difficult to isolate; however, the suspected parts should be carefully checked for proper value, leakage, shorted turns, etc. Should it be impossible to locate the fault by such a method, the receiver should be placed in operation and allowed to operate at full volume for several hours. The weakened or defective part will generally fail completely under such condition and its identification can be established by the regular continuity or voltage tests.

Alignment Procedure

There are a total of eight trimmer adjustments provided. Four of these are involved with the i-f system and the remainder are associated with the antenna, oscillator and first detector coils. They are precisely adjusted at the factory to give the correct performance. Their settings should remain intact indefinitely when the receiver is used under ordinary conditions, however, necessity for re-adjustment may occasionally occur from continued extremes of climate, tampering, purported alteration for service purposes, or after repairs have been made to the r-f or i-f tuned circuits. Improper alignment usually causes the receiver to be insensitive, nonselective, and subnormal in respect to tone quality. Such indications will usually exist simultaneously.

In re-adjusting the trimmers to their normal settings, it is important to apply a definite procedure and to use adequate and reliable test equipment. A standard test oscillator such as the RCA Stock No. 9595, will be required as the source of signal at the specified alignment frequencies. Means for indication of the receiver output during alignment is also necessary to accurately show when the correct point of adjustment is reached. Two indication methods are applicable. One requires use of Cathode-Ray Oscillograph equipment and the other requires a voltmeter or glow type of indicator. The Cathode-Ray alignment method is advantageous in that the indication provided is in the form of a wave image which represents the resonance characteristics of the circuits being tuned. This type of alignment is possible through use of apparatus such as the RCA Stock No. 9558 Frequency Modulator and the RCA Stock No. 9545 Cathode Ray Oscillograph. Alignment by the output meter method should be indicated by an instrument such as the RCA Stock No. 4317 Neon Glow Indicator. The two procedures are outlined as follows:

OUTPUT METER ALIGNMENT

Place the receiver in operation with its two covers removed. Attach the Output Indicator across the loudspeaker voice coil circuit or across the output transformer primary. Advance the receiver volume control to its maximum position, letting it remain in such position for all adjustments. For each trimming operation, regulate the test Oscillator output control so that the signal level is as low as possible and still observable at the receiver output. Use of such small signal will obviate broadness of tuning which would otherwise result from a.v.c. action on a stronger one.

I-F Adjustments

(a) Connect the output of the test Oscillator between the control grid cap of the i-f tube (RCA-6D6) and chassis-ground. Adjust the frequency of the Oscillator to 260 kc. Tune the receiver to a point where no interference is received from the heterodyne oscillator or local stations.

(b) Adjust the trimmers, C-46 and C-17, of the second i-f transformer so that each produces maximum (peak) receiver output as shown by the indicating device.

(c) Remove the Oscillator from the i-f tube input and connect it between the control grid cap of the first detector tube (RCA-6A7) and chassis-ground. Allow its tuning to remain at 260 kc. Tune the receiver to avoid interference as in (a).

(d) Adjust the trimmers, C-14 and C-13, of the first i-f transformer for maximum (peak) receiver output. The indication for this adjustment will be broad due to the "flat-top" characteristic of the i-f system. The two trimmers, C-14 and C-13, should, therefore, be very carefully aligned so that the indicator remains fixed at maximum as the Oscillator is shifted through a range 2 kc. above and below its nominal setting of 260 kc. *An irregular double peaked indication is to be avoided.*

R-F Adjustments

(a) Check the calibration of the dial scale of the remote control unit by rotating the tuning control until the variable condenser plates are in full mesh (maximum capacity). This will carry the dial pointer to its minimum frequency position. The knurled shaft at the rear of the control box should then be turned until the dial pointer sets exactly on the last graduation at the low frequency end of the dial scale.

(b) Connect the output of the test Oscillator to the antenna-ground terminals of the receiver with a 100 mmfd. capacitor in series with the antenna lead. Tune the Oscillator to 1400 kc. Allow the Output Indicator to remain attached to the receiver output.

(c) Tune the receiver so that the dial reading is 1400 kc. Then adjust the oscillator, detector and antenna coil trimmers, C-10, C-7 and C-3 respectively, tuning each to the point producing maximum indicated receiver output.

(d) Shift the Oscillator frequency to 600 kc. and tune the receiver to pick up this signal, disregarding the dial reading at which it is best received. The oscillator series trimmer, C-8, should then be adjusted, simultaneously rocking the receiver tuning control backward and forward through the signal until maximum (peak) receiver output results from the combined operations. The adjustment of C-10 should be repeated as in (c) to correct for any change in its alignment due to the adjustment of C-8.

CATHODE-RAY ALIGNMENT

Place the receiver in operation with its two covers removed. Attach the Cathode-Ray Oscillograph vertical input terminals to the second detector output, with the "Hi" connected to the high side of the volume control potentiometer and the "O" connected to the receiver chassis. Advance the vertical amplifier gain control of the Oscillograph to full-on, allowing it to remain at such position for all adjustments. Turn the vertical "A" amplifier to "On". Set the Oscillograph power switch to "On" and adjust the intensity and focusing controls to give a sharply defined spot on the screen. Interconnect the Frequency Modulator impulse generator terminals to the Oscillograph "Ext. Sync." terminals as shown by Figure 5.

I-F Adjustments

(a) [illegible] test Oscillator between [illegible] of the i-f tube [illegible] ground. Tune the [illegible] modulation switch to "On" and its output range switch to "Hi". The Frequency Modulator must not be connected to the Oscillator for the preliminary adjustments.

(b) Set the Cathode-Ray Oscillograph horizontal "B" amplifier to "Timing" and the synchronizing switch (timing) to "Int". Place the synchronizing input and frequency controls to about their mid-positions. Turn the range switch to its No. 1 position.

(c) Increase the output of the Oscillator until a deflection is noticeable on the Oscillograph screen. The figure obtained represents several waves of the detected signal, the amplitude of which may be observed as an indication of output. Cause the wave image formed (400 cycle waves) to be spread completely across the screen by advancing the horizontal "B" gain control. The image should be synchronized and made to remain motionless by adjustment of the synchronizing input and frequency controls.

(d) Adjust trimmers C-46 and C-17 of the second i-f transformer to produce maximum vertical deflection of the oscillographic wave which is present on the screen. This adjustment places the transformer in exact resonance with the 260 kc. signal.

(e) The sweeping operation should follow, using the Frequency Modulator. Shift the Oscillograph synchronizing switch to "Ext", change its range switch to No. 2 position and set the frequency control to its midposition. Place the Frequency Modulator in operation with its sweep range switch in the "Lo" position. Interconnect the test Oscillator and Frequency Modulator with the special shielded patch cord provided. Turn the Oscillator modulation switch to "Off".

(f) Increase the frequency of the test Oscillator by slowly turning its tuning control until two separate, distinct and similar waves appear on the screen. These waves will be identical in shape but will be totally disconnected and appearing in reversed positions. They will have a common base line which is discontinuous. Adjust the frequency and synchronizing input controls of the Oscillograph to get the proper waves and to make them remain motionless on the screen. Continue increasing the Oscillator frequency until the forward and reverse curves move together and overlap with their highest points exactly coincident. This condition will obtain at an Oscillator setting of approximately 280 kc.

(g) With the images established as in (f), retune the second i-f trimmers, C-46 and C-17, so that they cause the curves on the Oscillograph screen to become exactly coincident throughout their lengths and have maximum amplitude.

(h) Without altering the adjustments of the apparatus, shift the output connections of the Oscillator to the input of the i-f system, i.e., between the first detector (RCA-6A7) control grid and ground. Regulate its output so that the amplitude of the oscillographic image is approximately the same as used above for adjustment (g) of the second i-f transformer.

(i) The first i-f transformer trimmers, C-14 and C-13, should then be adjusted so that they cause the forward and reverse curves to become coincident throughout their lengths and have maximum amplitude. The composite wave obtained in this manner represents the resonance characteristic of the total i-f system. Lack of symmetry or irregularity of the resultant image will indicate the presence of a defect in the i-f system.

R-F Adjustments

(a) Calibrate the scale of the receiver by rotating the tuning control until the variable condenser is at full mesh, and then turning the knurled shaft at the rear of the control box to bring the dial pointer to the last graduation at the low frequency end of the scale.

(b) Attach the output of the test Oscillator to the receiver input, i.e., between the antenna and ground terminals with a 100 mmfd. capacitor in series with antenna lead. Accurately tune the Oscillator to 1400 kc. [illegible] second detector output [illegible] adjustments. Return the [illegible] to its "Int" position [illegible] to its No. 1 position.

(c) [illegible] reading of 1400 kc. Then regulate the Oscillator output so as to increase the amplitude of the waves on the Oscillograph screen to a conveniently observable size. The several waves of detected signal, as appearing on the screen, should be synchronized by operation of the synchronizing and frequency controls. Trimmers, C-10, C-7 and C-3, of the oscillator, detector and antenna coils should then be adjusted so that each causes maximum vertical deflection (amplitude) of the images.

(d) The Oscillator modulation should then be turned to "Off" and the Frequency Modulator placed in operation connected to the Oscillator with the shielded patch cord. Change the Oscillograph synchronizing switch to "Ext", set its range switch to its No. 2 position and the frequency control slightly above its mid-position.

(e) Increase the frequency of the test Oscillator gradually, until the point is reached where the two similar, distinct and separate wave images appear on the screen and become coincident at their highest points. This will occur at an Oscillator setting of approximately 1500 kc. These waves should be synchronized on the Oscillograph screen by careful re-adjustment of the synchronizing and frequency controls. Re-adjust trimmers C-10, C-7 and C-3 to produce complete coincidence at maximum amplitude of the two waves.

(f) Disconnect the Frequency Modulator from the Oscillator. Switch the modulation switch of the Oscillator to "On" and tune the Oscillator to 600 kc. Set the synchronizing switch of the Oscillograph to "Int" and turn the range switch to No. 1 position.

(g) Tune the receiver station selector control so as to pick up the 600 kc. signal, disregarding the dial reading at which it is best received.

(h) Change the Oscillograph synchronizing switch to "Ext", and place the Oscillator modulation switch to "Off". Interconnect the Frequency Modulator and Oscillator with the special shielded patch cord. Return the range control of the Oscillograph to its No. 2 position and set the frequency control slightly above its mid-position.

(i) Shift the test Oscillator to its 200-400 kc. range and tune it to the point at which the forward and reverse waves show on the Oscillograph screen. This condition will obtain at an Oscillator setting of approximately 230 kc. The signal obtained from the Oscillator for this adjustment will be the third harmonic of 200 kc. An increase in the Oscillator output may be necessary. The trimmer C-8 should then be adjusted to the point which produces maximum amplitude of the oscillographic images. It will not be necessary to rock the tuning control for this adjustment, inasmuch as the Frequency Modulator is varying the signal in an equivalent manner.

(j) Retune trimmers C-10, C-7 and C-3 as in (c), (d) and (e) to correct for any change in high frequency alignment which may have been caused by the adjustment of C-8.

Tuning Condenser Drive

Smooth control should be obtained over the entire tuning range of the variable condenser. If irregularity is present, check the action of the gear mechanism for binding or backlash at every point within the tuning range. A bind may be due to improper mesh between the small pinion gear and the large gears on the condenser shaft. To correct such a condition, remove the insulating coupling on the pinion of the tuning gear, loosen the two screws holding the gear plate and adjust the mesh of the gears to a position which gives smooth operation.

Gear backlash is prevented by the small compression spring between the two large gears on the rotor shaft. [illegible]k for this backlash, rotate the pinion slowly in [illegible]ections, observing the free gear (on rotor shaft) [illegible]y to determine if it shifts without turning the [illegible] If backlash is apparent, the large gear assembly [illegible] be removed and the free gear moved (against spring compression) 2 to 3½ teeth in relation to the fixed gear, and the assembly slid in place on the shaft and in mesh with the pinion. The set screws holding the large gears should be securely tightened.

Interrupter

The mechanical interrupter used in combination with a tube rectifier in the power system is constructed with a plug-in base so as to be easily removed from the receiver. Its adjustments have been correctly set during manufacture by means of special equipment. In cases of faulty operation of the interrupter, a renewal should be made.

MODEL H-6 Hudson
Voltage, Parts
Installation

RCA MFG. CO., INC.

Radiotrons

Deterioration of tubes and their approach to failure is usually evidenced by noisy or intermittent operation, loss of sensitivity and distorted tone quality. When suspected as faulty, the tubes should be removed from the receiver and checked with standard tube testing apparatus. It is not feasible to test the tubes while in the receiver due to measurement inaccuracies which would result from the effects of the circuits.

A "lasso" formed with a strong cord will be found helpful in removing the tubes from their sockets. The loop in the cord should be placed over the tube and tightened around the tube base. A direct pull upward will disengage the tube.

Circuit Voltages

The voltages indicated at the socket contacts on Figure 6 will serve to assist in analyzing defective circuit conditions. Each value as specified should hold within ± 20% when the receiver is normally operating at rated supply voltage. They are actual operating values and do not take into account measurement inaccuracies which may be due to the loading effect of a voltmeter's internal resistance. For the majority of readings a meter having an internal resistance of 1000 ohms per volt will be satisfactory when the range used for each check is chosen as high as possible, consistent with good readability. The amount of circuit resistance shunting the meter during measurement will determine the accuracy to be obtained, the error increasing as the meter resistance becomes comparable to or less than the circuit resistance.

Receiver Housing

The screws holding the receiver chassis to the case and those securing the covers must all be in place and tightly installed, inasmuch as they appreciably affect the ground resistance of the assembly and will consequently have a bearing on the amount of ignition noise received.

(Measured at 6.3 volts battery supply—Volume Control Maximum—No Signal)

Radio Installation-Operation

1—Lift floor mat and install three ground forks (Part No. 171210) to front, rear and left of floor board opening so that spring fingers contact transmission control housing. (See Insert EE.) The paint must be removed from the floor panel and transmission tower to provide good electrical contact. A spacer (Part No. 171435) should be placed under each ground fork and the parts secured to the floor board with two sheet metal screws (Part No. 71648) and three tapping plates (Part No. 171436).

2—Remove finish plate from center of instrument panel—attached with studs and nuts on back of panel.

3—Put the Radio Receiver in place on top of the steering column support bracket with the control shaft connections E and F on the right, and secure with two cap screws "A." On right-hand drive models, the receiver is mounted with the control shaft connections to the left. NOTE: There are three threaded holes in the bottom of the receiver so that it can be mounted in 1934 and 1935 models as well as 1936.

4—Punch a hole through the front dash pad, using the ⅜" hole located just above the center of the dash reinforcement ribs as a guide.

5—Place wooden spacer on speaker mounting stud and insert stud through hole in dash and dash pad, securing with a washer and nut on the engine side of dash.

6—Remove the control knobs from the control head, and also the nuts located behind the knobs. Insert control head from back of panel, securing by replacing nuts, and then replace control knobs.

7—Insert the driving tongue of the control cable from the right (tuning) knob into the rear (front on right-hand drive) socket F and tighten nut and the driving tongue of the control cable from the left (volume) knob into the forward (rear on right-hand drive) socket and tighten nut. NOTE: On right-hand drive installations the long control cable should be attached to the volume (left) control knob.

8—Insert speaker lead plug "J" into case. The plug has three prongs, unequally spaced—be sure they are aligned with the sockets in the case.

9—Insert pilot light in control head.

10—Attach feed wire to Battery Terminal of the ignition lock "N" and connect to socket "M," being sure that fuse is in place in socket.

11—Lay out antenna on floor under car with lead-in end at front of left running board. Remove all twist and kinks. Attach hook at lead-in to front hole in left running board, second hook to front hole in right running board, continuing back and forth until all but the last hook has been put in place. Start at the right front and work backward, drawing the antenna wire tight to take up slack and permit the last hook to be attached to the right running board.

Insert the lead-in through the hole in body floor panel in line with left front door, front pillar post, leading up behind kick panel behind radio receiver and connect to socket "L."

13—Attach one small condenser on gasoline tank gauge unit with one unit mounting screw, attaching condenser terminal to gauge unit terminal. (Insert "DD")

14—Attach one small condenser to upper rear cap screw in engine water manifold and attach condenser terminal to terminal of water temperature gauge element. (Insert "CC"). NOTE: This condenser not required on Terraplane models.

15—Attach large condenser to cap screw at rear of generator and connect condenser terminal to generator battery terminal. (Insert "AA")

16—Install 48763 ground strap from the front muffler bracket to chassis frame. The paint must be removed from points of attachment to insure good electrical contact.

17—Install suppressor in central terminal of distributor.

18—When installing radio on Terraplane Special models with air cooled generator, mount generator charge regulator in place of relay with two screws in two threaded holes in dash provided for the purpose. Fuse cap bar should be on upper face. Remove ground cap from generator "F" terminal. See illustration inserts for wiring diagram. Connect "F" terminal on side of charge regulator to "F" terminal (engine side) of generator. Adjust generator output to 22 amps. cold—17 amps., warm.

19—Turn on volume and tune set to a known local station. Adjust the dial head to give correct dial reading by turning knurled knob on back of control head.

Radio Kit—1936—Hudson and Terraplane

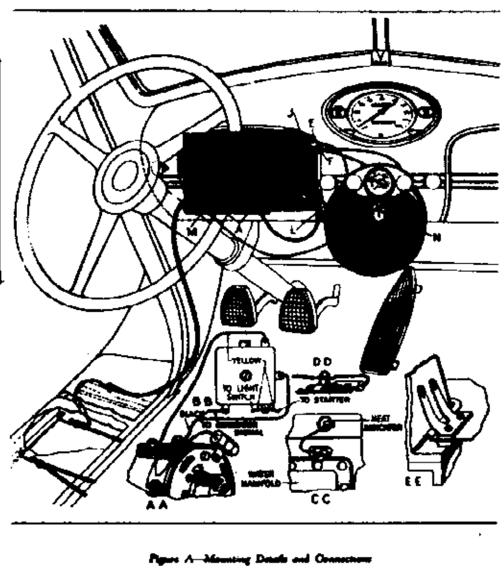

Figure A—Mounting Details and Connections

The Radio Kit, Part No. 47750 includes—

1—Receiver Complete
1—Speaker Complete
1—Control Head complete with cables
1—Pilot Light Bulb
1—Feed Cable Assembly and Fuse
1—Aerial Assembly
1—Aerial Lead In with shield and clip
1—Distributor Suppressor
3—Small Condensers (one required on Terraplane Deluxe Models)
1—Large Condenser
1—Ground Strap
3—Ground Forks
Bolts, Nuts, Screws and Lock Washers for mounting units

In order to complete the installation on Terraplane Deluxe Models, a Charge Control (Part No. 47979) is required in addition to the Radio Kit.

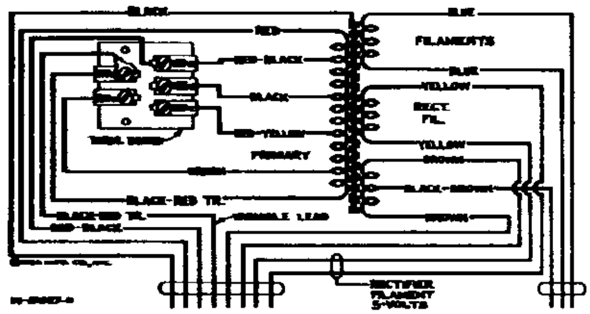
Resistance Measurement

The resistance values shown between Radiotron socket contacts, grid caps, resistors, terminals, and receiver chassis ground, on figure 4, have been carefully selected so as to facilitate a rapid continuity check of the circuits. The use of this diagram in conjunction with the Schematic Circuit Diagram, figure 1, and Chassis Wiring Diagram, figure 2, will permit the location of certain troubles which might otherwise be difficult to ascertain. Each value as specified should hold within ±20%. Variations in excess of this limit will usually be indicative of trouble in circuit under test. Resistance values were measured with the Radiotrons in sockets; tuning condenser in full mesh, and volume control set at maximum except where otherwise noted. In all cases of measuring the resistance between points of the circuit and ground, it will be necessary to connect the negative terminal of the resistance meter to chassis-ground. If the polarity of the resistance meter is not known, it may be readily ascertained by connecting a d-c voltmeter of indicated polarity across the terminals of the device.

RCA MFG. CO., INC.

Phonograph Attachment

A terminal board is provided for connecting a phonograph into the audio amplifying circuit. Typical



Primary Resistance—24.5 ohms Total
Secondary Resistance—668 ohms Total

Figure 5—Universal Transformer

methods of connecting a low-impedance pick-up, or the RCA Victor Models R-93, R-93-2, and R-93S Record Players are shown on the schematic diagram (figure 1).

Loudspeaker

Centering of the loudspeaker voice coil is made in the usual manner with three narrow paper feelers

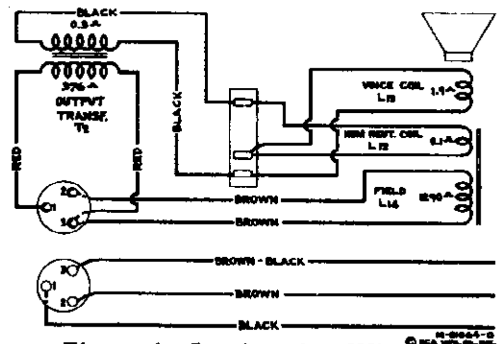


Figure 6—Loudspeaker Wiring

after first removing the front paper dust cover. This may be removed either permanently by cutting it away with a sharp knife, or by softening its cement with a very light application of acetone using care not to allow the acetone to flow down into the air gap. The dust cover may be cemented back in place with ambroid upon completion of adjustment.

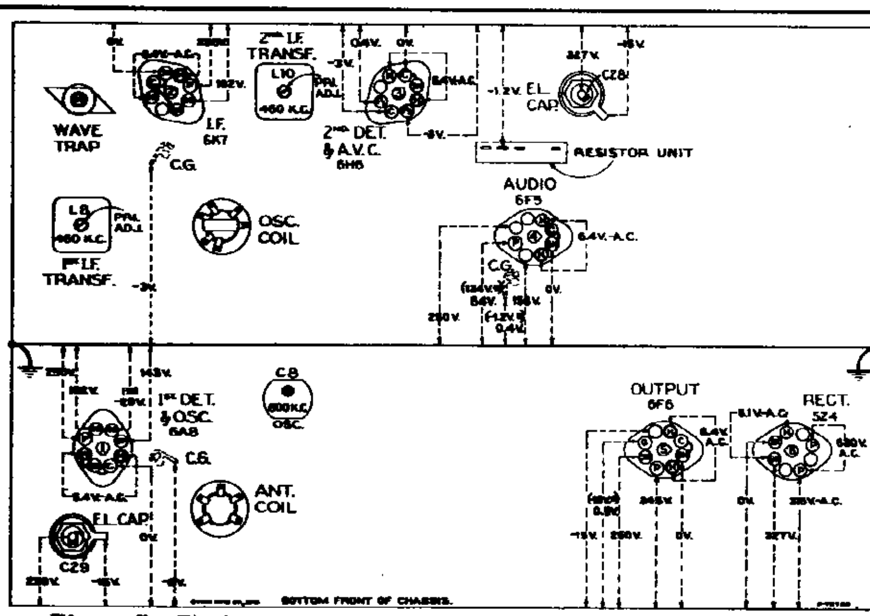

Figure 7—Radiotron Socket Voltages, Coil and Trimmer Locations

Measured at 115 volts, 60-cycle supply—Tuned to approximately 1,000 kc. ("Standard broadcast")—No signal being received—Volume control minimum

Radiotron Socket Voltages

***Note:** Two voltage values are shown for some readings. The higher value shown in parenthesis with asterisk (*) indicates operating conditions without voltmeter loading. The lower value is the actual measured voltage and differs from the higher value because of the additional loading of the voltmeter through the high series circuit resistance.*

The voltage values indicated from the Radiotron socket contacts, grid caps, resistors, and terminals to receiver chassis ground on figure 7 will assist in locating cause for faulty operation. Each value as specified should hold within ±20% when the receiver is normally operative at its rated line voltage. Variations in excess of this limit will usually be indicative of trouble in the basic circuits. These voltages were measured with receiver tuned to approximately 1,000 kc, no signal being received, and volume control set at minimum. To duplicate the conditions under which the voltages were measured requires a 1,000-ohm-per-volt d-c meter, having ranges of 10, 50, 250, 500, and 1,000 volts. Use the nearest range above the voltage to be measured. A-c voltages were measured with a corresponding a-c meter.

Chassis Base Dimensions 12 inches x 7 inches x 2½ inches
Over-all Chassis Height......................... 7½ inches

General Features

These receivers employ the same chassis and have many distinctive features. Model 6T employs an 8-inch dynamic loudspeaker and Model 6K employs a 12-inch dynamic loudspeaker. The superheterodyne circuit is used with such features of design as: magnetite core adjusted i-f transformers, improved core adjusted antenna wave-trap, aural compensated volume control, continuously variable tone control with music-voice switch, automatic volume control, resistance coupled audio system, phonograph terminal board, band selective illumination of dial scales, and a dust-proof loudspeaker.

Tuning is continuous through the "Standard broadcast" and "Short wave" bands (including 49 meters). The "Short wave" position of this extensive range also includes channels assigned for police, amateur, and aviation communication. Trimming adjustments are located at accessible points. Their number is reduced to the least that is consistent with efficient operation. The tuning dial ratio of ten to one permits ease of tuning, especially in the "Short wave" band.

Circuit Arrangement

The first detector and oscillator functions are accomplished in a single tube, an RCA-6A8. The input of this tube is coupled to the antenna through a tuned transformer. A shunt (magnetite core adjusted) wave-trap is connected across the primary of this transformer to prevent signals of intermediate frequency (460 kc) from being introduced into the first stage as interference. The two-section gang condenser, which tunes the antenna transformer secondary and the heterodyne oscillator coil, has adjustable trimmers for obtaining exact alignment. Each of these coils is tapped so that the range switch increases the range of tuning by decreasing the amount of inductance.

The intermediate-frequency stage is coupled to the RCA-6A8 and to the RCA-6H6 by means of tuned transformers. These transformers resonate with fixed capacitors and are adjusted by molded magnetite cores to tune to 460 kc.

The modulated signal, as obtained from the output of the i-f system, is detected by one of the diodes of the RCA-6H6 tube. Audio frequency secured by this process is passed on to the control grid of the RCA-6F5 for amplification before final reproduction. The d-c voltage, which results from detection of the signal, is used for automatic volume control. This voltage, which develops across resistor R7, is applied as automatic control grid bias to the first detector and i-f tubes through a suitable resistance filter. The second diode of the RCA-6H6 is used to supply residual bias for the controlled tubes under conditions of little or no signal. This auxiliary diode, under such conditions, draws current which flows through resistors R5 and R7, thereby maintaining the desired minimum operating bias on such tubes. On application of signal energy above a certain level, however, the auxiliary bias diode ceases to draw current and the a.v.c. diode takes over the biasing function.

Manual volume control is effected by means of an acoustically tapered potentiometer connected as a variable coupling element between the output of the second detector and the first audio control grid. After amplification by the RCA-6F5, the audio signal is transmitted by resistance-capacitance coupling to the input of the RCA-6F6 power-output stage, which, in turn, is transformer-coupled to the dynamic speaker.

Continuously variable tone control is effected by means of capacitor C26 and variable resistor R14 shunting the plate circuit of the output tube. Extreme clockwise rotation of this tone control disconnects the resistor R14 from the circuit and places an additional capacitor C27 in shunt with capacitor C20, thereby reducing the low-frequency response of the amplifier. This point is known as the "Speech" position and provides optimum intelligibility of speech.

The power-supply system consists of an RCA-5Z4 rectifier tube which is supplied from an efficiently designed power transformer and which works into a suitable filter. The various potentials required for the plate, screen, control grid, and cathode circuits are obtained from the output of the filter. The electro-dynamic loudspeaker field coil is used as a filter reactor.

SERVICE DATA

The various diagrams of this booklet contain such information as will be needed to isolate causes for defective operation if such develops. The ratings of the resistors, capacitors, coils, etc., are indicated adjacent to the symbols signifying these parts on the diagrams. Identification titles, such as R3, L2, C1, etc., are provided for reference between the illustrations and the Replacement Parts List. The coils, reactors, and transformer windings are rated in terms of their d-c resistances only. Ratings of less than one ohm are generally omitted.

Alignment Procedure

There are three alignment trimmers provided in the antenna transformer and oscillator coil tuned circuits. The i-f transformer adjustments are made by means of screws attached to molded magnetite cores. All of these circuits have been accurately adjusted during manufacture and should remain properly aligned unless affected by abnormal conditions or altered during servicing. Loss of sensitivity, improper tone quality, and poor selectivity are the usual indications of improper alignment.

The correct performance of this receiver can only be obtained when the aligning has been done with adequate and reliable apparatus. The manufacturer of this receiver has available, for sale through its distributors and dealers, a complete assortment of such service equipment as may be needed for the alignment operation.

A test oscillator, such as the RCA Stock No. 9595, is required as a source of the specified alignment frequencies. Visual indication of receiver output during the adjustment is necessary and should be accomplished by the use of an indicator such as the RCA Stock No. 4317 Neon Output Indicator.

The procedure outlined below should be followed in adjusting the various trimmer capacitors and molded cores:

I-F Core Adjustments

The four adjustment screws (attached to molded magnetite cores) of the two i-f transformers (one on top and one on bottom of each i-f transformer) are located as shown by figures 3 and 7. Each circuit must be aligned to a basic frequency of 460 kc. To do this, attach the output indicator across the loudspeaker voice coil.

Connect the output of the test oscillator to the control grid of the RCA-6A8 through a .05 mfd. capacitor. Connect the test oscillator ground terminal to the ground terminal of the receiver chassis. Range selector should be in "Short wave" position. Tune the oscillator to 460 kc. Advance the receiver volume control to its full-on position and adjust the receiver tuning control to a point, within its range, where no interference is encountered either from local broadcast stations or from the heterodyne oscillator. Increase the output of the test oscillator until a slight indication is present on the output indicator. Adjust the two magnetite core screws of the second i-f transformer to produce maximum (peak) indicated receiver output. Then, adjust the two magnetite core screws of the first i-f transformer for maximum (peak) receiver output as shown by the indicating device. During these adjustments, regulate the test oscillator output so that the indication is always as low as possible. By doing so, broadness of tuning due to a.v.c. action will be avoided. It is advisable to repeat the adjustment of all i-f magnetite core screws to assure that the interaction between them has not disturbed the original adjustment.

Wave-Trap Adjustment

Attach the output of the test oscillator to the receiver "Antenna" terminal through a 200 mmfd. (important) capacitor. The ground connections remain connected together. Leave the test oscillator adjusted to 460 kc and range selector in "Short wave" position as before. Then adjust the wave-trap screw to the point which causes maximum suppression of the 460 kc signal.

R-F Trimmer Adjustments

Calibrate the tuning dial by setting the pointer to a horizontal position (53 on "Standard broadcast" scale) with the two-gang tuning condenser in full mesh. The output indicator should be left connected to the system. Connections for the test oscillator remain the same as for "Wave-trap adjustment." Adjust the test oscillator to 1,700 kc and set the receiver tuning control to a dial reading of 1,700 kc. Leave the volume control of the receiver at its maximum position. Make sure that the range selector is at its broadcast position. Regulate the output of the test oscillator until a slight indication is perceptible at the receiver output. Then adjust the two trimmers, C6 and C3, of the oscillator and antenna transformer coils (mounted on the variable condenser) so that each produces maximum (peak) receiver output. After this maximum has been accurately obtained, shift the test oscillator to 600 kc. Tune the receiver to pick up this signal, disregarding the dial reading at which it is best received. Then, adjust the receiver oscillator series trimmer, C8, simultaneously rocking the tuning control backward and forward through the signal until maximum receiver output results from these combined operations. The adjustment at 1,700 kc should then be repeated to correct for any change which may have been caused by the oscillator series trimmer adjustment.

REPLACEMENT PARTS

Stock No.	Description	List Price
	RECEIVER ASSEMBLIES	
5237	Bushing—Variable condenser mounting bushing assembly—Package of 3	$0.45
12511	Cap—Grid contact cap—Package of 5	.15

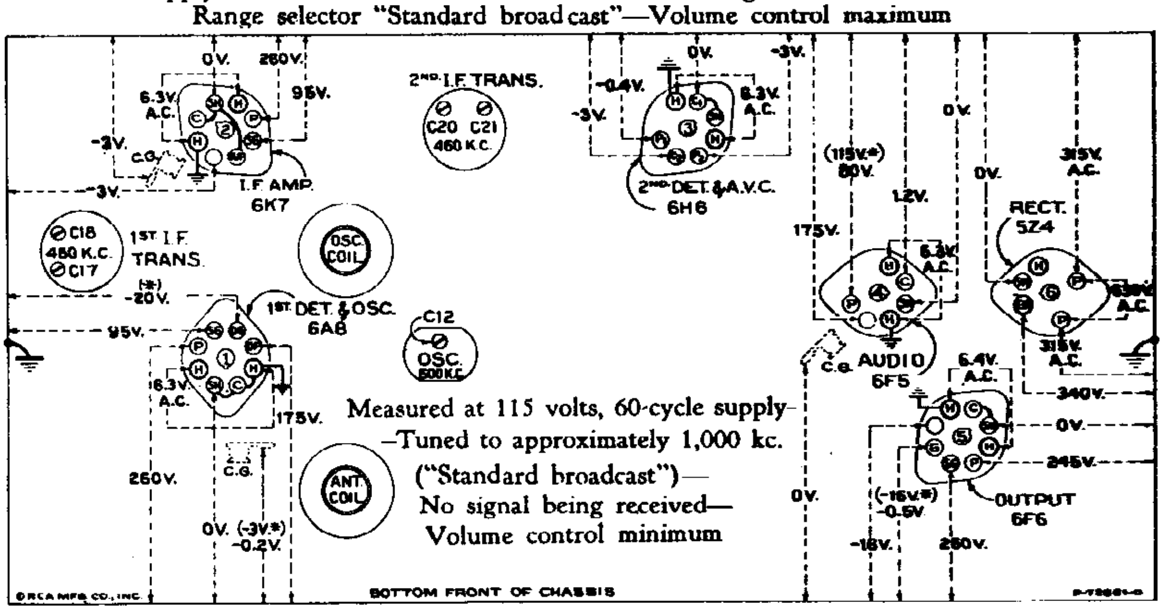

Figure 7—Radiotron Socket Voltages, Coil, and Trimmer Locations

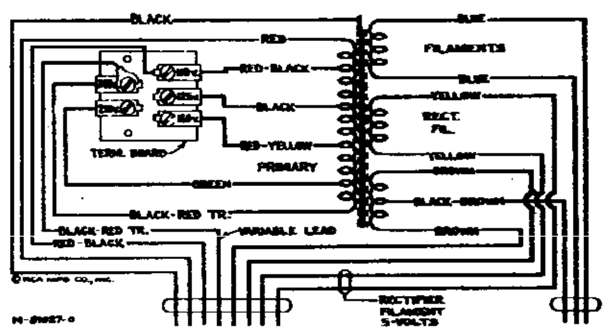
Note: *Two voltage values are shown for some readings. The higher value shown in parentheses with asterisk (*) indicates operating conditions without voltmeter loading. The lower value is the actual measured voltage and differs from the higher value because of the additional loading of the voltmeter through the high series circuit resistance.*

The voltage values indicated from the Radiotron socket contacts, grid caps, resistors, and terminals to receiver chassis ground on figure 7 will assist in locating cause of faulty operation. Each value as specified should hold within ±20% when the receiver is normally operative at its rated line voltage. Variations in excess of this limit will usually be indicative of trouble in the basic circuits. These voltages were measured with receiver tuned to approximately 1,000 kc., no signal being received, and volume control set at minimum. To duplicate the conditions under which the voltages were measured requires a 1,000-ohm-per-volt d-c meter, having ranges of 10, 50, 250, 500, and 1,000 volts. Use the nearest range above the voltage to be measured. A-c voltages were measured with a corresponding a-c meter.



Primary Resistance—17.3 ohms total
Secondary Resistance—355 ohms total

Figure 5—Universal Transformer

RCA MFG. CO., INC.

General Features

These receivers employ the same chassis and have many distinctive features. Model 6T2 employs an 8-inch dynamic loudspeaker and Model 6K2 employs a 12-inch dynamic loudspeaker. The superheterodyne circuit is used with such features of design as: Antenna wave-trap, aural compensated volume control, continuously variable tone control with music-voice switch, automatic volume control, resistance coupled audio system, phonograph terminal board, and band selective indication of dial scales. The tuning range is continuous through the "Standard broadcast" band, "Medium wave" band, and the "Short wave" band. It includes domestic broadcast, police, aircraft and amateur services, and also the important foreign short-wave broadcast bands at 49, 31, 25, 19, and 16 meters.

Circuit Arrangement

The first detector and oscillator functions are accomplished in a single tube, an RCA-6A8. The input of this tube is coupled to the antenna through a tuned transformer. This transformer consists of a single primary and three series-connected secondary windings to provide the three ranges of tuning. The oscillator coil system is similarly wound on a single form. A range-selector switch S3 is used for connecting the various sections of these two coil systems into the circuit to provide operation on the band desired. The coils are tuned by a variable two-section gang condenser having trimming capacitors in shunt with each section. There are additional trimming capacitors across the section of each coil used for the "Standard broadcast" band. A series trimming capacitor is also associated with the "Standard broadcast" oscillator coil.

The intermediate-frequency stage is coupled to the RCA-6A8 and to the RCA-6H6 by means of tuned transformers. The windings of these transformers (both primary and secondary) are resonated with adjustable trimming capacitors to tune to 460 kc.

The modulated signal as obtained from the output of the i-f system is detected by an RCA-6H6 twin-diode tube. Audio frequency secured by this process is passed on to the a-f system for amplification and final reproduction. The d-c voltage which results from detection of the signal is used for automatic volume control. This voltage which develops across resistor R7 is applied as automatic control-grid bias to the first detector and i-f tubes. The second (auxiliary) diode of the RCA-6H6 is used to supply residual bias for the controlled tubes under conditions of little or no signal. This diode, under such conditions, draws current which flows through resistors R6 and R7, thereby maintaining the desired operating bias on such tubes. On application of signal energy above a certain level, however, the auxiliary bias-diode ceases to draw current, and the a.v.c. diode takes over the biasing function.

Manual volume control is effected by means of an acoustically tapered potentiometer connected as a variable coupling element between the output of the second detector and the first-audio control grid. After amplification by the RCA-6F5, the audio signal is transmitted by resistance-capacitance coupling to the input of the RCA-6F6 power-output stage, which, in turn, is transformer-coupled to the dynamic loudspeaker.

Continuously variable tone control is effected by means of the combination of a capacitor C28 and variable resistor R9 shunting the plate circuit of the output tube. Extreme clockwise rotation of the tone control disconnects the resistor R9 from the circuit and places an additional capacitor, C33, in shunt with capacitor C25, thereby reducing the low-frequency response of the amplifier. This point is known as the "Speech" position and provides optimum intelligibility of speech.

The power-supply system consists of an RCA-5Z4 rectifier tube, which is supplied from an efficiently designed power transformer, and which works into a suitable filter. The various potentials required for the plate, screen, control grid, and cathode circuits, are obtained from the output of the filter. The electro-dynamic loudspeaker field coil is used as a filter reactor.

Phonograph Attachment

A terminal board is provided for connecting a phonograph into the audio amplifying circuit. Typical methods of connecting a low-impedance pickup, or the RCA Victor Models R-93, R-93-2, and R-93-S Record Players are shown on the schematic diagram (figure 1).

SERVICE DATA
Alignment Procedure

There are six adjustments required for the alignment of the antenna, oscillator, and wave-trap tuned circuits. The i-f transformer adjustments are made by four trimming capacitor screws. Improper alignment usually causes the impairment of sensitivity, selectivity, and tone quality. Such conditions will usually exist simultaneously.

A standard test oscillator, such as the RCA Stock No. 9595, will be required as a source of signal at the specified alignment frequencies. Means for indication of the receiver output during alignment is also necessary to show when the correct point of adjustment is reached. The RCA Stock No. 4317 Neon Glow Indicator is designed for this purpose.

Attach the output indicator across the loudspeaker voice coil. Advance the receiver volume control to its maximum position, letting it remain in such position for all adjustments. For each adjusting operation, regulate the test-oscillator output control so that the signal level is as low as possible and still be observable at the receiver output. Use of such small signal will obviate broadness of tuning which would otherwise result from a.v.c. action on a stronger one.

I-F Adjustments

(a) Connect the test oscillator to the grid cap of the RCA-6A8 through a .001 mfd. capacitor, and connect the test oscillator ground to the receiver chassis. Set test oscillator to 460 kc.

(b) Adjust the two trimming capacitors (C20 and C21) of the second i-f transformer to produce maximum (peak) output.

(c) Adjust the two trimming capacitors (C17 and C18) of the first i-f transformer, to produce maximum (peak) output.

It is advisable to repeat the adjustment of all i-f trimming capacitors a second time to assure that the interaction between them has not disturbed the original adjustment.

R-F Adjustments

Calibrate the tuning dial by adjusting the scale pointer to the extreme end calibration mark (beyond 55 on dial) while the two-gang tuning condenser plates are in full mesh. Alignment (see figure 3 for location of trimming adjustments) of "Wave-trap," "Short wave" band and "Standard broadcast" band should be made in the following order and sequence.

"Wave-Trap"

(a) Connect the output of the test oscillator to the antenna terminal through a 200 mmfd. (important) capacitor, leaving the test oscillator ground connected to the receiver chassis. With the range selector in its "Standard broadcast" position, set the receiver dial to position of no extraneous signals, near 600 kc. (60 on dial). Set the test oscillator to 460 kc. Adjust the wave-trap trimming capacitor C1 to a point which causes minimum amplitude of output. An increase of the test oscillator output may be necessary before the point of minimum amplitude, obtained by adjustment of wave-trap screw, becomes apparent on the output indicator.

"Short Wave" Band

(a) Connect the output of the test oscillator to the antenna terminal through a 300-ohm resistor, leaving the test oscillator ground connected as before.

(b) Set the range selector to its "Short wave" position. Set receiver dial pointer to 15,000 kc. (15 on dial). Adjust the test oscillator to 15,000 kc. Adjust the oscillator trimming capacitor C8 to the point which produces maximum (peak) output. Two points may be found, each of which produces a maximum. The one of maximum trimmer capacitance (most clockwise) is correct and should be used.

(c) Adjust the antenna trimming capacitor C5 of the variable condenser, simultaneously rocking the receiver tuning control backward and forward through the 15,000 kc. input signal, until maximum (peak) output results from these combined operations.

"Standard Broadcast" Band

(a) Connect the output of the test oscillator to the antenna terminal through a 200 mmfd. capacitor, leaving test oscillator ground connected as before.

(b) Set the range selector to its "Standard broadcast" position. Set the receiver dial pointer to 1,400 kc. (140 on dial). Adjust the test oscillator to 1,400 kc. Adjust the oscillator and antenna trimming capacitors, C10 and C3 respectively, to the points where each produces maximum (peak) output.

(c) Shift the test oscillator frequency to 600 kc. and tune the receiver to pick up this signal, disregarding the dial reading at which it is best received.

(d) Adjust the low-frequency oscillator trimming capacitor, C12, simultaneously rocking the tuning control of the receiver backward and forward through the signal, until maximum (peak) output results from these combined operations. Repeat adjustments in (b) to compensate for any changes caused by the adjustment of the low-frequency oscillator coil trimming capacitor.

Electrical Specifications

Frequency Ranges
"Standard broadcast" (A) .... 540-1,625 kc.
"Medium wave" (B) .... 1,625-5,700 kc.
"Short wave" (C) .... 5,700-18,000 kc.

Alignment Frequencies
"Standard broadcast" (A) ... 600 kc. (osc.), 1,400 kc. (osc. and ant.)
"Medium wave" (B) .... None required
"Short wave" (C) .... 15,000 kc. (osc. and ant.)

Figure 5—Vibrator Power Unit Wiring

RCA MFG. CO., INC.

Circuit Arrangement

The conventional Superheterodyne circuit is used. The first stage combines the local oscillator and first detector functions in one tube, an RCA-1C6. Coils of the detector input and oscillator are tuned by a two-section variable condenser and are aligned by a total of five adjustable trimmers. Selection of the individually wound coil systems is made by the range selector. The oscillator operates at a fundamental frequency which is at all times above the incoming signal by 460 kc.

An RCA-34 is employed as an i-f amplifier. Its input and output are coupled by transformers to the first detector and second detector, respectively. Each transformer has both its secondary and primary windings tuned to 460 kc. by adjustable trimmer capacitors.

The modulated signal, as obtained from the output of the i-f system, is detected by the diode section of the RCA-75. The a-f voltage appearing across the diode load resistor, R-6, is selected by the variable arm of the volume control (R-6) and passed on to the a-f system for amplification and final reproduction. The d.c. which occurs in resistor R-6 due to signal detection, is used for automatic volume control by varying the control-grid bias on the first detector and i-f tubes.

Resistance-capacitance coupling is used between the RCA-75 and the RCA-30 driver tube. A high-frequency tone control, consisting of a switch in series with a condenser, is shunted across the plate circuit of the RCA-75. When this switch is closed, the high a-f frequencies are reduced.

The power output stage is arranged for Class "B" operation. The high level of power afforded is fed to the permanent magnet dynamic speaker through an output transformer.

Battery "On-Off" control is by means of a double pole switch, one side of which controls the filaments and bias circuits, while the other side controls the vibrator power unit circuit. A fuse is provided in the V. P. U. circuit.

General Description

These instruments each employ a synchronous type vibrator and require only one 6-volt storage battery for power supply.

The receiver chassis of both models are identical. An 8-inch loudspeaker is used in the table model (BT 6-5) and a 10-inch loudspeaker is used in the console model (BC 6-6).

The tuning range afforded by these instruments includes (1) the standard 540-1,600 kc. broadcast band which extends to cover the 1,700 kc. police channels, and (2) a shortwave band from 5,600-18,000 kc. which covers the principal shortwave broadcast stations on the 49, 31, 25, 19, and 16 meter bands.

Outstanding features include automatic volume control, two-point tone control, antenna wave trap, airplane type dial, dual ratio tuning drive, class "B" output stage, and vibrator power unit (V.P.U.)

SERVICE DATA

Alignment Procedure

In readjusting the trimmers to their normal settings, it is quite important to apply a definite procedure and to use adequate and reliable test equipment. A standard source of the specified alignment frequencies is required. It is recommended that such a source consist of an **RCA Stock No. 9595 Full-Range Test Oscillator.** Means for indication of the receiver output during alignment is also necessary to accurately show when the correct point of adjustment is reached. This indication should be obtained by means of such an instrument as the **RCA Stock No. 4317 Neon Glow Indicator.** Proceed with the alignment as follows:

Place the receiver in operation where it will be easily accessible. Attach the output indicator across the loudspeaker voice coil circuit, or across the output transformer primary. Advance the receiver volume control to its maximum position, letting it remain in such position for *all* adjustments. For each trimming operation, regulate the test oscillator output control so that the signal level is as low as possible and still observable at the receiver output. Use of such a small signal will avoid broadness of tuning which would otherwise result from A.V.C. action on a stronger one.

I-F Adjustments

(a) Connect the output of the test oscillator between the control-grid cap of the first detector tube (RCA-1C6) and chassis-ground. Adjust the frequency of the oscillator to 460 kc. Tune the receiver to a point where no interference is received from the heterodyne oscillator or local station.

(b) Adjust the trimmers, C-19 and C-18, of the second i-f transformer, and C-17 and C-16 of the first i-f transformer, so that each produces maximum (peak) receiver output as shown by the indicating device. This completes the i-f trimmer adjustments.

R-F Adjustments

(a) Check the calibration of the dial scale by rotating the tuning control until the variable condenser plates are in full mesh. (Maximum capacity.) Then adjust the dial pointer until it points to the *horizontal* line at the low frequency end of the broadcast band scale.

(b) Connect the output of test oscillator to the antenna-ground terminals of the receiver. Adjust the receiver range switch to its Band A (broadcast) position. Tune the oscillator to 1,720 kc. Allow the output indicator to remain attached to the receiver output.

(c) Tune the receiver so that the dial reading is 1,720 kc. Then adjust the oscillator and antenna coil trimmers, C-12 and C-4 respectively, tuning each to the point producing maximum indicated receiver output.

(d) Shift the oscillator frequency to 600 kc. and tune the receiver to pick up this signal, disregarding the dial reading at which it is best received. The oscillator series trimmer, C-15, should then be adjusted, simultaneously rocking the receiver tuning control backward and forward through the signal until maximum receiver output results from the combined operations. The adjustment of C-12 should be repeated as in (c) to correct for any changes in its alignment due to the adjustment of C-15.

(e) Shift the oscillator frequency to 18,000 kc. Adjust the receiver range switch to its Band C (shortwave) position, and set the receiver dial to a reading of 18,000 kc. The oscillator and antenna trimmers, C-11 and C-3, should then be adjusted for maximum indicated receiver output.

Retune receiver to 17,080 kc. and check for image signal. If C-11 has been correctly aligned, the 18,000 kc. signal will be received. It may be necessary to increase the oscillator output for this indication of the "image." ***No adjustments should be made during this check.***

Vibrator Power Unit

The Vibrator Power Unit supplies the necessary plate, screen, and cathode voltage for proper operation of the receiver. It contains a plug-in type vibrator, step-up transformer, and an efficient filter system. Rectification of the high voltage is by means of the synchronous vibrator. The complete unit is acoustically shielded to prevent noise. *The radio chassis is 1 volt negative with respect to the vibrator chassis and, therefore, it is necessary to insulate the vibrator power unit from the chassis when they are removed for service purposes.* The vibrator unit has been carefully adjusted by means of special equipment to insure quiet operation over an extensive period of life. No adjustments should be attempted on a vibrator suspected of being in a defective condition, but a renewal installed. A convenient plug-in base is provided for effecting a quick replacement.

Radiotron Socket Voltages

Voltage values indicated at the Radiotron socket contacts on Figure 4 form a reference basis for test of the receiver. All voltages are given in respect to chassis-ground. The values shown are obtainable when the receiver is in normal operating condition. They do not take into account inaccuracies caused by current consumed in the voltmeter used for the tests. The lower the meter resistance, the lower will be the degree of accuracy. Allowances must therefore be made, dependent upon the type of test instrument used, for the loading effect of the voltmeter on the circuit.

Wave-Trap Adjustment

With the receiver in operation using its normal antenna, tune station selector to the point at which the intermediate frequency interference is most intense. Then adjust the wave trap trimmer to the point which causes maximum suppression of the interference.

NOTES

(1) **Beat notes or heterodyning (whistles)** may be encountered in some instances on these receivers due to excessive antenna capacitance. This condition may be corrected by reducing the size of the antenna or by inserting a 150 mmfd. capacitor in series with the antenna lead at the antenna terminal. Interference in the form of "beats" from a combination of local stations may frequently be remedied by tuning the wave trap to one of the interfering stations.

RCA MFG. CO., INC.

General Features

These two models each employ the same six-tube chassis. They have the new metallic tubes. The tuning range is from 540 to 18,000 kc. The coverage includes domestic broadcast, police, aircraft and amateur services, and also the important foreign short-wave broadcast bands at 49, 31, 25, 19 and 16 meters. Chassis features include automatic volume control, high-frequency tone control, antenna wave trap and audio tone compensation. The table model (T 6-7) uses an 8-inch dynamic speaker, and the console model (C 6-8) uses an improved 12-inch dynamic speaker. The tuning dial is an illuminated semi-airplane type. Positions of the range selector knob are marked on the control panel to show which tuning band is in use. The tuning control is of the dual-ratio type, which permits rough tuning through a 10-1 drive ratio and vernier tuning through a 50-1 drive ratio. The latter is especially advantageous for accurate tuning of the short-wave stations.

Circuit Arrangement

The conventional superheterodyne type of circuit, consisting of a combined first detector-oscillator stage, a single i-f stage, a diode detector-automatic volume control stage, an audio voltage amplifier stage, an audio power output stage and a half-wave rectifier power supply stage, is used.

Tuned Circuits

The antenna coil system consists of a single primary and three series-connected secondary windings to provide the three ranges of tuning. The oscillator coil system is similarly wound on a single form. A range selector switch (S-1) is used for connecting the various sections of these two coil systems into the circuit to provide operation on the band desired. The coils are tuned by a variable two-section gang condenser having trimmer capacitors in shunt with each section. There are additional trimmer capacitors across the section of each coil used for Band "A." A series trimmer is also associated with the Band "A" oscillator coil.

The intermediate frequency amplifier system consists of an RCA-6K7 in a transformer-coupled circuit. This stage operates at a basic frequency of 460 kc. Each winding of both i-f transformers (input and output) is tuned by an adjustable trimmer.

Detector and A.V.C.

The modulated signal as obtained from the output of the i-f stage is detected by an RCA-6H6 twin-diode tube. The audio frequency secured by this process is transferred to the a-f system for amplification and final reproduction. The d-c voltage which results from detection of the signal is used for automatic volume control. This voltage, which develops across resistor R-8, is applied as automatic control grid bias to the first detector and i-f tubes through a suitable resistance filter circuit. The second (auxiliary) diode of the RCA-6H6 is used to supply residual bias for the controlled tubes under conditions of little or no signal. This diode, under such conditions, draws current which flows through resistors R-8, R-9 and R-10, thereby maintaining the desired minimum operating bias on such tubes. As soon as the rectified signal current develops sufficient voltage across resistor R-8, in opposition to that across resistors R-20 and R-21, current ceases to flow in the auxiliary diode circuit and the signal A.V.C. diode takes over the biasing function.

Audio System

The manual volume control consists of an acoustically tapered potentiometer in the audio circuit between the output of the detector diode and the input grid of the audio voltage amplifier tube. This control has a tone compensating filter connected to it, so that the correct aural balance will be obtained at different volume settings.

Resistance-capacitance coupling is used between the first audio stage and the power output stage. The output of the power amplifier is transformer-coupled into the dynamic loudspeaker. High-frequency tone control is effected by a capacitor across the plate circuit of the output tube. This capacitor may be cut in or out of the circuit as desired by means of a switch (S-3).

Rectifier

The plate, grid, and cathode voltages required for the operation of this receiver are supplied by the RCA-25Z6 rectifier (plates and cathodes connected in parallel respectively) in series with the supply line operating as a half-wave rectifier. The field of the loudspeaker is connected across the input to the filter. The filter circuit consists of reactor L-19 and capacitors C-37 and C-38. An additional capacitance C-36 is connected in parallel with C-37 in models designed for 25-cycle operation.

The filaments of all six tubes are connected in series and are fed direct from the supply line, the voltage being dropped to the required value by resistors R-18 and R-19. The correct operating voltage for the pilot lamp is developed across resistor R-19. This voltage across the pilot lamp will be slightly high when the set is first turned on, but will quickly drop to a normal value as soon as the tube filaments reach their operating temperature.

SERVICE DATA

CAUTION: Grid caps, tuning condenser, and resistor on top of chassis may be hot with respect to external ground and should be avoided when servicing, unless due precautions are taken.

The various diagrams of this bulletin contain such information as will be needed to isolate causes for defective operation when such a condition develops. Ratings of the resistors, capacitors, coils, etc., are indicated adjacent to the symbols signifying these parts on the diagrams. Identification titles, such as R-3, L-2, C-1, etc., are provided for reference between the diagrams and the replacement parts list. Locating of the parts in the schematic circuit is facilitated by the fact that the numerical titles increase from left to right on the diagram. The coils, reactors, and transformer windings are rated in terms of their d-c resistances only.

Alignment Procedure

Precise alignment is vital to the proper functioning of this receiver. There are four trimming adjustments provided in the i-f system, three in the oscillator coil system and two in the antenna coil system. These trimmers have been accurately adjusted during manufacture and should remain properly aligned unless affected by abnormal conditions of climate, or have been altered for service purposes. Incorrect alignment is usually evidenced by loss of sensitivity, improper tone quality and poor selectivity. These indications will generally be present together.

The correct performance of the receiver can only be obtained when the alignment is performed with adequate and reliable test apparatus. The manufacturer of this instrument has a complete assortment of such service equipment available. This equipment may be purchased from authorized distributors and dealers.

An oscillator (signal generator) is required as a source of the specified alignment frequencies. Visual indication of receiver output during the adjustment is necessary to enable the serviceman to obtain an accuracy of alignment which is not possible by listening to the signal. The RCA Victor Stock No. 9595 Full Range Oscillator and the RCA Victor Stock No. 4317 Neon Output Indicator are especially suitable and fulfill the above requirements.

The following procedure should be followed in adjusting the various trimmer capacitors:

I-F Trimmer Adjustments

The four trimmers of the two i-f transformers are located as shown by Figure 4. Each must be aligned to a basic frequency of 460 kc. To do this, attach the output indicator across the voice coil circuit or across the output transformer primary. Connect the output of the test oscillator through a .05 mfd. condenser to the RCA-6A8 control grid. Tune the oscillator to 460 kc. Advance the receiver volume control to its full-on position and adjust the receiver tuning control to a point within its range where no interference is encountered either from local broadcast stations or the heterodyne oscillator. Increase the output of the test oscillator until a slight indication is apparent on the output indicator. Then adjust the two trimmers, C-23 and C-24, of the second i-f transformer to produce maximum (peak) indicated receiver output. Then, adjust the two trimmers, C-20 and C-21, of the first i-f transformer for maximum (peak) receiver output as shown by the indicating device. During these adjustments, regulate the test oscillator output so that the indication is always as low as possible. By doing so, broadness of tuning due to A.V.C. action will be avoided. It is advisable to repeat the adjustment of all i-f trimmers a second time to assure that the interaction between them has not disturbed the original adjustment.

R-F Trimmer Adjustments

The two trimmers, which are at all times directly in shunt with the variable tuning condenser, necessitate that the high-frequency range (Band C) be aligned first. The range selector switch should, therefore, be turned to its Band C position for the initial adjustment. The output indicator should be left connected to the output system and the volume control kept at maximum. Attach the output terminals of the test oscillator to the antenna and ground terminals of the receiver input.

Calibrate the dial by rotating the tuning control until the variable condenser plates are in their full mesh (maximum capacity) position and adjusting the dial pointer so that its end points to the horizontal graduation (approximately 530 kc) at the low-frequency end of the Band A scale.

Proceed further as follows:

(a) Adjust the test oscillator to 18,000 kc. and set the receiver tuning control to a dial reading of 18,000 kc.

(b) Regulate the output of the test oscillator until a slight indication is perceptible at the receiver output. Then adjust the trimmer C-13 on the oscillator section of the variable condenser to the point at which it produces maximum indicated receiver output. Two points may be found, each of which produces such a maximum. The one of *maximum trimmer capacitance* is correct and should be used. (The oscillator will be 460 kc. below the signal frequency at this adjustment point.)

(c) Adjust the trimmer C-5 of the antenna section of the variable condenser, simultaneously rocking the receiver tuning control backward and forward through the 18,000 kc. input signal, until maximum receiver output results from these combined operations. Rocking of the variable condenser will prevent inaccurate adjustment, which would otherwise be caused by the interaction between the heterodyne oscillator circuit and the antenna tuned circuit.

(d) Change the receiver range selector to its Band A position and set the receiver tuning control to a dial reading of 1400 kc. Tune the test oscillator to this same frequency and regulate its output to produce a slight indication on the receiver output indicating device.

(e) Adjust the high-frequency trimmers of the Band A oscillator and antenna coils, C-14 and C-7 respectively, to the points at which each produces maximum indicated receiver output.

(f) Shift the test oscillator frequency to 600 kc. and tune the receiver to pick up this signal, disregarding the dial reading at which it is best received.

(g) Tune the low-frequency trimmer C-16 of the oscillator Band A coil, simultaneously rocking the tuning control of the receiver backward and forward through the signal, until maximum indicated receiver output results from these combined operations. The adjustment of C-14 and C-7 should be corrected at 1400 kc. to compensate for any changes caused by the adjustment of the low-frequency oscillator coil trimmer.

Radiotron Socket Voltages

The voltage values indicated from the Radiotron socket contacts and grid caps to –B ground bracket on Figure 4 will assist in the location of causes for faulty operation. Each value as specified should hold within ±20% when the receiver is normally operative at its rated line voltage. Variations in excess of this limit will usually be indicative of trouble in the basic circuits. These voltages were measured with set tuned to approximately 900 kc. (Band A) no signal being received and volume control at minimum. To duplicate the conditions under which the voltages were measured requires a 1000-ohm-per-volt d-c meter, having ranges of 10, 50 and 250 volts. Voltages below 10 read on 10-volt scale, between 10 and 50 on 50-volt scale, and between 50 and 250 on 250-volt scale. A-C voltages were measured with a corresponding a-c meter.

Wave Trap Adjustment

With the receiver in operation using its normal antenna, tune station selector to the point at which the intermediate frequency interference is most intense. Then adjust the wave trap trimmer to the point which causes maximum suppression of the interference.

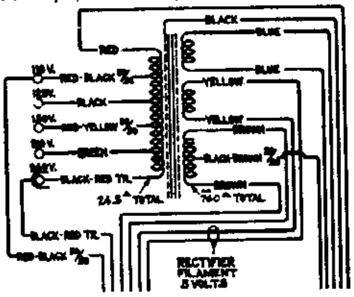
Circuit Data, Alignment
Transformer. Parts

General Features

These receivers each employ the same chassis and have many distinctive features. Model T6-11 employs an 8-inch dynamic loudspeaker and Model C6-12 employs a 12-inch dynamic loudspeaker.



An adjustable wave trap, in parallel with the antenna input, serves to suppress code interference which may be encountered in certain localities from intermediate frequency radio telegraph signals.

The first detector and oscillator functions are accomplished in a single tube, an RCA-6A8. The input of this tube is coupled to the antenna through a tuned transformer. A shunt (permeability tuned) wave trap is connected across the primary of this transformer to prevent signals of intermediate frequency (460 kc.) from being introduced into the first stage as interference. The two-section gang condenser, which tunes the antenna transformer secondary and the heterodyne oscillator coil, has adjustable trimmers for obtaining exact alignment. Each of these coils is tapped so that the range switch increases the range of tuning by decreasing the amount of inductance.

Circuit Arrangement

The intermediate frequency stage is coupled to the RCA-6A8 and to the RCA-6H6 by means of tuned transformers. These transformers resonate with fixed capacitors and are tuned by molded cores to 460 kc.

The modulated signal as obtained from the output of the i-f system is detected by an RCA-6H6 twin-diode tube. Audio frequency secured by this process is passed on to the a-f system for amplification and final reproduction. The d-c voltage, which results from detection of the signal, is used for automatic volume control. This voltage, which develops across the volume control resistor R-7, is applied as automatic control grid bias to the first detector and i-f tubes through a suitable resistance filter. The second diode of the RCA-6H6 is used to supply residual bias for the controlled tubes under conditions of little or no signal. This auxiliary diode, under such conditions, draws current which flows through resistors R-5 and R-7, thereby maintaining the desired minimum operating bias on such tubes. On application of signal energy above a certain level, however, the auxiliary bias diode ceases to draw current and the a.v.c. diode takes over the biasing function.

Manual volume control is effected by means of an acoustically tapered potentiometer connected as a variable coupling element between the output of the second detector and the first audio control grid. After amplification by the RCA-6F5, the audio signal is transmitted by resistance-capacitance coupling to the input of the RCA-6F6 power output stage, which, in turn, is transformer-coupled to the dynamic speaker. High-frequency tone control is provided by means of a shunt capacitor across the plate circuit of the output tube, which may be cut in or out of the circuit with a control switch (S-4).

The power supply system consists of an RCA-5Z4 rectifier tube which is supplied from an efficiently designed power transformer and which works into a suitable filter. The various potentials required for the plate, screen, control grid, and cathode circuits are obtained from the output of the filter. The electrodynamic loudspeaker field coil is used as a filter reactor.

SERVICE DATA

The various diagrams of this booklet contain such information as will be needed to isolate causes for defective operation when such develops. The ratings of the resistors, capacitors, coils, etc., are indicated adjacent to the symbols signifying these parts on the diagrams. Identification titles, such as R-3, L-2, C-1, etc., are provided for reference between the illustrations and the Replacement Parts List. The coils, reactors, and transformer windings are rated in terms of their d-c resistances only. Ratings of less than one ohm are generally omitted.

Alignment Procedure

There are three alignment trimmers provided in the antenna transformer and oscillator coil tuned circuits. The i-f transformer adjustments are made by means of screws attached to molded cores. All of these circuits have been accurately adjusted during manufacture and should remain properly aligned unless affected by abnormal conditions or altered during servicing. Loss of sensitivity, improper tone quality, and poor selectivity are the usual indications of improper alignment.

The correct performance of this receiver can only be obtained when the aligning has been done with adequate and reliable apparatus. The manufacturer of this receiver has available, for sale through its distributors and dealers, a complete assortment of such service equipment as may be needed for the alignment operation.

An oscillator is required as a source of the specified alignment frequencies. Visual indication of receiver output during the adjustment is necessary and should be accomplished by the use of an indicator.

The following method of procedure should be followed in adjusting the various trimmer capacitors and molded cores:

I-F Core Adjustments

The four adjustment screws (attached to molded cores) of the two i-f transformers (one on top and one on bottom of each i-f transformer) are located as shown by Figures 3 and 6. Each circuit must be aligned to a basic frequency of 460 kc. To do this, attach the output indicator across the loudspeaker voice coil or across the output transformer primary. Connect the output of the test oscillator between the control grid of the RCA-6A8 and chassis ground. Tune the oscillator to 460 kc. Advance the receiver volume control to its full-on position and adjust the receiver tuning control to a point, within its range, where no interference is encountered either from local broadcast stations or from the heterodyne oscillator. Increase the output of the test oscillator until a slight indication is present on the output indicator. Then, adjust the two screws of the second i-f transformer to produce maximum (peak) indicated receiver output. Then, adjust the two screws of the first i-f transformer for maximum (peak) receiver output as shown by the indicating device. During these adjustments, regulate the test oscillator output so that the indication is always as low as possible. By doing so, broadness of tuning due to a.v.c. action will be avoided. It is advisable to repeat the adjustment of all i-f screws to assure that the interaction between them has not disturbed the original adjustment.

R-F Trimmer Adjustments

Calibrate the tuning dial by setting pointer to horizontal line at low-frequency end of broadcast band scale while variable condenser is at maximum capacity.

The output indicator should be left connected to the output system. Attach the output of the test oscillator between the antenna and ground terminals of the receiver input. Adjust the oscillator to 1,720 kc. and set the receiver tuning control to a dial reading of 1,720 kc. Leave the volume control of the receiver at its maximum position. Make sure that the range selector is at its broadcast position. Regulate the output of the test oscillator until a slight indication is perceptible at the receiver output. Then adjust the two trimmers, C-6 and C-4, of the oscillator and antenna transformer coils (mounted on the variable condenser) so that each produces maximum (peak) receiver output. After this maximum has been accurately obtained, shift the test oscillator to 600 kc. Tune the receiver to pick up this signal, disregarding the dial reading at which it is best received. Then, adjust the receiver oscillator series trimmer, C-9, simultaneously rocking the tuning control backward and forward through the signal until maximum receiver output results from these combined operations. The adjustment at 1,720 kc. should then be repeated to correct for any change which may have been caused by the oscillator series trimmer adjustment.

Radiotron Socket Voltages

Voltage values indicated at the Radiotron socket contacts on Figure 6 form a reference basis for test of the receiver. It is to be noted that all voltages are given with respect to chassis ground, excepting those appearing across the heaters (H-H). The values shown are obtainable when the receiver is in normal operating condition, with all tubes intact. They do not take into account inaccuracy caused by the resistance of the voltmeter used for the tests, the lower the voltmeter resistance the lower the degree of accuracy. Allowance must, therefore, be made, dependent upon the type of test instrument used, for the loading effect of the voltmeter on the circuit.

Wave-Trap Adjustment

With the receiver in operation using its normal antenna, tune station selector to the point at which the intermediate frequency interference is most intense. Then adjust the wave trap screw (core) to the point which causes maximum suppression of the interference.

General Description

These receivers represent the result of thorough development, design, and substantial manufacture. Noteworthy technical improvements have been applied in achieving marked advantages of operation and efficiency of performance.

Model 7T is a seven-tube, table-type, superheterodyne receiver with an eight-inch electrodynamic loudspeaker. Model 7K differs from the Model 7T in that it is of the console type and has a twelve-inch electrodynamic loudspeaker.

Models 8T and 8K are similar to Models 7T and 7K respectively, except for the addition of a tuning tube "Magic Eye" and different cabinet designs.

Design features incorporated in these receivers include: built-in doublet antenna coupler; improved plunger-type air-dielectric adjustable trimming capacitors in the antenna and oscillator coil circuits; high-efficiency first detector (converter) with separate oscillator; magnetite core adjusted i-f transformers, low-frequency oscillator tracking, and wave-trap; aural compensated volume control; continuously variable tone control with music-voice switch; automatic volume control; phonograph terminal board; band selective indication of dial scales; and a dust-proof electrodynamic loudspeaker.

The tuning range is continuous through the "Standard broadcast," "Medium wave," and "Short wave" bands. This extensive range includes the important short-wave broadcast bands at 49, 31, 19, 16, and 13 meters in addition to channels assigned for police, amateur, and aviation communication. Trimming adjustments are located at accessible points. Their number is reduced to the least that is consistent with efficient operation. A double tuning knob arrangement permits the choice of either a ten-to-one or a fifty-to-one dial ratio, the latter permits ease of tuning, especially in the "Medium wave" and "Short wave" bands.

Circuit Arrangement

The conventional type of superheterodyne circuit is used. It consists of a first-detector (converter) stage, separate oscillator stage, a single i-f stage, a diode-detector — automatic-volume-control stage, an audio voltage-amplifier stage, a pentode power-output stage, and a full-wave rectifier stage. Models 8T and 8K also have a tuning indicator "Magic Eye."

A single-wire antenna, or a doublet antenna, when connected to the proper input terminals of the receiver, is coupled to control grid No. 1 of the RCA-6L7 through a tuned r-f transformer. This transformer is tapped so that the range selector increases the range of tuning by decreasing the amount of inductance. A unique method of switching causes L5 to become the primary with L4, L3, and L2 as secondary, L4 to become the primary with L3 and L2 as secondary, and L3 to become the primary with L2 as secondary, for range selector positions "Standard broadcast," "Medium wave," and "Short wave" respectively. Separate windings are employed in the oscillator stage for each position of the range selector. All unused portions of the antenna and oscillator coils are shorted out to prevent undesirable interaction. Air-dielectric trimming capacitors are used for obtaining exact alignment. Proper low-frequency tracking of the oscillator for "Standard broadcast" is accomplished by adjusting the inductance of the respective coil with a molded magnetite core.

The intermediate-frequency amplifier consists of an RCA-6K7 in a transformer-coupled circuit. The windings of these transformers are resonated with fixed capacitors, and are adjusted by molded magnetite cores (both primary and secondary) to tune to 460 kc.

Detector and A.V.C.

The modulated signal as obtained from the output of the i-f stage is detected by an RCA-6H6 twin-diode tube. The audio frequency secured by this process is transferred to the a-f system for amplification and final reproduction. The d-c voltage which results from detection of the signal is used for automatic volume control. This voltage, which develops across resistor R9, is applied as automatic control-grid bias to the first-detector and i-f tubes. The second (auxiliary) diode of the RCA-6H6 is used to supply residual bias for the controlled tubes under conditions of little or no signal. This diode, under such conditions, draws current which flows through resistors R7 and R9, thereby maintaining the desired operating bias on such tubes. On application of signal energy above a certain level, however, the auxiliary bias-diode ceases to draw current and the a.v.c.-diode takes over the biasing function.

Audio System

The manual volume control consists of an acoustically tapered potentiometer in the audio circuit between the output of the detector diode and the input grid of the audio voltage-amplifier tube. This control has a tone-compensating filter connected to it so that the correct aural balance will be obtained at different volume settings. Phonograph terminals are inserted at this point for feeding the output of an external phonograph pickup to the control grid of the audio amplifier. Resistance-capacity coupling is used between the first-audio stage and the power-output stage. The power-output stage is transformer-coupled to the electrodynamic loudspeaker. Continuously-variable tone control is effected by means of capacitor C34 and variable resistor R16 shunting the plate circuit of the output tube. Extreme clockwise rotation of this tone control disconnects the resistor R16 from the circuit and places an additional capacitor C33 in shunt with capacitor C27, thereby reducing the low-frequency response of the amplifier. This point is known as the "Speech" position and provides optimum intelligibility of speech.

Tuning Indicator (Models 8T and 8K only)

An RCA-6E5 cathode-ray tuning tube is used as a means of visually indicating when the receiver is accurately tuned to the incoming signal. This tube consists of an amplifier section and a cathode-ray section built in the same glass envelope. Maximum sensitivity of the tuning indicator is acquired in the "Short wave" position of the range selector S2 by removing the ground connection from resistor R21. In this position, resistors R20 and R21 no longer act as a voltage divider and maximum voltage is applied to the grid of the tuning tube.

SERVICE DATA

Alignment Procedure

There are eight adjustments required for the alignment of the antenna, oscillator, and wave-trap tuned circuits. Six of these adjustments are made with plunger-type air trimming capacitors, and require the use of an **RCA Stock No. 12636 adjusting tool**. The other two adjustments are screws attached to molded magnetite cores and are used to adjust the wave-trap and to align the oscillator at 600 kc. Before adjusting the plunger-type air trimmers, they must be unlocked by loosening their hexagon lock nuts. The lock nuts should be tightened upon completion of adjustments.

The i-f transformer adjustments are made by means of four screws attached to molded magnetite cores.

All of the adjustable circuits of this receiver have been properly aligned at the factory to give correct performance, and their settings should remain intact indefinitely when the receiver is used under ordinary conditions. However, necessity for re-adjustment may occasionally occur from continued extremes of temperature, climate, tampering, or purported alteration for services, or after repairs have been made to the r-f or i-f tuned circuits. Improper alignment usually causes the impairment of sensitivity, selectivity, and tone quality. Such conditions will generally exist simultaneously.

In re-adjusting the tuned circuits, it is important to apply a definite procedure and to use adequate and reliable test equipment. A standard test oscillator, such as an **RCA Stock No. 9595**, will be required as the source of signal at the specified alignment frequencies. Means for indication of the receiver output during alignment is also necessary to accurately show when the correct point of adjustment is reached. Two indication methods are applicable—one requires use of the cathode-ray oscillograph, and the other requires a voltmeter or glow-type indicator. The cathode-ray alignment method is advantageous in that the indication provided is in the form of a wave image which represents the resonance characteristics of the circuits being tuned. This type of alignment is possible through use of apparatus such as the **RCA Stock No. 9558 Frequency Modulator** and the **RCA Stock No. 9545 Cathode-Ray Oscillograph**. The output indicator method should be performed with an instrument such as the **RCA Stock No. 4317 Neon Glow Indicator**. The two procedures are outlined as follows:

Cathode-Ray Alignment

Make alignment apparatus connections shown on figure 4. Remove the plug of the frequency modulator cable from the test oscillator jack. Connect the receiver chassis to a good external ground. Connect oscillograph "Vertical" input terminals as indicated on figure 2. Set oscillograph power switch to "On" and adjust "Intensity" and "Focus" controls to give a clearly defined spot, or line, on the screen. Set oscillograph "Ampl. A" switch to "On," "Vertical gain" control full clockwise, "Ampl. B" switch to "Timing," "Range" switch to No. 2 position, and "Timing" switch to "Int." Place the "Sync." control, "Freq." control, and "Horizontal gain" control to about their mid-positions. For each of the following adjustments, the test oscillator output must be regulated so that the image obtained on the oscillograph screen will be of the minimum size for accurate observation. The receiver volume control setting is optional.

I-F Adjustments

(a) Connect the "Ant." output of the test oscillator to the grid cap of RCA-6K7 (with grid lead in place) through a .001-mfd. capacitor, with "Gnd." to receiver chassis. Tune the test oscillator to 460 kc, place its modulation switch to "On" and its output switch to "Hi."

(b) Turn on the receiver and test oscillator. Increase the output of the test oscillator until a deflection is noticeable on the oscillograph screen. The figures obtained represent several waves of the detected signal, the amplitude of which may be observed as an indication of output. Cause the wave image formed (400-cycle waves) to be spread completely across the screen by adjusting the "Horizontal gain" control. The image should be synchronized and made to remain motionless by adjusting the "Sync." and "Freq." controls.

(c) Adjust the two magnetite core screws (see figures 3 and 7) of the second i-f transformer (one on top and one on bottom) to produce maximum vertical deflection of the oscillographic image. This adjustment places the transformer in exact resonance with the 460-kc signal.

(d) The sweeping operation should follow using the frequency modulator. Shift the oscillograph "Timing" switch to "Ext." Insert plug of frequency modulator cable in test oscillator jack. Turn the test oscillator modulation switch to "Off." Turn on the frequency modulator and place its sweep-range switch to "Hi."

(e) Increase the frequency of the test oscillator by slowly turning its tuning control until two separate, distinct, and similar waves appear on the screen. If only one wave appears, increase the "Freq." control on the oscillograph to obtain two waves. These waves will be identical in shape, totally disconnected, and appear in reversed positions. They will have a common base line, which is discontinuous. Adjust the "Freq." and "Sync." controls of the oscillograph to make them remain motionless on the screen. Continue increasing the test oscillator frequency until these forward and reverse curves move together and overlap, with their highest points exactly coincident. This condition will be obtained at a test oscillator setting of approximately 575 kc.

(f) With the images established as in (e), re-adjust the two magnetite core screws on the second i-f transformer so that they cause the curves on the oscillograph screen to become exactly coincident throughout their lengths and have maximum amplitude.

(g) Without altering the adjustments of the apparatus, shift the "Ant." output of the test oscillator to the input of the i-f system, i.e., to the RCA-6L7 first-detector grid cap through a .001-mfd. capacitor (with grid lead in place). Regulate the test oscillator output so that the amplitude of the oscillographic image is approximately the same as used above for adjustment (f).

(h) The two first i-f transformer magnetite core screws (one on top and one on bottom) should then be adjusted so that they cause the forward and reverse curves to become coincident throughout their lengths and have maximum amplitude. The composite wave obtained in this manner represents the resonance characteristic of the total i-f system. Lack of symmetry or irregularity of the resultant image will indicate the presence of a defect in the i-f system.

R-F Adjustments

Calibrate the pointer of the tuning dial by adjusting it to the extreme low-frequency end of dial scale (beyond 55 on dial) with the plates of the gang tuning condenser in full mesh. Alignment must be made in the sequence of "Short wave" band, "Medium wave" band, "Wave-trap," and "Standard broadcast" band.

"Short Wave" Band

(i) Connect the "Ant." output of the test oscillator to the antenna terminal "A1" through a 300-ohm resistor. Remove the plug of the frequency modulator cable from the test oscillator. Turn test oscillator modulation switch to "On." Shift the oscillograph "Timing" switch to "Int."

(j) Set receiver range selector to its "Short wave" position and dial pointer to 20,000 kc. Adjust the test oscillator to 20,000 kc. Set oscillator air trimmer C13 to minimum capacity (plunger full out), and antenna air trimmer C5 to maximum capacity (plunger full in). Slowly push in oscillator trimmer C13 until maximum (peak) amplitude of output is reached. Two peaks may be found. Adjust C13 to the peak with minimum capacity (plunger near out) for maximum indication. Tighten lock nut. Slowly pull out plunger of antenna air trimmer C5 until maximum (peak) amplitude of output is reached while slightly rocking the gang tuning condenser back and forth through the signal. Two peaks may be found with this circuit. The peak with maximum capacity (plunger near in) should be used. Tighten lock nut.

"Medium Wave" Band

(k) Place receiver range selector to its "Medium wave" position with the receiver dial pointer set to 6,000 kc. Tune the test oscillator to 6,000 kc. Carefully adjust the oscillator and antenna air trimmers C14 and C6 respectively, so that each brings about maximum (peak) amplitude of output as shown by the wave on the oscillograph. When adjusting the oscillator trimmer C14, two peaks may be found. The one of minimum capacitance (plunger near out) should be used. Tighten lock nuts.

"Wave-Trap" Adjustment

(l) Connect the output of the test oscillator to the antenna terminal "A1" through a 200 mmfd. (important) capacitor. Place receiver range selector in "Standard broadcast" position. Set the receiver dial to a position of no extraneous signals near 600 kc. Tune the test oscillator to 460 kc. Adjust the wave-trap magnetite core screw to the point which causes minimum amplitude of output (maximum suppression of signal) as shown by the wave on the oscillograph. An increase of the test-oscillator output may be necessary before this point of minimum amplitude, obtained by correct adjustment of wave-trap screw, becomes apparent on oscillograph screen.

"Standard Broadcast" Band

(m) Reduce output of test oscillator to minimum. Set receiver dial pointer to 600 kc. Tune the test oscillator to 600 kc and increase its output until a deflection is noticeable on the oscillograph screen.

(n) Adjust oscillator magnetite core screw (top of oscillator coil) so that maximum (peak) amplitude of output is shown on the oscillograph screen.

(o) Set receiver dial pointer to 1,500 kc. Set the test oscillator to 1,500 kc (1,500-3,100-kc range) and increase its output to produce a registration on the oscillograph. Carefully adjust the oscillator and antenna air trimmers C16 and C7 respectively so that each brings about maximum (peak) amplitude of output as shown by the waves on the oscillograph. Shift the oscillograph "Timing" switch to "Ext." Place the frequency modulator sweep-range switch to "Lo" position and insert plug of the frequency modulator cable in test oscillator jack. Turn test oscillator modulation switch to "Off." Retune the test oscillator (increase frequency) until the forward and reverse waves show on the oscillograph screen and become coincident at their highest points. This will occur at a test oscillator setting of approximately 1,680 kc. Adjust the trimmers C16 and C7 again, setting each to the point which produces the best coincidence and maximum amplitude of the images.

(p) Remove the plug of the frequency modulator cable from test oscillator jack. Turn test oscillator modulation switch to "On." Set oscillograph "Timing" switch to "Int." Tune test oscillator to 200 kc. (200-400-kc range). Tune receiver for maximum response to this signal at a dial reading of approximately 600 kc. Third harmonic of 200 kc is used for this adjustment. Shift oscillograph "Timing" switch to "Ext." Insert the plug of the frequency modulator cable in test oscillator jack. Turn test oscillator modulation switch to "Off." Retune the test oscillator (increase frequency) until the forward and reverse waves show on the oscillograph screen. This will occur at a test oscillator setting of approximately 230 kc. Disregarding the fact that the two images may come together, adjust the oscillator magnetite core screw (top of oscillator coil) to produce maximum amplitude of images. Shift oscillograph "Timing" switch to "Int." Remove the plug of the frequency modulator cable from the test oscillator. Turn test oscillator modulation switch to "On." Repeat adjustment (o), and then lock C16 and C7.

Output Indicator Alignment

Attach the output indicator across the loudspeaker voice-coil circuit. Advance the receiver volume control to its maximum position, letting it remain in such position for all adjustments. For each adjusting operation, regulate the test oscillator output so that the signal level is as low as possible and still be observable at the receiver output. Use of such small signal will obviate broadness of tuning which would otherwise result from a.v.c. action on a stronger one.

I-F Adjustments

(a) Connect the "Ant." output of the test oscillator to the grid cap of the RCA-6L7 (with grid lead in place) through a .001-mfd. capacitor, with "Gnd." to receiver chassis. Tune the test oscillator to 460 kc, place its modulation switch to "On" and its output switch to "Hi."

(b) Adjust the two magnetite core screws of the second i-f transformer (one on top and one on bottom), to produce maximum (peak) output.

(c) The two first i-f transformer magnetite core screws (one on top and one on bottom) should be adjusted to produce maximum (peak) output

MODELS 7T,7K,8T,8K
Alignment,Part 2
Parts List

RCA MFG. CO., INC.

It is advisable to repeat the adjustment of all i-f magnetite core screws to assure that the interaction between them has not disturbed the original adjustments.

R-F Adjustments

Calibrate the pointer of the tuning dial by adjusting it to the extreme low-frequency end of dial scale (beyond 55 on dial) with the plates of the gang tuning condenser in full mesh. Alignment must be made in sequence of "Short wave" band, "Medium wave" band, "Wave-trap", and "Standard broadcast" band.

"Short Wave" Band

(d) Connect the "Ant." output of the test oscillator to the antenna terminal "A1" through a 300-ohm resistor, leaving the "Gnd." of the oscillator connected to the receiver chassis.

(e) Place range selector to its "Short wave" position. Set receiver dial pointer to 20,000 kc. Adjust test oscillator to 20,000 kc. Set oscillator air trimmer C13 to minimum capacity (plunger full out), and antenna air trimmer C5 to maximum capacity (plunger full in). Slowly push in oscillator trimmer C13 until maximum (peak) output is reached. Two peaks may be found. Adjust C13 to the peak with minimum capacity (plunger near out) for maximum indication. Tighten lock nut. Slowly pull out plunger of antenna air trimmer C5 until maximum (peak) output is reached while slightly rocking the gang tuning condenser back and forth through the signal. Two peaks may be found with this circuit. The peak with maximum capacity (plunger near in) should be used. Tighten lock nut.

"Medium Wave" Band

(f) Place the receiver range selector to its "Medium wave" position, with the receiver dial pointer set to 6,000 kc. Tune test oscillator to 6,000 kc. Carefully adjust the oscillator and antenna air trimmers C14 and C6 respectively, so that each brings about maximum (peak) output. When adjusting the oscillator trimmer C14, two peaks may be found. The one of minimum capacitance (plunger near out) should be used.

"Wave-Trap" Adjustment

(g) Connect the "Ant." output of the test oscillator to the antenna terminal "A1" through a 200 mmfd. (important) capacitor. Place the range selector to its "Standard broadcast" position and set the receiver dial pointer to a position of no extraneous signals near 600 kc. Tune the test oscillator to 460 kc. Adjust the wave-trap magnetite core screw to the point which causes minimum output (maximum suppression of signal) An increase of the test-oscillator output may be necessary before the point of minimum output, obtained by adjustment of wave-trap screw, becomes apparent on the output indicator.

"Standard Broadcast" Band

(h) Reduce output of test oscillator to a minimum. Tune the test oscillator to 600 kc and set receiver dial pointer to 600 kc. Adjust output of test oscillator until a slight indication of output is visible.

(i) Adjust the oscillator magnetite core screw (top of oscillator coil) so that maximum (peak) output results.

(j) Set receiver dial pointer to 1,500 kc. Tune the test oscillator to 1,500 kc. Carefully adjust the oscillator and antenna air trimmers C16 and C7 respectively so that each brings about maximum (peak) output.

(k) Tune the test oscillator to 600 kc. Tune the receiver to pick up this signal disregarding the dial reading at which it is best received. Adjust oscillator magnetite core screw (top of oscillator coil) for maximum (peak) output while rocking gang tuning condenser. After completing this adjustment, the trimmers C16 and C7 should be re-adjusted as in (j) to correct for any change in the oscillator high-frequency tuning which has been caused by the preceding adjustment.

Antenna and Ground Terminals

These receivers are equipped wih an antenna-ground terminal board having three terminals. These terminals are marked "A2," "A1," and "G," the latter being the ground terminal and should always be connected to a good external ground. The transmission line leads of the RCA RK-40A antenna system should be connected to terminals "A2" and "A1." The receiver coupling units of the RCA RK-40 and the RCA Spider-Web antenna systems should be connected to terminals "A1" and "G." Connect a single-wire antenna to terminal "A1."

Phonograph Terminal Board

A terminal board is provided for connecting a phonograph into the audio amplifying circuit. Typical methods of connecting a low-impedance pickup, or the RCA Victor Models R-93, R-93-2, and R-93-3 Record Players are shown on the Schematic Diagram (figure 1).

REPLACEMENT PARTS

Insist on genuine factory tested parts, which are readily identified and may be purchased from authorized dealers.

Stock No.	Description	List Price
	RECEIVER ASSEMBLIES	
12706	Arm—Hub and arm complete for operating shutter (located on range switch shaft)	.22
12716	Board—Antenna and ground terminal board	.20
12717	Board—Phonograph terminal board	.22
5237	Bushing—Variable capacitor mounting bushing assembly—Package of 3	.43
12730	Cable—Shielded cable approximately 14½-in. long—volume control to phono terminal board	.40
11625	Cable—Tuning tube cable and socket complete (Models 8T and 8K)	1.26
12511	Cap—Grid contact cap—Package of 5	.15
11315	Capacitor—.015 Mfd. (C33)	.20
12670	Capacitor—.035 Mfd. (C34)	.20
4836	Capacitor—.05 Mfd. (C40) (Models 8T and 8K)	.30
4841	Capacitor—0.1 Mfd. (C29)	.22
11414	Capacitor—0.1 Mfd. (C30)	.20
4840	Capacitor—0.25 Mfd. (C28)	.30
5170	Capacitor—0.25 Mfd. (C8, C21)	.20
11240	Capacitor—10 Mfd. (C36)	1.08
5212	Capacitor—18 Mfd. (C37)	1.16
12708	Coil—Antenna coil and shield (L2, L3, L4, L5)	2.04
12709	Coil—Oscillator coil and shield (L6, L7, L8)	2.02
12701	Condenser—2-gang variable tuning condenser (C4, C17)	4.00
5119	Connector—3-contact female connector for speaker cable	.25
12711	Core—Adjustable core and stud for Stock No. 12709	.16
12006	Core—Adjustable core and stud for Stock No. 12652 and 12653	.22
12664	Core—Adjustable core and stud for Stock No. 12654	.22
12703	Dial—Station selector dial scale	.80
12702	Drive—Vernier drive for tuning capacitor	.68
12712	Indicator—Station selector indicator pointer	.22
5226	Lamp—Indicator dial lamp 6.3 volt—Package of 5	.70
12718	Mask—Dial light diffuser complete with red, orange and green colored screen	.40
12738	Resistor—27,000 ohms, insulated, ¼ watt—Package of 5 (R10)	1.00
11282	Resistor—56,000 ohm, carbon type 1/10 watt—Package of 5 (R8)	.75
12286	Resistor—56,000 ohm, carbon type, ¼ watt—Package of 5 (R2)	1.00
11282	Resistor—56,000 ohm, carbon type, 1/10 watt—Package of 5 (R4)	.75
11281	Resistor—100,000 ohm, carbon type, 1/10 watt—Package of 5 (R13)	.75
11398	Resistor—220,000 ohm, carbon type, 1/10 watt—Package of 5 (R9)	.75
11453	Resistor—270,000 ohm, carbon type, 1/10 watt—Package of 5 (R14)	.75
11452	Resistor—470,000 ohm, carbon type, 1/10 watt—Package of 5 (R1, R15)	.75
12285	Resistor—470,000 ohm, insulated, ¼ watt—Package of 5 (R12)	1.00
12013	Resistor—1 meg., carbon type, 1/10 watt—Package of 5 (R22) (Models 8T and 8K)	.75
11626	Resistor—2.2 meg., carbon type, ¼ watt—Package of 5 (R7, R20, R21)	1.00
12004	Resistor—Voltage divider comprising one 216 ohm, one 27 ohm and one 22 ohm sections (R17, R18, R19)	.45
12715	Resistor—Wire wound comprising one 22,000 ohm and one 10,000 ohm sections (R3, R6)	.56
4669	Screw—No. 8-32 set screw for arm Stock No. 12706—Package of 10	.25
12651	Shield—Coil shield for Stock No. 12708	[illegible]
12710	Shield—Coil shield for Stock No. 12709	[illegible]
12735	Shield—Dial lamp shield—Package of 5	[illegible]
12008	Shield—I.F. transformer shield for Stock No. 12652 and 12653	[illegible]
12581	Shield—Shield top for I.F. transformer Stock No. 12653	.36
12607	Shield—Shield top for I.F. transformer Stock No. 12652	.30
12704	Shutter—Dial scale holder and shutter assembly for band indicator	.88
12714	Capacitor—Adjustable capacitor (C5, C6, C7, C13, C14, C16)	.38
12722	Capacitor—18 Mmfd. (C15)	.20
12723	Capacitor—56 Mmfd. (C9)	.20
12726	Capacitor—56 Mmfd. (C2)	.20
12724	Capacitor—120 Mmfd. (C18, C32)	.28
12404	Capacitor—120 Mmfd. (C20, C22, C23, C24)	.26
12725	Capacitor—150 Mmfd. (C1)	.28
12406	Capacitor—180 Mmfd. (C25)	.26
12727	Capacitor—555 Mmfd. (C12)	.20
12537	Capacitor—560 Mmfd. (C3)	.20
12729	Capacitor—1,550 Mmfd. (C11)	.26
12728	Capacitor—4,500 Mmfd. (C10)	.36
4868	Capacitor—.005 Mfd. (C19, C35)	.20
4858	Capacitor—.01 Mfd. (C26, C27, C31)	.25
11195	Socket—5-contact 5Z4 radiotron socket	.15
11198	Socket—7-contact 6J7, 6K7 or 6L7 radiotron socket	.15
11196	Socket—8-contact 6F5, 6F6, 6H6, radiotron socket	.15
11222	Socket—Dial lamp socket	.18
11381	Socket—Tuning tube socket and cover (Models 8T and 8K)	.45
12007	Spring—Retaining spring for core Stock No. 12006, 12664 and 12711—Package of 10	.36
12849	Spring—Tension spring for band indicator shutter link—Package of 5	.18
12707	Switch—Range switch (S1, S2)	1.64
12668	Tone Control—Control and operating switch (R16, S3)	1.22
12652	Transformer—First I.F. transformer complete (L9, L10, C20, C22)	1.60
11999	Transformer—Power transformer 105-125 volts, 60 cycle (T1)	3.80
12132	Transformer—Power transformer 105-125 volts, 25 cycle (T1)	5.48
12133	Transformer—Power transformer 100-250 volts, 60 cycle (T1)	6.25
12653	Transformer—Second I.F. transformer complete (L11, L12, C23, C24, C25, R8, R9)	2.06
12654	Trap—Wave trap complete (L1)	.75
13144	Volume Control—Control and operating switch (R11)	1.00
	REPRODUCER ASSEMBLIES	
12641	Board—Reproducer terminal board	.15
12640	Bracket—Output transformer mounting bracket	.18
12012	Coil—Field coil (L15)	1.85
11469	Coil—Neutralizing coil (L13)	.20
12642	Cone—Reproducer cone and dust cap (L14) (Models 7T and 8T)	.94
12667	Cone—Reproducer cone and dust cap (L14) (Models 7K and 8K)	1.00
5118	Connector—3-contact male connector for speaker cable	.25
12666	Cover—Speaker cover (Models 7K and 8K)	.65
9696	Reproducer Complete—(Models 7K and 8K)	6.90
9699	Reproducer Complete—(Models 7T and 8T)	6.38
11253	Transformer—Output transformer (T2)	1.56
11886	Washer—Spring washer to hold field coil securely—Package of 5	.20
	MISCELLANEOUS ASSEMBLIES	
11996	Bracket—Tuning tube mounting bracket (Models 8T and 8K)	.22
12698	Crystal—Station selector crystal and escutcheon	1.02
12742	Escutcheon—Tuning tube escutcheon (Models 8T and 8K)	.22
12699	Knob—Large tuning knob—Package of 5	.68
11582	Knob—Tone control knob—Package of 5	.50
12700	Knob—Vernier tuning knob (small)—Package of 5	.38
11347	Knob—Volume control or range switch knob—Package of 5	.75
11377	Screw—Chassis mounting screw assembly for Table Model—Package of 4	.12
11210	Screw—Chassis mounting screw assembly for Console Model—Package of 4	.28
4982	Spring—Retaining spring for knob Stock No. 12699—Package of 10	.26
11349	Spring—Retaining spring for knob Stock No. 11347, 11582 and 12700—Package of 5	.15

General Features

The Model 7U combination instrument consists of a seven-tube radio receiver and a manually-operated phonograph combined in one cabinet. The superheterodyne circuit is used with such features of design as: Antenna wave-trap, aural compensated volume control, continuously variable tone control with music-voice switch, automatic volume control, resistance-coupled audio system, tuning tube "Magic Eye," and band selective indication of dial scales. The tuning range is continuous through the "Standard broadcast" band, "Medium wave" band, and the "Short wave" band. It includes domestic broadcast, police, aircraft, and amateur services, and also the important foreign short-wave broadcast bands at 49, 31, 25, 19, and 16 meters.

Circuit Arrangement

The first detector and oscillator functions are accomplished in a single tube, an RCA-6A8. The input of this tube is coupled to the antenna through a tuned transformer. This transformer consists of a single primary and three series-connected secondary windings to provide the three ranges of tuning. The oscillator coil system is similarly wound on a single form. A range-selector switch S3 is used for connecting the various sections of these two coil systems into the circuit to provide operation on the band desired. The coils are tuned by a variable two-section gang condenser having trimming capacitors in shunt with each section. There are additional trimming capacitors across the section of each coil used for the "Standard broadcast" band. A series trimming capacitor is also associated with the "Standard broadcast" oscillator coil.

The intermediate-frequency stage is coupled to the RCA-6A8 and to the RCA-6H6 by means of tuned transformers. The windings of these transformers (both primary and secondary) are resonated with adjustable trimming capacitors to tune to 460 kc.

The modulated signal as obtained from the output of the i-f system is detected by an RCA-6H6 twin-diode tube. Audio frequency secured by this process is passed on to the a-f system for amplification and final reproduction. The d-c voltage which results from detection of the signal is used for automatic volume control. This voltage which develops across resistor R7 is applied as automatic control-grid bias to the first detector and i-f tubes. The second (auxiliary) diode of the RCA-6H6 is used to supply residual bias for the controlled tubes under conditions of little or no signal. This diode, under such conditions, draws current which flows through resistors R6 and R7, thereby maintaining the desired operating bias on such tubes. On application of signal energy above a certain level, however, the auxiliary bias-diode ceases to draw current, and the a.v.c. diode takes over the biasing function.

Manual volume control is effected by means of an acoustically tapered potentiometer connected as a variable coupling element between the output of the second detector and the first-audio control grid. After amplification by the RCA-6F5, the audio signal is transmitted by resistance-capacitance coupling to the input of the RCA-6F6 power-output stage, which, in turn, is transformer-coupled to the dynamic loudspeaker.

Continuously-variable tone control is effected by means of the combination of a capacitor C28 and variable resistor R9 shunting the plate circuit of the output tube. Extreme clockwise rotation of the tone control disconnects the resistor R9 from the circuit and places an additional capacitor, C33, in shunt with capacitor C25, thereby reducing the low-frequency response of the amplifier. This point is known as the "Speech" position and provides optimum intelligibility of speech.

An RCA-6E5 cathode-ray tuning tube is used as a means of visually indicating when the receiver is accurately tuned to the incoming signal. This tube consists of an amplifier section and a cathode-ray section, built in the same glass envelope. A component of the signal voltage developed across resistor R7 is used to actuate the control grid of the amplifier section.

The power-supply system consists of an RCA-5Z4 rectifier tube, which is supplied from an efficiently designed power transformer, and which works into a suitable filter. The various potentials required for the plate, screen, control grid, and cathode circuits, are obtained from the output of the filter. The electrodynamic loudspeaker field coil is used as a filter reactor.

The phonograph mechanism is of the manually operated type, having a synchronous motor which rotates the turntable at a speed of 78 r.p.m. The 10-inch turntable will accommodate either the 10-inch or 12-inch phonograph records. The pickup mechanism and tone arm are combined as one unit. The instrument may be purchased with any one of five ratings as specified under Electrical Specifications. *It is important that a machine of any particular rating be operated at the frequency and voltage for which it is rated.* Attempts to operate at ratings other than specified for the particular instrument will result in improper reproduction from the phonograph and may result in damage to both the phonograph motor and radio receiver. An automatic switch is provided to turn "off" the phonograph motor at the completion of the record.

SERVICE DATA

Alignment Procedure

There are six adjustments required for the alignment of the antenna, oscillator, and wave-trap tuned circuits. The i-f transformer adjustments are made by four trimming capacitor screws. Improper alignment usually causes the impairment of sensitivity, selectivity, and tone quality. Such conditions will usually exist simultaneously.

A standard test oscillator, such as the RCA Stock No. 9595, will be required as a source of signal at the specified alignment frequencies. Means for indication of the receiver output during alignment is also necessary to show when the correct point of adjustment is reached. The RCA Stock No. 4317 Neon Glow Indicator is designed for this purpose.

Attach the output indicator across the loudspeaker voice coil. Advance the receiver volume control to its maximum position, letting it remain in such position for all adjustments. For each adjusting operation, regulate the test-oscillator output control so that the signal level is as low as possible and still be observable at the receiver output. Use of such small signal will obviate broadness of tuning which would otherwise result from a.v.c. action on a stronger one.

I-F Adjustments

(a) Connect the test oscillator to the grid cap of the RCA-6A8 through a .001 mfd. capacitor, and connect the test oscillator ground to the receiver chassis. Set test oscillator to 460 kc.

(b) Adjust the two trimming capacitors (C20 and C21) of the second i-f transformer to produce maximum (peak) output.

(c) Adjust the two trimming capacitors (C17 and C18) of the first i-f transformer, to produce maximum (peak) output.

It is advisable to repeat the adjustment of all i-f trimming capacitors a second time to assure that the interaction between them has not disturbed the original adjustment.

R-F Adjustments

Calibrate the tuning dial by adjusting the scale pointer to the extreme end calibration mark (beyond 55 on dial) while the two-gang tuning condenser plates are in full mesh. Alignment (see figure 3 for location of trimming adjustments) of "Wave-trap," "Short wave" band, and "Standard broadcast" band should be made in the following order and sequence.

"Wave-Trap"

(a) Connect the output of the test oscillator to the antenna terminal through a 200-mmfd. (important) capacitor, leaving the test oscillator ground connected to the receiver chassis. With the range selector in its "Standard broadcast" position, set the receiver dial to a position of no extraneous signals, near 600 kc (60 on dial). Set the test oscillator to 460 kc. Adjust the wave-trap trimming capacitor C1 to a point which causes minimum amplitude of output. An increase of the test oscillator output may be necessary before the point of minimum amplitude, obtained by adjustment of wave-trap screw, becomes apparent on the output indicator.

"Short Wave" Band

(a) Connect the output of the test oscillator to the antenna terminal through a 300-ohm resistor, leaving the test oscillator ground connected as before.

(b) Set the range selector to its "Short wave" position. Set receiver dial pointer to 15,000 kc (15 on dial). Adjust the test oscillator to 15,000 kc. Adjust the oscillator trimming capacitor C8 to the point which produces maximum (peak) output. Two points may be found, each of which produces a maximum. The one of maximum trimmer capacitance (most clockwise) is correct and should be used.

"Standard Broadcast" Band

(a) Connect the output of the test oscillator to the antenna terminal through a 200-mmfd. capacitor, leaving test oscillator ground connected as before.

(b) Set the range selector to its "Standard broadcast" position. Set the receiver dial pointer to 1,400 kc (140 on dial). Adjust the test oscillator to 1,400 kc. Adjust the oscillator and antenna trimming capacitors, C10 and C3 respectively, to the points where each produces maximum (peak) output.

(c) Adjust the antenna trimming capacitor C5 of the variable condenser, simultaneously rocking the receiver tuning control backward and forward through the 15,000 kc input signal, until maximum (peak) output results from these combined operations.

(c) Shift the test oscillator frequency to 600 kc and tune the receiver to pick up this signal, disregarding the dial reading at which it is best received.

(d) Adjust the low-frequency oscillator trimming capacitor, C12, simultaneously rocking the tuning control of the receiver backward and forward through the signal, until maximum (peak) output results from these combined operations. Repeat adjustments in (b) to compensate for any changes caused by the adjustment of the low-frequency oscillator coil trimming capacitor.

Phonograph Mechanism

The phonograph motor is of the synchronous type and designed to be simple and foolproof. Under normal operating conditions, service difficulties should be negligible. Occasionally, however, certain adjustments may be required. These adjustments are illustrated and explained in figure 9.

Magnetic Pickup

The pickup used in the phonograph unit is of an improved design. The horseshoe magnet is rigidly welded to the pole pieces and is irremovable. There is a centering spring attached to the armature to maintain proper adjustment and to provide a limiting effect on the movement of the armature. The frequency response is substantially uniform over a wide range. Service operations which may be necessary on the pickup are as follows:

Centering Armature

Refer to figure 10 showing the pickup inner structure. The armature is shown in its proper relation to the magnet pole pieces, i. e., exactly centered. Whenever this centering adjustment has been disturbed it will be necessary to remove the pickup mechanism from the tone arm by removing the needle holding screw and the two mounting screws from the front of the tone arm, holding the pickup assembly to keep it from dropping. Unsolder the two leads from the lugs on the terminal board at the rear of the pickup. Insert a small rod or nail into the armature needle hole and replace the needle holding screw, tightening it to hold the rod securely. If the armature clamping screws A and B have not been disturbed, screw C should be loosened which will permit the armature to be moved from side to side, the rod acting as a lever to perform this operation. The proper adjustment is obtained when the armature is moved to the extreme position on each side (the movement being limited by the armature striking the pole pieces) and then brought to the mid position between these two extremes. Screw C should then be tightened. The armature position should then be central between the pole pieces and at right angles to them. With a little practice, the correct adjustment of the armature will be obtained. The air gap between the pole pieces and the armature should be kept free from dust, filings, and other foreign material which would obstruct the movement of the pickup armature.

Damping Block

The viscoloid damping block which is attached to the front end of the armature shank serves as a mechanical filter to eliminate undesirable resonances and to cause the frequency response to be uniform. Should it be necessary to replace this damping block,

MODEL 7U

Pickup Data, Part 2
Socket. Parts List

RCA MFG. CO., INC.

the pickup mechanism should be removed from the tone arm as explained above. Unsolder the pickup coil leads from the two lugs on the pickup terminal board and remove the terminal board mounting screw and the terminal board. Then remove screw D and the damping block from the pickup assembly. Make sure that the shaft of the armature which contacts the viscoloid is clean. Then insert the new damping block so that it occupies the same position as that of the original block, and is in correct vertical alignment with the armature. The hole in the block is somewhat smaller than the diameter of the armature in order to permit a snug fit. With the damping block properly aligned on the armature, screw D with its washer should then be replaced. Heat should be applied to the armature (viscoloid side) so that the damping block will fuse at the point of contact and become rigidly attached to the armature. A special-tip soldering iron, constructed as shown in figure 11, will be found very useful in performing this operation. The iron should be applied only long enough to slightly melt the block, causing a small bulge on both sides.

Replacing Coil

Whenever there is defective operation due to an open or shorted pickup coil, this coil should be replaced. Remove the pickup mechanism and terminal board as described above. Remove screws A and B and the magnet assembly. Remove the bakelite coil support (with coil attached) and insert the new coil support assembly in its place, after which replace the magnet assembly and center the armature as described above, then re-assemble the remainder of the unit. Only rosin core solder should be used for soldering the coil leads and pickup leads to the pickup terminal board. This same type of solder should be used when necessary for soldering the centering spring to the armature.

Magnetizing

Loss of magnetization will not usually occur when the pickup has received normal care because the magnet and pole pieces are one unit and the magnetic circuit remains practically closed at all times. When the pickup has been mishandled, subjected to a strong a-c field, jolted, or dropped, there may be an appreciable loss of magnetic strength, in which case it will be necessary to remagnetize the entire structure. To do this, it will be necessary to first remove the pickup mechanism from the tone arm, and then remove the magnet assembly. Place the magnet assembly on the poles of a standard pickup magnetizer such as the RCA Stock No. 9549 Pickup Magnetizer and charging the magnet in accordance with the instructions accompanying the magnetizer. It is preferable to check the polarity of the pickup magnet and to remagnetize it so that the same polarity is maintained.

11465	Capacitor—Adjustable trimmer—(C12)	.48

Stock No.	DESCRIPTION	List Price
11256	Capacitor—Adjustable trimmer for wave-trap, Stock No. 11391—(C1)	.48
11617	Coil—Antenna coil less shield—(L2, L3, L4, L5, C3, R1)	1.68
11618	Coil—Oscillator coil less shield—(L6, L7, L8, L9, L10, L11, C10)	2.22
12767	Condenser—2-gang variable tuning condenser—(C4, C5, C7, C8)	4.10
4573	Connector—2-contact female connector for motor cable—receiver section	.30
5119	Connector—3-contact female connector for chassis reproducer cable	.25
6123	Connector—4-contact male connector for cable, Stock No. 12032	.30
12768	Drive—Variable tuning condenser vernier drive	1.30
11619	Foot—Chassis mounting foot and bracket assembly—Package of 2	.65
12770	Holder—Dial scale holder and lamp bracket assembly	.55
12712	Indicator—Station selector indicator pointer	.22
4340	Lamp—Dial lamp—Package of 5	.60
12718	Mask—Dial light diffuser complete with red, orange and green-colored screen	.40
11466	Resistor—Voltage divider—comprising one 3,500-ohm, one 13,000-ohm, one 85-	
	MOTOR BOARD ASSEMBLIES	
11751	Bushing—Motor mounting bushing and spring assembly, comprising one bushing, one large washer, one cup washer, one spring, one small washer and two nuts	$0.25
13065	Lever—Brake mechanism actuating lever, fastens to pivot shaft under base	.20
3261	Rest—Pickup rubber rest—Package of 5	.40
11750	Screw—No. 4-40 x 9/32, cone pointed, headless set screw for lever, Stock No. 13065—Package of 10	.22
13099	Brake—Automatic brake and switch complete	4.90
4577	Connector—2-contact male connector for brake switch power supply leads	.30
12932	Lever—Friction lever assembly complete	.35
11753	Plunger—Automatic brake trip plunger	.18
12043	Screw—Automatic brake screw and friction leather assembly	.20
11756	Spring—Automatic brake trip lever spring—Package of 10	.22
11757	Spring—Automatic brake lever spring—Package of 10	.20
11755	Switch—Automatic brake switch—(S4)	.75
	PICKUP AND ARM ASSEMBLIES	
11731	Armature—Pickup armature	.64
11732	Coil—Pickup coil—(L23)	.60

General Features

These two models each employ the same seven-tube chassis. They have the new metal tubes. The tuning range is from 540 to 18,000 kc. The coverage includes domestic broadcast, police, aircraft and amateur services and also the important foreign short-wave broadcast bands at 49, 31, 25, 19, and 16 meters. Chassis features include automatic volume control, 3-point tone control, antenna wave trap, and audio tone compensation. A high level of output is available from the receiver for reproduction by the electrodynamic loudspeaker. The table model (T 7-5) uses an 8-inch dynamic speaker and the console model (C 7-6) uses an improved 12-inch dynamic speaker. The tuning dial is an illuminated semi-airplane type. Each band is distinctively marked with a separate color for each band. Positions of the range selector knob are plainly marked on the control panel with letters indicating each band position placed over color strips corresponding to the band colors on the dial. The tuning control is of the dual-ratio type, which permits fast tuning through a 10-to-1 drive ratio and vernier tuning through a 50-to-1 drive ratio. The latter is especially advantageous for accurate tuning of the short-wave stations.

Circuit Arrangement

The conventional Superheterodyne type of circuit, consisting of an r-f stage, a combined first-detector-oscillator stage, a single i-f stage, a diode-detector-automatic-volume-control stage, an audio voltage amplifier stage, an audio power output stage and a high-voltage rectifier power-supply stage, is used.

Tuned Circuits

The antenna coil system and the detector coil system each consist of a single primary and three series-connected secondary windings to provide the three ranges of tuning. The oscillator coil system is similarly wound on a single form. A range selector switch (S-1) is used for connecting the various sections of these three coil systems into the circuit to provide operation on the band desired. The coils are tuned by a variable three-section gang condenser having trimmer capacitors in shunt with each section. There are additional trimmer capacitors across the section of each coil used for Band "A." A series trimmer is also associated with the Band "A" oscillator coil.

The intermediate frequency amplifier system consists of an RCA-6K7 in a transformer-coupled circuit. This stage operates at a basic frequency of 460 kc. Each winding of both i-f transformers (input and output) is tuned by an adjustable trimmer.

Detector and A.V.C.

The modulated signal as obtained from the output of the i-f stage is detected by an RCA-6H6 twin-diode tube. The audio frequency secured by this process is transferred to the a-f system for amplification and final reproduction. The d-c voltage which results from detection of the signal is used for automatic volume control. This voltage, which develops across resistor R-8, is applied as automatic control-grid bias to the r-f, first-detector, and i-f tubes through a suitable resistance filter circuit. The second (auxiliary) diode of the RCA-6H6 is used to supply residual bias for the controlled tubes under conditions of little or no signal. This diode, under such conditions, draws current which flows through resistors R-8 and R-9, thereby maintaining the desired minimum operating bias on such tubes. On application of signal energy above a certain level, however, the auxiliary bias-diode ceases to draw current and the a.v.c. diode takes over the biasing function.

Audio System

The manual volume control consists of an acoustically tapered potentiometer in the audio circuit between the output of the detector diode and the input grid of the audio-voltage-amplifier tube. This control has a tone compensating filter connected to it so that the correct aural balance will be obtained at different volume settings.

Resistance-capacitance coupling is used between the first audio stage and the power output stage. The output of the power amplifier is transformer-coupled into the dynamic loudspeaker. High-frequency tone control is effected by a capacitor across the plate circuit of the output tube. Speech-music control is effected by a resistor connected to the compensated volume control circuit. Control of tone is obtained by means of the switch (S-2)

Rectifier

The power required for operation of this receiver is supplied through transformer T-1. This transformer has an efficient electrostatic shield between its primary and secondary windings. This shield prevents interference which is on the power-supply circuit from entering the receiver and conversely reduces the tendency of the receiver to re-radiate into the power circuit. An RCA-80 furnishes the d-c voltages necessary for plate, screen, cathode, and grid potentials. The field winding of the loudspeaker is used as a reactor in the filter circuit from which it simultaneously receives its magnetizing current. The heaters of all Radiotrons are supplied from a low voltage (6.3 volt) winding on the power transformer. One side of this winding is at ground potential.

SERVICE DATA

The various diagrams of this bulletin contain such information as will be needed to isolate causes for defective operation when such a condition develops. Values of the resistors, capacitors, coils, etc., are indicated adjacent to the symbols signifying these parts on the diagrams. Identification titles, such as R-3, L-2, C-1, etc., are provided for reference between the diagrams and the replacement parts list. Locating of the parts in the schematic circuit is facilitated by the fact that the numerical titles increase from left to right on the diagram. The coils, reactors, and transformer windings are rated in terms of their d-c resistances only. Resistances of less than one ohm are generally omitted.

Alignment Procedure

Precise alignment is vital to the proper functioning of this receiver. There are four trimming adjustments provided in the i-f system, three in the oscillator coil system, two in the detector coil system, and two in the antenna coil system. Each of these trimmers has been accurately adjusted during manufacture and should remain properly aligned unless affected by abnormal conditions of climate or have been altered for service purposes. Incorrect alignment is usually evidenced by loss of sensitivity, improper tone quality, and poor selectivity. These indications will generally be present together.

The correct performance of the receiver can only be obtained when the alignment is performed with adequate and reliable test apparatus. The manufacturer of this instrument has a complete assortment of such service equipment available. This equipment, illustrated and described on a separate page of this booklet, may be purchased from authorized distributors and dealers.

An oscillator (signal generator) is required as a source of the specified alignment frequencies. Visual indication of the receiver output during the adjustments is necessary to enable the serviceman to obtain an accuracy of alignment which is not possible by listening to the signal. **The RCA Victor Stock No. 9595 Full-Range Oscillator and the RCA Victor Stock No. 4317 Neon Output Indicator are especially suitable and fulfill the above requirements.**

The following procedure should be followed in adjusting the various trimmer capacitors:

I-F Trimmer Adjustments

The four trimmers of the two i-f transformers are located as shown by Figure 4. Each must be aligned to a basic frequency of 460 kc. To do this, attach the Output Indicator across the voice coil circuit or across the output transformer primary. Connect the output of the test oscillator between the control-grid of the RCA-6A8 first detector tube and chassis-ground. Tune the oscillator to 460 kc. Advance the receiver volume control to its full-on position and adjust the receiver tuning control to a point within its range where no interference is encountered either from local broadcast stations or the heterodyne oscillator. Increase the output of the test oscillator until a slight indication is apparent on the output indicator. Then adjust the two trimmers, C-25 and C-26, of the second i-f transformer to produce maximum (peak) indicated receiver output. Then, adjust the two trimmers, C-23 and C-24, of the first i-f transformer for maximum (peak) receiver output as shown by the indicating device. During these adjustments, regulate the test oscillator output so that the indication is always as low as possible. By doing so, broadness of tuning due to a.v.c. action will be avoided. It is advisable to repeat the adjustment of all i-f trimmers a second time to assure that the inter-action between them has not disturbed the original adjustment.

R-F Trimmer Adjustments

The seven trimmers associated with the r-f, first detector, and oscillator tuned circuits have their locations shown by Figure 3. The three trimmers which are at all times directly in shunt with the variable tuning condenser necessitate that the high-frequency range (Band C) be aligned first. The range selector switch should, therefore, be turned to its Band C position for the first adjustment. The Output Indicator should be left connected to the output system. Attach the output terminals of the test oscillator to the antenna and ground terminals of the receiver.

Calibrate the dial by rotating the tuning control until the variable condenser plates are in their full mesh (maximum capacity) position and adjusting the dial pointer so that its end points to the horizontal graduation (530 kc.) at the low frequency end of the Band A scale.

Proceed further as follows:

(a) Adjust the test oscillator to 18,000 kc. and set the receiver tuning control to a dial reading of 18,000 kc.

(b) Regulate the output of the test oscillator until a slight indication is perceptible at the receiver output. Then adjust the trimmer, C-20, on the oscillator section of the variable condenser to the point at which it produces maximum indicated receiver output. Two points may be found, each of which produces such a maximum. The one of maximum trimmer capacitance is correct and should be used. (The oscillator will be 460 kc. below the signal frequency at this adjustment point.)

(c) Adjust the trimmer, C-12, of the detector section of the variable condenser, simultaneously rocking the receiver tuning control backward and forward through the 18,000 kc. input signal, until maximum receiver output results from these combined operations. Rocking of the variable condenser will prevent inaccurate adjustment which would otherwise be caused by the inter-action between the heterodyne oscillator circuit and the detector tuned circuit.

(d) With the receiver tuning control set to 18,000 kc. adjust the trimmer, C-6, on the antenna section of the variable condenser to the point which produces maximum (peak) indicated receiver output.

(e) Change the receiver range selector to its Band A position and set the receiver tuning control to a dial reading of 1,400 kc. Tune the test oscillator to 1,400 kc. and regulate its output to produce a slight indication on the receiver output indicating device.

(f) Adjust the high frequency trimmers of the Band A oscillator, detector, and antenna coils, C-15, C-9, and C-4 respectively, to the points at which each produces maximum indicated receiver output.

(g) Shift the test oscillator frequency to 600 kc. and tune the receiver to pick up this signal, disregarding the dial reading at which it is best received.

(h) Tune the low frequency trimmer, C-18, of the oscillator Band A coil, simultaneously rocking the tuning control of the receiver backward and forward through the signal, until maximum indicated receiver output results from these combined operations. The adjustment of C-20, C-12, and C-6 should be corrected at 18,000 kc. as in (b), (c), and (d); also C-15, C-9, and C-4 should be corrected at 1,400 kc. as in (f) to compensate for any changes caused by the adjustment of the low frequency oscillator coil trimmer.

Wave-Trap Adjustment

With the receiver in operation using its normal antenna, tune station selector to the point at which the intermediate frequency interference is most intense. Then adjust the wave trap trimmer to the point which causes maximum suppression of the interference. This trimmer is adjusted to 460 kc. during manufacture, however, local conditions may require a readjustment, depending upon the interfering frequency.

Radiotron Socket Voltages

The voltage values indicated from the Radiotron socket contacts to chassis on Figure 4 will assist in the location of causes for faulty operation. Each value as specified should hold within ± 20% when the receiver is normally operative at its rated supply voltage. Variations in excess of this limit will usually be indicative of trouble in the basic circuits. The voltages given are actual operating values and do not allow for inaccuracies which may be caused by the loading effect of a voltmeter's internal resistance. This resistance should be duly considered for all readings. The amount of circuit resistance shunting the meter during measurement will determine the accuracy to be obtained, the error increasing as the meter resistance becomes comparable to or less than the circuit resistance. For the majority of readings, a meter having an internal resistance of 1000 ohms per volt will be satisfactory when the range used for each reading is chosen as high as possible consistent with good readability.

Universal Transformer

The special transformer used on some receivers of this type is adaptable to several ranges of voltage as given under Rating C of Electrical Specifications. Its schematic and wiring are shown by Figure 6. Terminals are provided at the top of the transformer case, for changing the primary connections to suit the voltage available. Note that a 110-volt tap is brought out separately for supplying a phonograph motor.

Electrical Specifications

FREQUENCY RANGES
Band A .... 540- 1,625 kc.
Band B .... 1,625- 5,700 kc.
Band C .... 5,700-18,000 kc.

Intermediate Frequency .... 460 kc.

ALIGNMENT FREQUENCIES
Band A ....600 kc. (osc.), 1,400 kc. (osc., det., ant.)
Band B .... None required

— NOTES —

(1) Beat notes or heterodyning (whistles) may be encountered in some instances on these receivers due to excessive antenna capacitance. This condition may be corrected by reducing the size of the antenna or by inserting a 150 mmfd. capacitor in series with the antenna lead. This may be accomplished in the receiver by removing the bus lead which connects from the antenna terminal to the wave trap inductance L-1 and inserting the condenser between these points.

Phonograph Mechanism

The phonograph mechanism is of the manually operated type, having a synchronous motor which rotates the turntable at a speed of 78 R.P.M. The 10-inch turntable will accommodate either the 10-inch or 12-inch phonograph records. The pickup mechanism and tone arm are combined as one unit. The instrument may be purchased with any one of five ratings as specified under Electrical Specifications. *It is important that a machine of any particular rating be operated at the frequency and voltage for which it is rated.* Attempts to operate at ratings other than specified for the particular instrument will result in improper reproduction from the phonograph and may result in damage to both the phonograph motor and radio receiver. An automatic switch is provided to turn "off" the phonograph motor at the completion of record play.

Tuning Dial

The tuning dial is an illuminated semi-airplane type. Each band is distinctively marked with a separate color for each band. Positions of the range selector knob are plainly marked on the control panel with letters indicating each band position placed over color strips corresponding to the band colors on the dial. The tuning control is of the dual-ratio type which permits fast tuning through a 10-to-1 drive ratio and vernier tuning through a 50-to-1 drive ratio. The latter is especially advantageous for accurate tuning of the short-wave stations. The new shock-proof condenser mounting reduces microphonic tendencies to a minimum.

Circuit Arrangement

The conventional Superheterodyne type of circuit, consisting of an r-f stage, a combined first-detector-oscillator stage, a single i-f stage, a diode-detector-automatic-volume-control stage, an audio voltage amplifier stage, an audio power output stage and a high-voltage rectifier power-supply stage, is used.

Tuned Circuits

The antenna coil system and the detector coil system each consist of a single primary and three series-connected secondary windings to provide the three ranges of tuning. The oscillator coil system is similarly wound on a single form. A range selector switch (S-1) is used for connecting the various sections of these three coil systems into the circuit to provide operation on the band desired. The coils are tuned by a variable three-section gang condenser having trimmer capacitors in shunt with each section. There are additional trimmer capacitors across the section of each coil used for Band "A." A series trimmer is also associated with the Band "A" oscillator coil.

The intermediate frequency amplifier system consists of an RCA-6K7 in a transformer-coupled circuit. This stage operates at a basic frequency of 460 kc. Each winding of both I-f transformers (input and output) is tuned by an adjustable trimmer.

Detector and A.V.C.

The modulated signal as obtained from the output of the i-f stage is detected by an RCA-6H6 twin-diode tube. The audio frequency secured by this process is transferred to the a-f system for amplification and final reproduction. The d-c voltage which results from detection of the signal is used for automatic volume control. This voltage, which develops across resistor R-8, is applied as automatic control-grid bias to the r-f, first-detector, and i-f tubes through a suitable resistance filter circuit. The second (auxiliary) diode of the RCA-6H6 is used to supply residual bias for the controlled tubes under conditions of little or no signal. This diode, under such conditions, draws current which flows through resistors R-8 and R-9, thereby maintaining the desired minimum operating bias on such tubes. On application of signal energy above a certain level, however, the auxiliary bias-diode ceases to draw current and the a.v.c. diode takes over the biasing function.

Audio System

The manual volume control consists of an acoustically tapered potentiometer in the audio circuit between the output of the detector diode and the input grid of the audio-voltage-amplifier tube. This control has a tone compensating filter connected to it so that the correct aural balance will be obtained at different volume settings.

Resistance-capacitance coupling is used between the first audio stage and the power output stage. The output of the power amplifier is transformer-coupled into the dynamic loudspeaker. High-frequency tone control is effected by a capacitor across the plate circuit of the output tube. Speech-music control is effected by a resistor connected to the compensated volume control circuit. Control of tone is obtained by means of the switch (S-2).

Rectifier

The power required for operation of this receiver is supplied through transformer T-1. This transformer has an efficient electrostatic shield between its primary and secondary windings. This shield prevents interference which is on the power-supply circuit from entering the receiver and conversely reduces the tendency of the receiver to re-radiate into the power circuit. An RCA-80 furnishes the d-c voltages necessary for plate, screen, cathode, and grid potentials. The field winding of the loudspeaker is used as a reactor in the filter circuit from which it simultaneously receives its magnetizing current. The heaters of all Radiotrons are supplied from a low voltage (6.3 volt) winding on the power transformer. One side of this winding is at ground potential.

SERVICE DATA
