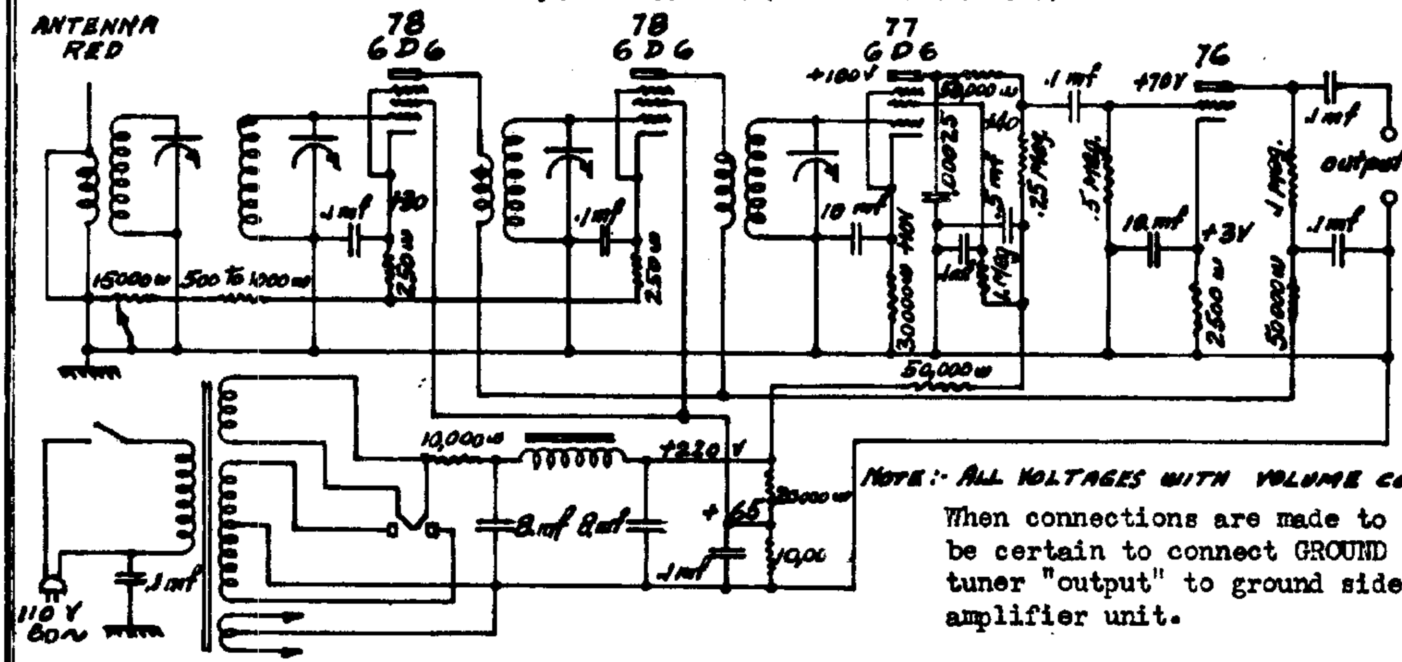
ACRATEST PRODUCTS

MODEL 194 P. A. TUNER



NOTE:- ALL VOLTAGES WITH VOLUME CONTROL FULL ON.

When connections are made to amplifiers, be certain to connect GROUND SIDE of the tuner "output" to ground side of the amplifier unit.

If the tube to line transformer is used, it should be placed a short distance away from the receiver and the proper method of orientation be employed to insure the minimum hum pickup between any power transformers either in the receiver or the amplifier.

If it becomes necessary to readjust the setting of the tuning condenser compensators; follow this procedure:

(1) Place receiver in operating condition.
(2) Connect local oscillator to antenna and ground terminals.
(3) Set tuning dial on receiver to "8" on the dial.
(4) Set oscillator to 1500 K.C.
(5) Adjust all four trimmers for maximum reading on output meter.
(6) Keep power from oscillator at a very low level to assure accurate tuning.
(7) Check at lower frequencies if desired but as the receiver has been designed and the coils and condensers are matched so that "8" on the dial is 1500 K.C., these adjustments should be sufficient for all channels unless the receiver has been damaged.

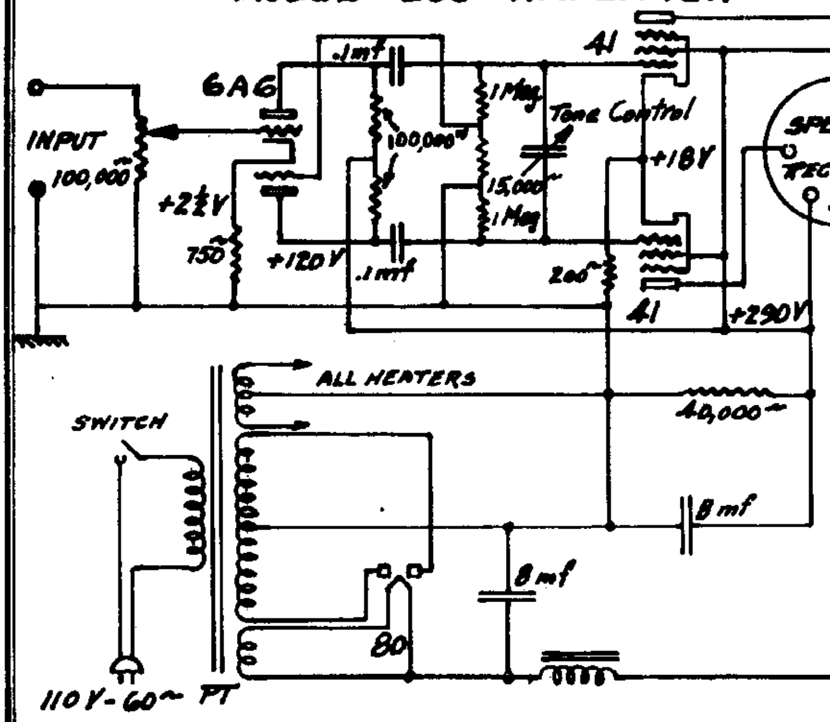
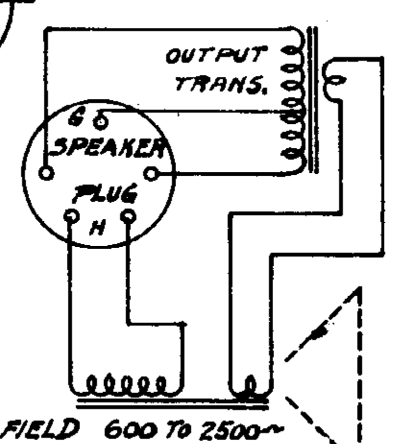
ACRATEST PRODUCTS

MODEL 200 AMPLIFIER

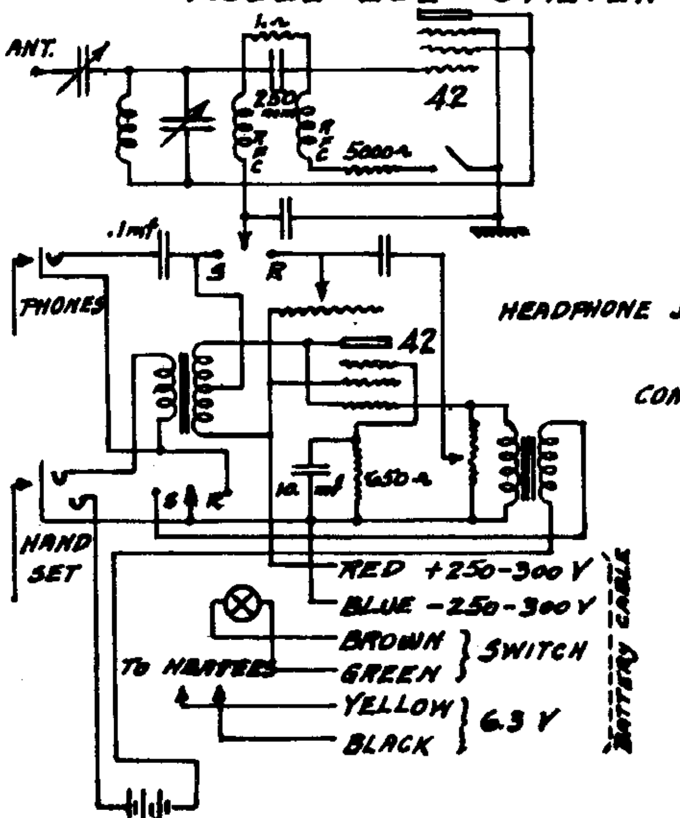


SPEAKER CONNECTIONS

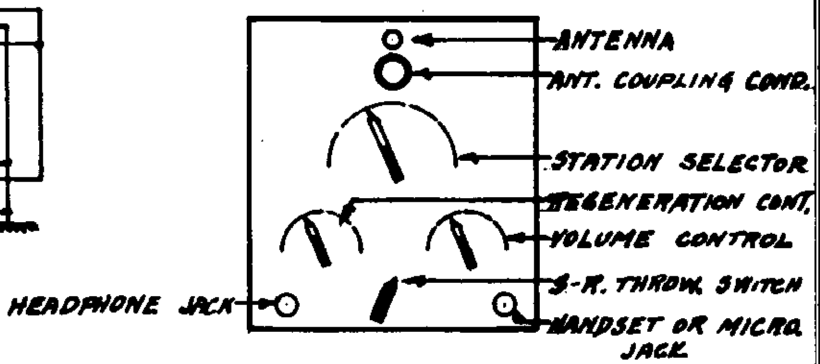


NOTE - IF FIELD SUPPLY IS NOT NEEDED, SHORT TERMINALS AT "H". ALL VOLTAGES WITH "H" SHORTED.

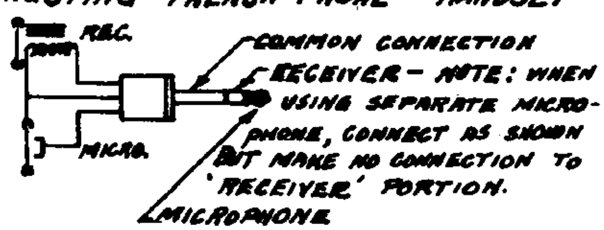
MODEL 202 5 METER TRANSCEIVER



4.5V - THESE LEADS DO NOT REQUIRE POLARIZING, AND ARE FOR MICROPHONE BAT.



CONNECTING 'FRENCH PHONE' HANDSET

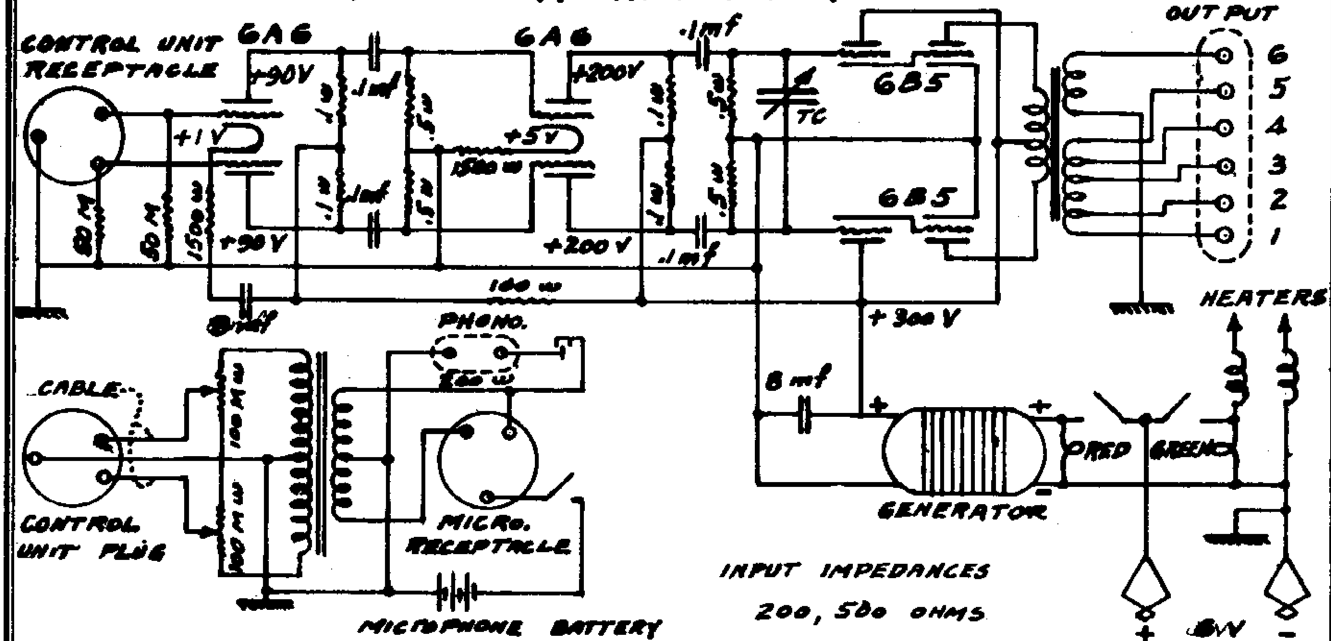


NOTE :- USE HEADPHONES IN 'PHONE' JACK ON TRANSCEIVER.

WITH DRY BATT. OR 6V. 'B' ELIMINATOR +250V - RED; -250V - BLUE. CONNECT BROWN AND BLACK. 6V. BATTERIES - YELLOW & GREEN. 'B' ELIM. THRU RELAY - YELLOW GND., GREEN THROUGH RELAY TO HOT 'A'. USE SWITCH ON TRANSCEIVER FOR MAIN CONTROL.

ACRATEST PRODUCTS

MODEL 47 AMPLIFIER



NOTE: Before attempting to use this amplifier, check the polarity of the car storage battery. If car frame or chassis is minus (-) it is safe to operate amplifier as is.

If frame or chassis is positive, remove bottom plate of amplifier look for slate colored wire with tag and change its connection as indicated on tag.

Be sure that the polarity of the generator input is correct. There is a knot in the positive battery feed wire.

The following output impedances are available.
Note that terminal No. 1 is grounded to the chassis.
The chassis is also B-.

Between	Terminals	1 and 2	- 2 ohms
"	"	4 and 5	- 3 ohms
"	"	3 and 4	- 4 ohms
"	"	2 and 3	- 6 ohms
"	"	3 and 5	- 7 ohms

INSTRUCTIONS MODEL "KNAVE" AC-DC SUPERHETERODYNE RECEIVER

ANTENNA AND GROUND CONNECTIONS. An antenna from 50 to 100 feet long is recommended. A good ground wire is absolutely essential on this receiver.

POWER SUPPLY. This receiver is designed to operate from the 110-125 v. lines normally, or 215-240 v. AC or DC lines if the receiver has a change over connector on back of chassis.

LOCATION OF CONTROLS. The knob on the lower left is the tone control, the knob on the lower right is the volume control and on-off switch, and the knob directly below the selector knob is the band switch.

OPERATION. To receive stations from 140 to 350 kilocycles, turn wave band switch to the extreme right position and turn set on by rotating volume control knob to the right. Turn station selector knob to secure desired stations. When tuning in a station, set tuning control carefully to maximum station volume, then adjust volume to desired level with volume control knob. For stations from 1700 to 540 kilocycles, turn band switch knob to center position, and for stations between 15 and 52 meters turn switch to extreme left position.

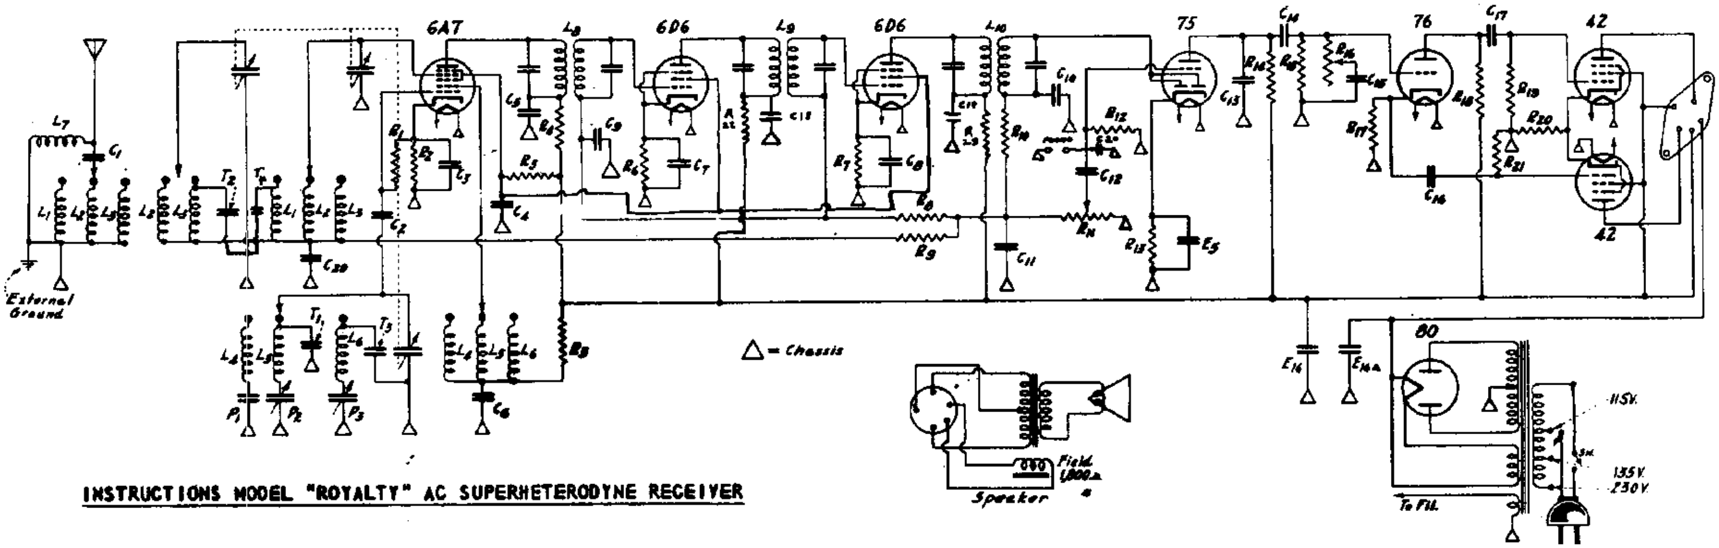
MODEL "ROYALTY"



INSTRUCTIONS MODEL "ROYALTY" AC SUPERHETERODYNE RECEIVER

ANTENNA AND GROUND CONNECTIONS. An antenna from 50 to 100 feet long is recommended. A good ground wire is absolutely essential on this receiver.

POWER SUPPLY. This receiver is designed to operate from the 115-135 or 220 A.C. 50 cycle lines. The voltage change is accomplished by removing the cover from the power transformer and connecting the flexible lead to the desired voltage terminal.

LOCATION OF CONTROLS. The knob on the lower left is the on-off switch and volume control. The knob on the lower right is the band switch and the knob directly below the selector knob is the tone control.

OPERATION. To receive stations from 140 to 350 kilocycles, turn wave band switch to the extreme right position and turn set on by rotating volume control knob to the right. Turn station selector knob to secure desired stations. When tuning in a station, set tuning control carefully to maximum station volume, then adjust volume to desired level with volume control knob. For stations from 1700 to 540 kilocycles, turn band switch knob to center position, and for stations between 15 and 52 meters turn switch to extreme left position.

INSTRUCTIONS MODEL 213 ST AC 3 BAND SUPERHETERODYNE RECEIVER

ANTENNA AND GROUND CONNECTIONS. An antenna from 50 to 100 feet long is recommended. A good ground wire is absolutely essential on this receiver.

POWER SUPPLY. This receiver is designed to operate from the 115-135 or 220 A.C. cycle lines. The voltage change is accomplished by removing the cover from the power transformer and connecting the flexible lead to the desired voltage terminal.

LOCATION OF CONTROLS. The knob on the extreme left is the on-off switch and tone control. The knob on the extreme right is the interchannel noise suppressor switch. The other lower knobs are wave change switch and volume control.

OPERATION. Turn station selector knob to secure desired stations. When tuning in a station, set tuning control carefully to maximum station volume, then adjust volume to desired level with volume control knob. When the knob on extreme fight is turned clockwise, the noise suppressor functions. This control is only effective on high wave stations.

ANTENNA AND GROUND CONNECTIONS. An antenna from 50 to 100 feet long is recommended. A good ground wire is absolutely essential on this receiver.

POWER SUPPLY. This receiver is designed to operate from A.C. or D.C. lines. On A.C. it will operate on the 50 or 60 cycle lines, but 25 cycle operation can be provided for by the addition of one 16 mfd. electrolytic in parallel with E8.

LOCATION OF CONTROLS. The knob on the lower right is the on-off switch and the tone control. The knob on the lower left is the volume control and the knob directly below the selector knob is the wave change switch.

OPERATION. Turn station selector knob to secure desired stations. When tuning in the set, set tuning control carefully to maximum station volume, then adjust volume to desired level with volume control knob.

INSTRUCTIONS MODELS 221-222-223-5T AC 2 BAND SUPERHETERODYNE RECEIVER

ANTENNA AND GROUND CONNECTIONS. An antenna from 50 to 100 feet long is recommended. A good ground wire is absolutely essential on this receiver.

POWER SUPPLY. This receiver is designed to operate from the 115 - 135 or 220 A.C. 50 cycle lines. The voltage change is accomplished by removing the cover from the power transformer and connecting the flexible lead to the desired voltage terminal.

LOCATION OF CONTROLS. The knob on the lower right is the on-off switch and the volume control. The knob on the lower left is the wave switch and the knob directly below the selector knob is the tone control.

OPERATION. Turn station selector knob to secure desired stations. When tuning in a set, set tuning control carefully to maximum station volume, then adjust volume to desired level with volume control knob.

ALLIED RADIO CORP.

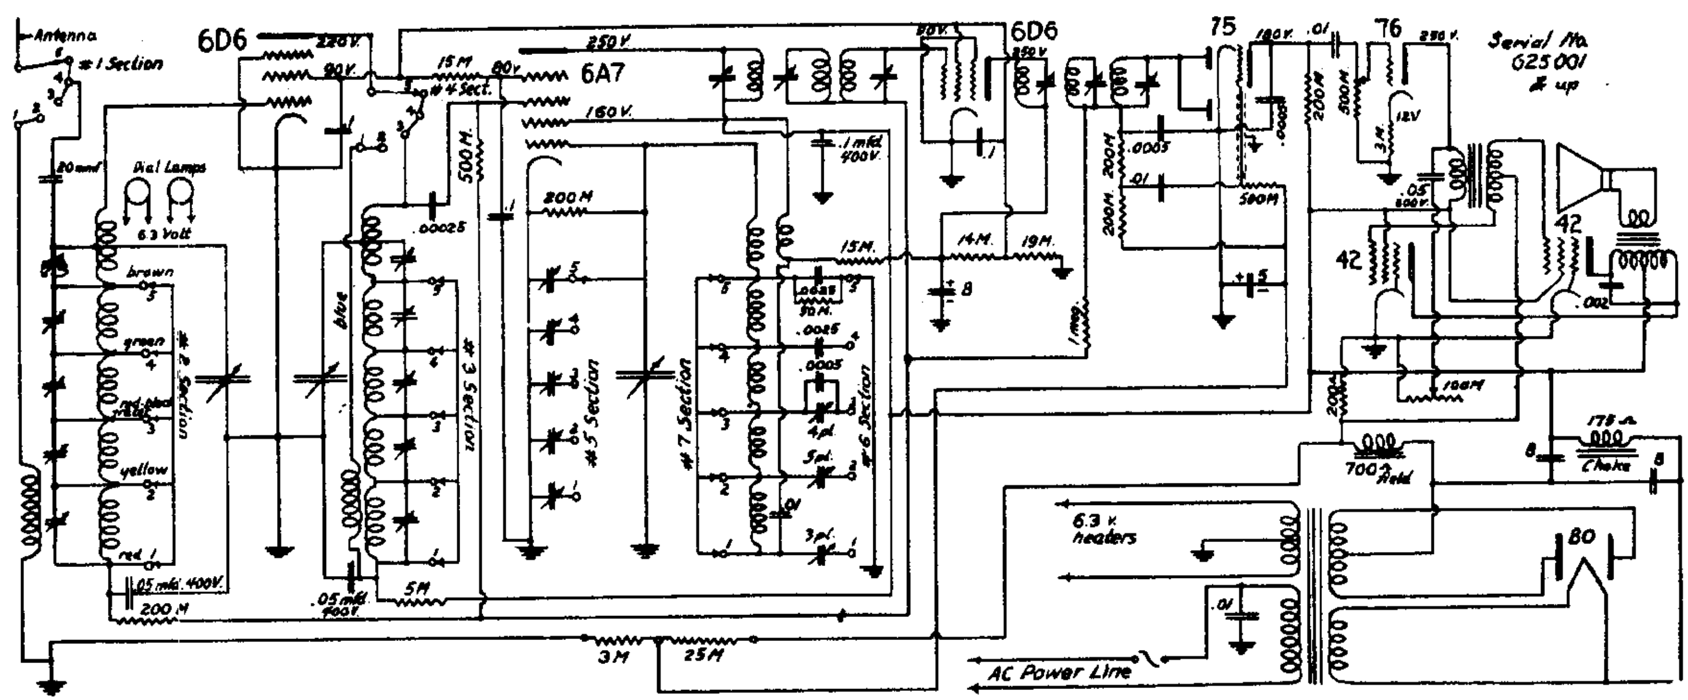
I.F. PEAK 456 K.C.



OPERATING INSTRUCTIONS — ALL WAVE 5-TUBE SUPERHETERODYNE

CAUTION: Do not attempt to operate on current other than that noted on the instrument.

INSTALLATION: A good aerial, 25 to 50 feet long, well away from surrounding metal structures and power lines, is essential for best results. Any of the new ALL-WAVE Antennas is recommended for best performance. Power noise interferes especially with short-wave reception. If the set is located where power noise is prevalent, it may be necessary to install an aerial high above the street and use a "transposition" lead-in to the set. A good ground connection (water pipe or equivalent) will also contribute to quieter reception.

SERVICE NOTES: If the radio fails to operate when unpacked, or stops working after a few days, proceed as follows: (1) Have the tubes checked. (2) Remove the chassis from the cabinet and check for loose connections. Do not return the receiver unless you have made the above tests. This set was shipped, carefully inspected.

The intermediate stages are carefully phased to 456 KC. Should rephasing be necessary, attach the output lead from a 456 KC test oscillator to the grid cap of the 6A7 tube; keep the signal to a very low audible value and carefully adjust the three trimmer screws, two in the top and one in the bottom of each of the two tall cans, to loudest volume. If an output meter is available, it should be used across the two outside black leads at the speaker transformer. An all-wave oscillator having a range from 150 KC to 20 MC will be necessary to rephase the frequency bands. The oscillator output is attached to the aerial lead of the set and the oscillator output kept always at a low audible level. The R.F. coil trimmers are reached through a series of five (5) holes in the side of the R.F. shield cans and correspond to frequency band Nos. 1, 2, 3, 4, and 5, from top down. The oscillator parallel trimmers are seen on the under side of the set when the front of it is raised and are located along side the band switch, #1 being the one nearest the back of chassis and #5 nearest the front. The dual porcelain trimmers at back of chassis are series padders, the left band for band #2 and the right hand one for band #1. The series padder for band #3 is the single trimmer at the center of the chassis. Each band is trimmed first at the minimum end of its range, band #5 being first, #4 second, then #3, etc. Bands 3, 2, and 1 are also tracked near their maximum ranges, or with the tuning condenser turned well in, by adjusting that series padder belonging to the particular band being used, location of which is given above.

NOTE: Should it be necessary to write us for parts or information, always give the serial number of the set as stamped on the back of the chassis.

SERVICE NOTES
for the
32 VOLT DIRECT CURRENT
FIVE TUBE SUPERHETERODYNE RECEIVER

ALIGNMENT PROCEDURE: For properly aligning either the intermediate transformer or the gang condenser, it is necessary that an accurately calibrated oscillator be used with some type of output measuring device.

INTERMEDIATE ALIGNMENT:

1. Connect the high side of the oscillator output to the control grid of the 6A7 tube leaving the grid cap disconnected. Connect the ground side of the oscillator to the receiver ground lead.

2. Set the test oscillator frequency to 465 kilocycles (this must be accurate).

3. Align the first intermediate transformer by turning one of the trimmer screws up and down until maximum reading is obtained on the output meter and then adjust the other trimmer screw of the same transformer for maximum sensitivity.

4. Adjust the second intermediate transformer in the same manner.

NOTE: Two type intermediate transformer trimmers have been used in this receiver. One type has two parallel holes in the top of the shield, one for each trimmer. The other type has a brass hex nut for adjusting one trimmer, the other intermediate trimmer being adjusted with the trimmer screw located insideof the brass hex nut. Regardless of which type trimmer is used, the procedure is the same.

TO ALIGN THE VARIABLE CONDENSER: It is important when aligning to follow the procedure carefully, otherwise the receiver will lack sensitivity and the dial calibration will be incorrect.

1. Connect the high output side of the oscillator to the green receiver antenna lead and the ground to the black ground lead.

2. Set the test oscillator frequency and adjust the receiver dial to exactly 1720 kilocycles. BRING IN THIS 1720 KILOCYCLE SIGNAL BY ADJUSTING THE TRIMMER CONDENSER LOCATED ON TOP OF THE OSCILLATOR SECTION (front section) OF THE GANG CONDENSER.

3. Tune the receiver to approximately 600 kilocycles and adjust the test oscillator to this frequency.

While rocking the variable condenser slightly to the right and left adjust the 600 kilocycle padding condenser, which is located on and accessible through the hole provided in the right hand side of the chassis, for maximum sensitivity.

This completes the alignment procedure. It is recommended that all of the adjustments be gone over again. Generally, it will be found that improved results can be obtained if this is done.

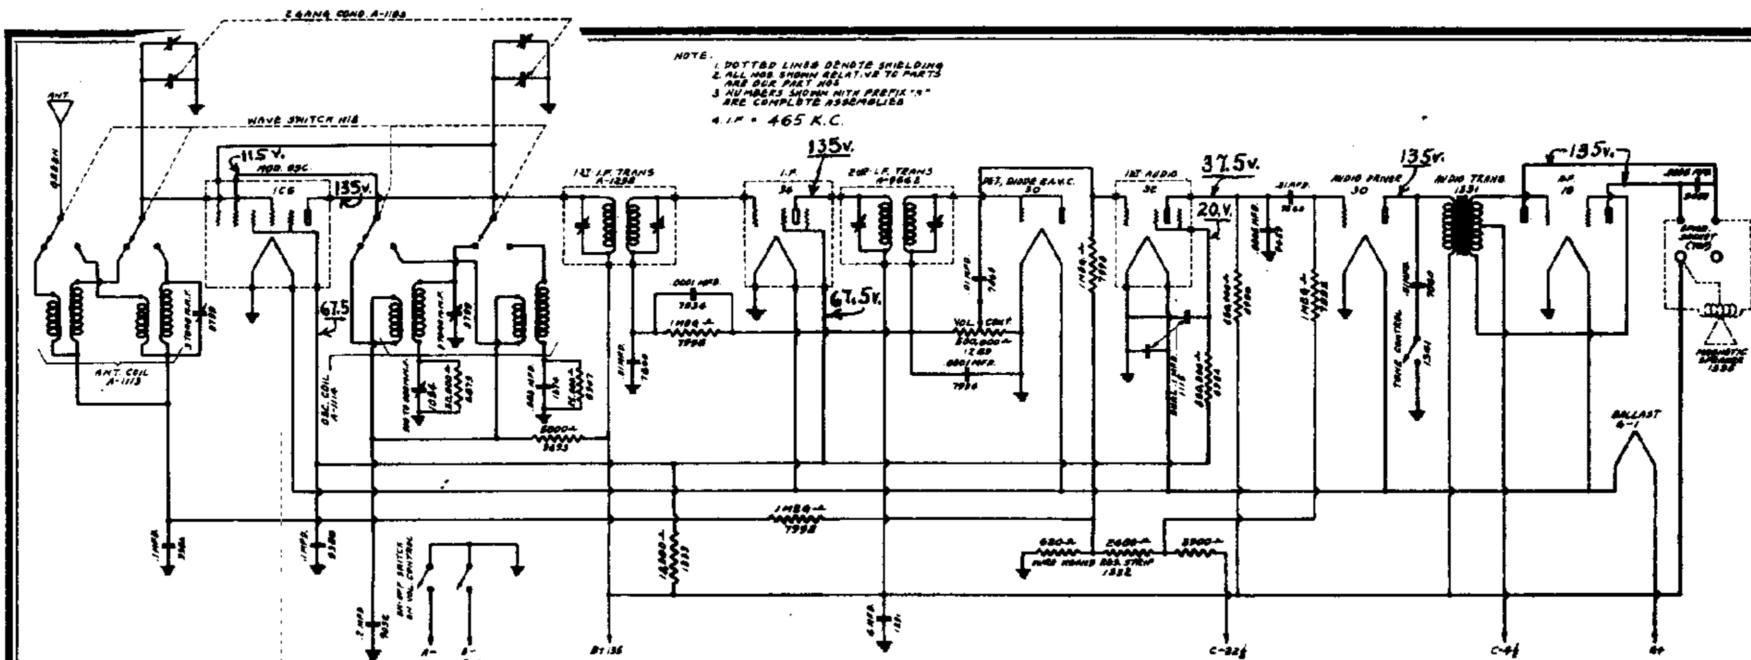
ALLIED RADIO CORP.



NOTE: Two type intermediate transformer trimmers have been used in this receiver. One type has two parallel holes in the top of the shield, one for each trimmer. The other type has a brass hex nut for adjusting one trimmer, the other intermediate trimmer being adjusted with the trimmer screw located inside of the brass hex nut. Regardless of which type trimmer is used the procedure is the same.

TO ALIGN THE VARIABLE CONDENSER: It is important when aligning to follow the procedure carefully, otherwise the receiver will lack sensitivity and the dial calibration will be incorrect.

1. Connect the high output side of the oscillator to the receiver antenna lead and the ground to the chassis.

2. Place the band selector switch for operation on the short wave band, tune the receiver to exactly 15 megacycles on the dial and set the test oscillator frequency to exactly 15 megacycles. THEN TUNE IN THE 15 MEGACYCLE SIGNAL BY ADJUSTING THE TRIMMER MOUNTED ON TOP OF THE OSCILLATOR SECTION OF THE GANG CONDENSER TO MAXIMUM OUTPUT.

Looking at the front of the receiver the oscillator section is the rear section of the gang condenser.

3. Set the band selector switch for operation on the broadcast band, adjust the test oscillator frequency to 1400 kilocycles and set the receiver dial to exactly 1400 kilocycles. NEXT, BRING IN THE 1400 KILOCYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING THE TRIMMER LOCATED UNDERNEATH AND NEAR THE CENTER FRONT OF THE CHASSIS.

4. After making this adjustment tune the dial to 1720 kilocycles and set theoscillator frequency to 1720 kilocycles. If the 1720 kilocycle signal cannot be received reduce the 1400 kilocycle trimmer capacity until the 1720 kilocycle signal is brought in.

5. Next, set the receiver dial and test oscillator to exactly 1400 kilocycles, and adjust the trimmer located on the front section of the gang condenser for maximum sensitivity.

6. Leave the band selecter switch for operation on the broadcast band, tune the receiver and set the oscillator to approximately 600 kilocycles. Then adjust the 600 kilocycle padding condenser,which is located on and accessible through the small hole in the front of the chassis, for maximum sensitivity. As this adjustment is quite critical it is necessary to rock the condenser slightly to the right and left to find the point of greatest sensitivity.

7. Place the band selector switch for operation on the short wave band, adjust the test oscillator frequency to exactly 15 megacycles and set the receiver dial to 15 megacycles. Turn the receiver on its back with the dial up and adjust the trimmer, which is mounted on the top of the coil underneath and near the right hand side of the chassis, for maximum output. Be sure to rock the condenser slightly to the right and left when making this adjustment.

SERVICE NOTES
for the
SEVEN TUBE AC OPERATED
THREE BAND SUPERHETERODYNE RECEIVER
1520-530 KILOCYCLES
1.5-4.2 MEGACYCLES
5.4-16 MEGACYCLES

Realignment of this receiver should never be necessary unless one of the oscillator, antenna, or RF coils has been replaced and then only the frequency band in which the coil is used will require realignment. Lack of sensitivity, selectivity, and poor tone quality may be due to any one or a combination of causes such as weak or defective tubes or speaker, inadequate or excessively long antenna, open or grounded bias resistor, bypass condenser, etc. Under no circumstances should realignment be attempted until all other possible sources of trouble have been first thoroughly investigated and have definitely proven not to be the cause. If an IF tube is replaced it is advisable to realign the IF amplifier particularly if the replacement tube is made by a different manufacturer than the one in the receiver.

NOTE: NEVER LIFT THE RECEIVER BY GRASPING THE CATACOMB SHIELD, TO DO SO MAY MOVE THE SHIELD THEREBY DETUNING THE RECEIVER.

ALIGNMENT PROCEDURE:

It is important when aligning to carefully follow the procedure in the order given, otherwise the receiver will lack sensitivity and the dial calibration will be incorrect. IT IS IMPERATIVE THAT AN ACCURATELY CALIBRATED OSCILLATOR BE USED WITH SOME TYPE OF OUTPUT MEASURING DEVICE.

INTERMEDIATE ALIGNMENT:

1. Connect the high side of the oscillator output to the control grid of the 6A7 tube, leaving the grid cap disconnected. Connect the ground side of the oscillator to the receiver chassis.

2. Set the test oscillator frequency to 465 kilocycles. (This must be accurate).

3. Align the first intermediate transformer by turning one of the trimmer screws up and down (increasing and decreasing capacity) until maximum reading is obtained on the output meter, after which adjust the other trimmer screw of the same transformer for maximum sensitivity.

4. Adjust the other intermediate transformer in the same manner.

NOTE: Two type intermediate transformer trimmers have been used in this receiver. One type has two parallel holes in the top of the shield, one for each trimmer. The other type has a brass hex nut for adjusting one trimmer, the other intermediate trimmer being adjusted with the trimmer screw located inside of the brass hex nut. Regardless of which type trimmer is used, the procedure is the same.

TO ALIGN THE VARIABLE CONDENSER:

Adjustment of the trimmer condensers, located inside of and accessible through the holes found in the top of the catacomb shield (mounted on top and in the left hand front corner of the receiver) will be referred to by numbers as indicated on the circuit diagram showing the relative location of these trimmers.

1. Connect the high output side of the test oscillator to the receiver antenna post through a 250 MMFD (.00025 MFD) condenser and the ground to the set ground post.

2. Place the band selector switch for operation on the 1520 to 530 kilocycle (broadcast) band. Tune the receiver to exactly 1400 kilocycles on the dial and set the test oscillator frequency to exactly 1400 kilocycles. THEN BRING IN THE 1400 KILOCYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING THE TRIMMER MARKED NO. 2 ON CATACOMB DIAGRAM, after which adjust No. 1 and No. 3 trimmers in the order named for maximum sensitivity.

3. Leave the band selector switch for operation on the broadcast band (1520 to 530 kilocycles) and tune the receiver and set the oscillator to approximately 600 kilocycles. Then adjust the 600 kilocycle padding condenser No. 9 which is located on and accessible through the hole in the left hand side of the chassis for maximum sensitivity. As this adjustment is quite critical, it is necessary to rock the variable condenser slightly to the right and to the left to find the point of greatest sensitivity.

4. Recheck the alignment at 1400 kilocycles as the 600 kilocycle adjustment may have changed the alignment at 1400 kilocycles.

5. Place the band selector switch for operation on the 1.5 to 4.2 megacycle band and set the test oscillator frequency and tune the receiver dial to exactly 3.8 megacycles. THEN TUNE IN THIS 3.8 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING CATACOMB TRIMMER NO. 4, next adjust trimmer No. 5 for maximum sensitivity.

6. With the band selector switch in the same position (1.5 to 4.2 megacycle band) tune the receiver dial and set the oscillator frequency to approximately 1.7 megacycles and then while rocking the variable condenser slightly to the right and left, adjust the 1.7 megacycle trimmer No. 10 (located on the left hand side of the chassis) for maximum sensitivity.

7. Recheck 3.8 megacycle adjustments.

8. Adjust the band selector switch for operation on the 5.2 to 16 megacycle band and tune the receiver dial and set the oscillator frequency to exactly 15 megacycles. When adjusting catacomb trimmer No. 6 two peaks (the fundamental and the image peak) will be noticed. CARE MUST BE TAKEN SO THAT THE FUNDAMENTAL PEAK AND NOT THE IMAGE PEAK IS USED FOR ALIGNING THE RECEIVER AT 15 MEGACYCLES. First back off catacomb trimmer No. 6 to minimum capacity, next screw down the trimmer (add capacity) until the first peak which is the fundamental and the one you are to use is tuned in. If the trimmer is screwed down beyond the point where this first peak is received the incorrect image peak will be tuned in. When the first peak has been located adjust catacomb trimmer No. 6 to BRING IN THE 15 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT. After completing this adjustment always check to see if the proper peak has been used. To do this leave the test oscillator frequency at 15 megacycles and increase the output of the test oscillator, then tune the receiver dial to approximately 14 megacycles. Vary the receiver dial slightly to the right and left of 14 megacycles and if the fundamental peak was used in aligning at 15 megacycles the test oscillator signal will be heard at approximately 14 megacycles on the set dial. If it is not possible to receive the signal then the fundamental peak was not used and the 15 megacycle adjustment of trimmer No. 6 must be gone over and properly adjusted. After correctly completing catacomb trimmer No. 6 adjustment adjust catacomb trimmer No. 7 to maximum sensitivity. Should two peaks be noticed with this trimmer always adjust trimmer No. 7 to the one that requires the most capacity to tune in.

MODELS G-9643,9645
Alignment,Part 2
Voltage,Parts List

ALLIED RADIO CORP.

9. Leave the band selector switch for operation on 5.4 to 16 megacycle band, set the oscillator frequency and tune the receiver dial to approximately 6 megacycles. While rocking the variable condenser slightly to the right and left, adjust the 6 megacycle trimmer No. 8 (located on the left hand side of the chassis) for maximum sensitivity.

10. Recheck 15 megacycle adjustments.

11. Some code and aircraft signals are broadcast on a frequency exactly the same or near the IF frequency of the receiver. To eliminate interference from these signals a 465 kilocycle filter (mounted in the coil shield located underneath and towards the front of the chassis) is incorporated in the set. To adjust, set the oscillator frequency (with oscillator output connected to set antenna and ground) TO EXACTLY 465 KILOCYCLES turn the receiver on end and adjust the trimmer located on and accessible through the top of the filter shield for MINIMUM 465 KILOCYCLE SIGNAL.

This completes the alignment and it is recommended that all of the adjustments be gone over again. Generally it will be found that improved results can be obtained if this is done. Assuming that all tubes and component parts of the set are okeh, extreme inaccuracies in the dial calibration, low sensitivity, and poor selectivity are indications that the alignment procedure has not been followed. Should these conditions be apparent, proceed to realign, starting at the IF alignment and carefully follow each step in the order given.

VOLTAGE TABLE

SERVICE NOTES
for the
TEN TUBE BATTERY OPERATED
FOUR BAND SUPERHETERODYNE RECEIVER
1520-535 KILOCYCLES
1.5 -4.2 MEGACYCLES
4 -11 MEGACYCLES
10 -20 MEGACYCLES

Realignment of this receiver should never be necessary unless one of the oscillator, antenna or RF coils has been replaced and then only the frequency band in which that coil is used will require realignment. Lack of sensitivity, selectivity, and poor tone quality may be due to any one or a combination of causes such as weak or defective tubes or speaker, inadequate or excessively long antenna, open or grounded bias resistor, bypass condenser, etc. Under no circumstances should realignment be attempted until all other possible sources of trouble have been first thoroughly investigated and have been definitely proven not to be the cause. If an IF tube is replaced it is advisable to realign the IF amplifier particularly if the replacement tube is one of a different manufacture than the one in the receiver.

NOTE: NEVER LIFT THE RECEIVER BY GRASPING THE CATACOMB SHIELD, TO DO SO MAY MOVE THE SHIELD THEREBY DETUNING THE RECEIVER.

ALIGNMENT PROCEDURE: It is important when aligning to carefully follow the procedure in the order given, otherwise the receiver will lack sensitivity and the dial calibration will be incorrect. IT IS IMPERATIVE THAT AN ACCURATELY CALIBRATED OSCILLATOR BE USED WITH SOME TYPE OF OUTPUT MEASURING DEVICE.

INTERMEDIATE ALIGNMENT:

1. Connect the high side of the oscillator output to the control grid of the 1C6 tube, leaving the grid cap disconnected. Connect the ground side of the oscillator to the receiver ground post.

2. Set the test oscillator frequency to 465 kilocycles. (This must be accurate).

3. Align the first intermediate transformer by turning one of the trimmer screws up and down (increasing and decreasing capacity) until maximum reading is obtained on the output meter, after which adjust the other trimmer screw of the same transformer for maximum sensitivity.

4. Adjust the other intermediate transformers in the same manner.

NOTE: Two type intermediate transformer trimmers have been used in this receiver. One type has two parallel holes in the top of the shield, one for each trimmer. The other type has a brass hex nut for adjusting one trimmer, the other intermediate transformer being adjusted with the trimmer screw located inside of the brass hex nut. Regardless of which type trimmer is used, the procedure is the same.

TO ALIGN THE VARIABLE CONDENSER:

Adjustment of the trimmer condensers, located inside of and accessible through the holes found in the top of the catacomb (mounted on top and in the left hand front corner of the receiver) will be referred to by numbers as indicated on the circuit diagram showing the relative location of these trimmers.

1. Connect the high output side of the oscillator through a 250 mmfd. (.00025 Mfd.) to the receiver antenna post and the ground to the ground post.

2. Place the band selector switch for operation on the 1520 to 535 kilocycle band (broadcast), tune the receiver to exactly 1400 kilocycles on the dial and set the test oscillator frequency to exactly 1400 kilocycles. THEN BRING IN THE 1400 KILOCYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING TRIMMER MARKED No. 2 ON CATACOMB DIAGRAM, after which adjust No. 1 and No. 3 trimmers in the order named for maximum sensitivity.

3. Leave the band selector switch for operation on the broadcast band (1520-535 kilocycles) and tune the receiver and set the test oscillator to approximately 600 kilocycles. Then while rocking the condenser slightly to the right and left adjust the 600 kilocycle padding condenser No. 11, which is located on and accessible through the hole provided on the left hand side of the chassis, for maximum sensitivity.

4. Recheck the alignment at 1400 kilocycles as the 600 kilocycle adjustment may have changed the alignment at 1400 kilocycles.

5. Place the band selector switch for operation on the 1.5 to 4.2 megacycle band and set the test oscillator frequency and tune the receiver dial to EXACTLY 3.8 MEGACYCLES. THEN TUNE IN THIS 3.8 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING CATACOMB TRIMMER NO. 7. Next adjust catacomb trimmer No. 4 for maximum sensitivity.

6. With the band selector switch in the same position (1.5-4.2 megacycle band) tune the receiver dial and set the oscillator frequency to approximately 1600 kilocycles, and then while rocking the variable condenser slightly to the right and left adjust the 1600 kilocycle trimmer No. 12 located on the left hand side of the chassis for maximum sensitivity.

7. Recheck 3.8 megacycle adjustments.

8. Adjust the band selector switch for operation on the 4 to 11 megacycle band and tune the receiver dial and set the oscillator frequency to exactly 10.5 megacycles. When adjusting catacomb trimmer No. 5 two peaks (the fundamental and the image peak) will be noticed. CARE MUST BE TAKEN SO THAT THE FUNDAMENTAL PEAK AND NOT THE IMAGE PEAK IS USED FOR ALIGNING THE RECEIVER AT 10.5 MEGACYCLES. First back off catacomb trimmer No. 5 to minimum capacity, next screw down the trimmer (add capacity) until the first peak which is the fundamental and the one you areto use is tuned in. If the trimmer is screwed down beyond the point where this first peak is received the incorrect image peak will be tuned in. When the first peak has been located adjust catacomb trimmer No. 5 to BRING IN THE 10.5 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT After completing this adjustment always check to see if the proper peak has been used. To do this leave the test oscillator frequency at 10.5 megacycles, increase its output, and tune the receiver dial to approximately 9.5 megacycles. Vary the receiver dial slightly to the right and left of 9.5 megacycles and if the fundamental peak was used in aligning at 10.5 megacycles the test oscillator signal will be heard at approximately 9.5 megacycles on set dial. If it is not possible to receive the signal then the fundamental peak was not used and the 10.5 megacycle adjustment of trimmer No. 5 must be gone over and properly adjusted. After correctly completing catacomb trimmer No. 5 adjustment adjust catacomb trimmer No. 6 for maximum sensitivity. Should two peaks be noticed with this trimmer always adjust trimmer No. 6 to the one that requires the most capacity.

Alignment,Part 2
Voltage,Parts List

9. With the band selector switch adjusted for operation on the same band (4-11 megacycles) set the test oscillator frequency and tune the receiver dial to approximately 4.8 megacycles. Then while rocking the variable condenser slightly to the right and left adjust the 4.8 megacycle trimmer No. 10, located on the left hand side of the chassis for maximum sensitivity.

10. Recheck the 10.5 megacycle adjustment.

11. Adjust the band selector switch for operation on the 10 to 20 megacycle band, tune the receiver dial and set the oscillator frequency to exactly 19 megacycles. When adjusting catacomb trimmer No. 8 two peaks (the fundamental and the image peak) will be noticed. CARE MUST BE TAKEN SO THAT THE FUNDAMENTAL PEAK AND NOT THE IMAGE PEAK IS USED FOR ALIGNING THE RECEIVER AT 19 MEGACYCLES. First back off catacomb trimmer No. 8 to minimum capacity, next screw down the trimmer (add capacity) until the first peak which is the fundamental and the one you are to use is tuned in. If the trimmer is screwed down beyond the point where this first peak is received the incorrect image peak will be tuned in. When the first peak has been located adjust catacomb trimmer No. 8 to BRING IN THE 19 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT. After completing this adjustment always check to see if the proper peak has been used. To do this leave the test oscillator frequency at 19 megacycles, increase its output, and tune the receiver dial to approximately 18 megacycles. Vary the receiver dial slightly to the right and left of 18 megacycles and if the fundamental peak was used in aligning at 19 megacycles the test oscillator signal will be heard at approximately 18 megacycles on set dial. If it is not possible to receive the signal then the fundamental peak was used and the 19 megacycle adjustment of trimmer No. 8 must be gone over and properly adjusted. After correctly completing catacomb trimmer No. 8 adjustment adjust catacomb trimmer No. 9 for maximum sensitivity. Should two peaks be noticed with this trimmer always adjust trimmer No. 9 to the one that requires the most capacity.

12. Some code and aircraft signals are broadcast on a frequency exactly the same or near the IF frequency of the receiver. To eliminate interference from these signals a 465 kilocycle filter (mounted in the coil shield located underneath and towards the front of the chassis) is incorporated in the set. To adjust, set the oscillator frequency (with oscillator output connected to set antenna and ground) TO EXACTLY 465 KILOCYCLES, turn the receiver on end and adjust the trimmer located on and accessible through the top of the filter shield for MINIMUM 465 KILOCYCLE SIGNAL.

This completes the alignment and it is recommended that all of the adjustments be gone over again. Generally it will be found that improved results can be obtained if this is done. Assuming that all tubes and component parts of the set are okeh, then extreme inaccuracies in the dial calibration, low sensitivity, and poor selectivity are indications that the alignment procedure has not been followed. Should these conditions be apparent, proceed to realign starting at the IF alignment and carefully follow each step in the order given.

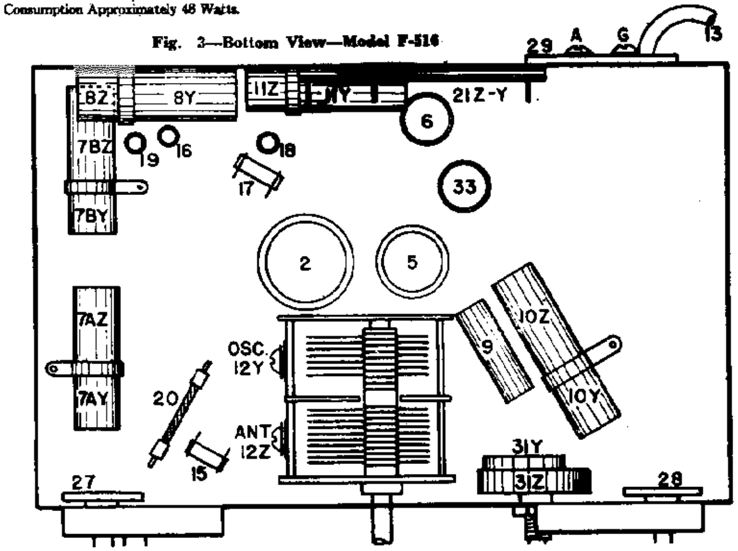
6B5	Output	6.3	200	—	—	0	210	0
80	Rectifier	4.9	289	—	—	—	—	—

Measured on 117.5 Volt—60 Cycle Line.
Power Consumption Approximately 48 Watts.
Power Output Approximately 2.5 Watts.

Fig. 3—Bottom View—Model F-516



SPECIFICATIONS

This model radio is a five-tube superheterodyne receiver designed for operation on an ALTERNATING CURRENT power supply. It is available with either of the following types of power transformers: 110 volt—60 cycles, 110 volt—25 cycles or 220 volts—25 cycles.

It is a two band receiver, tuning from approximately 540 to 1570 kilocycles in the American Broadcast Band and from 1570 to 4000 kilocycles in the Police and Amateur Band.

The tubes used are 6D6 Oscillator-Modulator, 6D6 I. F. Amplifier, 76 Detector, 6B5 Output and type 80 Rectifier.

SOCKET VOLTAGES

The tube socket voltages are measured from the socket contacts to the chassis with a 1000 ohm per volt, 250 volt voltmeter (except filaments) with receiver in operating condition and no signal input. Readings may vary plus or minus 10% of values given. Filament readings are taken with a low range A. C. voltmeter.

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and should need no further adjustment. However, if it is definitely known that an adjustment is necessary the circuits can best be aligned with the use of a modulated signal generator and an output meter.

CONNECTING OUTPUT METER

Connect one terminal of the output meter to P1 and the other terminal to P2 of the 6B5 output tube. Looking at the bottom of the tube with the filament prongs toward you P1 will be the first prong to the left of the filaments and P2 will be next to P1. Be sure the meter is protected from D. C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier to 450 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd. series condenser to the top cap of the 6D6 I. F. tube, leaving the tube's grid clip in place.

KEEP THE GENERATOR LEAD AS FAR AS POSSIBLE FROM THE OTHER S. G. TUBES.

(b) Connect the ground lead of the signal generator to the chassis frame or ground terminal of the receiver.

(c) Set the signal generator to 450 kilocycles.

(d) Rotate the receiver tuning condenser until the rotor plates are completely out of mesh.

(e) Turn the band selector switch to the right hand position. (Short Wave Band).

(f) Turn the volume control of the receiver on full.

(g) With the signal generator set to the lowest usable output level adjust the I. F. trimmer condensers located on top of the 2nd I. F. transformers, Fig. 2, for maximum output.

(h) Remove the signal generator lead from the 6D6 I. F. tube and connect it to the top cap of the 6D6 Osc.-Mod. tube, leaving the tube's grid clip in place.

(i) Adjust the trimmer condensers located on top of the 1st I. F. transformer for maximum output.

DO NOT RETUNE THE 2ND I. F. TRANSFORMER.

2. Aligning R. F. Circuits.

(a) Turn the band selector switch to the left hand position. (Broadcast Band).

(b) Leave the receiver tuning condenser rotor plates completely out of mesh.

(c) Connect the output lead from the signal generator through a .00025 mfd., series condenser to the antenna terminal of the receiver.

(d) Set the signal generator to approximately 1570 kilocycles.

(e) Adjust the trimmer on the "Osc." section of the tuning condenser gang for maximum output. (Fig. 3).

(f) Set the signal generator to 1400 kilocycles.

(g) Tune in the 1400 kilocycle signal with the station selector for maximum output.

NOTE: Do not disturb the setting of the "Osc." trimmer as this is adjusted at 1570 kilocycles only and any further adjustment at this point would affect both the tuning range of the receiver and the tracking of its circuits.

(h) Adjust the trimmer on the "Ant." section of the tuning condenser gang for maximum output.

NOTE: There are no adjustments on this receiver for the Police Band.

Power consumption approximately 2.2 amperes at 6.0 volts.
Power Output approximately .7 watt.

SPECIFICATIONS

The Amrad Model F-546 is a five-tube superheterodyne receiver designed for operation from a six-volt storage battery. It contains a completely shielded, built-in

GREEN 540-1730 Kilocycles
RED 2.3- 7.0 Megacycles

TUBES AND VOLTAGE LIMITS

The following table gives the functions of the tubes used, together with the voltage readings between the tube socket contacts and the chassis. Voltage readings should be taken with a 1000 ohm per volt, 250 volt power supply unit which employs a self-rectifying type vibrator.

The tuning range of the receiver is from 540 to 7000 kilocycles and is divided into two bands as follows:
(American Broadcast Band)
(High Frequency Band)

voltmeter (except filaments with the volume control full on and no signal input. The filament voltages should be measured with an accurate low range D-C voltmeter (approximately 0 to 10 volts). Voltage limits may vary plus or minus 10% of values given.

MODEL F-546

June, 1936

SIGNAL INPUT FREQUENCIES

		Shunt Alignment	Series Alignment
American Broadcast Band	(GREEN)	1400 Kc.	600 Kc.
High Frequency Band	(RED)	5000 Kc.	2800 Kc.

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and normally should need no further adjustment. However, if it is definitely known that an adjustment is necessary the circuits can best be properly aligned with the use of a modulated signal generator and an output meter.

CONNECTING OUTPUT METER

Connect one terminal of the output meter to the plate and the other terminal to the screen of the 38 Output tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. **Tuning I-F Amplifier to 450 Kilocycles.**

(a) Connect the output signal generator through a .02 mfd. condenser to the top cap of the 6A7 tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the "GND" terminal of the receiver. KEEP THE GENERATOR OUTPUT LEAD AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Set the station selector so that the tuning condenser plates are completely out of mesh. Turn the volume control knob to the right (ON) and turn the tone control knob to the left (TREBLE).

(c) Turn the band selector switch to the right (High Frequency Band).

(d) Set the signal generator to 450 kilocycles.

(e) Adjust both trimmers located on top of the 2nd I-F transformer for maximum output.

(f) Adjust both trimmers located on top of the 1st I-F transformer for maximum output.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

2. **Aligning R-F Amplifier.**

When aligning the R-F amplifier the output lead from the signal generator is connected to the antenna ("A-1") terminal of the receiver through a .00025 mfd. condenser.

Each band should first be shunt aligned and then series aligned. The band selector switch should be set for the band being aligned and the signal generator should be set to the frequency indicated for each adjustment.

Adjust the "OSC", "R-F" and "ANT" shunt trimmers in the order given for maximum output. Tune the station selector to the signal generator for maximum output and then check the adjustments of the "R-F" and "ANT" trimmers in the order given. Do not readjust the "OSC" trimmer. NOTE: When aligning the High Frequency Band care must be exercised so that the circuits will be aligned on the fundamental frequency rather than on the image frequency which is approximately 900 kilocycles less than the fundamental. To check on this, increase the output of the signal generator approximately ten times and try to tune-in the signal at both the generator frequency as indicated on the station selector dial and at approximately 900 kilocycles below the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct position.

To adjust the "series" trimmers set the signal generator to the frequency indicated and then tune-in this signal with the station selector for maximum output. Adjust the "series" trimmer while rocking the tuning condenser back and forth slightly, until no further improvement in output can be obtained.

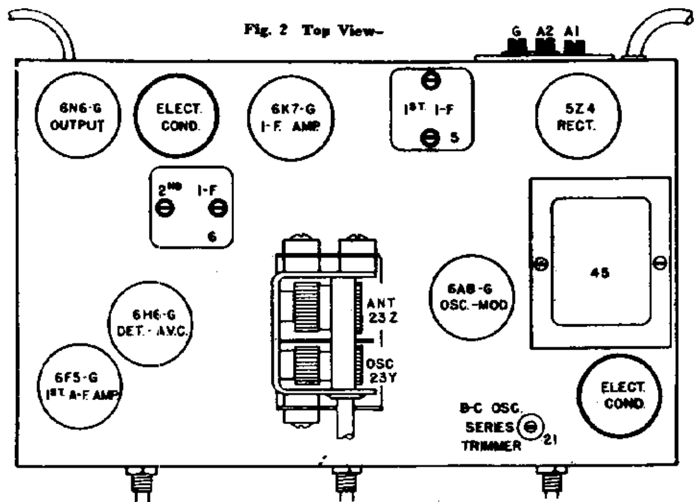
Voltage, Alignment

AMRAD CORP.

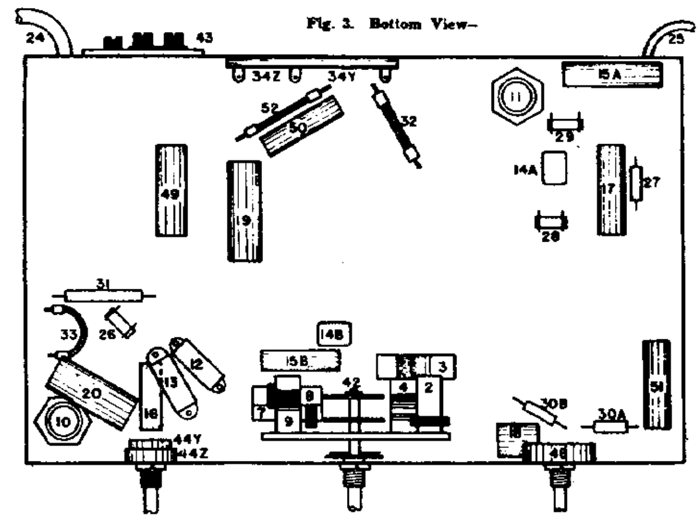
Fig. 2 Top View—



MODEL F-616

June, 1936

Fig. 3. Bottom View—



ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and normally should need no further adjustment. However, if it is definitely known that an adjustment is necessary the circuits can best be properly aligned with the use of a modulated signal generator and an output meter.

CONNECTING OUTPUT METER

Connect the output meter to the two plates of the 6N6 Output Tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier to 450 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd. condenser to the top cap of the 6A8 tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the "GND" terminal of the receiver. KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Set the station selector so that the tuning condenser plates are completely out of mesh. Turn the volume control knob to the right (ON) and turn the tone control knob to the left (TREBLE).

(c) Turn the band selector switch to the High Frequency Band.

(d) Set the signal generator to 450 kilocycles.

(e) Adjust both trimmers located on top of the 2nd I-F Transformer for maximum output.

(f) Adjust both trimmers located on top of the 1st I-F Transformer for maximum output.

(g) Check operations (e) and (f) for more accurate adjustments.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

2. Aligning R-F Amplifier.

When aligning the R-F Amplifier the output lead of the signal generator is connected to the "ANT" terminal of the receiver. For the GREEN and WHITE bands a .00025 mfd. condenser must be connected in series with the output lead of the signal generator and for the high-frequency band a 400 ohm carbon resistor should be used in place of the condenser.

Each band should first be shunt aligned and then series aligned, where provision is made for series alignment (GREEN band). The band selector switch should be set for the band being aligned and the station selector and signal generator should be set to the frequency indicated (c) for each adjustment.

(a) Adjust the "Osc." and "ANT" shunt trimmers in the order given for maximum output. Readjust the station selector slightly so that the generator signal is tuned-in with maximum output and then check the adjustments of the "ANT" trimmers. DO NOT READJUST the "OSC" TRIMMER.

NOTE: When shunt aligning the WHITE and RED bands care must be exercised so that the circuits will be aligned on the correct frequency rather than on the image frequency which is approximately 900 kilocycles less than the fundamental. To check on this, increase the output of the signal generator ten times, or more, and try to tune-in the signal both at the generator frequency as indicated on the station selector dial and at approximately 900 kilocycles less than the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct position.

(b) To align the series trimmer (Item 21, Fig. 2) set the signal generator to the frequency indicated (c) and then tune-in this signal with the station selector for maximum output. To obtain the best adjustment for the series trimmer it will be necessary to rotate the station selector back and forth slightly while adjusting the trimmer for maximum output.

(c) Signal Input Frequencies:

	Shunt Alignment	Series Alignment
American Broadcast Band (GREEN)	1700 Kilocycles	600 Kilocycles
Police Band (WHITE)	6000 Kilocycles	....
High-Frequency Band (RED)	18000 Kilocycles	....

SPECIFICATIONS

The Amrad Radio Model F-616 is a six-tube superheterodyne receiver designed to operate on an ALTERNATING CURRENT power supply. It is designed to use either metal tubes or the equivalent glass tubes with octal bases. If glass tubes are replaced with metal tubes or metal tubes are replaced with glass tubes it will be necessary to completely realign the circuits of the receiver.

It is a three band receiver and the dial is divided into three sections as follows:

GREEN	540-1800 Kilocycles	(American Broadcast Band)
WHITE	1.8- 6.0 Megacycles	(Police and Amateurs)
RED	6.0- 18.0 Megacycles	(High Frequency Bands)

SOCKET VOLTAGES

The tube socket voltages are measured from the tube socket contacts to the chassis with a 1000 ohm per volt, 500 volt D.C. voltmeter (except filaments) with the receiver in operating condition and no signal input. The filament voltages should be measured with an accurate low range A-C voltmeter (Approximately 0-10 volts). Readings may vary plus or minus 10% of values given.

MODEL F-626

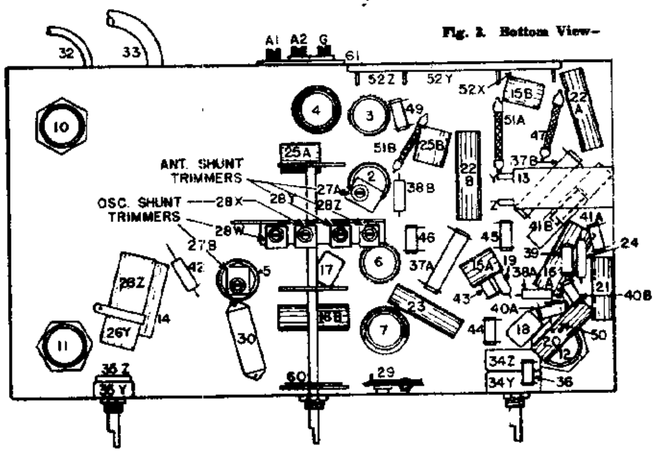
June, 1936

Fig. 3. Bottom View--



SPECIFICATIONS

The Amrad Model F-626 radio is a six-tube superheterodyne receiver designed to operate on an ALTERNATING CURRENT power supply. It is available with either of the following types of power transformers: 110 volt—60 cycles, 110 volt—25 cycles or 220 volts—25 cycles.

This receiver is designed to use either metal tubes or the equivalent glass tubes with octal bases. If glass tubes are replaced with metal tubes or metal tubes are replaced with glass tubes it will be necessary to completely realign the circuits of the receiver.

It is a three band receiver and the dial is divided into three sections as follows:

GREEN	540- 1800 Kilocycles	(American Broadcast Band)
WHITE	1600- 6000 Kilocycles	(Police and Amateurs)
RED	5800-18500 Kilocycles	(High Frequency Band)

SOCKET VOLTAGES

The tube socket voltages are measured from the tube socket contacts to the chassis with a 1000 ohm per volt, 500 volt D.C. voltmeter (except filaments) with the receiver in operating condition and no signal input. The filament voltages should be measured with an accurate low range A-C voltmeter (Approximately 0-10 volts). Reading may vary plus or minus 10% of values given.

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and normally should need no further adjustment. If it is definitely known that readjustment is necessary the circuits may be most accurately aligned with the aid of an oscilloscope. However, if an oscilloscope is not available a good alignment may be obtained by means of a signal generator and an output meter provided the following procedure is carefully observed.

CONNECTING OUTPUT METER

Connect the two terminals of the output meter to the two plates of the 6N6 Ouput tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier to 450 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd. condenser to the top cap of the 6K7 I-F Amplifier tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the receiver chassis. KEEP THE GENERATOR OUTPUT LEAD AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Turn the band selector switch to the Broadcast Band and rotate the station selector to approximately 60 on the dial. Turn the volume knob to the right (ON) and turn the tone control knob to the left (TREBLE).

(c) Set the signal generator to 450 kilocycles.

(d) Adjust the trimmer condensers located on top of the 2nd I-F transformer for maximum output (Fig. 2).

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

(e) Tansfer the output lead of the signal generator from the 6K7 tube to the top cap of the 6A8 Oscillator-Modulator tube, leaving the tube's grid clip in place.

(f) Close the middle trimmer (Tert. Fig. 4) on the 1st I-F transformer so that it is moderately tight. (Do not force adjusting screw).

(g) Adjust the top trimmer on the 1st I-F transformer for maximum output.

(h) Adjust the bottom trimmer on the 1st I-F transformer for maximum output.

(i) Transfer the signal generator output lead from the 6A8 tube to the "Ant" terminal of the receiver and increase the output of the signal generator if necessary.

(j) Check the adjustment of the bottom trimmer of the 1st I-F transformer. DO NOT READJUST THE TOP TRIMMER.

(k) Adjust the middle trimmer of the 1st I-F transformer by opening condenser until maximum output is obtained. DO NOT READJUST THE TOP AND BOTTOM TRIMMERS.

2. Aligning R-F Amplifier.

When aligning the R-F Amplifier the output lead of the signal generator is connected to the "ANT" terminal of the receiver. For the GREEN and WHITE bands a .00025 mfd. condenser must be connected in series with the output lead of the signal generator and for the high-frequency band a 400 ohm carbon resistor should be used in place of the condenser.

Each band should first be shunt aligned and then series aligned where provision is made for series alignment (GREEN and WHITE bands). The band selector switch should be set for the band being aligned and the station selector and signal generator should be set to the frequency indicated (c) for each adjustment.

(a) Adjust the "OSC" and "ANT" shunt trimmers in the order given for maximum output. Readjust the station selector slightly so that the generator signal is tuned-in with maximum output and then check the adjustments of the "ANT" trimmers. DO NOT READJUST the "OSC" TRIMMER.

NOTE: When shunt aligning the WHITE and RED bands care must be exercised so that the circuits will be aligned on the correct frequency rather than on the image frequency which is approximately 900 kilocycles less than the fundamental. To check on this, increase the output of the signal generator ten times or more and try to tune-in the signal both at the generator frequency as indicated on the station selector dial and at approximately 900 kilocycles less than the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct position.

(b) To align the series trimmers (29Y-29Z Fig. 4) set the signal generator to the frequency indicated (c) and then tune-in this signal with the station selector for maximum ouput. To obtain the best adjustment for each series trimmer it will be necessary to rotate the station selector back and forth slightly while adjusting the trimmer for maximum output.

(c) Signal Input Frequencies:

	Shunt Alignment	Series Alignment
American Broadcast Band (GREEN)	1700 Kilocycles	600 Kilocycles
Police Band (WHITE)	6000 Kilocycles	2500 Kilocycles
High-Frequency Band (RED)	18000 Kilocycles	....

TRIMMER CONDENSERS

Trimmers are precisely adjusted at the factory, and readjustment is never required except in the normal course of servicing. The following technical data is therefore intended only for the use of radio service experts who have the equipment and experience for this work.

GENERAL

When adjusting trimmers, keep the radio volume control and tone control turned full clockwise.

Use an Atwater Kent No. 42590 I.F. coupling unit to couple the signal generator while aligning I.F. trimmers. The coupling unit may be purchased through any Atwater Kent distributor.

In order to keep below the AVC level, it is necessary to use the weakest possible output from signal generator that will give a reading on a sensitive output meter.

I.F. TRIMMERS

Turn variable condenser full out of mesh.

Connect signal generator (264 KC) to cap of I.F. tube by means of No. 42590 coupling unit. Peak two trimmers on top of T5.

Connect signal generator to cap of 1st-detector tube and peak two trimmers on top of T4.

DIAL ADJUSTMENT

With variable condenser fully meshed, the arrow indicator should be adjusted (by means of screw in center of dial lamp opening at rear of tuning unit) to the mark beyond the 550 KC end of dial.

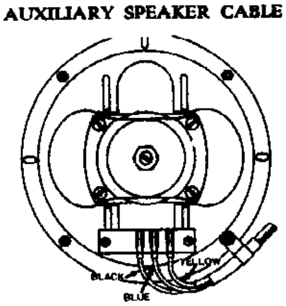
R.F. TRIMMERS

Connect signal generator (1500 KC) to antenna and chassis, using a 200 MMF fixed condenser in series with the antenna lead. With dial at 1500 KC, peak A3 (oscillator), A2 (1st-detector) and A1 (antenna). Use first peak as A3 is screwed in from a loose position.

With signal generator at 550 KC, peak tracking condenser A4 while rocking tuning control slightly around the 550 KC mark.

Repeat adjustments at 1500 and 550 KC if necessary.

CONNECTIONS OF AUXILIARY SPEAKER CABLE



PARTS LIST MODELS 126, 136, 416, 446 and 556

32104	Set container with volume control chuck
29298	Station selector chuck
26035	Inner plate
29226	Chuck nut
32106	Ground clip (edge of set)
32319	Bottom lid
32128	Snap buttons (2 used)
32108	Snap buttons (8 used)
32142	T head mounting bolt
32204	Mounting washer
24485	Lockwasher
32171	Mounting nut
32217	Cable and socket from chassis to lid
49990	Var. condenser assembly
32097	Var. cond. mounting clips
32187	No. 1 I.F.T. shield
32189	No. 2 I.F.T. shield
32219	Oscillator trans. shield
32218	R.F.T. shield
32211	Clips on R.F., I.F. shields
32109	Clips on Osc. shield
32102	VOL. CONTROL .5 MEG.
45370	TONE CONTROL SWITCH
32182	Tone control nut
32168	Tube shield (half)
32169	Holding ring for the above
32266	Tube shield clip on base

SOCKETS

30058	Universal 8 prong
32114	Vibrator socket
29057	Speaker socket

TRANSFORMERS

T1	50060	No. 1 R.F. Trans.
T2	50070	No. 2 R.F. Trans.
T3	50080	Oscillator Trans.
T4	50030	No. 1 I.F. Trans.
T5	50050	No. 2 I.F. Trans.
T6	32148	Output Trans.
T7	32134	Power Trans. (126, 136, 416, 446)
T7	26291	Power Trans. (556)

TRIMMERS

A1	32121	Antenna trimmer
	29119	Double I.F. trimmer

RESISTORS

For tubular resistors, refer to lists in previous supplements.

Molded resistors with a band of color instead of a dot are rated at ½ watt. These resistors are physically the same size as the standard ¼ watt molded type, but a special internal construction permits rating safely at ½ watt.

CHOKES

CK1	50270	Antenna choke
CK2	19210	"B" Choke
CK3	36630	"A" choke
CK4	36630	"A" choke
CK5	50160	"A" choke
CK6	36630	"A" choke
CK7	32135	Iron core filter choke

CONDENSERS

Tubular condensers with letter "H" before code number are slightly smaller than the standard Atwater Kent tubular condensers, but otherwise identical in voltage rating and capacity. The standard condensers may be used in place of the "H" type.

C1	25661	8 MMF (green paint)
C2	25661	8 MMF (green paint)
C5	34460	10 MMF (in T2)
C7	31180	660 MMF
	29687	120 MMF
C16	25379	10 MF, 25 V
C16A	25379	10MF, 25 V (556)
C27	32136	8-8 MF 300 V (126, 136, 416, 446)
C27	32273	8-8 MF 300 V (556)
C28	50210	.003 MF 800 V (801)

POWER UNIT

50170	Power unit complete with tube (126, 136, 416, 446)
50240	Power unit complete with tube (556)
32209	Base and socket assembly
26045	Power trans. brackets
32138	VIBRATOR
32095	Container less covers
32258	Top cover
32096	Bottom cover

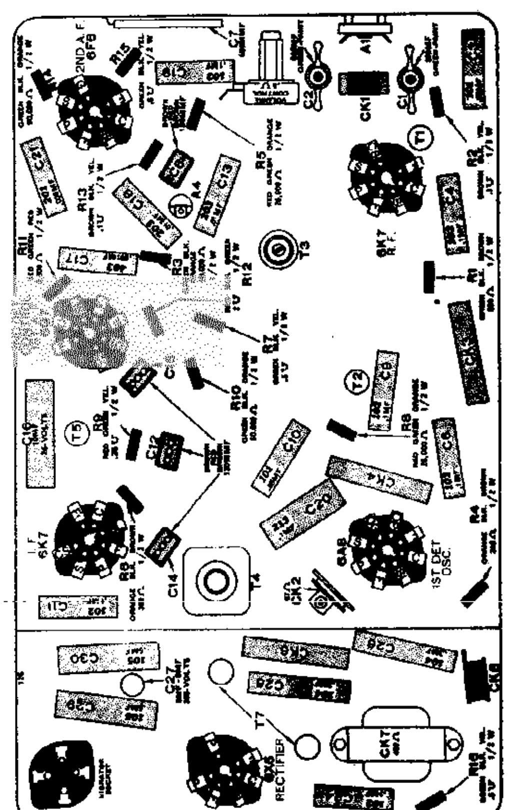
32122	Tuning unit*
32222	Switch and bracket assem. complete with leads
32221	Switch and bracket assem. less leads
32172	Arrow indicator disc
30091	Crystal
30092	Dial plate
30093	Disc screw 7/32"
32223	Disc screw 3/8"
30099	Disc screw 3/4"
30101	Disc bushing 3/16"
30094	Disc bushing 33/64"
32225	Sheath-clamping nut
32123	Tuning flexible drive assem.
32151	Volume control flexible drive assembly

*Parts of tuning unit assembly are not sold separately.

MODELS 126, 136, 416 and 446



Model 556 is similar except for differences in the Power Unit and the 2nd A-F bias circuit

ATWATER KENT MFG. CO.

Remote and Header Type
SPEAKER COMBINATIONS
FOR
ATWATER KENT AUTO RADIO

MODELS 126, 416 and 556

Models 126, 416 and 556 have a self-contained speaker in lid. One additional speaker may be used with these models. The additional speaker may be one of the following three types:—

(1) HF (header type) for 1936 Ford only. The HF speaker has cable "A" packed with it.

(2) S6 (6½" diameter).*

(3) S8 (8½" diameter).*

MODELS 136 and 446

Models 136 and 446, which do not have a self-contained speaker, may be used with either one or two speakers. **If only one speaker is to be used, with Models 136 and 446, there is choice of:—**

(1) HF (header type) for 1936 Ford only.

(2) S6 (6½" diameter).

(3) S8 (8½" diameter).

No extra cables are required to connect one of these speakers to Models 136 and 446. **If two speakers are to be used with Models 136 and 446,** the following combinations are available:—

(1) S6 and HF speakers* (1936 Ford only).

(2) S8 and HF speakers* (1936 Ford only).

(3) S6 and S8 speakers*.

*The combinations of speakers marked above and in illustrations at right with star require auxiliary cable No. 50230. When necessary, additional double-conductor shielded cable (No. 32284) may be used to lengthen the auxiliary cable No. 50230. Specify the desired length of extra cable. See page 4 for connections.

INSTALLING HEADER TYPE SPEAKER "HF" IN 1936 FORD

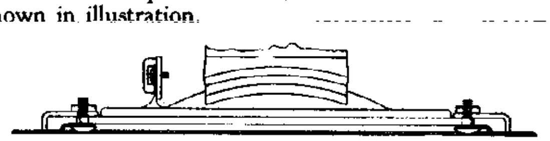
The type "HF" dynamic speaker is designed to fit in the header strip (above windshield) in 1936 Ford cars. The header has a cut-out space for this purpose.

Two small mounting brackets are provided for quickly fastening the speaker, and a shielded two-wire cable, with plug at one end, and three tip contacts at the other end, is supplied for quick, easy connection.

Procedure:

1. Remove header. Take off paper cover from speaker opening in the header.

2. Fasten speaker to header with two brackets as shown in illustration.

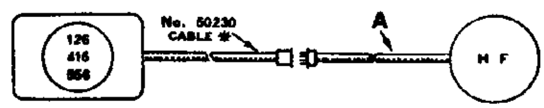


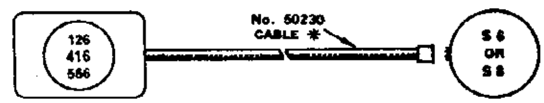
3. Tie the tip-end of cable to lower end of string that car manufacturer has provided in right-hand front column. Pull cable gently up through the column.

4. Insert cable tips in terminal strip, with cable leads corresponding to colors on terminals in speaker. Fasten cable to cone housing by means of clamp.

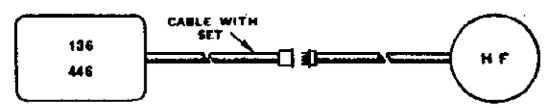
5. Replace header, pulling slack cable down column.

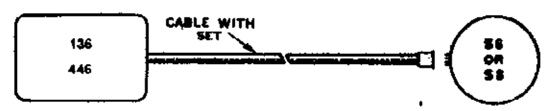
6. The correct connections for the header speaker in various combinations are shown on this page.





Models 126, 416 and 556, with self-contained speaker, may be used with one additional speaker, HF, S6 or S8, as shown above.





Models 136 and 446 may be used with one speaker, HF, S6 or S8, as shown above, or with a combination of two speakers as shown below.

See page 4 for connections.

"B" current is dependent on actual "B" voltage, incoming signal strength, volume level, and other factors. The values given above are high averages, not maximum.
* In late 465Q, speaker is 44700. In late 655Q, speaker is 44800.
** Abbreviation "P. M. D." indicates a permanent-magnet dynamic speaker.
† Late sets only.
†† 525Q only.

IMPORTANT DATA FOR ATWATER KENT AUTO RADIO

(1931 to 1936 Inclusive)

Model	Year	"A" Battery Volts	"A" Battery Amps.	"B" Battery Volts	"B" Battery Mils.	"C" Battery Volts	Tubes	Dial Lamp	Speaker Cone No.	I.F. (KC)	Description
81 81B 81C	1931	6	4	135	25	30	3-36, 2-37, 2-38	MAZDA 50 (clear) AK$21407	21161	TRF	Model 81 has 3 units: Receiver-and-battery container, speaker, remote control. Models 81B and 81C have separate containers for the chassis and the "B" batteries. "C" batteries are mounted in the chassis container in 81B and 81C.
91 91B 91C	1932	6	4	135	30	30	3-36, 3-37, 2-38	MAZDA 50 (clear) AK$21407	21161	260	Same unit arrangement as 81, 81B and 81C.
636 756 756B	1933	6	5¼	DYNAMOTOR No. 30860		..	2-39, 1-36, 1-85, 2-41	MAZDA 50 (clear) AK$21407	21161	262½	Model 636 has 3 units: Chassis with controls, speaker, dynamotor. Model 756 has 3 units: Chassis with dynamotor, speaker, remote control. 756B has 4 units: Chassis, dynamotor, remote control, speaker.
424 534	1933	6	4	SYNCHRONOUS VIBRATOR No. 25595		..	1-77, 1-44, 1-75, 1-41	MAZDA 50 (clear) AK$21407	25604 (424) 25603 (534)	264 450	Model 424 is one complete unit. Model 534 is one unit, but with remote control.
816 926 936	1934 1934 1934	6 6 6	5 6 6	SYNCHRONOUS VIBRATOR No. 26863 GENEMOTOR No. 26734 GENEMOTOR No. 26734		.. .. ..	2-39 (6D6 in late), 1-6A7, 1-85, 2-41	MAZDA 40 (green) AK$16099	26826 (816) 26826 (926) 26822 (936)	264	Models 816 and 926 have chassis, speaker and power unit in one container, and separate remote control. Model 936 has 3 units: Chassis, speaker, remote control.
666	1934	6	6	VIBRATOR No. 27005		..	2-6D6, 1-6A7, 1-85, 1-41, 1-6Z4	MAZDA 40 (green) AK$16099	26826	264	Model 666 has 2 units: Chassis with speaker, and remote control.
776	1935	6	6	VIBRATOR No. 27005		..	2-6D6, 1-6A7, 1-85, 1-41, 1-6Z4	MAZDA 40 (green) AK$16099	26826	264	Model 776 has 2 units: Chassis with speaker, and remote control.
126 136 416 446 556	1936	6	6.8*	VIBRATOR No. 32138		..	Models 126, 136, 556 (glass tubes): 2-6K7G, 1-6A8G, 1-6Q7G, 1-6F6G, 1-6X5G Models 416, 446 (metal tubes): 2-6K7, 1-6A8, 1-6Q7, 1-6F6, 1-6X5	MAZDA 51 (clear) AK$28299	30096 (126) 30096 (416) 30096 (556) 30096 (S6) 26822 (S8)	264	Models 126, 416 and 556 are single unit sets, with remote control. 126 and 416 have tone control and chrom speaker grille. Models 136 and 446 have external speaker. These five models may be used with additional speaker, S6, S8 or HF (header type for 1936 Ford).

*Add 1 amp. if additional speaker is used.

R12	16520	1050 ohms, flexible
R14	17077	10 ohms, flexible
R15	25950	200 ohms, flexible
R17	31860	1 ohm, flexible

CHOKES

CH1,2	19210	R.F. choke
CH3	28970	Filter choke unit

MODEL E-145
Socket, Trimmers
Chassis, Alignment

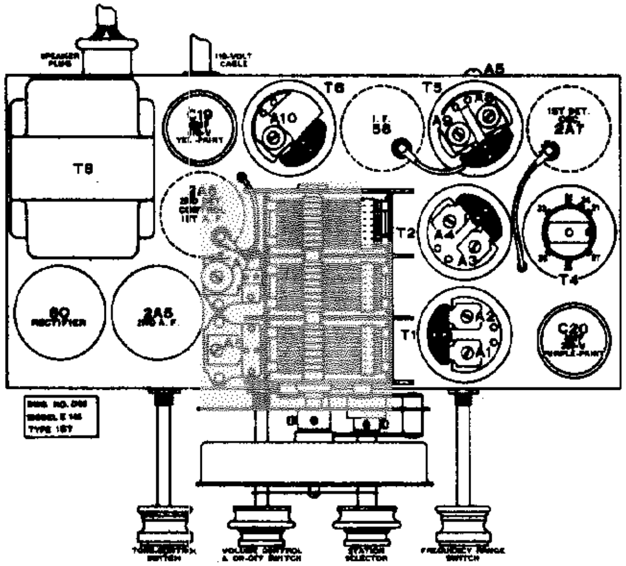
ATWATER KENT MFG. CO.

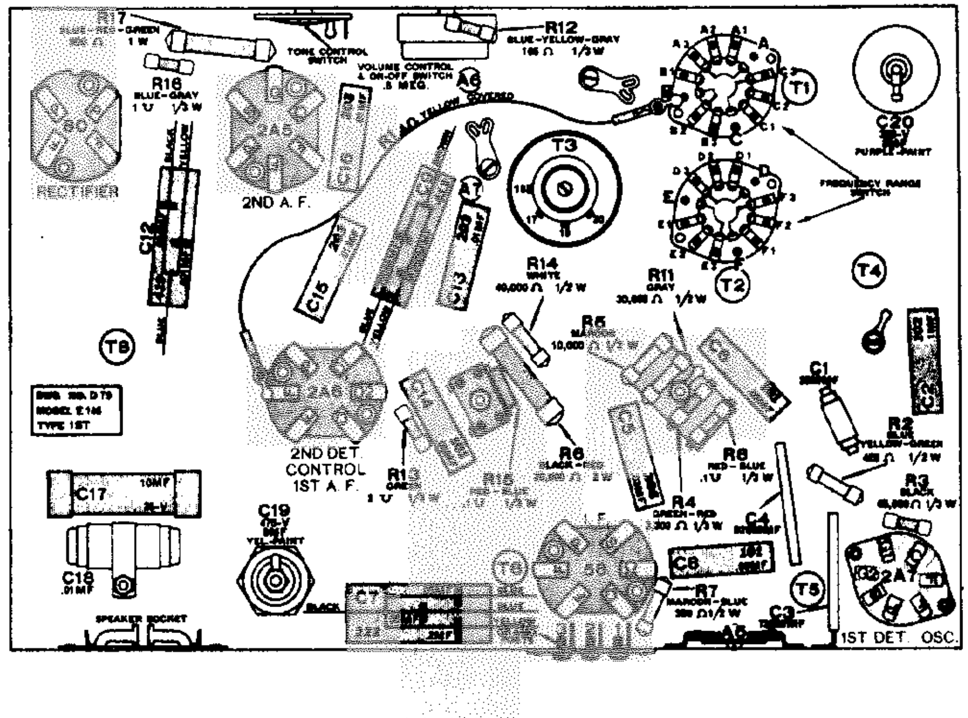
September 25, 1935.

Turn volume control on full, turn tone control to "high" and use the weakest possible signal that will give a reading on a sensitive output meter.

I. F. TRIMMERS.

Connect an I. F. test oscillator to the 1st-detector tube by means of the I. F. coupling unit No. 42590. Adjust the I. F. oscillator to 125 KC. Peak trimmers A8, A9 and A10.





DIAL POINTER ADJUSTMENT.

With the variable condenser, all the way in, the dial pointer should be a pointer's width beyond 500 KC (approximately 498 KC).

R. F. TRIMMERS.

Connect an R. F. test oscillator to the antenna and ground terminals of set. Use the weakest possible oscillator signal. Loosen the trimmer screws.

Short-wave range. There are no trimmer adjustments for this range.

Long-wave range. Oscillator at 400 KC and range switch in long-wave position, turn dial pointer to 400 KC. Peak trimmers A3, A4 and A7.

Medium-wave range. Oscillator at 1100 KC and range switch in medium-wave position, turn dial pointer to 1100 KC. Peak trimmers A1, A2 and A6. Tune oscillator and set to 560 KC. Peak A5. Repeat adjustments on A6 at 1100 KC and A5 at 560 KC until correct dial setting of pointer is obtained at these frequencies.

It should be observed that the first signal obtained as the oscillator trimmer A6 is turned in from open position must be used.

A1—Pre-selector, 1100 KC.
A2—1st-detector, 1100 KC.
A3—Pre-selector, 400 KC.
A4—1st-detector, 400 KC.
A5—Tracking, 560 KC.
A6—Oscillator, 1100 KC.
A7—Oscillator, 400 KC.

There are three I. F. trimmers, A8, A9 and A10. These are adjusted at 125 KC.

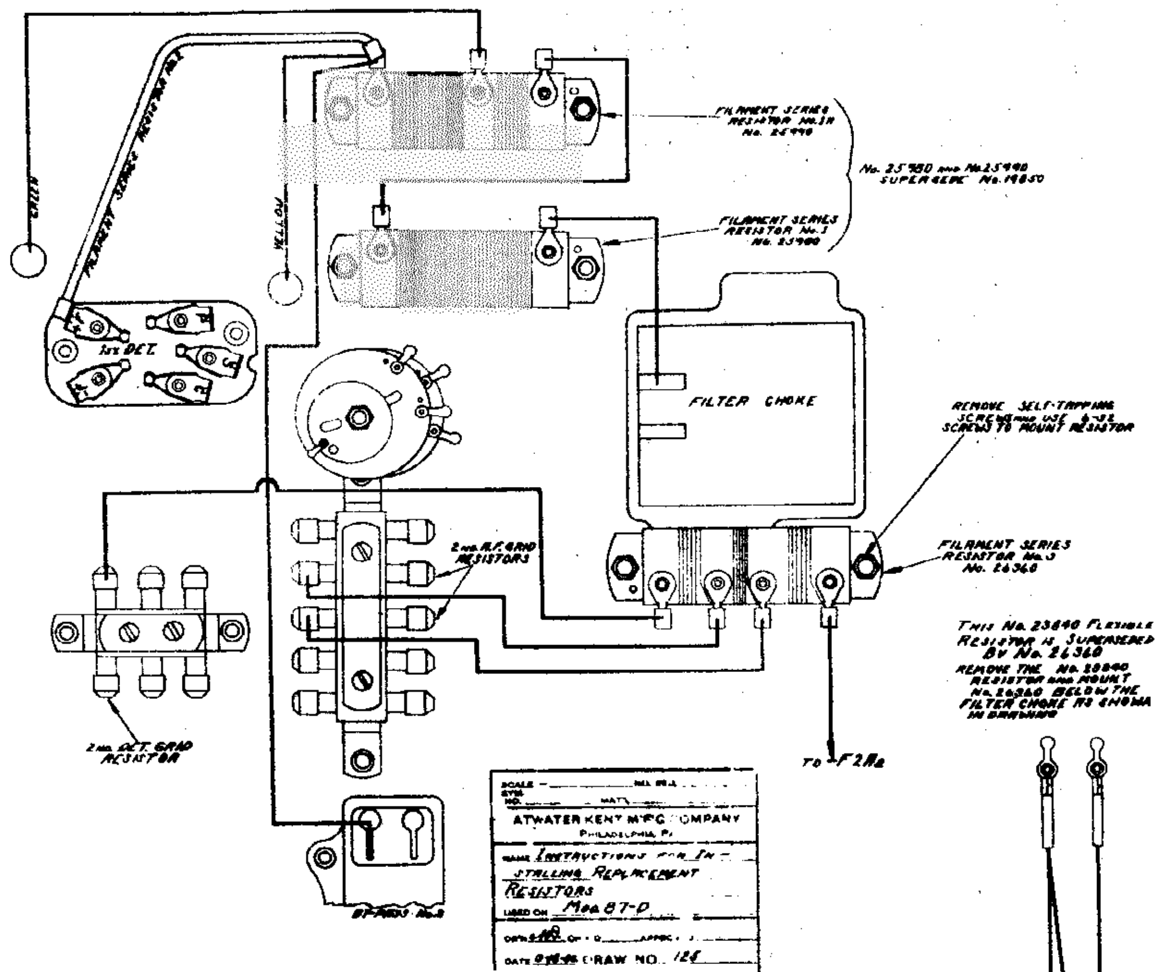
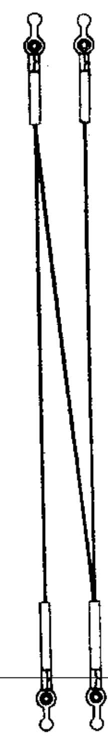
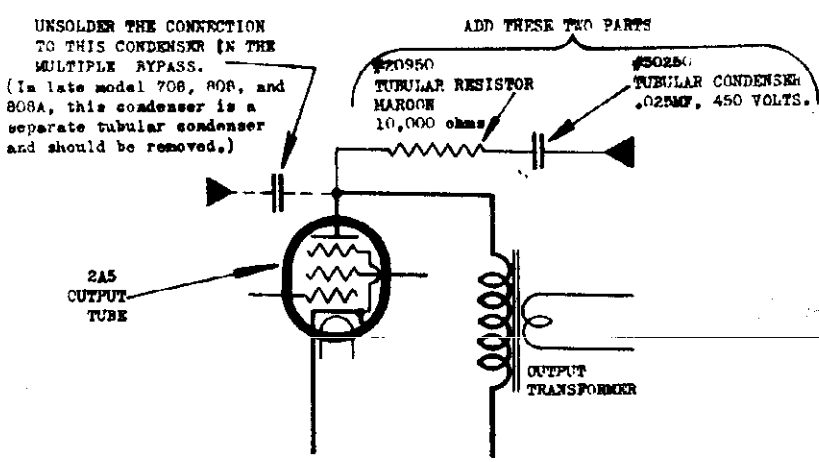
INSTRUCTIONS FOR INSTALLING No. 26360 RESISTOR IN PLACE OF No. 23840
AND
INSTRUCTIONS FOR INSTALLING No. 25980 & No. 25990 IN PLACE OF No. 19850





This No. 23840 Flexible Resistor is Superseded By No. 26360
Remove the No. 23840 resistor and mount No. 26360 below the filter choke as shown in drawing

IMPROVING TONE QUALITY IN MODELS 217, 427, 667, 708, 808, and 808A



To improve the tone quality of Models 217, 427, 667, 808, 808A, and 708, remove the connection to the original quality condenser on the plate of the 2A5 output tube, and add a #20950 10,000 ohm resistor and a #30250 tubular condenser (.025MF) as shown above.

11-23-33.

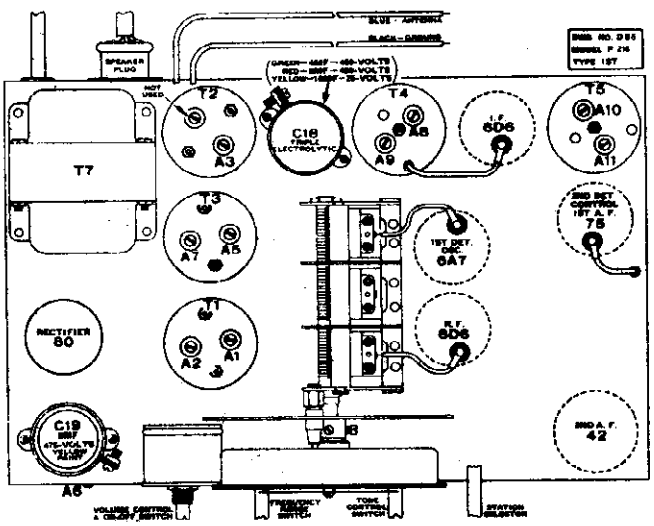
Chassis,Alignment

ATWATER KENT MFG. CO.



ADJUSTING TRIMMER CONDENSERS

Refer to general notes on trimmer-condenser adjustment published in previous supplements. Remember always to use the weakest possible oscillator signal that will give a reading on the output meter with the radio volume control full "on", and the radio tone control at high pitch. Use the first spot on oscillator trimmer, as it is screwed in from a loose or minimum-capacity position. Use the standard Atwater Kent I. F. coupling unit No. 42590. Note that no balancing resistors are used in aligning the I. F. trimmers on these particular models.

I. F. TRIMMERS.

Connect test oscillator (472½ KC) to I. F. tube by means of regular I. F. coupling unit. Peak A10, A11. Connect oscillator to 1st-detector tube and peak A8, A9.

DIAL POINTER ADJUSTMENT.

With rotor of variable condenser fully meshed, dial indicator should be at 535 KC.

R. F. TRIMMERS.

Connect an R. F. oscillator to antenna and ground of set.

Short-wave range. With oscillator and dial at 15 MC, peak A7, A1.

Police range. No trimmers on this range.

Broadcast range. With oscillator and dial at 1500 KC, peak A5, A3, A2. With oscillator and dial at 560 KC, peak A6.

August 2, 1935.

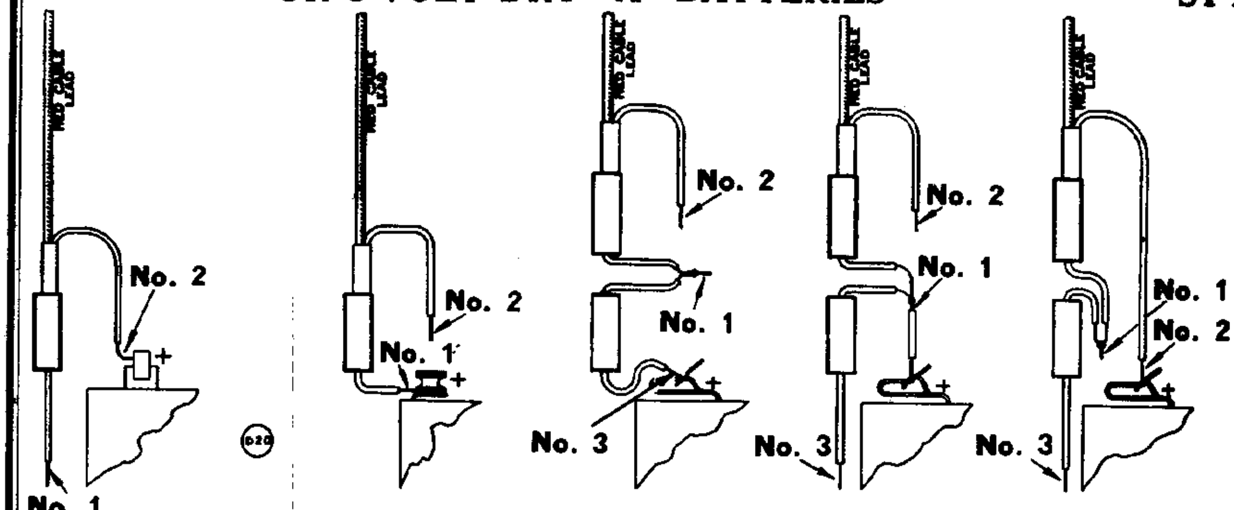
Installation Notes
Dry Cell Data
Speaker Adjustments

ATWATER KENT MFG. CO.

USING 2-VOLT AIR CELL, 2-VOLT STORAGE CELL OR 3-VOLT DRY "A" BATTERIES



2-VOLT STORAGE CELL
Connect No. 2 as shown, do not use No. 1

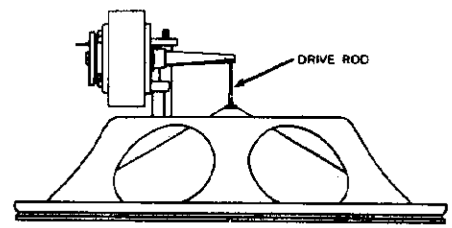
2-VOLT AIR CELL
Connect No. 1 as shown, do not use No. 2

Connections when battery is fresh — Connections after 300 hours' use — Connections after 600 hours' use

3-VOLT DRY "A" BATTERY
It is necessary to connect an extra resistor as shown when using a 3-volt dry "A" battery. This resistor is available through Atwater Kent distributors.

The extra resistor required when using a 3-volt dry "A" battery is Atwater Kent part No. 40340, 1.03 ohms.

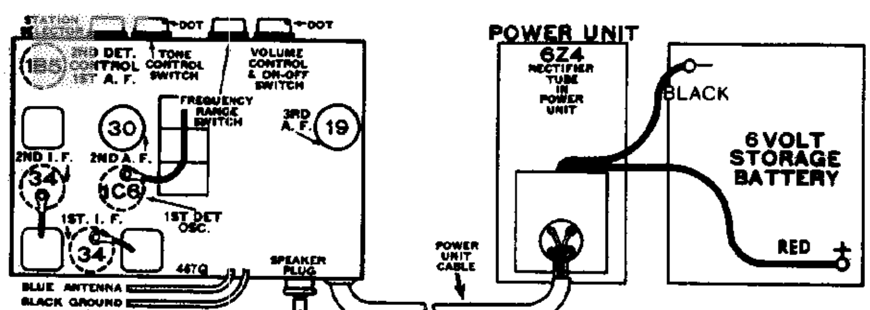
SPEAKER ADJUSTMENT



There are no adjustments for centering the armature in the magnet gap. If the coil becomes open, or if adjustment is required, it is necessary to replace the complete sound unit No. 29076.

The diaphragm is clamped to the drive rod between two nuts. When installing a new diaphragm or unit turn the rear nut back on the drive rod, fasten the diaphragm or unit to cone housing, and turn rear nut forward until it touches apex of diaphragm. Put the front nut on drive rod and fasten securely.

IMPORTANT INSTALLATION NOTES FOR MODELS 237Q AND 467Q



Do not lengthen the leads from the power unit to the storage battery, as this will cause excessive hum.

The spring clips must make good contact to the storage battery terminals. File and clean the battery terminals when necessary to ensure good contact.

Connections between the chassis, power unit, and storage battery are shown above.

Keep the antenna lead-in as far as possible from the power unit, power-unit cable, and storage battery.

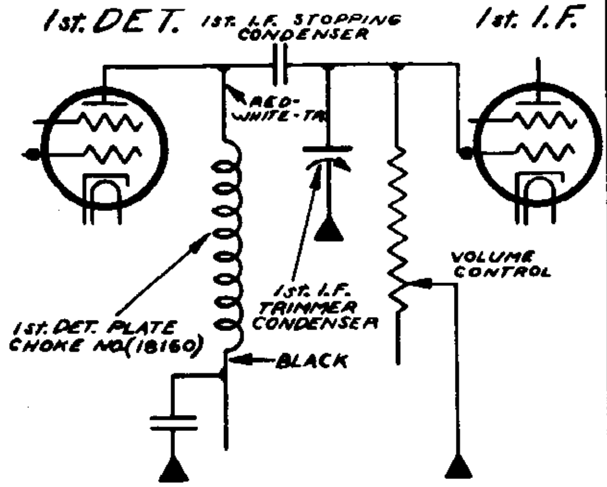
Original Connections in Type H-1 Chassis
(Below Serial #5,855,201)



Changes in Type H-1 Chassis
To Increase Sensitivity

CHANGE IN H-1 CIRCUIT TO SECURE GREATER SENSITIVITY

By making a slight change in the circuit of type H-1 Chassis, it is possible to secure considerably greater sensitivity. This change may be made in less than one-half hour, and only two small parts are required (one No. 18160 choke, and one No. 16272 adjusting disc). The procedure is as follows:-

1. Remove the bottom plate and locate the 1st-detector plate choke (part No. 17410). This choke is oval shaped and has two contacts, one at each end. The choke is mounted at the rear of the oscillator tube socket which is at the front center of set (UX-227). There are two small fixed condensers mounted on top of this choke, all three parts being held by one bolt. Of these two fixed condensers, the one toward the front of the set is the 1st-I.F stopping condenser (Part No. 17440): The other fixed condenser is the 1st-detector plate condenser (Part No. 17470).

2. Tag the 1st-I.F stopping condenser, No. 17440, as this part is to be used again.

3. Unsolder the leads to these three parts and remove them from the set. It will be found that there are two brass washers and a nut on the mounting bolt between the choke and the chassis. Remove the nut and one washer. Leave the other washer on the bolt.

4. Screw a No. 16272 aluminum adjusting disc all the way down on the mounting bolt. Slip a lock washer down on top of the disc and then screw on a No. 6186 nut.

5. With its two leads facing out, put a No. 18160 choke on the mounting bolt. Then put the No. 17440 1st- I.F stopping condenser back in its original position.

6. Connect as shown in the right hand diagram.

7. Put the set in operation with the volume control turned on full.

8. Adjust the 1st-I.F. trimmer condenser (on top, at the front center of chassis) to a point just below the position at which the I.F. amplifier begins to oscillate. (The bottom plate must be in place while making this adjustment of the 1st-I.F. trimmer condenser.)

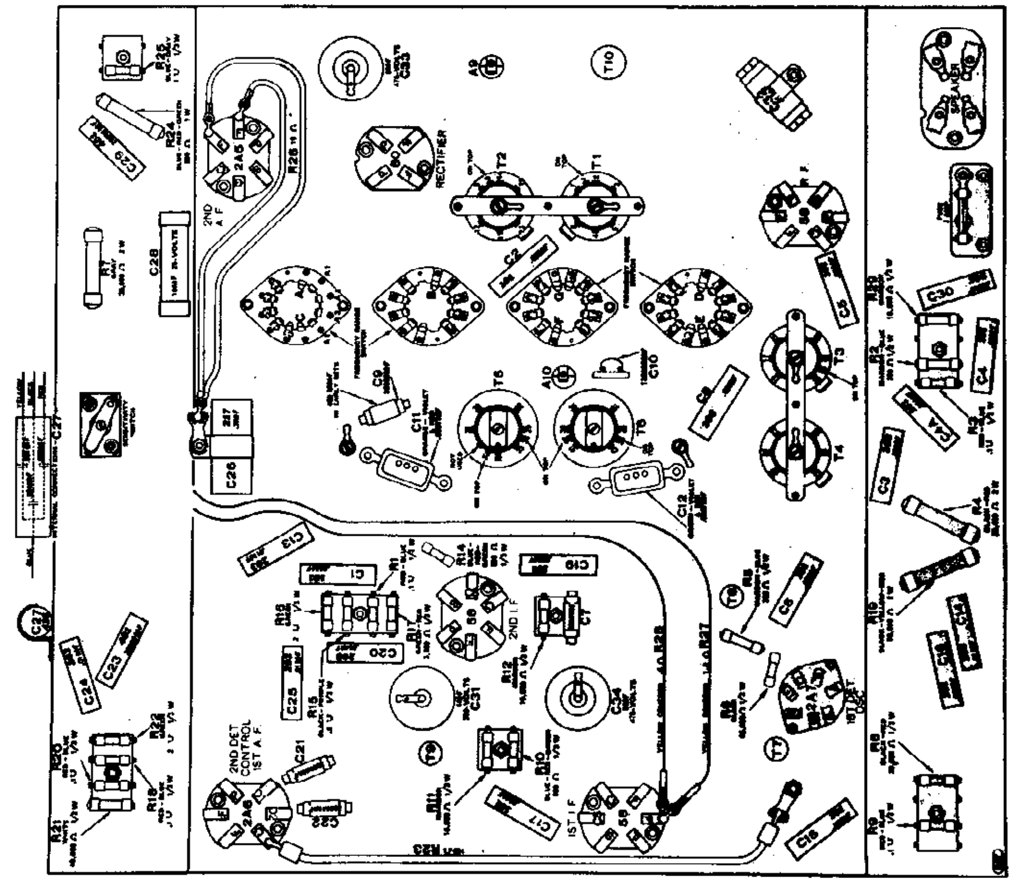
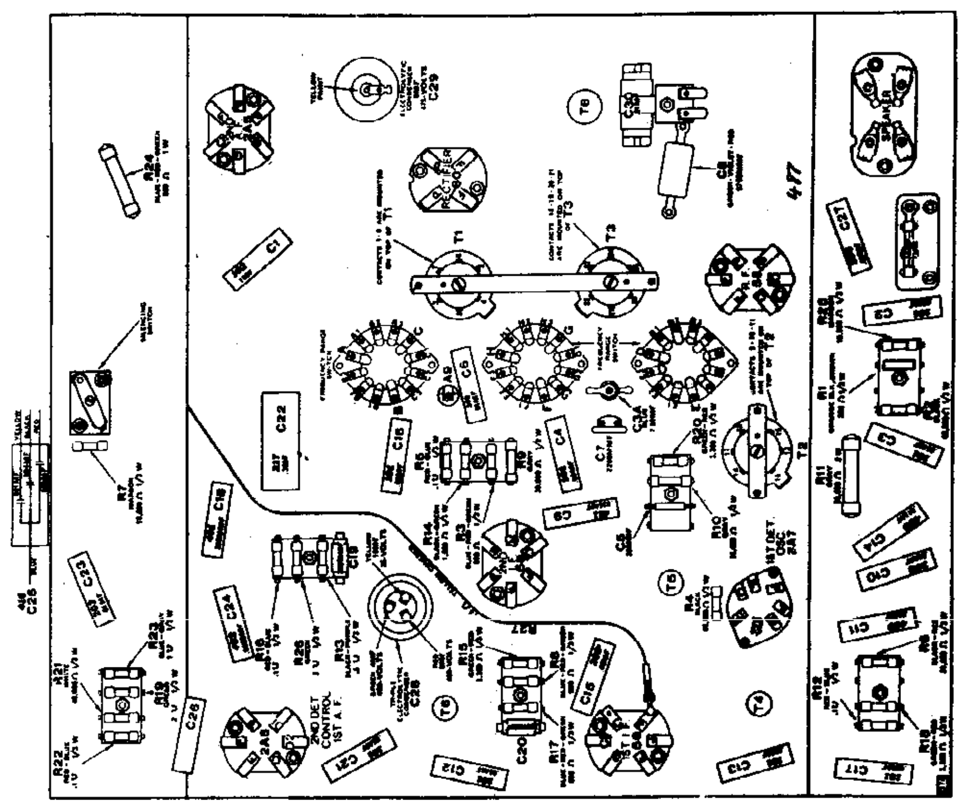
Chassis Layouts

ATWATER KENT MFG. CO

MODEL 447

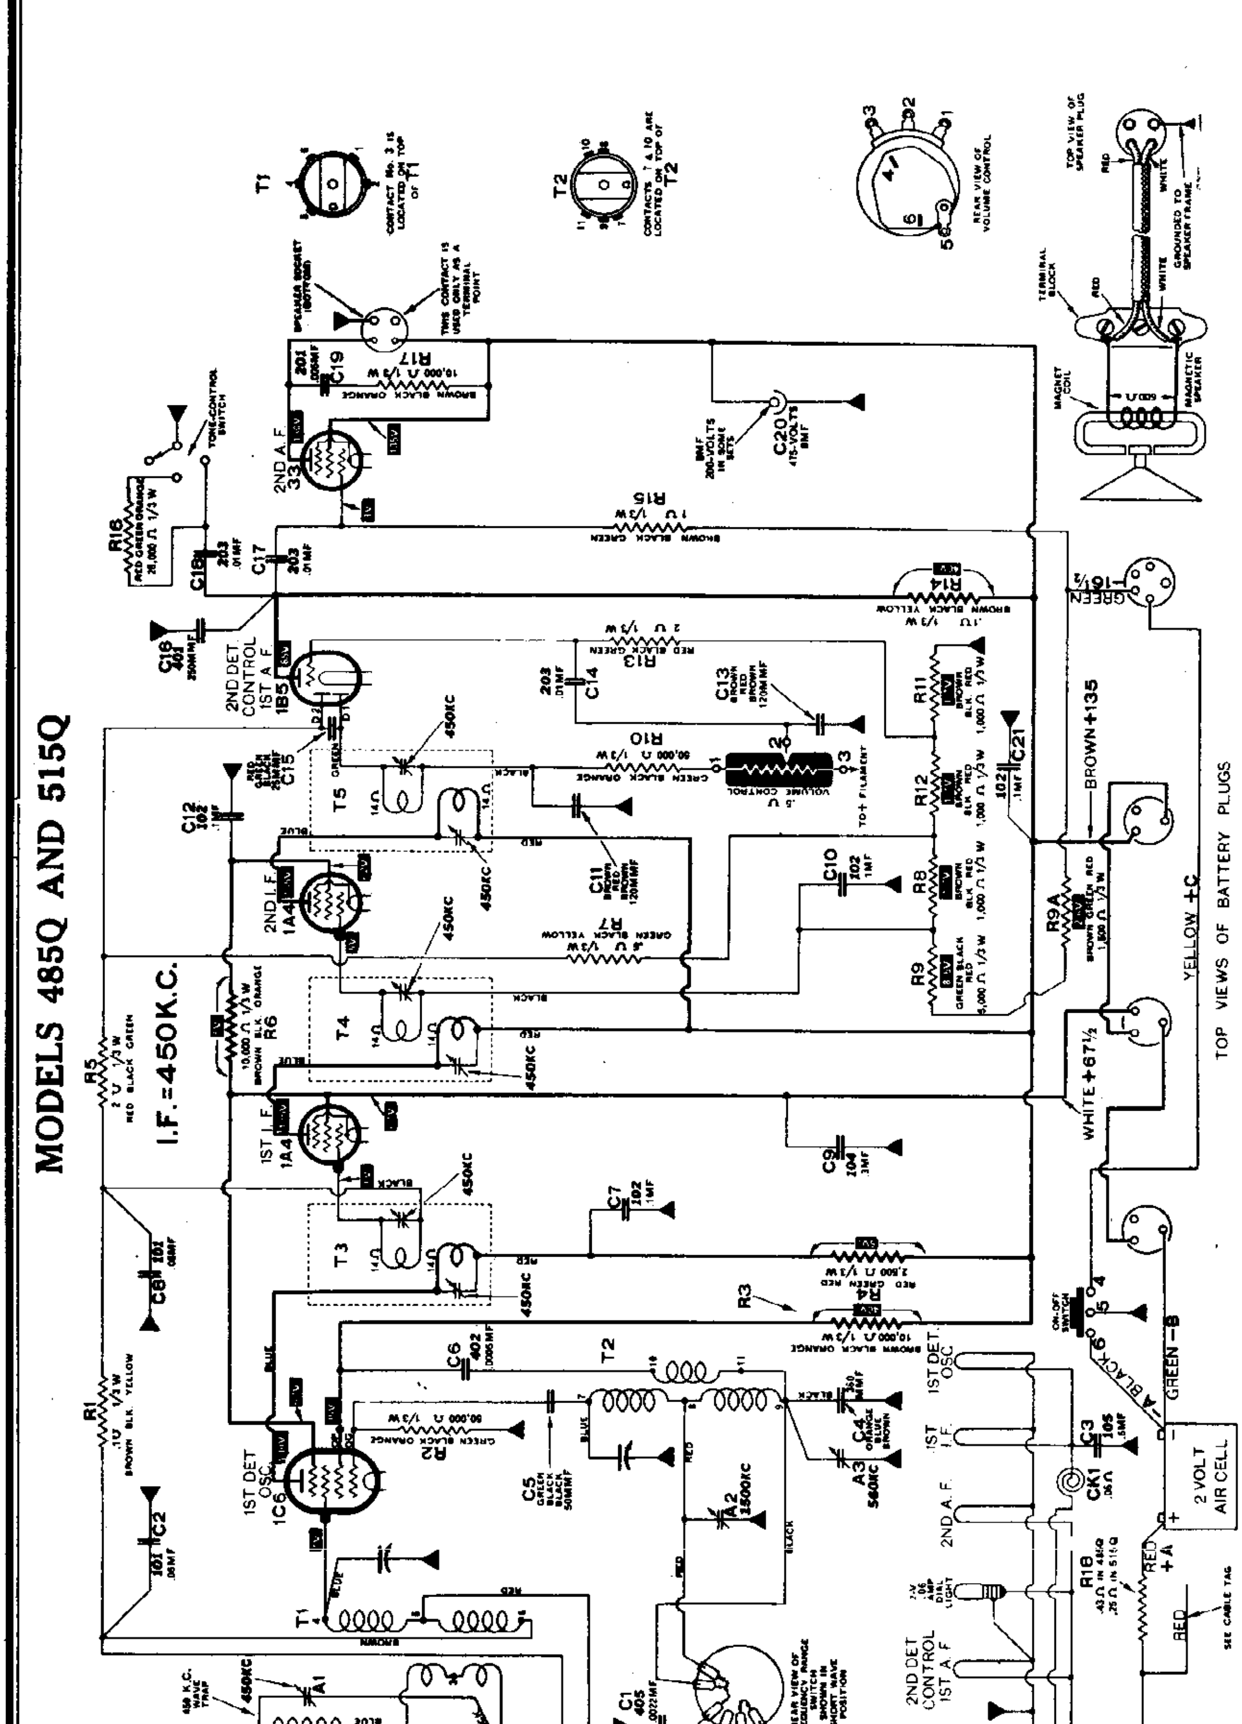


MODEL 487



MODEL 485Q,515Q Schematic

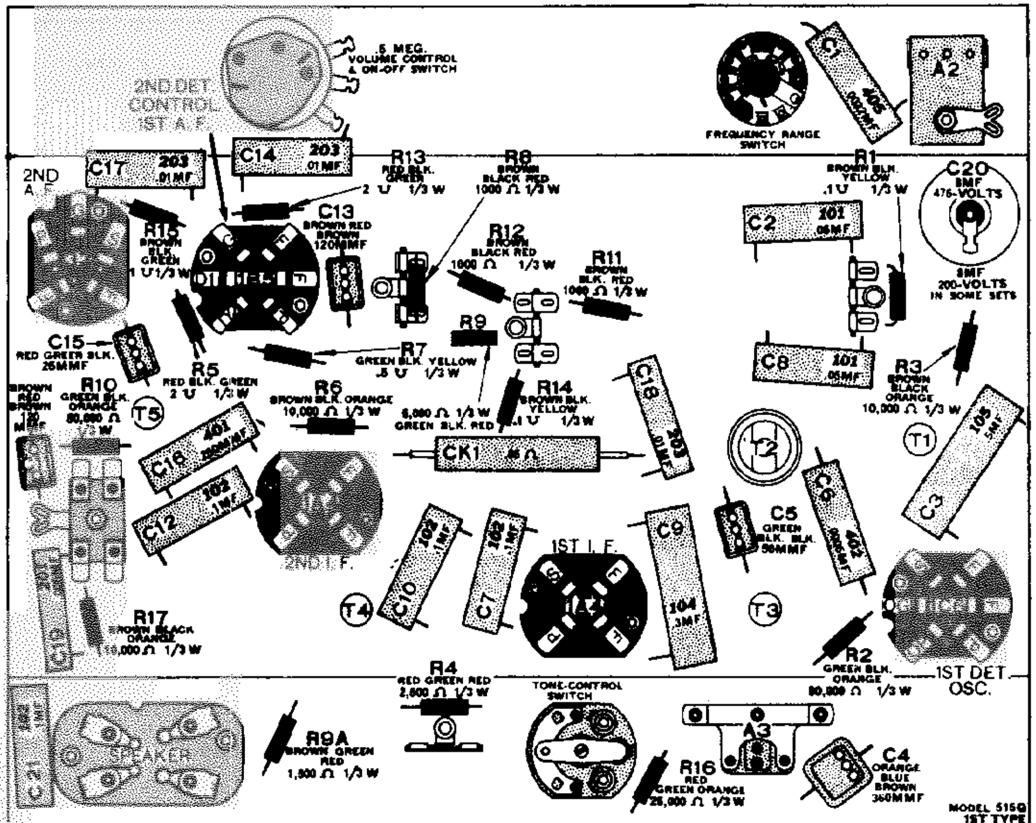
ATWATER KENT MFG. CO.

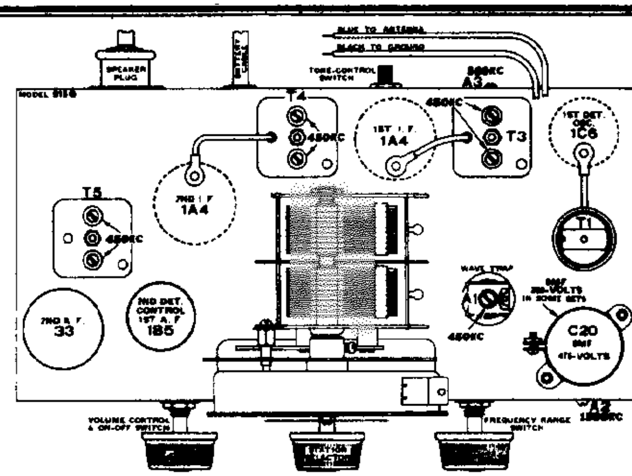


The I. F. is 472½ KC in some of these sets as specified on label at rear of chassis. The I. F. transformers, trimmers, etc., are exactly the same for 450 or 472½ KC. March 25, 1936. "B" voltage was 135 V. for above measurements.

MODEL 485Q, 515Q
Socket, Trimmers
Chassis, Alignment

ATWATER KENT MFG. CO.





MODELS 485Q AND 515Q

I. F. TRIMMERS

Connect signal generator (450 KC) to 2nd-I. F. grid cap by means of No. 42590 coupling unit. Peak two trimmers on top of T5 (3rd I. F. transformer).

Connect signal generator to cap of 1st-I. F. tube and peak two trimmers on top of T4 (2nd I. F. transformer).

Connect signal generator to cap of 1st-detector tube and peak two trimmers on top of T3 (1st I. F. transformer).

DIAL POINTER ADJUSTMENT

With the variable condenser fully meshed, the arrow-indicator disc should be set at 540 KC.

A1—Trap trimmer, 450 KC.
A2—Broadcast oscillator, 1500 KC.
A3—Broadcast tracking, 560 KC.

There are six I. F. trimmers, two on top of each I. F. transformer (T3, 4 and 5).

These are peaked at 450 KC.

R. F. TRIMMERS

In location where severe electrical interference is present, it is necessary, when aligning R. F. trimmers, to connect a 40,000-ohm resistor in series with a .02 M. F. condenser from the grid cap of the 1st-I. F. tube to chassis. This reduces the I. F. sensitivity and permits use of a stronger output from the signal generator to over-ride the local noise level without bringing the AVC into action.

Short-wave Range

No trimmers on this range.

Broadcast Range

Connect signal generator to antenna and ground of set, using a 250 MMF condenser in series with the antenna lead. With signal generator and dial at 1500 KC, peak the broadcast oscillator trimmer A2. Use the first peak as A2 is screwed in from a loose position. Tune generator to 560 KC and peak broadcast tracking trimmer A3 while rocking variable condenser one division around the 560 KC mark. Repeat adjustments at 1500 and at 560 KC if necessary.

I. F. Trap

Feed 450 KC signal into antenna and ground of set, using a .00025 MFD condenser in series with the antenna lead. Adjust A1 trap trimmer for minimum response.

I. F. is 472½ KC in Some of These Models

In some Models 485Q and 515Q sets, the I. F. is 472½ KC as indicated by label on rear of chassis. With these models, all adjustments mentioned above for 450 KC should be made at 472½ KC.

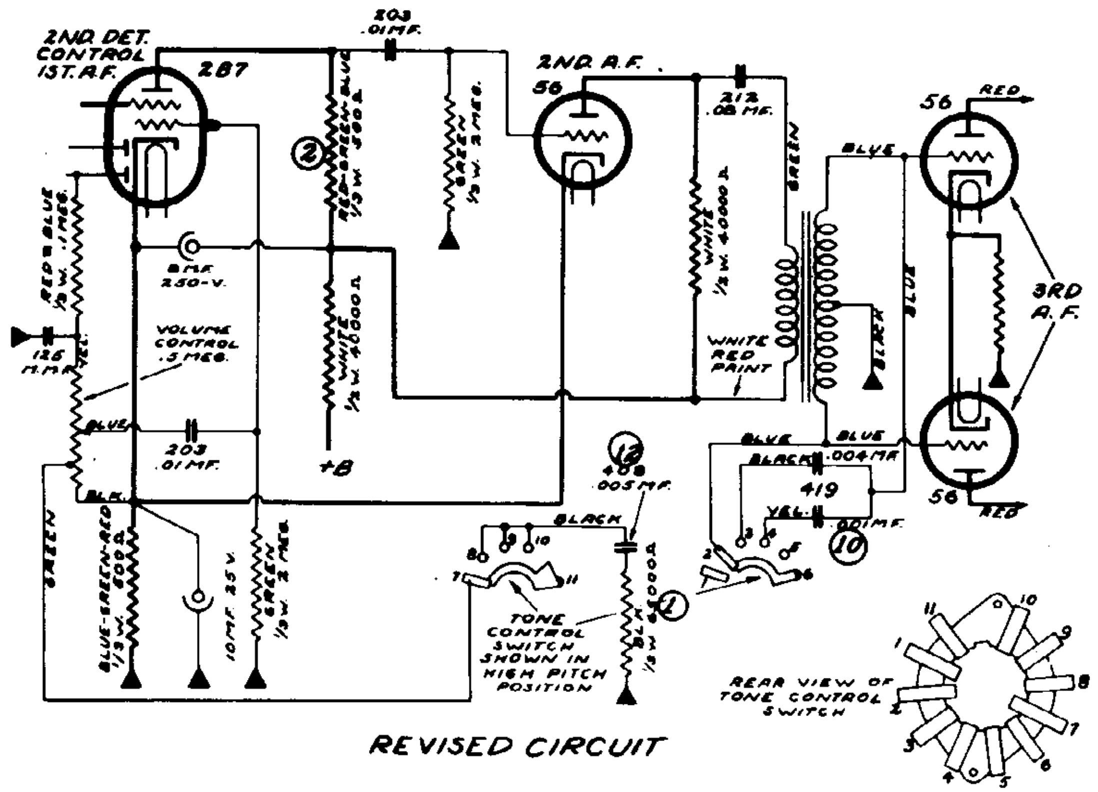
CHANGE IN MODEL 511 AUDIO TO REDUCE HUM



REVISED CIRCUIT

A. Remove resistors 1, 2, 3 and 4. Save resistor 4 for use in the revised circuit.

B. Remove condensers 5, 6, 7 and 8.

C. Remove choke 11.

D. Add one tubular condenser No. 39650 (code No. 419) and change the wiring of the tone control circuit as shown in the revised circuit. Mount the 419 condenser on the front of the chassis between the front panel and the chassis by means of a No. 28826 clamp. Use the screw that fastens the tubular-resistor mounting strip on the front flange of the chassis, to fasten the clamp for the 419 condenser.

E. Connect a 500-ohm tubular resistor (No. 39790) in the plate of the 2B7 as shown in the revised circuit.

MATERIAL REQUIRED

1 No. 39650 tubular condenser (419).
1 No. 28826 clamp for condenser.
1 No. 39790 500-ohm 1/3 watt tubular resistor.

ADJUSTING TRIMMER CONDENSERS

Turn volume on full, turn tone control to "high", and turn switch to "selectivity." Use the weakest possible signal that will give a reading on a sensitive output meter.

I. F. TRIMMERS.

Connect I. F. test oscillator (472½ KC) to 2nd-I. F. grid by means of the regular I. F. coupling unit No. 42590. Peak two trimmers on top of T9.

Connect I. F. oscillator to 1st-I. F. grid. Peak two trimmers on T8.

Connect I. F. oscil[illegible] to 1st-detector grid. Peak two trimmers on T7.

DIAL POINTER ADJUSTMENT.

If the dial gear and indicator have not been tampered with, leave them alone; but if they have been changed in any way, reset as follows:

1. Loosen the two set screws which hold pointer gear on condenser shaft.
2. Turn condenser to minimum.
3. See illustration (Fig. 1). Place straight-edge gauge in vertical position with the long flat face against the front mounting plate of the variable condenser as shown. Turn the condenser until the front edge of the rotor spacing bar just touches the straight edge. Hold the condenser in this position and move the pointer arm so the pointer is at 1562 KC, after which tighten the set screws to hold the dial gear securely.
4. Loosen the screws which hold the pointer to the pointer arm, and adjust the pointer so that when the condenser is completely meshed, the pointer is at 535 KC.

Recheck at 1562 KC and repeat procedure 3 and 4, if necessary.

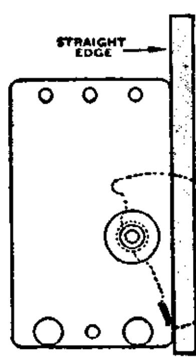

Fig. 1

This illustration shows the correct position of the variable condenser rotor for a dial-pointer setting of 1562 KC. The straight edge is held firmly against the front mounting plate of the variable condenser and the rotor is turned so the spacing bar (shown at lower edge of rotor) is just touching the straight edge. The straight edge is a strip of bakelite or hard rubber ¼" thick, ⅝" wide, and 6" long. The ⅝" side is held against the mounting plate.

R. F. TRIMMERS.

Connect an R. F. test oscillator to the antenna and ground terminals of set. Use the weakest possible oscillator signal that will give a reading on the output meter. Loosen the trimmer screws for the frequency range or ranges that are to be adjusted.

Short-wave range. Oscillator at 18 MC, dial pointer at 18 MC, peak A8 and A1.

Medium-wave range. Oscillator at 1500 KC, dial pointer at 1500 KC, peak A7, A4 and A2. Tune oscillator to 560 KC, turn dial to 560 KC, and peak A9. Repeat adjustment on A7 at 1500 KC, and A9 at 560 KC, if necessary.

Long-wave range. Oscillator at 405 KC, dial pointer at 405 KC, peak A6, A5 and A3. Tune oscillator to 160 KC, turn dial to 160 KC, and peak A10. Repeat adjustments on A6 at 405 KC and A10 at 160 KC, if necessary.

August 30, 1935.

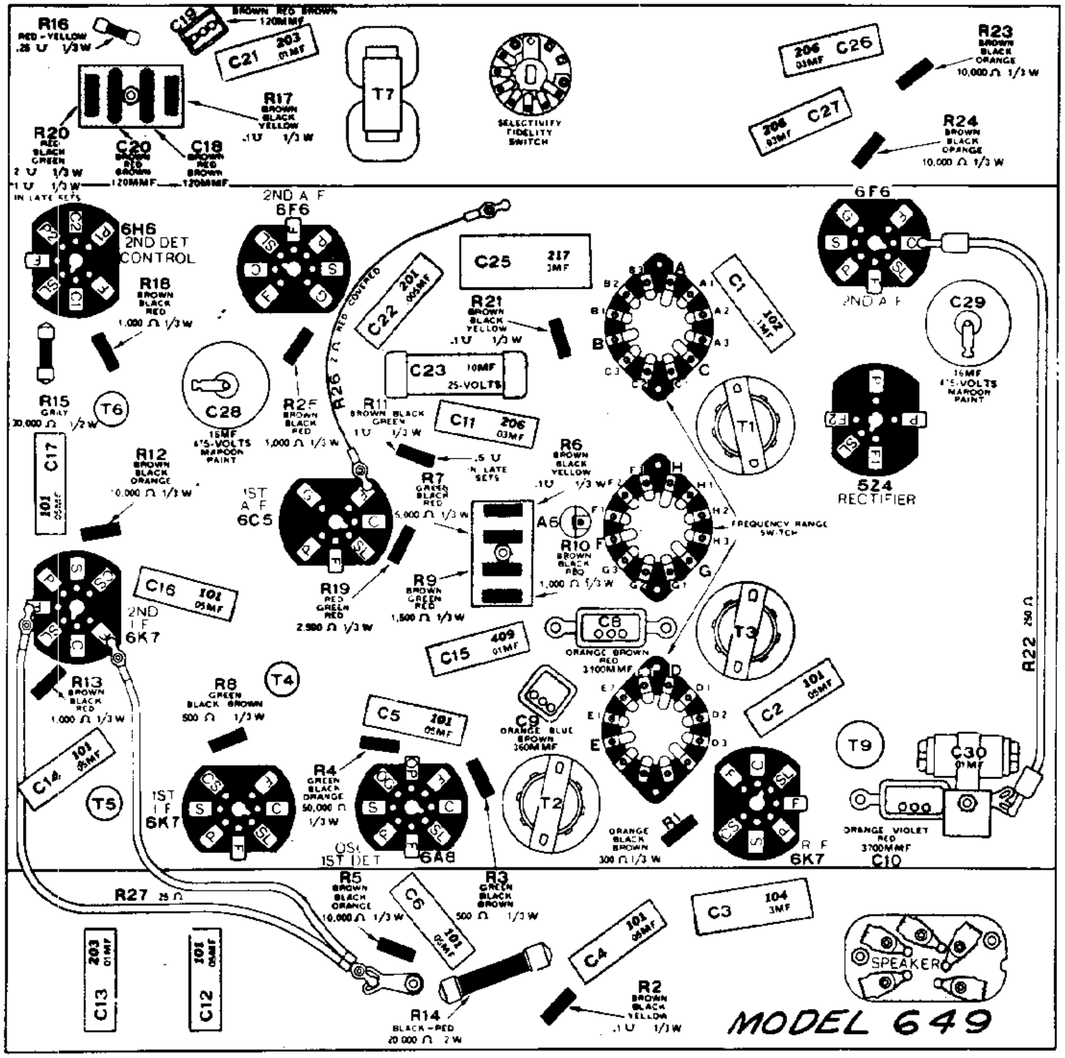
MODELS 649, P649
Chassis, Parts



MODEL P649

Model P649 is same as standard Model 649, except for phono terminals and a universal power transformer No. 46330.

MODELS 649 AND 649-RP

29367	Variable condenser assembly
27832	Base cover
30048	Tone control switch assembly
28908	Shaft and blade for above
47340	Range switch
29409	Selectivity switch
27321	Volume control, .5 megohm
25689	Shadow meter complete
30053	Front panel assembly
31222	Escutcheon
29373	Dial plate only
29848	Lamp, 6.3-V., bayonet base
27254	Dial pointer
29547	Coil shield (T1, 2)
29548	Oscillator trans. shield (T3)
29619	I. F. T. shield (T4, 5, 6)
28349	Phono. terminal card
31183	Instruction sheet, F-1289
48040	Shipping container (649)
49050	Shipping container (649 RP)

ELECTROLYTICS

C23	25379	10 MF, 25-V.
C28,29	29691	16 MF, 475-V.

TRANSFORMERS

T1	44390	No. 1 R. F. T.
T2	44410	No. 2 R. F. T.

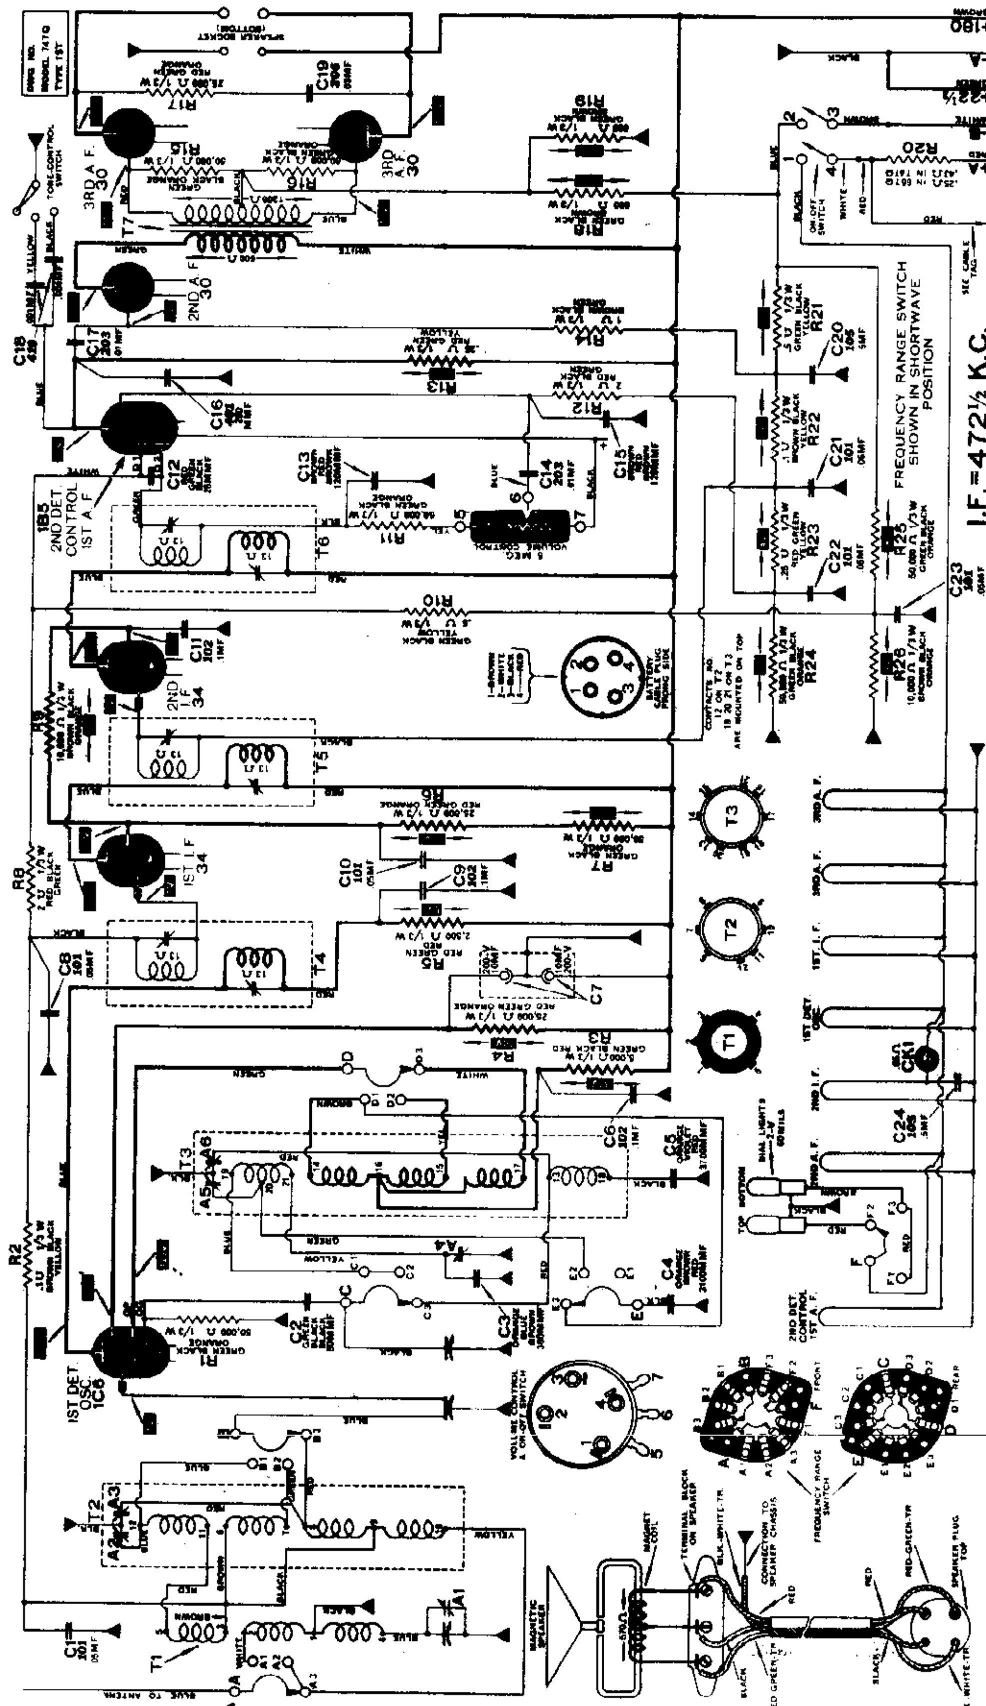
MODELS 657Q, 747Q
Schematic

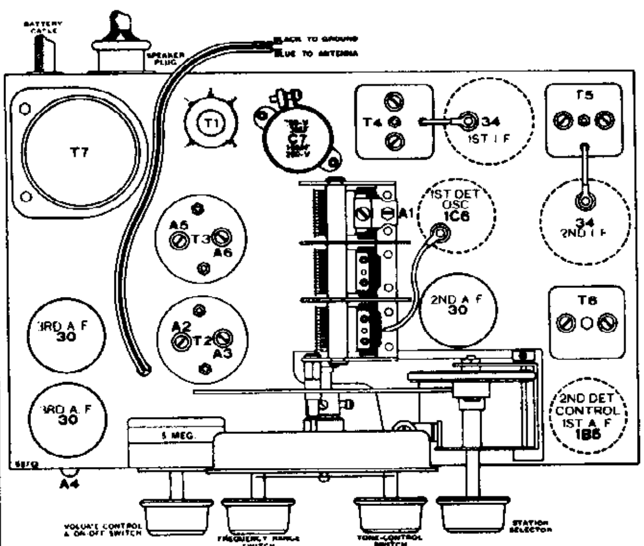
MODELS 657Q AND 747Q



March 25, 1936.

MODELS 657Q, 747Q

A1—Pre-selector, 1500 KC.
A2—1st-detector, 1500 KC.
A3—1st-detector, 18 MC.
A4—Oscillator tracking, 560 KC.
A5—Broadcast oscillator, 1500 KC.
A6—Short-wave oscillator, 18 MC.
There are six I. F. trimmers, two on top of each I. F. transformer (T4, 5 and 6). These are peaked 472½ KC.



I. F. TRIMMERS

Connect signal generator (472½ KC) to 2nd-I. F. grid cap by means of No. 42590 coupling unit. Peak two trimmers on top of T6 (3rd I. F. transformer).

Connect signal generator to cap of 1st-I. F. tube and peak two trimmers on top of T5 (2nd I. F. transformer).

Connect signal generator to cap of 1st-dectector tube and peak two trimmers on top of T4 (1st I. F. transformer).

DIAL POINTER ADJUSTMENT

With the variable condenser fully meshed, the dial pointer should be set at 535 KC.

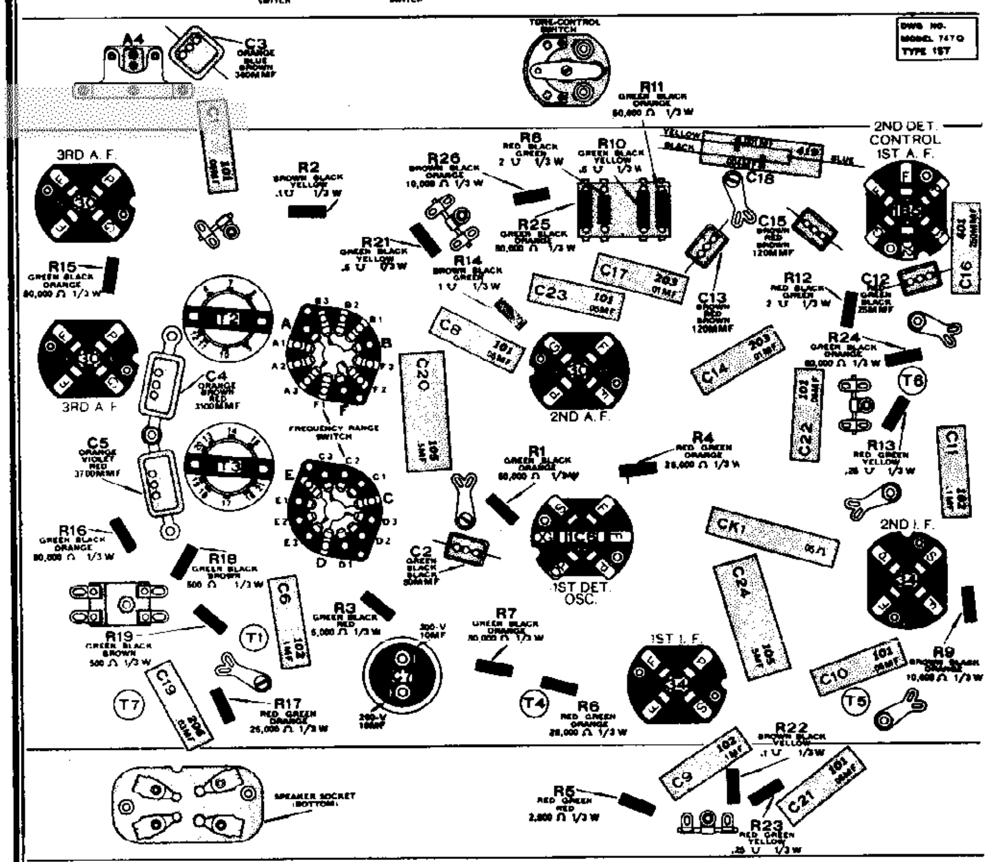
R. F. TRIMMERS

Connect signal generator to antenna and ground terminals of set. Loosen R. F. trimmer screws.

In location where severe electrical interference is present, it is necessary, when aligning R. F. trimmers, to connect a 40,000-ohm resistor in series with a .02 M. F. condenser from the grid cap of the 1st-I. F. tube to chassis. This reduces the I. F. sensitivity and permits use of a stronger output from the signal generator to over-ride the local noise level without bringing the AVC into action.

BROADCAST RANGE

Connect signal generator to antenna and ground of set, using a 250 MMF condenser in series with the antenna lead. With signal generator and dial at 1500 KC, peak the broadcast trimmers A5, A2 and A1 (oscillator, detector, and antenna). Use the first peak as A5 is screwed in from a loose position. Tune generator to 560 KC and peak broadcast tracking trimmer A4 while rocking variable condenser one division around the 560 KC mark. Repeat adjustments at 1500 and at 560 KC if necessary.



SHORT-WAVE RANGE

Connect a 400-ohm resistor in series with the generator pick-up lead at the antenna terminal of set. With signal generator and dial at 18 MC peak the short-wave oscillator trimmer A6, using the first peak as this trimmer is screwed down from a loose position. Check to determine that A6 has been adjusted to the correct point by tuning in the double spot at 17.05 MC. The signal generator should be left at 18 MC while making this check.

Retune the set to 18 MC and while slowly rocking the variable condenser, peak the short-wave detector trimmer A3. A better method of setting A3 is to connect a 400 MMF vernier-type variable condenser across the oscillator section of the gang condenser (*after* setting A6) and increase the capacity of this extra condenser until the 18 MC signal is again heard. Then peak A3. This method avoids inter-locking between the detector tuned circuit and the oscillator tuned circuit.

POLICE RANGE

No trimmers on this range.

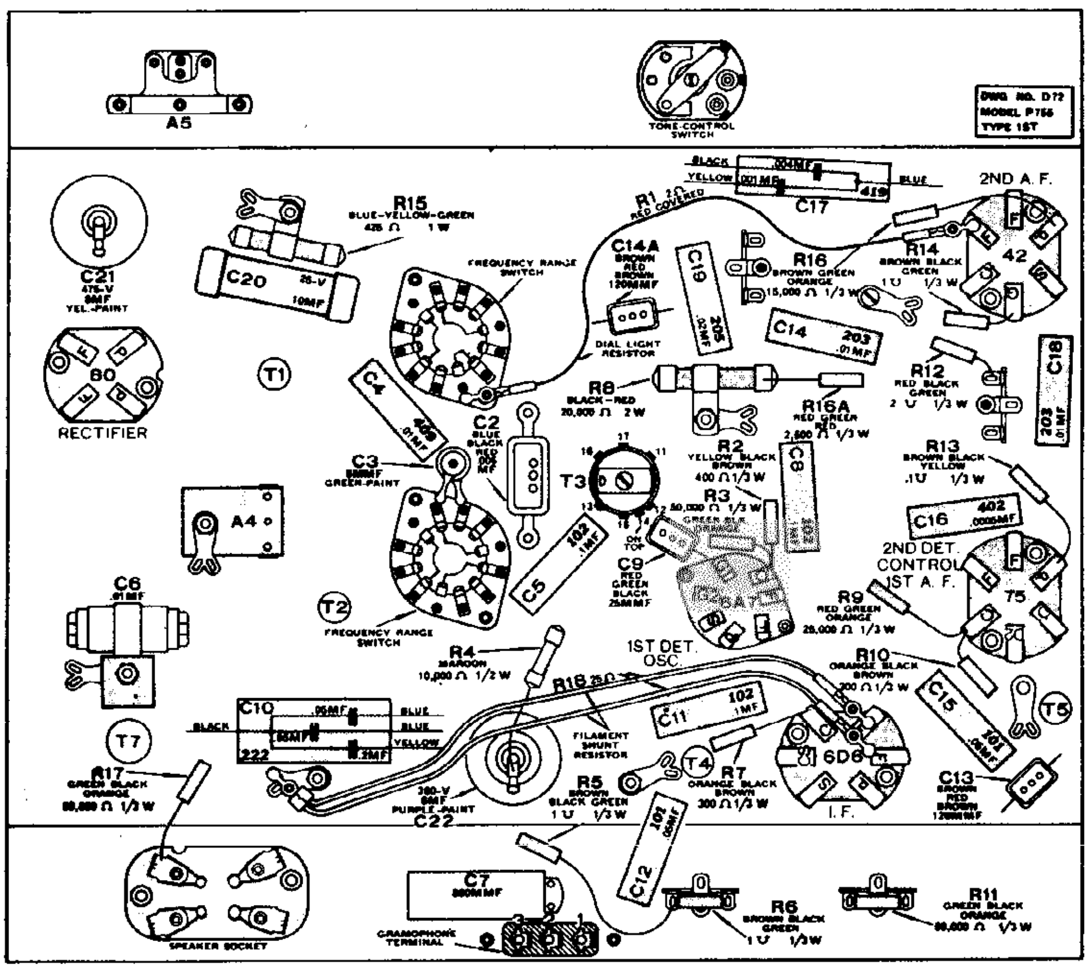
ADJUSTING TRIMMER CONDENSERS

I. F. TRIMMERS.
Connect I. F. test oscillator (264 KC) to I. F. tube by means of regular I. F. coupling unit. Peak A9, A8. Connect I. F. oscillator to 1st-detector tube and peak A7, A6.

DIAL POINTER ADJUSTMENT.
With rotor of variable condenser fully meshed, dial indicator should be at 535 KC.

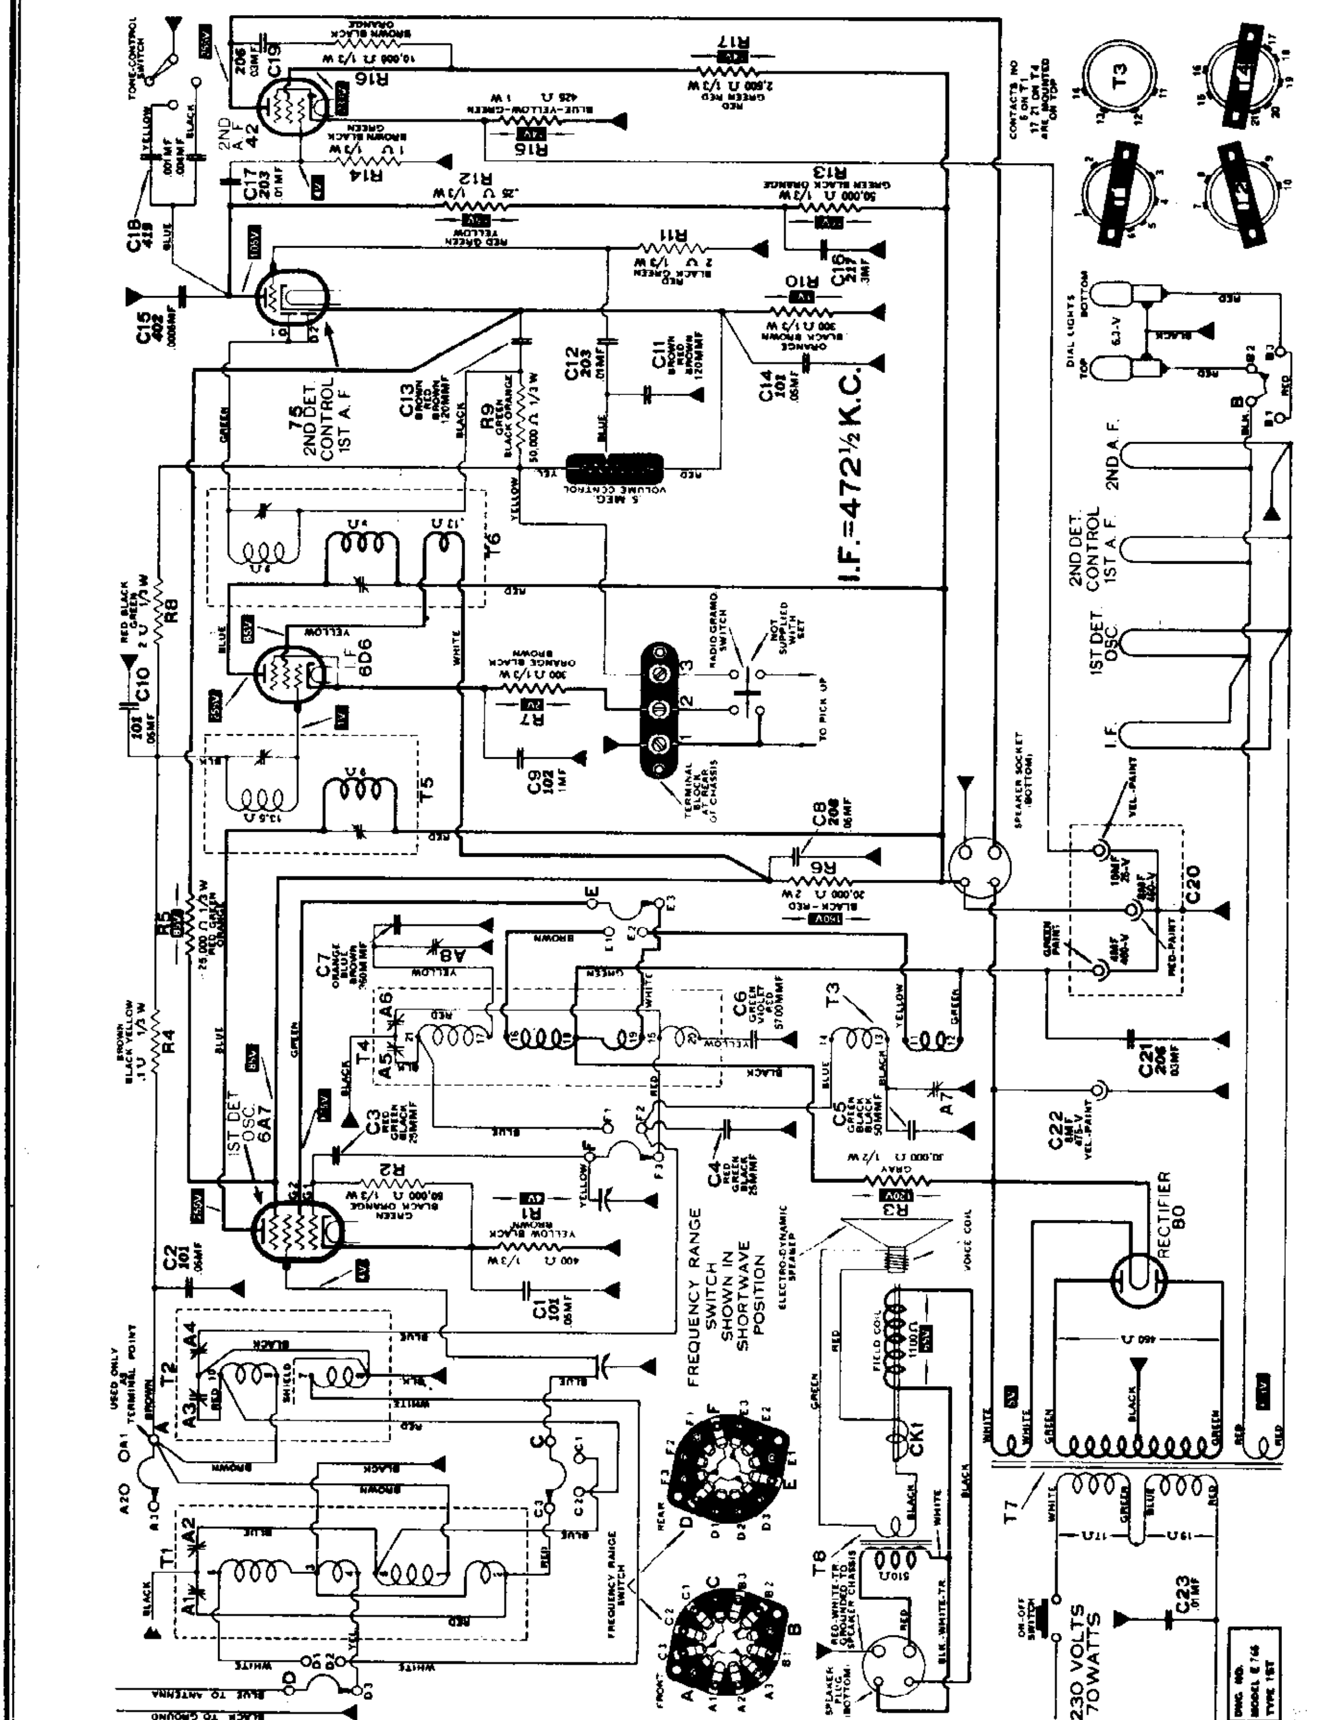
R. F. TRIMMERS.
Connect an R. F. oscillator to antenna and ground of set.
Short-wave range. With oscillator and dial at 15 MC, peak A3. Use the first point on the trimmer, as it is screwed in from a loose or minimum-capacity position.
Police range. No trimmers on this range.
Broadcast range. With oscillator and dial at 1500 KC, peak A4, A2 and A1. With oscillator and dial at 560 KC, peak A5.



August 2, 1935.

ATWATER KENT MFG. CO.

MODEL E-765
Schematic



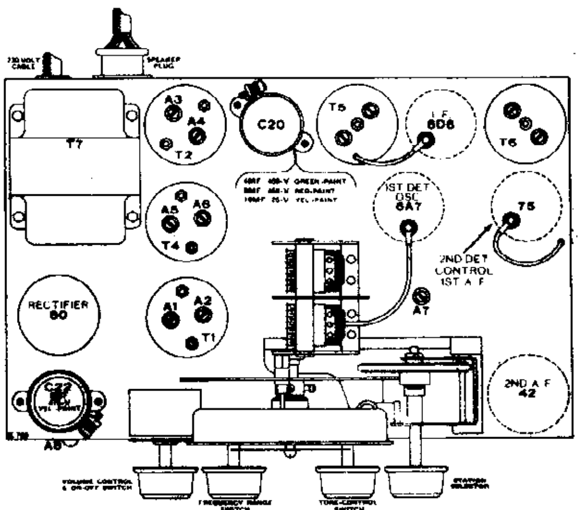
September 25, 1935.

ADJUSTING TRIMMER CONDENSERS

Turn volume control full on, turn tone control to "high," and use the weakest possible signal that will give a reading on a sensitive output meter.

I. F. TRIMMERS.

Connect an I. F. test oscillator (472½ KC) to the I. F. grid by means of the regular I. F. coupling unit No. 42590. Peak the two trimmers on top of T6. Connect I. F. oscillator to 1st-detector grid and peak the two trimmers on T5.



DIAL POINTER ADJUSTMENT.

With the variable condenser fully meshed, the dial pointer should be set at 538 KC.

R. F. TRIMMERS.

Connect an R. F. test oscillator to the antenna and ground leads of set. Loosen the trimmer screws for the range or ranges that are to be adjusted.

Short-wave range. Oscillator and dial at 18 MC, peak A6 and A1.

Long-wave range. Oscillator and dial at 405 KC, peak A4 and A3. Oscillator and dial at 160 KC, peak A7.

Medium-wave range. Oscillator and dial at 1500 KC, peak A5 and A2. Oscillator and dial at 540 KC, peak A8.

A1—1st-detector, 18 MC.
A2—1st-detector, 1500 KC.
A3—1st-detector, 405 KC.
A4—Oscillator, 405 KC.
A5—Oscillator, 1500 KC.
A6—Oscillator, 18 MC.
A7—Tracking, 160 KC.
A8—Tracking, 540 KC.

There are four I. F. trimmers, two on top of each I. F. transformer (T5 and T6). These are adjusted at 472½ KC.

ATWATER KENT MFG. CO.

INSTRUCTIONS FOR INSTALLATION OF 32-VOLT D. C. RECEIVERS

The power unit may be placed at some distance from the set if desired. Under certain conditions this will be found an advantage in reducing hum and background noise.

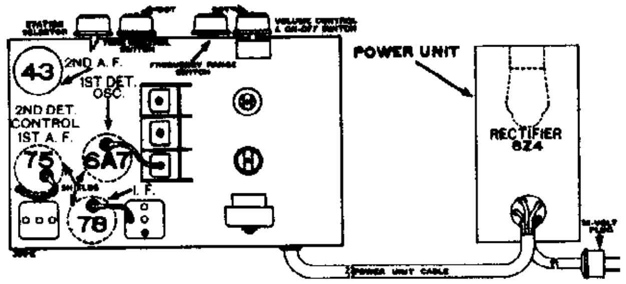
ANTENNA

An outside antenna is best, and we suggest a single wire (continuous if possible) between 50 and 100 feet total length, including lead-in. The antenna should be as high as possible.

Run the antenna at right angles to the power line from the lighting plant to the house. Erect the antenna and lead-in away from the lighting plant.

The antenna lead-in must be short and direct, and it must be kept away from the ground and from the power line. Do not use a shielded lead-in.

Connect the antenna lead-in to the blue wire at rear of chassis.



IMPORTANT

FOR MAXIMUM EFFICIENCY ON ALL WAVES, use the Atwater Kent Type "D" No. 28076 doublet antenna kit and the Atwater Kent Model "DT" No. 28083 doublet transformer. These parts have been designed especially for this receiver. Complete installation instructions are furnished with the kit.

The orange lead at rear of chassis is to be used only if the antenna is extra long. In this case, connect the orange lead (together with black lead) to ground. If the antenna is average length, do not use the orange lead and make certain that the end of this lead is covered with the rubber tubing.

GROUND

A ground is required and should be made by running a wire from the back lead at rear of chassis to the nearest water pipe or radiator, using a ground clamp to provide good contact to the pipe. Keep ground lead short.

LIGHTING PLANT INTERFERENCE

When the charging generator is running, a certain amount of electrical interference or noise may be picked up by the radio receiver. This originates in the ignition system of the lighting plant, and at the brushes of the lighting plant generator.

This interference can be eliminated by placing a spark-plug suppressor (No. 21143) on the engine-end of the lead from the high-tension coil. If this does not entirely correct the trouble, connect an Atwater Kent generator condenser No. 38270 from each brush of the generator to the generator frame.

Plants having more than one cylinder should have a suppressor on each spark plug and also a distributor-type suppressor (No. 21144) on the high-tension lead to the distributor cap.

Practically all ignition interference is eliminated by use of the suppressors and condensers as specified above. However, if there is still some electrical interference present after these parts have been correctly installed, in many cases this can be reduced and often entirely eliminated by employing one or more of the following methods:

(It is important to make all listening sets for ignition interference with the radio volume control full on, and with the lighting-plant generator in operation.)

1. Replace all leaky or old high-tension cables.

2. Make certain that all high-tension leads make good contact with their terminals. Soldered joints are preferable.

3. Reduce the gap between the rotor electrode and the distributor electrodes to a minimum by peening the rotor electrodes. If this is not feasible add solder to the end of the rotor electrode or to the distributor contacts.

4. Check the spacing of the spark-plug electrodes. in general, small gaps reduce interference.

5. Check the condition of the low-tension interrupter contacts. If necessary, file or replace the points.

6. Check for defective suppressors. The correct resistance is approximately 15,000 ohms.

7. Remove spark "boosters" on ignition coil or spark plugs.

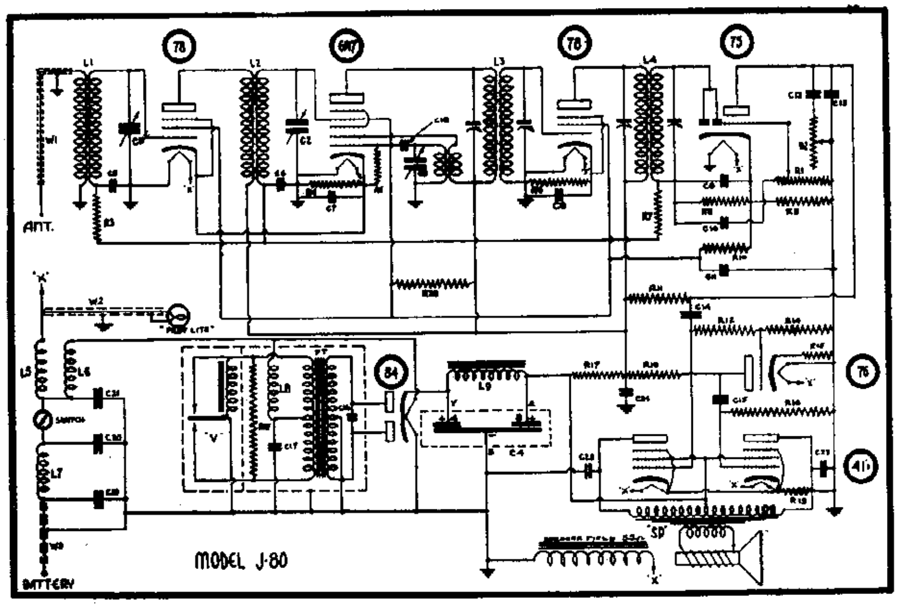
Alignment

AUTOMATIC RADIO MFG. CO., INC.

MODEL J-80 AUTO RADIO



ALIGNMENT PROCEDURE

I. F. Alignment. Connect a signal generator set at 456kc to the 6A7 input and connect an output meter to the speaker output. Using a weak signal tune the two I. F. condensers on the composite coil and the two I. F. condensers on the output I. F. coil for maximum response.

Connect the signal generator set at 1400kc to the antenna lead using a dummy antenna of 150 mmf. Tune the set by means of the dial to 1400kc position. Adjust oscillator trimmer for this frequency. Then trim RF stage and antenna stage for maximum response. Repeating the alignment may result in improved sensitivity.

REPLACEMENT PARTS AND PRICE LIST

All orders for replacement parts must indicate both the Serial Number and Model Number of the Chassis in addition to the part number and description of the unit desired.

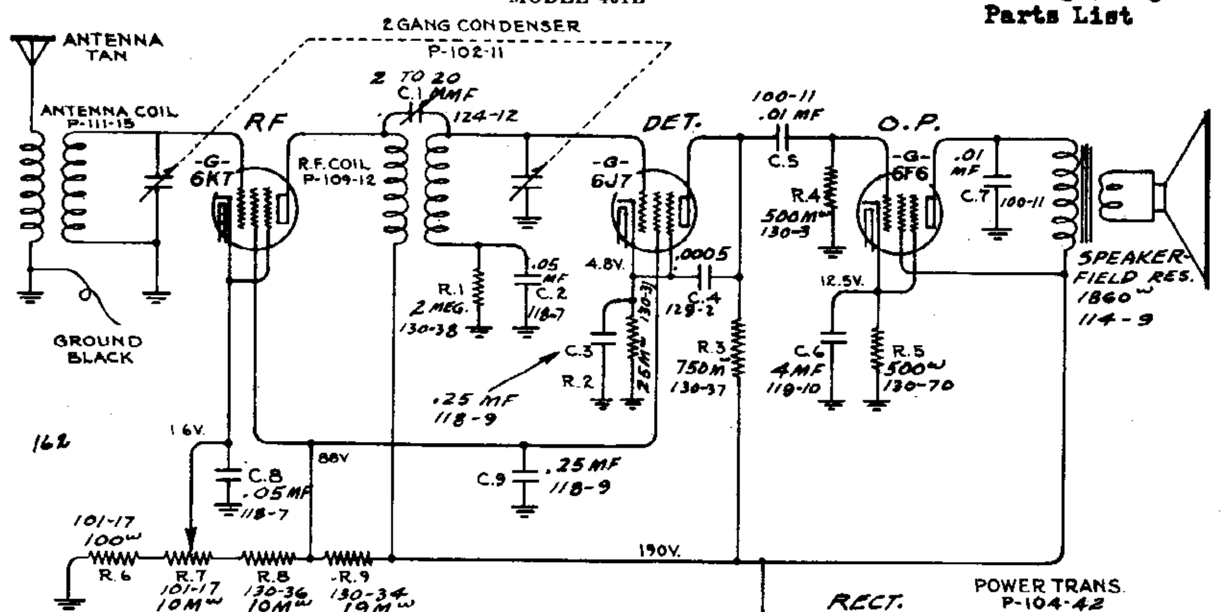
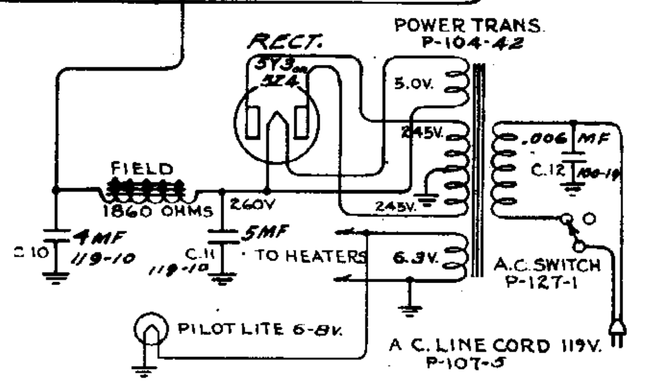
MODEL 401, Series
Schematic, Socket
Voltage, Alignment
Parts List

BELMONT RADIO CORP.

MODEL 401B





ALIGNING INSTRUCTIONS

1. With an external oscillator set at 1720 kilocycles connected to the grid of the type 6K7 R. F. tube (cap at top of tube) and with the variable condenser at its minimum capacity position, plates entirely out of mesh, adjust trimmer on R. F. coil (accessible from the under side of the chassis) to resonance.

2. Re-set external oscillator to 1400 kilocycles and connect in series with a 50 mmfd. condenser, to the tan antenna lead and black ground lead and adjust the antenna trimmer (front section of variable condenser—see illustration) to resonance. When making this adjustment, rock the condenser back and forth with the selector knob while adjusting the trimmer until maximum output is obtained.

3. Bend plates of antenna, front section of condenser, to resonance with external oscillator set at 1200, 1000, 800, 600 kilocycles. Output should be fairly uniform over the entire band; dropping off slightly at the higher frequencies.

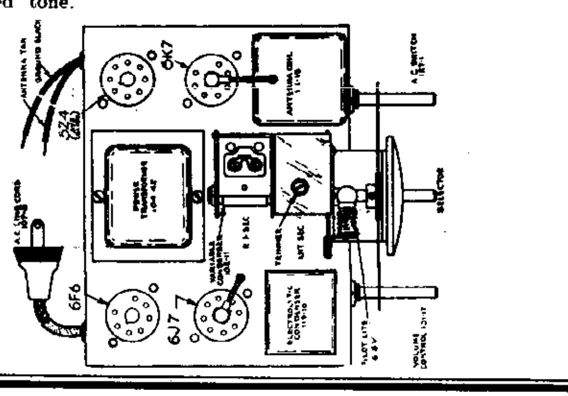
Regular Transformer supplied is for 105-125 volts 60 cycle alternating current. For voltages in excess of 125, a special transformer or line resistor is required, also for 25 cycle current. Universal transformers are not available for this model.

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt. These voltages are clearly indicated on the circuit diagram.

All voltages are to be measured with 119 volts on the primary of the power transformer.

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

Excessive hum, stuttering, low volume and a reduction in all D.C. voltages is usually caused by a shorted electrolytic condenser, open by-pass condensers frequently cause oscillation and distorted tone.



PARTS LIST
MODEL 401—SERIES B

When ordering parts, always specify part and model number as well as serial number of chassis.

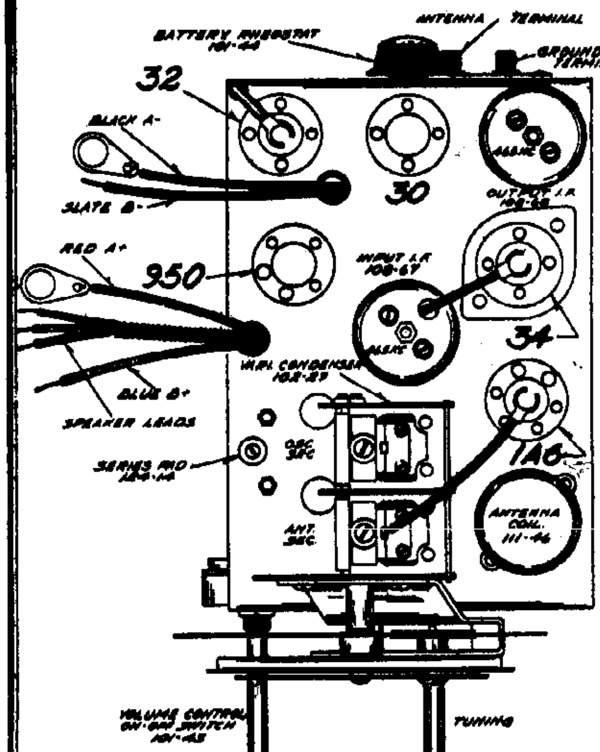
L	114-19	Six Inch Magnetic Speaker



ALIGNING I.F. TRANSFORMERS: (465 K.C.)

1. With volume control full on and with variable condenser at its minimum capacity position, plates entirely out of mesh, and with external oscillator set at 465 K.C. connected in series with a .1 mfd. condenser, to the grid of the 1A6 tube (cap at top of tube), adjust I.F. transformers, parts number 108-67 and 108-68, to resonance. Both of these transformers have two (2) adjustments each, they are accessible from the tops of the cans (for location see top view).

Use as a resonance indicator an output meter connected across the outside terminals of the speaker or by means of an adapter to the plate and screen of the type 950 output tube. Maximum deflection of the volt meter indicates resonance.

Use only enough signal to get a readily readable output.

A low range output meter or the low scale of a multi-range meter should be used.

BROADCAST BAND ALIGNMENT:

1. Set external oscillator to 1720 K.C. and connect it in series with a 200 mmfd. condenser to the antenna and ground posts.
   - (a) With variable condenser in its minimum capacity position, plates entirely out of mesh, adjust oscillator trimmer (rear section of variable condenser) to resonance.
   - (b) Re-set external oscillator to 1400 K.C. Rotate variable condenser, pick up signal and adjust antenna trimmer (front section of variable condenser) to resonance.
   - (c) Re-set external oscillator to 600 K.C., move dial pointer to 600 K.C., and adjust series pad, part number 124-14 (see top view), to resonance. While making this adjustment, slowly rock variable condenser to and fro until maximum output is obtained.
   - (d) Check for sensitivity at 1400, 1000, 600 K.C. DO NOT BEND PLATES.

BELMONT RADIO CORP.

Belmont Model 556 5-Tube A. C. 3-Band Superheterodyne Receiver

200-260 Volts 50-60 Cycles Alternating Current

(THIS MODEL IS FOR EXPORT ONLY)

DESCRIPTION

Tubes:

The Tube complement of this chassis is as follows:

1 Type 6A7—pentagrid converter.
1 Type 6D6—remote cut-off pentode as I.F. amplifier.
1 Type 6B7—duplex diode pentode as diode detector, A.V.C. and A.F.
1 Type 42E—pentode output tube.
1 Type 80—high vacuum rectifier.

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a voltmeter having a resistance of 1000 ohms per volt. These voltages are clearly indicated on circuit diagram.

All voltages are measured with 235 volts 50-100 cycles on the primary of the power transformer.

Resistance of coils and transformer windings are indicated in ohms on schematic circuit diagram.

Transformers are available and chassis are sometimes equipped with universal transformers for operation on 40 and 60 cycles and with primary taps for 105, 125, 150, 220 and 250 volts (see illustrations) and also sometimes equipped with 25 cycle transformers with 105-115 volt or 235 volt primaries, not universals.

Should the receiver be equipped with a special transformer, connect primary tap on voltage terminal which corresponds as nearly as possible to the actual line voltage. If an exact agreement cannot be secured, suitable allowances of other measured voltages must be made.

ALIGNING INSTRUCTIONS—SERIES A

Description of various dummy antennas used and referred to in these instructions:

(1) I.F. Dummy—Consists of a .1 mfd. condenser connected in series with the external oscillator.

(2) Broadcast Dummy—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

(3) Intermediate and Short Wave Dummy—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

Resonance Indicator:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer, or by means of an adapter between the plate and screen terminals of the type 42E output tube. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range volt meter should be used.

TEST FREQUENCIES

	Wave Length Meters	Frequency Kilocycles
Long Wave	2000	150
	923	325
I.F.	645.1	465
Broadcast	500	600
	300	1000
	214.2	1400
Short Wave	50.0	6000
	16.7	18000

ALIGNMENT:

No aligning adjustments should be attempted without first thoroughly checking over all other possible causes of trouble, such as poor installations, open or grounded antenna systems, low line voltages, defective tubes, condensers and resistors. In order to properly align this chassis, an oscillator (generator) is absolutely necessary. No aligning adjustments should be attempted with the chassis in the cabinet. To remove the knobs, pull them off and to take the chassis out of the cabinet, remove the three bolts by which it is fastened and the speaker plug which you will find on the front flange of the chassis panel.

ALIGNING I. F. TRANSFORMERS:

1. With volume control full on, the extreme right of its rotation, and with wave changing switch in the broadcast position, center of its rotation, and with variable condenser at its minimum capacity position, plates entirely out of mesh, adjust the I.F. transformers (two adjustments at the top of parts number 108-47 and 108-53—see top view)

(a) Connect external oscillator which has been adjusted to 645.1 meters in series with I.F. dummy antenna, to the control grid cap of the type 6D6 tube and chassis ground. Adjust output I.F. transformer, part number 108-47, to resonance.

(b) Move generator output clip from grid of 6D6 to grid cap of 6A7 tube and align input I.F. transformer, part number 108-53.

(c) With generator connected to grid of type 6A7 tube, readjust output I.F. transformer, part number 108-47, to resonance.

BROADCAST BAND ALIGNMENT:

(188-595 meters)

1. With wave changing switch in the broadcast position, center of its rotation, and with gang condenser in its minimum capacity position, plates entirely out of mesh, connect an external oscillator in series with broadcast dummy antenna to tan antenna and black ground leads and make the following adjustments:

(a) With external oscillator set at 187.5 meters, adjust oscillator trimmer to resonance. for location of this adjustment, number 5, see diagram.

(b) Re-set external oscillator to 214.2 meters, rotate condenser, pick up oscillator signal and adjust antenna trimmer to resonance. For location of this adjustment, number 2, see diagram.

(c) Re-set external oscillator to 500 meters and adjust series pad to resonance, rotate condenser and move dial pointer to 500 meters by gently rocking condenser to and fro. Pick up oscillator signal while adjusting series pad to resonance, maximum deflection on an output meter. This adjustment is accessible from the top of the chassis and is located between variable condenser and power transformer, rear hole see top view—part number 124-19.

(d) Check for tracking and sensitivity at 300 meters.

SHORT WAVE BAND ALIGNMENT:

(16.5-56.6 meters)

1. Set wave changing switch to short wave position, extreme right of its rotation, set dial pointer to 16.7 meters.

(a) With external oscillator adjusted to 16.7 meters and connected in series with short wave dummy antenna to tan antenna and black ground leads, adjust the oscillator short wave trimmer until generator signal is picked up. For location of this adjustment, number 4; see diagram.

(b) Adjust short wave antenna trimmer to resonance. For location of this adjustment, number 1, see diagram.

(c) Re-set external oscillator to 50 meters, rotate condenser, move dial pointer to 50 meters, and check for tracking and sensitivity. Do not bend plates. Note: It is extremely necessary in making all of the above adjustments that the fundamental signal of the oscillator be tuned in and not the image frequency, which will fall at a higher wave length.

LONG WAVE BAND ALIGNMENT:

(925-2140 Meters)

1. With wave changing switch in long wave position (extreme left of its rotation) and with variable condenser in its minimum capacity position (plates entirely out of mesh), make the following adjustments:

(a) With external oscillator set at 923 meters and connected in series with "Dummy 2" to the tan antenna lead, adjust rear trimmer of oscillator coil (adjustment No. 6, see diagram) until oscillator signal is picked up.

(b) Adjust rear trimmer of antenna coil to resonance with oscillator (adjustment No. 3, see diagram).

(c) Re-set external oscillator to 2000 meters and rotate variable condenser (move pointer) and pick up oscillator signal, adjust L.W. pad (front adjustment accessible from top of chassis and located between variable condenser and power transformer) to resonance. While making this adjustment, slowly rock variable condenser to and fro until maximum output is obtained.

SERVICE NOTES:

To check for open by-pass condensers, shunt each condenser with another of similar capacity and of the same voltage rating, which is known to be good, until the defective unit is located. Open by-pass condensers frequently cause oscillation and distorted tone. Defective and shorted electrolytic filter condensers cause excessive hum, motor-boating, low volume and a reduction in all D.C. voltages. Open or shorted electrolytic and by-pass condensers (across bias resistor of type 42E tube) will cause low volume and distorted tone.

Should the planetary vernier dial drive mechanism fail to function properly, it will probably be found to be due to a cracked or broken compression spring. The drive may be disassembled to replace the compression spring (part number 112-31) by removing the two screws which fasten it to the dial bracket. Before re-assembling all parts should be carefully cleaned and a small amount of vaseline applied to the ball bearings. All other dial parts are hardened and should cause no trouble.

Tuning Range

16.5 — 56.6 meters
188 — 595 meters
925 — 2140 meters

ASSEMBLIES

Part No.	Description
117-41	Drive Bracket including:
	1—No. 117-19—Tuning Shaft Bushing
117-40	Switch Disc and Link Assembly, including:
	1—No. 117-12 —Switch Arm
	1—No. 117-35 —Bushing with Screws
	1—No. 117-40B—Switch Link
	2—No. 131-36 —Spring Washers
	2—No. 162-5 —Rivets
	1—No. 112-144—Switch Disc—Inc. Red Tape

DIAL PARTS ONLY

Part No.	Description
112-135	Drive Belt
112-146	Oval Escutcheon complete with Celluloid Crystal
112-166	Dial Scale complete
112-147	Tuning Shaft
112-151	Pointer complete with Screw
112-155	Pilot Light Assembly
116-15	6.3 Volt T-51 Pilot Light
117-28A	Tuning Shaft Pulley
117-35	Stud, for take-up Spring
117-39	Pulley, for take-up Spring
120-14	Take-up Spring
124-9	Horse Shoe Washer
134-40	Rubber Grommet

All resistors and mica condensers are RMA color coded—specify value and/or resistor or condenser (per schematic diagram) and model number.

Mica condensers are coded with an additional dot indicating tolerance:

Tolerance Percent	Color of Dot
2½ %	White
5%	Green
10%	Blue
15%	Yellow
20%	Red
More than 20%	None

When ordering condensers, specify part number, model and/or capacity (per schematic diagram) and model number.

When ordering parts, always specify part and model number as well as serial number of chassis.

WHEN ORDERING SPEAKER PARTS: CONES, FIELD COILS, OUTPUT TRANSFORMERS, SPECIFY PART NUMBER OF SPEAKER AND MAKE.

MODEL 566
Alignment, Notes

BELMONT RADIO CORP.

CONNECTIONS TO BATTERY:

The battery cable, number 183-2, (red wire with fuse receptacle at one end and terminal lug at other end) must be connected to battery terminal of ammeter. At the same time connect ammeter capacitor, number 148-3, to battery terminal of ammeter, other end of condenser to any convenient grounded screw on back of instrument panel. Make certain that insulating sleeve is slipped over fuse when fuse is placed in receptacle, before connecting to short battery cable from receiver.

When connected properly, the discharge due to current drawn by the receiver should not indicate on the ammeter. This is important, since if improperly connected, as shown by the deflection of ammeter, additional motor interference may be encountered.

GENERATOR INTERFERENCE:

Remove the generator cutout mounting screw and fasten the condenser (148-1) bracket on the generator cutout mounting lug. Replace the cutout mounting screw and tighten down securely.

Connect the condenser lead to the battery terminal of the cutout. The generator condenser is absolutely necessary as it is used to eliminate a high pitched whining noise which would otherwise be heard as the motor is accelerated.

ANTENNA CONNECTION:

The antenna is connected to the receiver by means of the antenna cable. The antenna wire is the single black wire projecting from the end of the cable. Splice this wire to the roof antenna lead and ground the pig-tail shielding as close to the corner post of the car as possible.

On open and convertible models where underslung strap or plate antennas are used it may be necessary to ground the exhaust pipe and muffler to the frame at both ends with heavy copper braid.

Aerials suitable for open and convertible cars can be purchased from your dealer. They should be mounted as far to the rear of the car as possible and on the side opposite to the tail light wiring.

DIAL ADJUSTMENT:

Tune set to some station of a known frequency (between 800 and 1200 K.C.) hold selector knob, then with a screw driver adjust the slotted screw on the back of the control head, and in that way adjust the dial pointer to the correct frequency setting.

CHECK FOR MOTOR NOISE (Chassis Pickup):

After the above instructions have been followed, with the hood clamped down to prevent radiation and the motor running, the receiver should be turned on and the dial turned off a station, with volume control at maximum. If motor noise is objectionable the next step is to determine whether the interference is originating through chassis pickup or from the antenna.

To check for chassis pickup, disconnect the antenna from the antenna cable and ground the antenna lead to shield of cable. Chassis pickup is due to the electrical interference being radiated or fed back through the frame of the car into the receiver or through the storage battery to the receiver.

It may be necessary when chassis pickup is present to ground the choke and gas throttle rods securely to the firewall at the point which they enter the drivers compartment.

Chassis pickup can be reduced by reducing the gap between contacts and the rotating arm in the distributor head. To do this apply solder to the end of the rotor arm. Replace the rotor in the distributor and turn the engine over slowly with the crank in order to clean the excess solder. The rotor should not brush or wipe the contacts inside the distributor cap, but should just clear them. As an additional precaution check the breaker points. They should be thoroughly cleaned and adjusted or new points installed if they are badly worn. In stubborn cases a good grade mica .002 to .006 condenser connected across the breaker points will reduce interference. The ignition system of a car must be kept in good condition and leaky cracked high tension wires and bad spark plugs should be replaced. In many cars the low tension battery leads, etc., are grouped together with the high tension wires. These leads will very often pick up motor noise and feed it into the receiver through the battery circuit. In cases such as these it will be necessary to separate the low tension from the high tension wires and run them through another hole if they run from the engine compartment up to the instrument panel. This condition, as explained previously, is particularly true on the V-8 Ford as the battery and primary leads run through a special tube which also houses the high tension leads. Shield and ground these leads.

NOTE—Where ignition coils are mounted in motor compartments a .5 mfd cond (148-1 or 148-3) connected between primary coil terminal and receiver mounting bolt will often reduce motor noise.

Accessories such as lighters, electric motor heaters, horns, light switches, automatic relays, electrical gauges such as oil, water and gas are often a source of interference. In these cases the procedure is to try a condenser from ground to various accessories until the interference is eliminated, then install the condensers in those places permanently. Spark intensifiers should not be used.

ANTENNA PICK UP:

Now connect the antenna to the receiver and test for motor noise pick-up, it is entirely probable that if any noise is present it will be very slight and only noticeable between stations. No absolute rule for complete motor noise elimination can be specified inasmuch as many times two cars of the same make present entirely different problems and require bonding or shielding at different points. If motor noise is objectionable, it is due to the interference being radiated and picked up through the antenna system. Motor noise can be radiated into the drivers compartment through the drivers body due to the fact that in the majority of cars the toe board is wood. This can be remedied by covering the entire floor board with copper screen grounded in several places to the frame of the car. This condition is only true in cars which have roof antennas. Under-slung antennas, either of the strap or plate type, will very often pick up motor noise if mounted too far forward on the frame of the car, the noise naturally being picked up due to the close proximity of the antenna to the engine.

It is recommended that if an under-slung antenna is used, that it be mounted as far towards the rear of the car as possible and preferably on the side of the car opposite to the tail light wiring. Naturally the performance of any radio depends on the effectiveness of the antenna. The later model cars are coming through with very good Antennas, already installed and no trouble should be experienced from this angle with of course an occasional exception. Many of the older cars on the market today have a wire network in the roof which is nothing more than ordinary chicken wire. This wire network acts as a support to the roof and is in the majority of cases grounded directly to the body of the car at the point at which the roof meets the sides of the body. Service men frequently tack antennas to the underside of the top material in these cars, this is not satisfactory. There are but two things to do. Either an underslung (plate or strap) antenna must be used or the wire network must be cut from all grounds to the car. If this is done this network will in itself make a very good antenna, but it will be necessary to cut the wire network back for a distance of at least three inches from all sides of the car.

When running the lead-in up the corner post of the car to the roof antenna ground it every few inches to the frame of the body of the car. If this is not possible insulate it, otherwise scratchy noises will result.

STEEL TOP OR TURRET TOP CARS do not contain built-in roof antennas. In cars of this type an under-slung, strap or plate, antenna must be used.

If after all standard methods to reduce motor noise, as outlined above, have been tried and trouble still persists, carefully check the following: the dome light is usually the greatest source of antenna pick-up interference. First check the dome light by disconnecting the dome light connection on the back of the dash and grounding the wire (for location of this wire see car wiring diagram). If this eliminates the interference it indicates clearly that motor noise is being picked up by the dome light wire and radiated into the antenna. A small R.F. choke connected in series with the dome light wire and by-passed to ground at the dome light side of the choke with a .5 or 1 mfd. condenser, will eliminate this source of interference. Wheel or brake noise is probably the most peculiar type of interference and is due to accumulated static charges. This type of interference is only noticeable while the car is in motion and could very easily be confused with ignition interference. Check for this with car running at a good speed, turn the ignition switch off and if the interference continues it is due to either wheel static or a loose electrical connection. To overcome the wheel static condition, use graphite grease in the wheel bearings or insert grounding springs in the hub caps. In the case of external brakes, it is necessary to ground the brake bands to the frame of the car.

Loose connections are a frequent cause of interference. Make certain that light bulb contacts are clean and that they fit tight in their sockets, that all battery cable connections are tight and well grounded. Secondary high tension leads at the distributor cap or the coil very often work loose and a sparking contact results. Make certain that clips on all high tension wires are clean and bright and are pressed firmly into the receptacles on the distributor cap and the ignition coil.

Ignition noise should, if possible, be checked in a location that is free from electrical disturbances such as power lines, electrical equipment, neon signs, street car and elevated lines. This receiver is a very sensitive instrument and will pick up over its antenna system electrical disturbances in its immediate vicinity.

ALIGNING INSTRUCTIONS:

All of the adjustments have been very carefully set with signal generators at the factory and require no further adjustment, unless it becomes necessary to replace a coil or transformer or if the adjustments have been tampered with in the field. Under no circumstances attempt any adjustments without first making certain that adjustment is necessary and only after voltages, tubes and condensers have been checked and found to be normal. To properly re-align this receiver, a test oscillator, as well as an output meter, must be used.

DUMMY ANTENNAS:

The dummy antennas referred to in the following instructions are:

"I.F. Dummy" —A .1 mfd. condenser connected in series with the test oscillator output lead.

"Broadcast Dummy"—A 175 mmfd. condenser connected in series with the output lead of the test oscillator.

RESONANCE INDICATOR:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer, or by means of an adapter between the plate and the screen of the type 41 output tube. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used.

I.F. ALIGNMENT

1. With variable condenser in its minimum capacity position (plates entirely out of mesh) and with volume control full on, connect test oscillator set at 456 K.C. in series with I.F. dummy antenna, to grid of 6K7 tube.
2. Adjust trimmer condensers of output I.F. transformer (No. 108-70) to resonance with oscillator.
3. Move test oscillator connection to grid of 6A8 tube and adjust trimmer condensers of input I.F. transformer (No. 108-69) to resonance with oscillator, again going over trimmers of output I.F. transformer (No. 108-70). See top view for location of these transformers. There are two adjustments on each and they are accessible from the top of the transformer shield and should be adjusted with an insulated screw driver.

BROADCAST ALIGNMENT

1. With variable condenser in its minimum capacity position, connect test oscillator set at 1500 K.C. in series with broadcast dummy to the antenna lead of the receiver.
2. Adjust oscillator trimmer of variable condenser to resonance. (This adjustment is rear section of gang—see top view.)
3. Shift test oscillator to 1400 K.C. and pick up signal by rotating condenser and adjust antenna trimmer to resonance—see top view.
4. Re-set test oscillator to 600 K.C. and rotate variable condenser to 600 K.C. Adjust series pad, rocking gang condenser to and fro, at the same time adjusting series pad for maximum gain.

   This adjustment is accessible from the top of chassis—see top view.
5. Go back and check 1400 K.C. If adjustment is made here, check 600 K.C. again.
6. Check for sensitivity at 1000 K.C. by setting test oscillator to this frequency and picking up the signal by rotating variable condenser. UNDER NO CIRCUMSTANCES BEND PLATES OF VARIABLE CONDENSER SECTIONS TO CORRECT TRACKING.

MODEL 566
NO SPARK PLUG SUPPRESSORS ARE REQUIRED

MOTOR NOISE SUPPRESSION:

The ignition system of every automobile generates high frequency electrical disturbances which interfere to some extent with the operation of the radio receiver. This disturbance arises from the ignition coil, the distributor and associated wiring. It must either be suppressed at its origin or must be prevented from feeding into the input of the radio receiver through the common storage battery. By proper shielding and by-passing these disturbances are prevented from entering the receiver. The first essential procedure towards minimizing this disturbance is to disconnect the high tension lead to the distributor and insert a distributor suppressor, part number 168-2, as indicated in illustration.

Note: For Ford V-8's, no distributor suppressor is used.

For cap type distributors, exchange standard type 168-2 for a special cable type suppressor, part 168-3, from your dealer.

In cars where the ignition coil is located on the back side of the instrument panel it is often necessary to use an additional capacitor, part number 148-3, obtainable from your dealer. It must be installed from the battery side of the ignition coil to the closest ground on the instrument panel.

Short leads are very important. Where coils are mounted either on the instrument panel or in the driver's compartment, it is necessary to shield the high tension lead from the coil to the distributor.

This can be done by covering the lead first with flexible loom and then with shielded braid, grounding one side of the braid to the instrument panel and the other to a point on the motor block closest to the distributor. This lead should be run as nearly as possible directly from the coil to the distributor, even if it is necessary to drill an extra hole in the fire wall. It may even be necessary in some stubborn cases to move the coil from the driver's compartment and mount it on the motor block as close as possible to the distributor. The new primary wire should be No. 14 shielded low tension cable. Do not run wires close to the high tension leads and make certain that shields are well grounded.

Make certain that the instrument panel has a ground connection to the frame of the car.

For Ford V-8's, it is necessary to remove from the high tension housing attached to the left bank of 4 cylinders the master cable containing the generator wire (yellow wire with black tracer) and the red low tension wire connecting ignition coil to the ignition switch.

These two wires must be removed from high tension housing and shielded. Shielding must be grounded at both ends. A capacitor must be connected between the primary of the ignition coil and ground. Your dealer can supply a special type capacitor for this purpose (part No. 148-6).

Cars with floating power must have the motor bonded to the bulkhead and again to the frame to provide a direct path for the high frequency interference developed in the ignition system. ¾" copper braid will be necessary. SMALL DIAMETER WIRE WILL NOT DO. Bond flexible shaft leads, such as free wheeling, choke wires, etc., which pick up motor noise and reradiate it into the car. Free wheeling cables should be grounded at the point at which they go through the fire wall of the car. In extreme cases it has been found necessary to ground the steering column.

Great care of design has been given the Model 566 to minimize motor noise pick-up. Three sources of motor noise pick-up are antenna pick-up, "A" line pick-up, and chassis pick-up.

Chassis pick-up is reduced to an absolute minimum by completely insulating the inner chassis from the outer case and grounded at carefully selected points to outer case so as to get minimum impedance drops induced by eddy currents around the R.F. end of the chassis. The "A" line pick-up was eliminated by a carefully designed low pass filter which is completely shielded in a can of its own.

Antenna pickup was reduced to a minimum by removing all capacity coupling in the antenna stage and this is further augmented by a low pass filter which discriminates against all frequencies outside the broadcast band.

A further precaution that was taken against motor noise is the insulated couplings used on the end of the volume control shaft and variable condenser shaft. This completely kills any motor noise loop that would have been caused by the grounding of the flexible control cables through variable condenser.

SERVICE NOTES:

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt. These voltages are clearly indicated on the circuit diagram.

In order to prevent signal from acting upon A.V.C. and affecting accuracy of voltage measurements, aerial and ground leads should be short circuited while making measurements.

All voltages are to be measured with 6.3 volts input to receiver. Resistances of coils and transformer windings are indicated in ohms on schematic circuit diagram.

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

Failure to operate, noisy or weak reception is usually due to defective tubes, the tubes making poor contact with sockets or grid clips making poor contact with the caps of the tubes. Tubes may be checked very easily by replacing with other tubes which are known to be good. If fuse blows out frequently and insulating sleeve has been properly placed over fuse, the trouble is probably in the vibrator, it should be replaced. Do not attempt to make any adjustments on the vibrators.

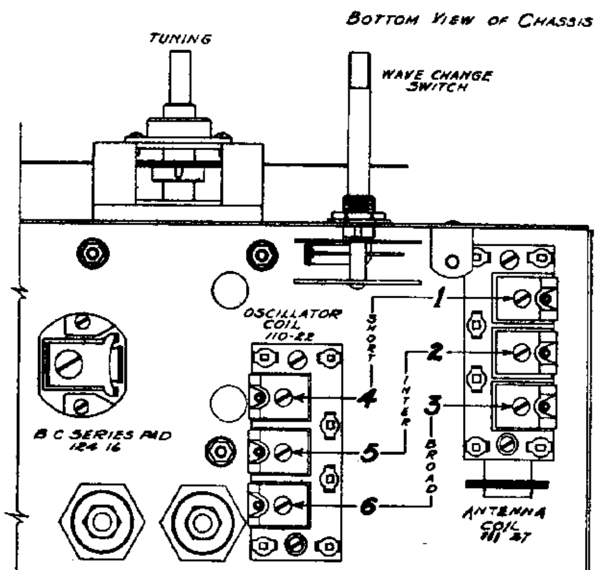
Intermediate Band
2350-7700 Kilocycles.

Short Wave Band
7.6-19.0 Megacycles.



MODEL 585, Series D
Alignment, Parts

BELMONT RADIO CORP.

DESCRIPTION

The Tube complement of this chassis is as follows:
1 Type 6F7—triode pentode as oscillator and first detector.
1 Type 6K7—remote cut-off pentode as I.F. amplifier.
1 Type 75—duplex diode triode as diode detector, A.V.C. and A.F.
1 Type 6F6—pentode output tube.
1 Type 80—high vacuum rectifier.

Transformers are available and chassis are sometimes equipped with universal transformers for operation on 40 and 60 cycles and with primary taps for 108, 125, 150, 220 and 250 volts (see instructions) and also sometimes equipped with 25 cycle transformers with 105-115 volt or 220 volt primaries, not universals.

SERVICE NOTES

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt. These voltages are clearly indicated on the circuit diagrams.

IN ORDER TO PREVENT SIGNAL FROM ACTING UPON AVC AND AFFECTING ACCURACY OF VOLTAGE MEASUREMENTS, AERIAL AND GROUND LEADS SHOULD BE SHORT CIRCUITED WHILE MAKING MEASUREMENTS.

All voltages are to be measured with 119 volts on the primary of the power transformer.

Resistances of coils and transformer windings are indicated in ohms on schematic circuit diagrams.

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

ALIGNING INSTRUCTIONS

No aligning adjustments should be attempted without first thoroughly checking over all other possible causes of trouble, such as poor installations, open or grounded antenna systems, low line voltages, defective tubes, condensers and resistors. In order to properly align this chassis, an oscillator (generator) is absolutely necessary. No aligning adjustments should be attempted with the chassis in the cabinet. To remove the knobs, pull them off and to take the chassis out of the cabinet, remove the three bolts by which it is fastened and the speaker plug which you will find on the front flange of the chassis panel.

Aligning I. F. Transformers

1. With volume control full on, the extreme right of its rotation, and with wave changing switch in the broadcast position, extreme left of its rotation, and with variable condenser at its minimum capacity position, plates entirely out of mesh, adjust the I.F. transformers (two adjustments at the top of parts number 108-38 and 108-40—see top view).
   (a) Connect external oscillator which has been adjusted to 465 kilocycles in series with I.F. dummy antenna, to the control grid cap of the type 6K7 tube and chassis ground. Adjust output I.F. transformer, part number 108-40, to resonance.
   (b) Move generator output clip from grid of 6K7 to grid cap of type 6F7 tube and align input I.F. transformer, part number 108-38.
   (c) With generator connected to grid of type 6F7 tube, readjust output I.F. transformer, part number 108-40, to resonance.

Broadcast Band Alignment—
(540 - 1720 Kilocycles)

1. With wave changing switch in the broadcast position, extreme left of its rotation, and with gang condenser in its minimum capacity position, plates entirely out of mesh, connect an external oscillator in series with broadcast dummy antenna to tan antenna and black ground leads and make the following adjustments:
   (a) With external oscillator set at 1720 kilocycles, adjust oscillator trimmer to resonance, for location of this adjustment, number 6, see diagram.
   (b) Re-set external oscillator to 1400 kilocycles, rotate condenser, pick up oscillator signal and adjust antenna trimmer to resonance. For location of this adjustment, number 3, see diagram.

MODEL 585 - Series D

5-Tube 3-Band Superheterodyne with Avc.

   (c) Re-set external oscillator to 600 kilocycles and adjust series pad to resonance, rotate condenser and move dial pointer to 600 kilocycles by gently rocking condenser to and fro. Pick up oscillator signal while adjusting series pad to resonance, maximum deflection on an output meter. This adjustment is accessible from the top of the chassis and is located between variable condenser and power transformer, see top view—part number 124-16.
   (d) Check for tracking and sensitivity at 1000 kilocycles.

NOTE (Series "B", "C" and "D" only)
25 Cycle Chassis differ only from 60 cycle chassis in that part number 104-18 transformer is used in place of 50/60 cycle transformer, part number 104-14.

Short Wave Band Alignment—
(7.6 - 19.0 Megacycles)

1. This band is aligned after the I.F. adjustments have been completed. Set wave changing switch to short wave position, extreme right of its rotation, set dial pointer to 18 megacycles.
   (a) With external oscillator adjusted to 18 megacycles and connected in series with short wave dummy antenna to tan antenna and black ground leads, adjust the oscillator short wave trimmer until generator signal is picked up. For location of this adjustment, number 4, see diagram.
   (b) Adjust short wave antenna trimmer to resonance. For location of this adjustment, number 1, see diagram.
   (c) Re-set external oscillator to 9 megacycles, rotate condenser, move dial pointer to 9 megacycles and check for tracking and sensitivity. Do not bend plates. NOTE: It is extremely necessary in making all of the above adjustments that the fundamental signal of the oscillator be tuned in and not the image frequency, which will fall below the fundamental.

Intermediate Band Alignment—
(2.35 - 7.7 Megacycles)

1. With wave changing switch in center position, and with dial pointer set to 7 megacycles, make the following adjustments:
   (a) With external oscillator set at 7 megacycles and connected in series with short wave dummy antenna, as for short wave adjustments, adjust trimmer of oscillator coil, part number 110-22 until 7 megacycle signal is picked up. For location of this adjustment, number 5, see diagram.
   (b) Adjust antenna trimmer to resonance, adjustment number 2, see diagram.
   (c) Re-set external oscillator to 2.5 megacycles (2500 kilocycles), rotate variable condenser, move pointer, pick up oscillator signal and check for tracking and sensitivity. NOTE: It is extremely necessary in making all of the above adjustments that the fundamental signal of the oscillator be tuned in and not the image frequency, which will fall below the fundamental.

All resistors are RMA color coded—specify value and/or resistor number (per schematic diagram) and model number.

When ordering condensers, specify part number, model number and/or capacitor (per schematic diagram) and model number.

All prices quoted are list and are subject to the usual trade discounts.
Prices subject to change without notice.

Shipments are F.O.B. our Factory. When remitting in advance, please include postage.

We cannot supply speaker cases only. We can replace a speaker on which the cone has been damaged for $1.50, if defective speaker is returned.

ALIGNING I.F. TRANSFORMERS: (465 K.C.):

Part No. 108-76 Output I.F. Transformer
Part No. 108-75 Input I.F. Transformer

These I.F. transformers have two adjustments, both of which are accessible from the top of chassis (see top view).

1. With volume control full on (the extreme right of its rotation), the band changing switch in the broadcast position, (extreme left of its rotation), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:

(a) Connect external oscillator set at 465 kilocycles, in series with "Dummy 1," to the control grid cap of the type 78 tube, and adjust the output I.F. transformer (No. 108-76) to resonance.

(b) With "Dummy 1" still connected, move oscillator output clip from grid of 78 to grid cap to 6A7 and adjust input I.F. transformer (No 108-75) to resonance.

(c) With oscillator still connected to 6A7, readjust output I.F transformer (108-76) if necessary.

DUMMY ANTENNAS:

The following dummy antennas are used in aligning and are referred to in the following alignment instructions as "Dummy 1," "Dummy 2," and "Dummy 3."

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.

Dummy 2: (Broadcast)—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

SHORT WAVE BAND ANTENNA ADJUSTMENT:

1. With the band switch in the short wave position, and with external oscillator connected in series with "Dummy 3," to the tan antenna lead and black ground lead, make following adjustment:

(a) Set external oscillator to 6 megacycles and adjust the short-wave antenna trimmer to resonance. This adjustment is the trimmer mounted on the rear section of the variable gang condenser.

BROADCAST AND SHORT WAVE BAND ALIGNMENT

Broadcast Band: -535 to 1720 Kilocycles.
Short Wave Band:—2200 to 6600 Kilocycles.

Important:—These adjustments must be made in the following order:

SHORT WAVE OSCILLATOR ADJUSTMENT:

1. With band switch in the short wave band position, extreme right of its rotation, and with the gang condenser in its minimum capacity position, plates entirely out of mesh, and with the external oscillator connected in series with "Dummy 1" to grid cap of the 6A7 tube, make the following adjustment:

(a) Set external oscillator to 6.6 megacycles and adjust short wave oscillator trimmer to resonance. This adjustment is marked "S.W. Osc." (see top view of chassis, Fig. 1, for location of this adjustment).

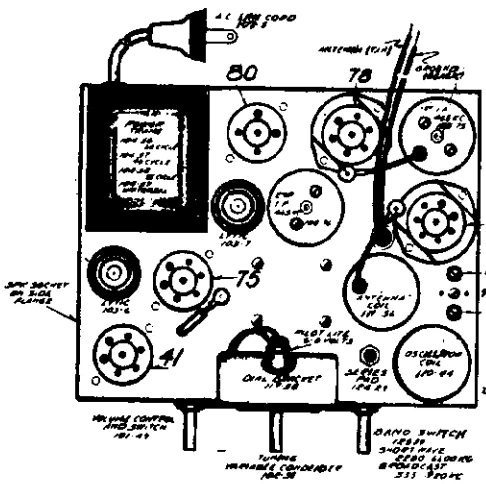

FIG. 1—TOP VIEW

NOTE: Make certain that the fundamental 6.6 megacycles signal has been tuned in and not the image frequency, noting that the image appears when the tuning knob is moved to approximately 5.7 megacycles.

BROADCAST BAND OSCILLATOR ADJUSTMENT:

1. With band switch in the broadcast position, extreme left of its rotation, and with the gang condenser in its minimum capacity position, plates entirely out of mesh, and with external oscillator connected in series with "Dummy 1" to grid cap of the 6A7 tube, make the following adjustment:

(a) Set external oscillator to 1720 K.C. and adjust broadcast oscillator trimmer to resonance. This adjustment is the trimmer mounted on the front section of the variable gang condenser.

BROADCAST BAND ANTENNA ADJUSTMENT:

1. With the band switch still in the broadcast position, move the external oscillator from the grid cap of the 6A7 tube to the tan antenna lead and black ground lead, in series with "Dummy 2" and make the following adjustments:

(a) Set external oscillator to 1550 K.C., rotate variable gang condenser and pick up signal. Adjust broadcast antenna trimmer to resonance. This adjustment is marked "B.C. Ant." (See top view of chassis, Fig. 1, for location of this adjustment.)

(b) Re-set external oscillator to 600 K.C. and adjust broadcast series pad to resonance by rotating condenser to approximately 600 K.C., rocking it slowly to and fro until, by adjusting series pad, maximum output is attained. This adjustment is located on the top of the chassis directly in front of the antenna coil. (See top view of chassis, Fig. 1).

(c) Repeat adjustments "a" and "b" until sensitivity is at its maximum.

MODEL 601, Series A & B
Schematic, Socket, Parts
Alignment, Notes

BELMONT RADIO CORP.

ALIGNING I.F. TRANSFORMERS: (465 K.C.):

Part No. 108-83 Output I.F. Transformer
Part No. 108-82 Input I.F. Transformer

These I.F. transformers have two adjustments, both of which are accessible from the top of chassis (see top view).

1. With volume control full on (the extreme right of its rotation), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:

(a) Connect external oscillator set at 465 kilocycles, in series with .1 mfd. condenser, to the control grid cap of the type 78 tube, and adjust the output I.F. transformer (No. 108-83) to resonance.

(b) Move oscillator output clip from grid of 78 grid cap of 6A7 and adjust input I.F. transformer (No. 108-82) to resonance.

(c) With oscillator still connected to 6A7, readjust output I.F. transformer (108-83) if necessary.

R.F. ALIGNMENT: (535-1720 K.C.)

1. Unsolder the antenna wire from its terminal on the antenna coil and with gang condenser in its minimum capacity position, plates entirely out of mesh, connect an external oscillator in series with a 50 mmf. condenser to the antenna terminal on the antenna coil and chassis ground and make the following adjustments:

(a) With external oscillator set at 1720 kilocycles, adjust oscillator trimmer (rear of gang condenser).

(b) Re-set external oscillator to 1550 kilocycles, rotate condenser, pick up oscillator signal and adjust antenna trimmer to resonance (front section of gang condenser).

(c) Check sensitivity at 600 and 1000 kilocycles.

Type 6A7 Pentagrid Mixer, First Detector-oscillator
Type 78 Remote Cut-Off Pentode, I.F. Amplifier (465 K.C.)
Type 75 Duplex Diode Triode Second Detector, A.V.C. and First Audio.
Type 43 Pentode Output Amplifier
Type 25Z5 High Vacuum Rectifier.
Type L49B Ballast Tube.

BELMONT RADIO CORP.

MODEL 587 - Series A

5-TUBE

2-Band A. C. Superheterodyne Receiver

TUBES:

The tube complement of this chassis consists of the following tubes.

The type and function of each tube is as follows:

1—Type 6A8 Pentagrid Mixer, First Detector-oscillator
1—Type 6K7 Remote Cut-Off Pentode, I. F. Amplifier (465 K.C.)
1—Type 6Q7-G Duplex Diode Triode Second Detector, A.V.C. and First Audio.
1—Type 6F6-G Pentode Output Amplifier.
1—Type 5Y3 High Vacuum Rectifier.

Transformers are available and chassis are sometimes equipped with universal transformers for operation on 40 and 60 cycles and with primary taps for 108, 125, 150, 220 and 250 volts (see parts list) and also sometimes equipped with 25 cycle transformers with 105-115 volt or 220 volt primaries, not universals.

SERVICE NOTES:

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt.

All voltages as indicated on diagram are measured with 119 volts on the primary of the power transformer.

Resistances of coil windings are indicated in ohms on the schematic circuit diagram.

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good; until the defective unit is located.

Excessive hum, stuttering, low volume and a reduction in all D.C. voltages is usually caused by a shorted electrolytic condenser; open by-pass condensers frequently cause oscillation and distorted tone.

ALIGNING INSTRUCTIONS:

CAUTION:—No aligning adjustments should be attempted without first thoroughly checking over all other possible causes of trouble, such as poor installations, open or grounded antenna systems, low line voltages, defective tubes, condensers and resistors. In order to properly align this chassis, an oscillator (generator) is absolutely necessary. No aligning adjustments should be attempted with the chassis in the cabinet. Remove the knobs and the four bolts which are used to fasten the chassis.

RESONANCE INDICATOR:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer, or by means of an adapter between the plate and screen terminals of the type 6F6-G output tube. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used.

DUMMY ANTENNAS:

The following dummy antennas are used in aligning and are referred to in the following alignment instructions as "Dummy 1," "Dummy 2," and "Dummy 3."

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.

Dummy 2: (Broadcast)—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

ALIGNING I.F. TRANSFORMERS: (465 K.C.):

Part No. 108-76A Output I.F. Transformer
Part No. 108-75A Input I.F. Transformer.

These I.F. transformers have two adjustments, both of which are accessible from the top of chassis (see top view).

1. With volume control full on (the extreme right of its rotation), the band changing switch in the broadcast position, (extreme left of its rotation), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:
   (a) Connect external oscillator set at 465 kilocycles, in series with "Dummy 1," to the control grid cap of the type 6K7 tube, and adjust the output I.F. transformer (No. 108-76A) to resonance.
   (b) With "Dummy 1" still connected, move oscillator output clip from grid of 6K7 to grid cap to 6A8 and adjust input I.F transformer (No. 108-75A) to resonance.
   (c) With oscillator still connected to 6A8, readjust output I.F. transformer (108-76A) if necessary.

BROADCAST AND SHORT WAVE BAND ALIGNMENT

Broadcast Band:—535 to 1720 Kilocycles.
Short Wave Band:—2280 to 6600 Kilocycles.

Important:—These adjustments must be made in the following order:

SHORT WAVE OSCILLATOR ADJUSTMENT:

1. With band switch in the short wave band position, extreme right of its rotation, and with the gang condenser in its minimum capacity position, plates entirely out of mesh, and with the external oscillator connected in series with "Dummy 1" to grid cap of the 6A8 tube, make the following adjustment:
   (a) Set external oscillator to 6.6 megacycles and adjust short wave oscillator trimmer to resonance. This adjustment is marked "S.W Osc." (see top view of chassis, Fig. 1, for location of this adjustment).

NOTE: Make certain that the fundamental 6.6 megacycles signal has been tuned in and not the image frequency, noting that the image appears when the tuning knob is moved to approximately 5.7 megacycles.

BROADCAST BAND OSCILLATOR ADJUSTMENT:

1. With band switch in the broadcast position, extreme left of its rotation, and with the gang condenser in its minimum capacity position, plates entirely out of mesh, and with external oscillator connected in series with "Dummy 1" to grid cap of the 6A8 tube, make the following adjustment:
   (a) Set external oscillator to 1720 K.C. and adjust broadcast oscillator trimmer to resonance. This adjustment is the trimmer mounted on the front section of the variable gang condenser.

BROADCAST BAND ANTENNA ADJUSTMENT:

1. With the band switch still in the broadcast position, move the external oscillator from the grid cap of the 6A8 tube to the tan antenna lead and black ground lead, in series with "Dummy 2" and make the following adjustments:
   (a) Set external oscillator to 1550 K.C., rotate variable gang condenser and pick up signal. Adjust broadcast antenna trimmer to resonance. This adjustment is marked "B.C. Ant." (See top view of chassis, Fig. 1, for location of this adjustment.)
   (b) Re-set external oscillator to 600 K.C. and adjust broadcast series pad to resonance by rotating condenser to approximately 600 K.C., rocking it slowly to and fro until, by adjusting series pad, maximum output is attained. This adjustment is located on the top of the chassis directly in front of the antenna coil. (See top view of chassis, Fig. 1).
   (c) Repeat adjustments "a" and "b" until sensitivity is at its maximum.

SHORT WAVE BAND ANTENNA ADJUSTMENT:

1. With the band switch in the short wave position, and with external oscillator connected in series with "Dummy 3," to the tan antenna lead and black ground lead, make following adjustment:
   (a) Set external oscillator to 6 megacycles and adjust the short-wave antenna trimmer to resonance. This adjustment is the trimmer mounted on the rear section of the variable gang condenser.

MODEL 666
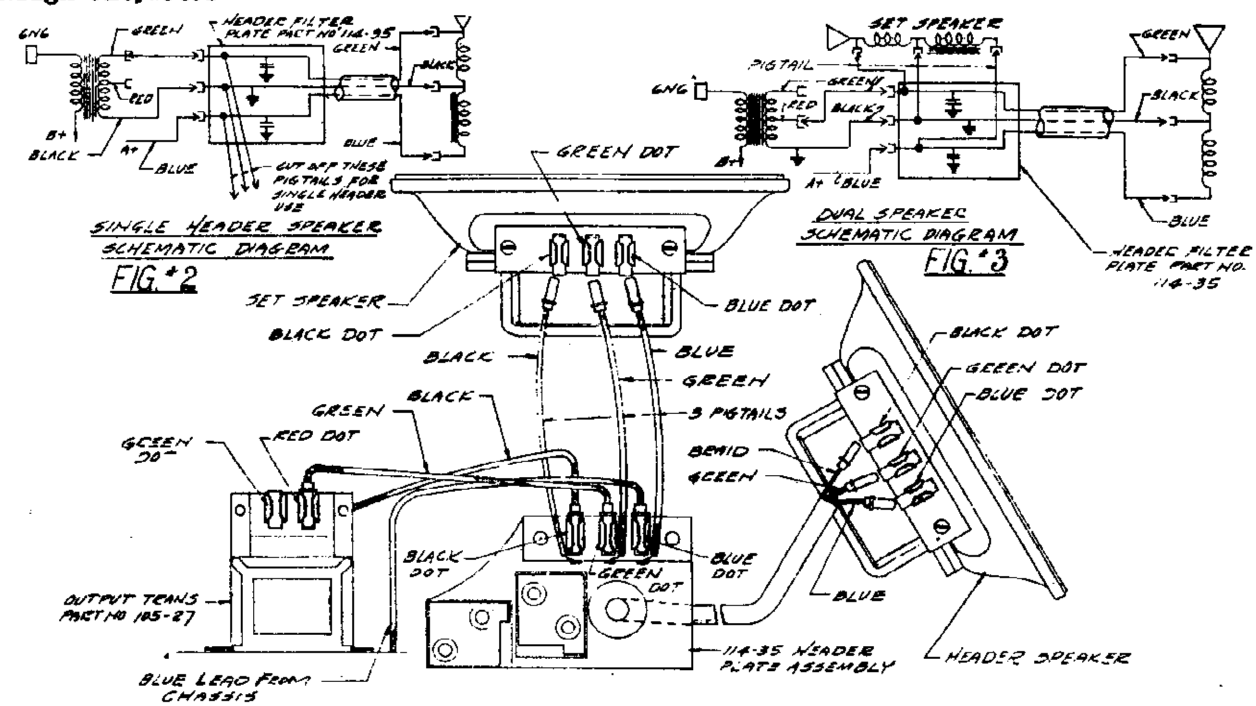
Alignment, Notes

BELMONT RADIO CORP.



NO SPARK PLUG SUPPRESSORS ARE REQUIRED

DESCRIPTION:

Model No. 666 is a six-tube superheterodyne receiver having a tuning range of 530 K.C. to 1550 K.C., operates from a 6.0 volt storage battery and uses the automotive type 6.3 volt tubes. The "B" supply is obtained from a vibrator with a tube rectifier.

The I.F. frequency used is 165 K.C., the R.F. end of the receiver consisting of a high gain iron core antenna coil which gives high signal to noise ratio and an R.F. stage especially designed to give high image rejection and high I.F. attenuation. The I.F. transformers are designed to give high gain and selectivity and yet to have a broad nose for ease of tuning and hi-fidelity response. They are of the air core type and wound with solid wire to give *minimum* drift and variation of gain due to climatic changes.

The receiver is so designed that it may be used as either a single or two unit installation. Taps are provided on the output transformer to a pin jack terminal board, a red dot distinguishing dual speaker tap and green dot for single speaker operation.

For complete details see illustration and Header speaker data chart.

Dash kits for the remote control head are available for 1936 cars drilled for dash plates.

This receiver has been carefully designed to facilitate servicing, the top and bottom covers are both removable and are fastened in place by spring clips, self tapping screws and trimount buttons.

All adjustments are accessible and any part replaceable without removing the chassis from the case.

TUBE COMPLEMENT

1—Type No. 6K7—Remote Cut-off Pentode as an R.F. Amplifier
1—Type No. 6A8—Pentagrid Converter (composite first detector and oscillator)
1—Type No. 6K7—Remote Cut-off Pentode as an I.F. Amplifier (465 K.C.)
1—Type No. 6Q7—Duplex Diode Triode Second Detector, A.V.C. and First Audio
1—Type No. 6N6—Twin Triode Output Amplifier
1—Type No. 6X5—High Vacuum Rectifier

The tube complement consists of the latest "Metal-Glass" tubes which are interchangeable with metal tubes.

Cars with floating power must have the motor bonded to the bulkhead and again to the frame to provide a direct path for the high frequency interference developed in the ignition system. ⅝" copper braid will be necessary, SMALL DIAMETER WIRE WILL NOT DO. Bond flexible shaft leads, such as free wheeling, choke wires, etc., which pick up motor noise and reradiate it into the car. Free wheeling cables should be grounded at the point at which they go through the fire wall of the car. In extreme cases it has been found necessary to ground the steering column.

I.F. ALIGNMENT

1. With variable condenser in its minimum capacity position (plates entirely out of mesh) and with volume control full on, connect test oscillator set at 465 K.C. in series with I.F. dummy antenna, to grid of 6K7 I.F. tube.
2. Adjust trimmer condensers of output I.F. transformer No. 108-72 to resonance with oscillator.
3. Move test oscillator connection to grid of 6A8 tube and adjust trimmer condensers of input I.F. transformer No. 108-69 to resonance with oscillator. See top view for location of these transformers. There are two adjustments on each and they are accessible from the top of the transformer shield and should be adjusted with an insulated screw driver.

BROADCAST ALIGNMENT

1. With variable condenser in its minimum capacity position, connect test oscillator set at 1550 K.C. in series with broadcast dummy to the antenna lead of receiver.
2. Adjust oscillator trimmer of variable condenser to resonance. (This adjustment is on the middle section of the three-gang condenser—see top view).
3. Shift test oscillator to 1400 K.C. and pick up signal by rotating condenser and adjust R.F. and antenna trimmers to resonance (see top view).
4. Re-set test oscillator to 600 K.C. and rotate variable condenser to 600 KC. Adjust series pad rocking gang condenser to and fro at the same time adjusting series pad for maximum gain. This adjustment is accessible from the top of chassis (see top view.
5. Go back and check 1400 K.C. If adjustment is made here, check 600 K.C. again.
6. Check for sensitivity at 1000 K.C. by setting test oscillator to this frequency and picking up the signal by rotating variable condenser. Under no circumstances bend plates of variable condenser sections to correct tracking.

Make certain that the instrument panel has a ground connection to the frame of the car.

NOTE—Where ignition coils are mounted in motor compartments a .5 mfd cond (148-1 or 148-3) connected between primary coil terminal and receiver mounting bolt will often reduce motor noise.

Alignment, Notes

BELMONT RADIO CORP.

Model 685 Series A   Model 686 Series A & B   Model 786 Series A

DESCRIPTION

Model 686 is a six tube A.C. all wave superheterodyne receiver. It has a tuning range of 535 K.C. to 18.3 megacycles in three bands, and is characterized by its exceptional stability, and by a sensitivity both high and uniform, with high signal to noise ratio on all bands. The I.F. frequency used is 465 K.C., which in conjunction with the pre-selector circuit, gives high image and I.F. attenuation (freedom from whistles and telegraphic interference).

A separate oscillator; effective automatic volume control; broad nose sharp skirt selectivity and new type oval airplane dial, are a few of the outstanding features of this model.

NOTE:

Model 686 series "A" chassis are equipped with a tone control (No. 101-48) which is mounted on the rear flange of the chassis, and has three controls on the front of the chassis, namely, "Volume Control and Switch;" "Tuning Control;" and "Band Switch."

Model 686 series "B" chassis differs only from series "A" in that the tone control is removed from the rear flange of the chassis and mounted on the front. Series "B" chassis has four controls, namely, "Volume Control and Switch," "Tone Control," "Tuning Control," and "Band Switch."

Model 786 series "A" chassis is the same as model 686 series "B" except that the "Cathode-Ray Tuning Indicator" has been added.

Model 685 is the same chassis as model 686 series "A" except that it has no tone control and the tube complement consists of two metal and four glass tubes. The alignment procedure is the same for all models, and the circuit diagram differs only in that the tone control and cathode-ray tuning indicator is omitted on the model 685, and the cathode-ray tuning indicator only is omitted on the model 686. The tube complement of the model 685 differs, however, circuit constants and values of resistors and condensers are the same in all models.

Transformers are available and chassis are sometimes equipped with universal transformers for operation on 25, 40, and 60 cycles and with primary taps for 108, 125, 150, 220 and 250 volts (see instructions), and also sometimes equipped with 25 cycle transformers with 105-115 volt or 220 volt primaries, not universals.

TUBE COMPLEMENT

The tube complement of the model 686 and model 786 consists of the latest "Metal-Glass" tubes which are interchangeable with metal tubes. They are as follows:

1-Type 6L7 Pentagrid Mixer, First Detector.
1-Type 6C5 Oscillator.
1-Type 6K7 Remote Cut-off Pentode, I.F. Amplifier (465 K.C.).
1-Type 6Q7 Duplex Diode Triode Second Detector, A.V.C. and First Audio.
1-Type 6F6 Pentode Output Amplifier.
1-Type 5Y3 or 5W4 High Vacuum Rectifier. (Note: 5Y3 available in "Metal-Glass" only.)
1-Type 6G5 Cathode-Ray Tuning Indicator. (Note: 6G5 available in all glass only, and only with model 786.)

The tube complement of the model 685 is as follows:

1-Type 6L7 Pentagrid Mixer, First Detector.
1-Type 6C5 Oscillator.
1-Type 6K7G Remote Cut-off Pentode, I.F. Amplifier (465 K.C.).
1-Type 6Q7G Duplex Diode Triode Second Detector, A.V.C. and First Audio.
1-Type 6F6G Pentode Output Amplifier.
1-Type 5Y3 High Vacuum Rectifier.

SERVICE NOTES:

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt.

All voltages as indicated on diagram are measured with 119 volts on the primary of the power transformer.

Resistances of coil windings are indicated in ohms on the schematic circuit diagram.

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

Excessive hum, stuttering, low volume and a reduction in all D.C. voltages is usually caused by a shorted electrolytic condenser; open by-pass condensers frequently cause oscillation and distorted tone.

ALIGNING INSTRUCTIONS:

CAUTION:—No aligning adjustments should be attempted without first thoroughly checking over all other possible causes of trouble, such as poor installations, open or grounded antenna systems, low line voltages, defective tubes, condensers and resistors. In order to properly align this chassis, an oscillator (generator) is absolutely necessary. No aligning adjustments should be attempted with the chassis in the cabinet. Remove the knobs and the four bolts which are used to fasten the chassis.

All adjustments should be made with a non-metallic screw driver.

DUMMY ANTENNAS:

The following dummy antennas are used in aligning and are referred to in the following alignment instructions as "Dummy 1," "Dummy 2," and "Dummy 3."

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.

Dummy 2: (Broadcast)—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Middle and Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

RESONANCE INDICATOR:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer, or by means of an adapter between the plate and screen terminals of the type 6F6 output tube. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used.

ALIGNING I.F. TRANSFORMERS; (465 K.C.):

Part No. 108-73 Output I.F. Transformer.
Part No. 108-74 Input I.F. Transformer.

These I.F. transformers have two adjustments, both of which are accessible from the top of chassis (see top view).

1. With volume control full on (the extreme right of its rotation), the band changing switch in the broadcast position, (extreme left of its rotation), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:
   (a) Connect external oscillator set at 465 kilocycles, in series with "Dummy 1," to the control grid cap of the type 6K7 tube, and adjust the output I.F. transformer (No. 108-73) to resonance.
   (b) With "Dummy 1" still connected, move oscillator output clip from grid of 6K7 to grid cap to 6L7 and adjust input I.F. transformer (No. 108-74) to resonance.
   (c) With oscillator still connected to 6L7, readjust output I.F. transformer (108-73) if necessary.

ALIGNMENT PROCEDURE

The following adjustments to be made after the I.F.'s have been aligned as explained above.

BROADCAST BAND ALIGNMENT:

535 to 1720 Kilocycles

1. With band changing switch in the broadcast position, extreme left of its rotation, and with gang condenser in its minimum capacity position, plates entirely out of mesh, and with external oscillator connected in series with "Dummy 2" to tan antenna lead and black ground lead, make following adjustments:
   (a) Set external oscillator to 1720 K.C. and adjust broadcast oscillator trimmer to resonance (adjustment number 1; see bottom view of coil assembly. Fig. 3.)
   (b) Re-set external oscillator to 1550 K.C., rotate variable gang condenser and pick up signal. Adjust broadcast antenna trimmer (Adjustment number 4) to resonance; also adjust preselector trimmer which is mounted on the top of the rear section of the three gang variable tuning condenser to resonance. (See top view of chassis, Fig. 1, for location of this adjustment.)
   (c) Re-set external oscillator to 600 K.C., and adjust broadcast series pad to resonance by rotating condenser to approximately 600 K.C., rocking it slowly to and fro until by adjusting series pad maximum output is attained. This adjustment is located on the bottom of the chassis directly under the variable gang condenser. (See bottom view of chassis, Fig. 3.)
   (d) Repeat adjustments "a" and "b" until sensitivity is at its maximum.
   (e) Check for tracking and sensitivity at 1000 kilocycles. Under no circumstances bend plates of variable condenser sections to correct tracking.

SHORT WAVE BAND ALIGNMENT:

5.2 to 18.3 Megacycles

1. With band changing switch in the short wave position, extreme right of its rotation, and with external oscillator set at 17 megacycles and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:
   (a) Move dial pointer to 17 megacycles and adjust short wave oscillator (Adjustment number 3) and short wave antenna (Adjustment number 6) to resonance.
   (b) Re-set external oscillator to 6 megacycles and pick up signal by rotating variable condenser and check sensitivity.
   (c) Re-set external oscillator and check set at 18.1 megacycles and 5.3 megacycles for band coverage.

NOTE: It is extremely necessary in making all of these adjustments that the fundamental oscillator signal be tuned in and not the image frequency which will fall below the fundamental. An example of this is an image of a fundamental 18.3 megacycle signal appears near 17.4 megacycles.

MIDDLE WAVE BAND ALIGNMENT:

1665 to 5500 Kilocycles

1. With band changing switch in the middle wave position, center of its rotation, and with external oscillator set at 5000 kilocycles and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:
   (a) Move dial pointer to 5000 kilocycles and adjust middle wave oscillator (Adjustment number 2) and middle wave antenna (Adjustment number 5) to resonance.
   (b) Re-set external oscillator to 1800 kilocycles and pick up signal by rotating variable condenser and check sensitivity.
   (c) Re-set external oscillator and check set at 5400 kilocycles and 1700 kilocycles for band coverage.

BELMONT RADIO CORP.

Model 746 - Series A

7-Tube Including Cathode-Ray Tuning Indicator 3-Band A. C. Superheterodyne Receiver

190-280 Volts 50 Cycles A. C.

POWER SUPPLY:

This receiver is normally supplied with a transformer for operation on 50 cycles (may be higher in frequency, not lower) and with a primary designed for operation on 190-280 volts.

Mains transformer is provided with two taps, one for voltages 190-240 volts another for voltages 240-280 volts. These taps are accessible upon removing plate fastened with two wing nuts to back of chassis.

Transformers are available and chassis are sometimes equipped with universal transformers for operation on 25 and 50 cycles and with primary taps for 108, 127, 150, 225 and 260 volts (see illustrations).

Should the receiver be equipped with a special transformer, connect primary tap on voltage terminal which corresponds as nearly as possible to the actual mains voltage.

SERVICE NOTES

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt. These voltages are clearly indicated on the circuit diagram.

IN ORDER TO PREVENT SIGNAL FROM ACTING UPON AVC AND AFFECTING ACCURACY OF VOLTAGE MEASUREMENTS, AERIAL AND GROUND LEADS SHOULD BE SHORT CIRCUITED WHILE MAKING MEASUREMENTS.

All voltages are to be measured with 220 volts on the primary of the power transformer.

With special transformers select primary tap nearest to actual mains voltage at time voltage measurements are to be made.

Resistances of coils and transformer windings are indicated in ohms on schematic circuit diagrams.

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

Excessive hum, stuttering, low volume and a reduction in all D.C. voltages is usually caused by a shorted electrolytic condenser, open by-pass condensers frequently cause oscillation and distorted tone.

ALIGNING INSTRUCTIONS

Dummy Antennas

The following dummy antennas are used in aligning the receiver, and are referred to in the following alignment instructions as "Dummy 1", "Dummy 2", and "Dummy 3".

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.

Dummy 2: (Broadcast and long wave)—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

TEST FREQUENCIES USED

	Kilocycles	Meters
I. F.	465	645.1
Long Wave	150	2000
	350	860
	325	925
Broadcast	600	500
	1400	214
	1600	187
Short Wave	6000	50.0
	17000	17.6
	18200	16.5

Resonance Indicator:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer, or by means of an adapter between the plate and screen terminals of the type 6F6 output tube. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used

CAUTION:

No aligning adjustments should be attempted without first thoroughly checking over all other possible causes of trouble, such as poor installations, open or grounded antenna systems, low line voltages, defective tubes, condensers and resistors. In order to properly align this chassis, an oscillator (generator) is absolutely necessary. No aligning adjustments should be attempted with the chassis in the cabinet. To remove the knobs, pull them off and to take the chassis out of the cabinet, remove the four bolts by which it is fastened.

ALIGNING I.F. TRANSFORMERS

(465 K.C.) (645.1 Meters)

Part No. 108-73 Output I.F Transformer.
Part No. 108-74 Input I.F. Transformer.

These I.F. transformers have two adjustments, both of which are accessible from the top of chassis (see top view).

1. With volume control full on (the extreme right of its rotation), the band changing switch in the broadcast position, (center of its rotation), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:

(a) Connect external oscillator set at 465 kilocycles, in series with "Dummy 1," to the control grid cap of the type 6K7 tube, and adjust the output I.F. transformer (No. 108-73) to resonance.

(b) With "Dummy 1" still connected, move oscillator output clip from grid of 6K7 to grid cap to 6L7 and adjust input I.F. transformer (No. 108-74) to resonance.

(c) With oscillator still connected to 6L7, readjust output I.F. transformer (108-73) if necessary.

ALIGNMENT PROCEDURE

The following adjustments to be made after the I.F.'s have been aligned as explained above.

SHORT WAVE BAND ALIGNMENT:

16.5 Meters (18.2 Mc.) to 56.5 Meters (5.3 Mc.)

With band changing switch in the short wave position, extreme right of its rotation, and with the gang condenser in its minimum capacity position, plates entirely out of mesh, and with external oscillator connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments.

(a) Set external oscillator to 16.5 meters (18.2 Mc.) and adjust short wave oscillator trimmer (adjustment number 3, see Fig. 2) to resonance.

(b) Re-set external oscillator to 17.6 meters (17.0 Mc.) and pick up signal by rotating gang condenser. Adjust short wave antenna trimmer (adjustment number 6) to resonance.

(c) Re-set external oscillator to 50 meters (6.0 Mc.) and check for sensitivity.

NOTE: It is extremely necessary in making all of these adjustments that the fundamental oscillator signal be tuned in and not the image frequency which will fall below the fundamental. An example of this is an image of a fundamental 18.3 megacycle signal appears near 17.4 megacycles.

MEDIUM OR BROADCAST BAND ALIGNMENT:

588 Meters (510 K.C.) to 187 Meters (1600 K.C.)

With band changing switch in the medium wave position, center of its rotation, and with gang condenser in its minimum capacity position, plates entirely out of mesh, and with external oscillator connected in series with "Dummy 2" to tan antenna lead and black ground lead, make following adjustments:

(a) Set external oscillator to 187 meters (1600 K.C.) and adjust medium wave oscillator trimmer to resonance (adjustment number 2; see bottom view of coil assembly. Fig. 2.)

(b) Re-set external oscillator to 214 meters (1400 K.C.), rotate variable gang condenser and pick up signal. Adjust medium wave antenna trimmer (Adjustment number 5) to-resonance; also adjust preselector trimmer which is mounted on the top of the rear section of the three gang variable tuning condenser to resonance. (See top view of chassis, Fig. 1, for location of this adjustment.)

(c) Re-set external oscillator to 500 meters (600 K.C.), and adjust medium wave series pad to resonance by rotating condenser to approximately 600 K.C., rocking it slowly to and fro until by adjusting series pad maximum output is attained. This adjustment is located on the bottom of the chassis directly under the variable gang condenser. (See bottom view of chassis, Fig. 2.)

(d) Repeat adjustments "a" and "b" until sensitivity is at its maximum.

(e) Check for tracking and sensitivity at 300 meters (1000 K.C.) Under no circumstances bend plates of variable condenser sections to correct tracking.

IMPORTANT: This band must be completely rechecked after the long wave band has been adjusted.

LONG WAVE BAND ALIGNMENT:

860 Meters (350 K.C.) to 2150 Meters (140 K.C.)

With band changing switch in the long wave position, extreme left of its rotation, and with gang condenser in its minimum capacity position, plates entirely out of mesh, and with external oscillator connected in series with "Dummy 2" to tan antenna lead and black ground lead, make following adjustments:

(a) Set external oscillator to 860 meters (350 K.C.), and adjust long wave oscillator trimmer to resonance (adjustment number 1; see bottom view of coil assembly. Fig. 2.)

(b) Re-set external oscillator to 925 meters (325 K.C.), rotate variable gang condenser and pick up signal. Adjust long wave antenna trimmer (Adjustment number 4) to resonance

(c) Re-set external oscillator to 2000 meters (150 K.C.), and adjust long wave series pad to resonance by rotating condenser to approximately 2000 meters, rocking it slowly to and fro until by adjusting series pad maximum output is attained. This adjustment is located on the bottom of the chassis directly under the variable gang condenser. (See bottom view of chassis, Fig. 2.)

(d) Repeat adjustments "a" and "b" until sensitivity is at its maximum

IMPORTANT: This band must be completely rechecked after the medium wave band has been rechecked.

120 110	1 Meg. Ohm—1/10 Watt—10%—200 Volt Carbon

All resistors and mica condensers are RMA color coded—specify value and/or resistor or condenser (per schematic diagram) and model number

Mica condensers are coded with an additional dot indicating tolerance:

Tolerance Percent	Color of Dot
2½%	White
5%	Green
10%	Blue
15%	Yellow
20%	Red
More than 20%	None

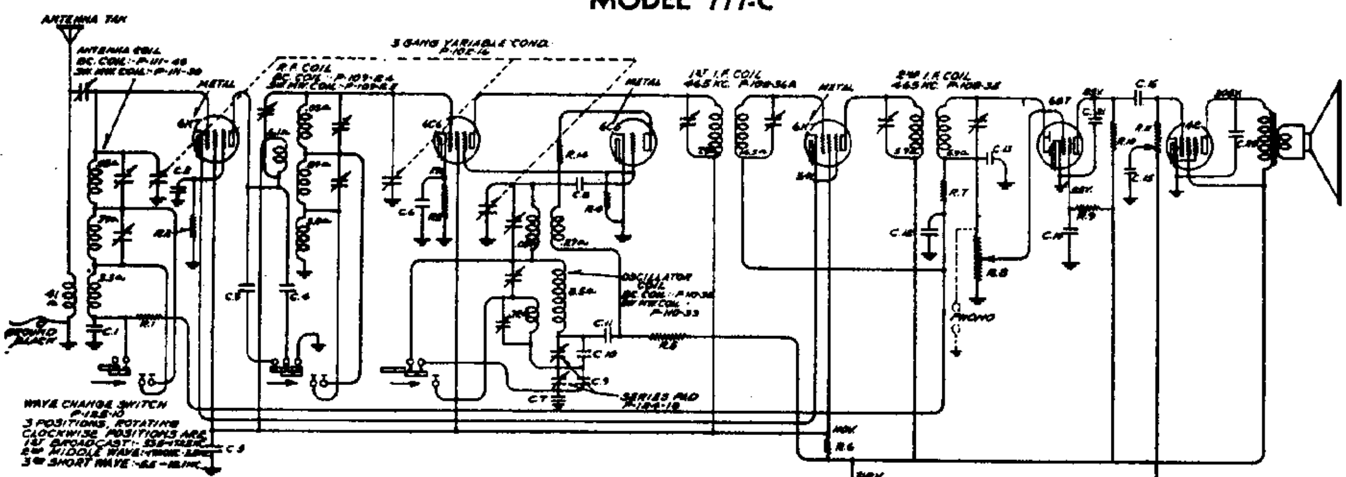
When ordering condensers, specify part number, model and/or capacitor (per schematic diagram) and model number.

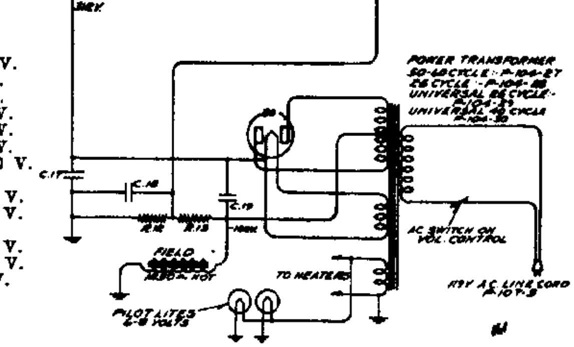
When ordering parts, always specify part and model number as well as serial number of chassis.

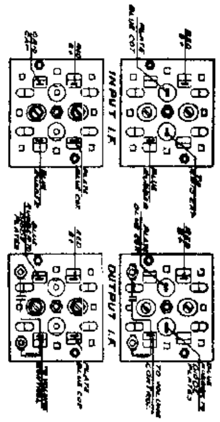
WHEN ORDERING SPEAKER PARTS: CONES, FIELD COILS, OUTPUT TRANSFORMERS, SPECIFY PART NUMBER OF SPEAKER AND MAKE

BELMONT RADIO CORP.

MODEL 777-C







The two upper sketches show connections for the General Mfg. Co. transformers and the lower pair are those of the Meissner Mfg. Co., both types being used in Series A, B, and C.

104—29	Power Transformer 25 Cycle Universal
104—30	Power Transformer 40 Cycle Universal

The resistor, R-5, has been changed from 19,000 ohms to 12,000 ohms and condenser C-9 has been changed from 0.0014 mf. to 0.0012 mf. A trimmer condenser has been shunted across the oscillator coil, having a resistance of 0.72 ohm, as it was in the Series A model, but not in the Series B. The frequencies covered by the three bands have been revised; they are now: Broadcast, 535 to 1725 kc.; Middle Wave, 1720 kc. to 5.5 mc., and Short Wave, 5.5 to 18.0 mc.

The chassis layout for the Series C is the same as that shown on *Belmont page 6-30* for the Series B, with the following exceptions: 6K7 tubes are used instead of the 6D6 tubes and the 76 is replaced by a 6C5.

The alignment data is the same as that given on *page 6-31 of Rider's Volume VI.*

Two types of i-f. transformers are used in the production of Model 777 Series A, B, and C. The operation and performance of these coils are identical, the only difference being in the way they are connected. The accompanying drawing shows the way each transformer is connected. The i-f. peak is 465 kc.

BELMONT RADIO CORP.

DESCRIPTION

MODEL 777, SERIES C

The tube complement of this chassis is as follows:

1—Type 6K7—remote cut-off pentode R.F. amplifier.
1—Type 6C6—pentode first detector.
1—Type 6C5—oscillator.
1—Type 6K7—remote cut-off pentode I.F. amplifier
1—Type 6B7—duplex diode triode second detector, A.V.C. and audio.
1—Type 42—pentode output.
1—Type 80—high vacuum rectifier.

Transformers are available and chassis are sometimes equipped with universal transformers for operation on 40 and 60 cycles and with primary taps for 108, 125, 150, 220 and 250 volts (see instructions) and also sometimes equipped with 25 cycle transformers with 105-115 volt or 220 volt primaries, not universals.

I. F. Freq. 465 Kilocycles

SERVICE NOTES

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt. These voltages are clearly indicated on the circuit diagrams

IN ORDER TO PREVENT SIGNAL FROM ACTING UPON AVC AND AFFECTING ACCURACY OF VOLTAGE MEASUREMENTS, AERIAL AND GROUND LEADS SHOULD BE SHORT CIRCUITED WHILE MAKING MEASUREMENTS.

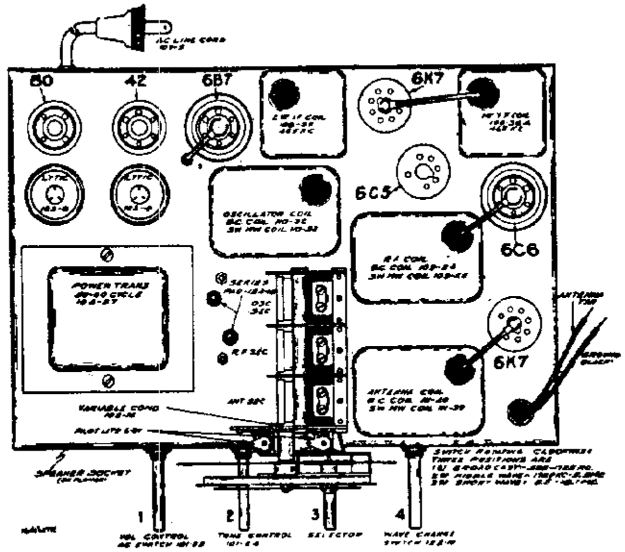
All voltages are to be measured with 119 volts on the primary of the power transformer.

Resistances of coils and transformer windings are indicated in ohms on schematic circuit diagrams.

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

Excessive hum, stuttering, low volume and a reduction in all D.C. voltages is usually caused by a shorted electrolytic condenser, open by-pass condensers frequently cause oscillation and distorted tone.

Top View Model 777, Series C



INTERMITTENT HUM

MODEL 777 SERIES B-C AND 770 SERIES A

In a few isolated cases, difficulty has been experienced with intermittent hum. This hum usually appears only after the receiver has been allowed to operate for some time and temporarily disappears upon snapping the line switch off and on. This difficulty is generally due to the opening up of the common lead of the dual condenser (.1—.25—220 V.—part No. 118—12), at the point of attachment of the lead to the condenser foil.

This condenser is indicated as C-18 and C-14 on the circuit diagram, C-14 being the .1 mfd. x 200 V. screen bypass of the 6B7, while C-18 is a .25 mfd. x 200 V. unit acting as a hum filter for the bias voltage of the type 42 tube. Examination of the circuit will show that when this occurs, the entire hum voltage of the filter is impressed on the screen of the type 6B7 tube. When the above difficulty occurs, it is generally advisable to replace the entire unit by two separate units of identical capacity and voltage rating as the components of the original unit.

SCINTILLATION NOISE DURING WARM-UP OF TUBES

MODEL 777 SERIES B-C AND MODEL 770 SERIES A

When a model 777 or model 770 receiver is first turned on, a frying noise will generally be noted. This noise continues until the tubes warm-up and the receiver begins to draw current. It is created by scintillation of the electrolytic filter condensers. During the time the tubes are warming up, they draw no current from the rectifier causing the voltage across the first condenser to exceed the scintillating voltage of the electrolytic condenser. The condensers used however are of the regulating type and are purposely designed in such a manner that during the heating period of the tubes, the condensers draw considerable leakage current, thereby loading the rectifier and preventing excessive voltage on other circuit components. The condensers are designed to withstand this temporary overload without detrimental effect on the life of the electrolytic or the receiver. DO NOT THEREFORE REPLACE CONDENSERS BECAUSE OF THIS SCINTILLATION NOISE. RATHER CONSIDER IT AS A SIGN OF NORMAL OPERATION.

I.F. TRANSFORMERS

MODEL 777 SERIES A-B-C

Two types of I.F. transformers were used in the production of Model 777 Series A-B-C. The operation and performance of these coils are identical, the only difference being in the manner in which they are connected. Following are drawings of both types of I.F. transformers showing connections for input and output I.F. transformers.

For drawings, see previous page

ALIGNING INSTRUCTIONS—Aligning procedure same as for Series B.

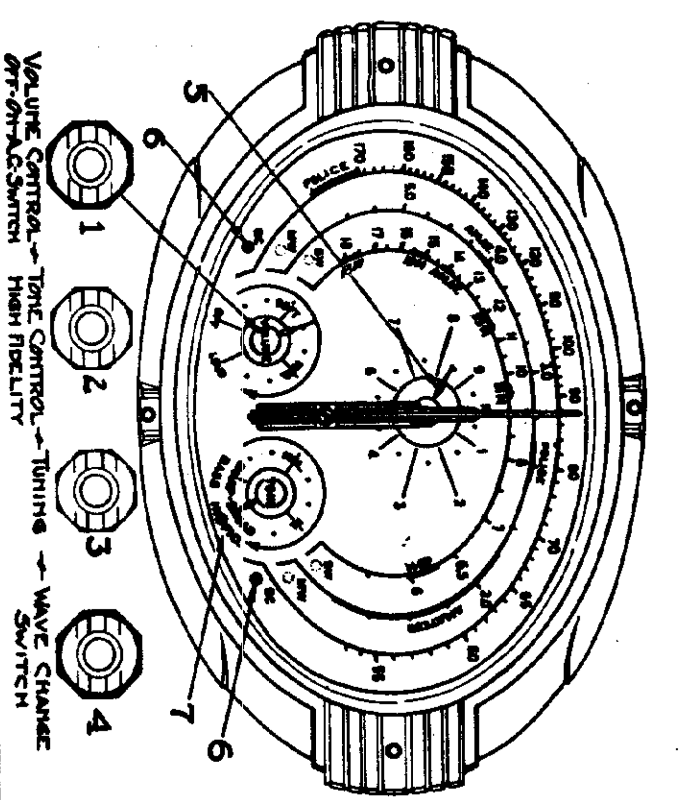
MODEL 778, Series A
Alignment, Notes

BELMONT RADIO CORP.



MODEL 778 - Series A

7-Tube A. C. All Wave

3-Band High Fidelity Superheterodyne Receiver

DESCRIPTION

The tube complement of this chassis is as follows:

1—Type 6K7 Remote cut-off pentode R.F. amplifier
1—Type 6J7—pentode first detector.
1—Type 6C5 Oscillator
1—Type 6K7 Remote cut-off pentode I.F. amplifier (465 K.C.)
1—Type 6Q7 duplex diode pentode second detector, A.V.C. and audio.
1—Type 6F6—pentode output amplifier.
1—Type 5Y3 or 5W4—high vacuum rectifier.

Transformers are available and chassis are sometimes equipped with universal transformers for operation on 40 and 60 cycles and with primary taps for 108, 125, 150, 220 and 250 volts (see instructions) and also sometimes equipped with 25 cycle transformers with 105-115 volt or 220 volt primaries, not universals.

SERVICE NOTES

NOTE: Chassis with serial numbers from 6C229300 to 6D242726 were equipped with a fuse in the primary circuit of the power transformer and supplied with a type 5Z4 rectifier tube.

This fuse is made accessible for replacement by removing fuse cover located on back flange of chassis, replace only with a 2 ampere fuse. If replacement fuse blows out, check tubes, (particularly 5Z4 rectifier) circuit, repair or replace defective tubes or parts.

NEVER ATTEMPT TO REPLACE FUSE WITHOUT FIRST DISCONNECTING POWER.

NEVER REPLACE WITH FUSE OTHER THAN 2 AMPERE RATING.

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt. These voltages are clearly indicated on the circuit diagram.

IN ORDER TO PREVENT SIGNAL FROM ACTING UPON AVC AND AFFECTING ACCURACY OF VOLTAGE MEASUREMENTS, AERIAL AND GROUND LEADS SHOULD BE SHORT CIRCUITED WHILE MAKING MEASUREMENTS.

All voltages are to be measured with 110 volts on the primary of the power transformer.

Resistances of coils and transformer windings are indicated in ohms on schematic circuit diagrams.

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

Excessive hum, stuttering, low volume and a reduction in all D.C. voltages is usually caused by a shorted electrolytic condenser, open by-pass condensers frequently cause oscillation and distorted tone.

ALIGNING INSTRUCTIONS

Dummy Antennas

The following dummy antennas are used in aligning and are referred to in the following alignment instructions as "Dummy 1", "Dummy 2", and "Dummy 3"

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.

Dummy 2: (Broadcast)—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Intermediate and Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

Resonance Indicator:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer or by means of an adapter between the plate and screen terminals of the type 6F6 output tube. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used.

CAUTION:

No aligning adjustments should be attempted without first thoroughly checking over all other possible causes of trouble, such as poor installations, open or grounded antenna systems, low line voltages, defective tubes, condensers and resistors. In order to properly align this chassis, an oscillator (generator) is absolutely necessary. No aligning adjustments should be attempted with the chassis in the cabinet. To remove the knobs, pull them off and to take the chassis out of the cabinet, remove the four bolts by which it is fastened.

ALIGNING I.F. TRANSFORMERS (465 K.C.)

Part No. 108-63 Output I.F. Transformer
Part No. 108-64 Input I.F. Transformer

These I.F. transformers have two adjustments, both of which are accessible from the underside of chassis (see bottom view).

1. With volume control full on, (the extreme right of its rotation), the wave changing switch in the broadcast position, (extreme left of its rotation), the tone control on "Hi" part of the sharp position (as much right rotation as possible without operating the Hi Fidelity switch), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:

(a) Connect external oscillator set at 465 kilocycles, in series with "Dummy 1", to the control grid cap of the type 6K7 tube, located between the two I.F. transformers, and adjust the output I.F. transformer (108-63) to resonance.

(b) With "Dummy 1" still connected, move oscillator output clip from grid of 6K7 to grid cap to 6J7 and adjust input I.F. transformer (108-64) to resonance.

(c) With oscillator still connected to 6J7, re-adjust output I.F. transformer if necessary.

ALIGNMENT PROCEDURE

The following adjustments to be made after the I.F.'s have been aligned as explained above.

BROADCAST BAND ALIGNMENT:

1. With wave changing switch in the broadcast position, extreme left of its rotation, and with external oscillator set at 600 kilocycles and connected in series with "Dummy 2" to the tan antenna and black ground lead, make the following adjustments:

(a) Adjust broadcast series pad (adjustment number 5) to resonance with oscillator. Keep set in tune with oscillator by slowly rocking to and fro the variable condenser until maximum output is obtained. Note: This adjustment is accessible from the top of the chassis and is located between the variable condenser and the 108-63 output I.F. transformer. See top view, Fig. 3.

(b) Re-set external oscillator to 1400 K.C., move dial pointer to 1400 K.C. and adjust oscillator (adjustment number 4), R.F. (adjustment number 6) and antenna (adjustment number 7) to resonance. See bottom view for location of these adjustments, Fig. 1.

(c) Repeat adjustments "a" and "b" until sensitivity is at its maximum.

NOTE: IT IS EXTREMELY NECESSARY IN MAKING ALL OF THESE ADJUSTMENTS THAT THE FUNDAMENTAL OSCILLATOR SIGNAL BE TUNED IN AND NOT THE IMAGE FREQUENCY WHICH WILL FALL BELOW THE FUNDAMENTAL.

SHORT WAVE BAND ALIGNMENT:

1. With wave changing switch in the short wave position, extreme right of its rotation, and with external oscillator set at 17 megacycles and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:

(a) Move dial pointer to 17 megacycles and adjust short wave oscillator (adjustment number 1), short wave R.F. (adjustment number 8) and short wave antenna (adjustment number 9) to resonance.

(b) Re-set external oscillator to 6 megacycles and pick up signal by rotating variable condenser and check for sensitivity.

INTERMEDIATE BAND ALIGNMENT:

1. With wave changing switch in the intermediate wave position, center of its rotation, and with external oscillator set at 1800 K.C. and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:

(a) Rotate variable condenser to approximately 1800 K.C. tune in oscillator signal and adjust M.W. series pad (adjustment number 3) (see top view) to resonance.

Slowly rock condenser to and fro while making this adjustment to be sure maximum output is obtained.

(b) Set external oscillator at 5 M.C., rotate condenser, pick up signal and adjust intermediate wave R.F. (adjustment number 10), intermediate wave antenna (adjustment number 11) and intermediate wave oscillator (adjustment number 2) to resonance.

(c) Re-check broadcast alignment and if it is found necessary to re-adjust either R.F. or antenna trimmers, repeat the 17 M.C. short wave and 5 M.C. intermediate wave adjustments.

BELMONT RADIO CORP.

Model 845 - Series A

8-Tube Including Cathode-Ray Tuning Indicator
3-Band A. C.-D. C. Superheterodyne Receiver
110-220-260 Volts A. C. (Any Cycles) or D. C.

TUBES:

The tube complement of this chassis consists of the latest metal type tubes, which are interchangeable with "metal-glass" types, or glass tubes with octal bases.

The type and function of each tube is as follows:

1—Type 6L7 Pentagrid Mixer, First Detector.
1—Type 6C5 Oscillator.
1—Type 6K7 Remote Cut-Off Pentode, I. F. Amplifier (465 K.C.)
1—Type 6Q7 Duplex Diode Triode Second Detector, A.V.C. and First Audio.
2—Type 25A6 Output Pentodes in Push Pull.
1—Type 25Z6 High Vacuum Rectifier.
1—Type 6G5 Cathode-Ray Tuning Indicator.
(Note:—6G5 available in all glass only.)

POWER SUPPLY:

This receiver is supplied for operation on 110-220-260 volts A.C. (any cycle) or D.C.

Three taps are provided for mains voltages. These taps are accessible upon removing the plate fastened with two wing nuts to back of chassis.

Set the tap at the voltage supplied by the local power company.

This is important.

NOTE:

If set does not operate in one minute on Direct Current reverse plug in receptacle.

SERVICE NOTES

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt. These voltages are clearly indicated on the circuit diagram.

IN ORDER TO PREVENT SIGNAL FROM ACTING UPON AVC AND AFFECTING ACCURACY OF VOLTAGE MEASUREMENTS, AERIAL AND GROUND LEADS SHOULD BE SHORT CIRCUITED WHILE MAKING MEASUREMENTS.

All voltages as indicated on diagram are measured with 119 volt A.C. or D.C. mains.

With special mains voltages select tap nearest to actual mains voltage at time voltage measurements are to be made.

Resistances of coils and transformer windings are indicated in ohms on schematic circuit diagrams.

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

Excessive hum, stuttering, low volume and a reduction in all D.C. voltages is usually caused by a shorted electrolytic condenser, open by-pass condensers frequently cause, oscillation and distorted tone.

ALIGNING INSTRUCTIONS
Dummy Antennas

The following dummy antennas are used in aligning the receiver, and are referred to in the following alignment instructions as "Dummy 1", "Dummy 2", and "Dummy 3".

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.

Dummy 2: (Broadcast and long wave)—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

TEST FREQUENCIES USED

	Kilocycles	Meters
I. F.	465	645.1
Long Wave	150	2000
	350	860
	325	925
Broadcast	600	500
	1400	214
	1600	187
Short Wave	6000	50.0
	17000	17.6
	18200	16.5

Resonance Indicator:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer or by means of an adapter between the plate and cathode terminals of the 5 prong speaker socket. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used.

CAUTION:

No aligning adjustments should be attempted without first thoroughly checking over all other possible causes of trouble, such as poor installations, open or grounded antenna systems, low line voltages, defective tubes, condensers and resistors. In order to properly align this chassis, an oscillator (generator) is absolutely necessary. No aligning adjustments should be attempted with the chassis in the cabinet. To remove the knobs, pull them off and to take the chassis out of the cabinet, remove the four bolts by which it is fastened.

(465 K.C.) (645.1 Meters)

Part No. 108-73 Output I.F. Transformer.
Part No. 108-74 Input I.F. Transformer.

These I.F. transformers have two adjustments, both of which are accessible from the top of chassis (see top view).

1. With volume control full on (the extreme right of its rotation), the band changing switch in the broadcast position, (center of its rotation), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:
   (a) Connect external oscillator set at 465 kilocycles, in series with "Dummy 1," to the control grid cap of the type 6K7 tube, and adjust the output I.F. transformer (No. 108-73) to resonance.
   (b) With "Dummy 1" still connected, move oscillator output clip from grid of 6K7 to grid cap to 6L7 and adjust input I.F. transformer (No. 108-74) to resonance.
   (c) With oscillator still connected to 6L7, readjust output I.F. transformer (108-73) if necessary.

ALIGNMENT PROCEDURE

The following adjustments to be made after the I.F.'s have been aligned as explained above.

SHORT WAVE BAND ALIGNMENT:
16.5 Meters (18.2 Mc.) to 56.5 Meters (5.3 Mc.)

1. With band changing switch in the short wave position, extreme right of its rotation, and with the gang condenser in its minimum capacity position, plates entirely out of mesh, and with external oscillator connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:
   (a) Set external oscillator to 16.5 meters (18.2 Mc.) and adjust short wave oscillator trimmer (adjustment number 3, see Fig. 2) to resonance.
   (b) Re-set external oscillator to 17.6 meters (17.0 Mc.) and pick up signal by rotating gang condenser. Adjust short wave antenna trimmer (adjustment number 6) to resonance.
   (c) Re-set external oscillator to 50 meters (6.0 Mc.) and check for sensitivity.

NOTE: It is extremely necessary in making all of these adjustments that the fundamental oscillator signal be tuned in and not the image frequency which will fall below the fundamental. An example of this is an image of a fundamental 18.3 megacycle signal appears near 17.4 megacycles.

MEDIUM OR BROADCAST BAND ALIGNMENT:
588 Meters (510 K.C.) to 187 Meters (1600 K.C.)

1. With band changing switch in the medium wave position, center of its rotation, and with gang condenser in its minimum capacity position, plates entirely out of mesh, and with external oscillator connected in series with "Dummy 2" to tan antenna lead and black ground lead, make following adjustments:
   (a) Set external oscillator to 187 meters (1600 K.C.) and adjust medium wave oscillator trimmer to resonance (adjustment number 2; see bottom view of coil assembly, Fig. 2.)
   (b) Re-set external oscillator to 214 meters (1400 K.C.), rotate variable gang condenser and pick up signal. Adjust medium wave antenna trimmer (Adjustment number 5) to resonance; also adjust preselector trimmer which is mounted on the top of the rear section of the three gang variable tuning condenser to resonance. (See top view of chassis, Fig. 1, for location of this adjustment.)
   (c) Re-set external oscillator to 500 meters (600 K.C.), and adjust medium wave series pad to resonance by rotating condenser to approximately 600 K.C., rocking it slowly to and fro until by adjusting series pad maximum output is attained. This adjustment is located on the bottom of the chassis directly under the variable gang condenser. (See bottom view of chassis, Fig. 2.)
   (d) Repeat adjustments "a" and "b" until sensitivity is at its maximum.
   (e) Check for tracking and sensitivity at 300 meters (1000 K.C.) Under no circumstances bend plates of variable condenser sections to correct tracking.

IMPORTANT: This band must be completely rechecked after the long wave band has been adjusted.

LONG WAVE BAND ALIGNMENT:
860 Meters (350 K.C.) to 2150 Meters (140 K.C.)

1. With band changing switch in the long wave position, extreme left of its rotation, and with gang condenser in its minimum capacity position, plates entirely out of mesh, and with external oscillator connected in series with "Dummy 2" to tan antenna lead and black ground lead, make following adjustments:
   (a) Set external oscillator to 860 meters (350 K.C.), and adjust long wave oscillator trimmer to resonance (adjustment number 1; see bottom view of coil assembly. Fig. 2.)
   (b) Re-set external oscillator to 925 meters (325 K.C.), rotate variable gang condenser and pick up signal. Adjust long wave antenna trimmer (Adjustment number 4) to resonance.
   (c) Re-set external oscillator to 2000 meters (150 K.C.), and adjust long wave series pad to resonance by rotating condenser to approximately 2000 meters, rocking it slowly to and fro until by adjusting series pad maximum output is attained. This adjustment is located on the bottom of the chassis directly under the variable gang condenser. (See bottom view of chassis, Fig. 2.)
   (d) Repeat adjustments "a" and "b" until sensitivity is at its maximum.

IMPORTANT: This band must be completely rechecked after the medium wave band has been rechecked.

LIST OF REPAIR PARTS
Serial No. 6H374800 and up

Part No.	Description	Circuit Diagram Reference
	CONDENSERS	
100-11	.01 x 400 Volt Tubular	C2, C8, C12, C13, C14
100-20	.1 x 200 Volt Tubular	C17

102-28	Three Gang Variable Condenser	
105-32	250 ohm Filter Choke	
107-48	250 ohm Special Line Cord	R3
112-169	Phono-Radio Indicator Plate	
115-35	Antenna, Oscillator Shield	
115-54	Mains Cover Plate	
121-30	Three Prong Socket Assembly for Mains	
124-31	J. S. Long Wave Series Pad—300 mmf	C18
124-32	J. S. Broadcast Series Pad—565 mmf	C19
125-17	Band Switch	S
125-22	Phono-Radio Toggle Switch	
128-51	Small Wood Knob (with spring)	
133-24	Wing Nut for Mains Cover Plate (115-54)	
171-2	Phono Jack Assembly	

CATHODE RAY TUNING INDICATOR PARTS

Part No.	Description
107-49	Cable and Socket Assembly
111-168	Metal Oval Escutcheon
117-57	Holder and Clamp
130-110	1 Meg. Ohm—1/10 Watt—10%—100 Volt Carbon

DIAL PARTS LIST

ASSEMBLIES

117-41 Drive Bracket including:
- 1—No. 117-19—Tuning Shaft Bushing

117-66 Switch Disc and Link Assembly, including:
- 1—No. 117-12 —Switch Arm
- 1—No. 117-25 —Bushing with Screws
- 1—No. 117-40B—Switch Link
- 2—No. 131-26 —Spring Washers
- 5—No. 152-5 —Rivets
- 1—No. 112-144—Switch Dia.—Inc. Red Tape

DIAL PARTS ONLY

Part No.	Description
112-125	Drive Belt
112-148	Oval Escutcheon complete with Celluloid Crystal
112-172	Dial Scale comp. with Fastener, Pointer Disc, & Screw
112-147	Tuning Shaft
112-151	Pointer complete with Screw
112-156	Pilot Light Assembly
116-13	6.8 Volt T-51 Pilot Light
117-20A	Tuning Shaft Pulley
117-38	Stud, for take-up Spring
117-39	Pulley, for take-up Spring
120-14	Take-up Spring
134-2	Horse Shoe Washer
184-40	Rubber Grommet

BELMONT RADIO CORP.

10-Tube A. C. All Wave

3-Band High Fidelity Superheterodyne Receiver with Cathode Ray Tuning Indicator

MODEL 1070 - Series B

NOTE:—Operation of Cathode-Ray Tuning Indicator

Due to unsatisfactory indication of the cathode-ray tuning indicator on weak signals in some territories, a change was made in the circuit to correct this condition and still allow the tube to operate correctly on a strong signal.

Referring to the circuit diagram, resistors R26, R27 and condenser C32 were added and connected to the green wire from the cathode-ray tuning indicator as shown.

The dotted line on the circuit diagram indicates the manner in which the green wire for the cathode-ray tuning indicator cable was formerly connected, before resistors R26, R27 and condenser C32 were added.

1—Type 6G5 Cathode ray tuning indicator.

Form 1086 2M 8-36

MODEL 1070 - Series A

DESCRIPTION

The tube complement of this chassis is as follows:

1—Type 6K7 Remote cut-off pentode R.F. amplifier
1—Type 6L7 Pentode first detector
1—Type 6C5 Oscillator
1—Type 6K7 Remote cut-off pentode I.F. amplifier (465 K.C.)
1—Type 6H6 Duplex diode second detector and A.V.C.
1—Type 6C5 First audio amplifier
1—Type 6F5 Pentode driver stage
2—Type 6F6 Class AB Output pentodes in push-pull
1—Type 5Z4 High vacuum rectifier

Transformers are available and chassis are sometimes equipped with universal transformers for operation on 40 and 60 cycles and with primary taps for 108, 125, 150, 220 and 250 volts (see instructional and also sometimes equipped with 25 cycle transformers with 105-115 volt or 220 volt primaries, not universals.

SERVICE NOTES

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt. These voltages are clearly indicated on the circuit diagrams of series A.

IN ORDER TO PREVENT SIGNAL FROM ACTING UPON AVC AND AFFECTING ACCURACY OF VOLTAGE MEASUREMENTS, AERIAL AND GROUND LEADS SHOULD BE SHORT CIRCUITED WHILE MAKING MEASUREMENTS.

All voltages are to be measured with 110 volts on the primary of the power transformer.

Resistances of coils and transformer windings are indicated in ohms on schematic circuit diagrams.

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

Excessive hum, stuttering, low volume and a reduction in all D.C. voltages is usually caused by a shorted electrolytic condenser, open by-pass condensers frequently cause oscillation and distorted tone.

This chassis is protected against damage from faulty tubes or abnormal line conditions by a fuse in the primary circuit.

If when set is turned on pilot lights do not light, look for a blown fuse.

This fuse is made accessible for replacement by removing fuse cover located on back flange of chassis, replace only with a 2 ampere fuse. If replacement fuse blows out, check tubes, (particularly 5Z4 rectifier) circuit, repair or replace defective tubes or parts.

NEVER ATTEMPT TO REPLACE FUSE WITHOUT FIRST DISCONNECTING POWER.

NEVER REPLACE WITH FUSE OTHER THAN 2 AMPERE RATING.

NOTE: Chassis with serial numbers from 5K194500 to 5K195497 have the fuse mounted on the under-side of the chassis, it is necessary to remove the chassis from the cabinet to replace the fuse.

ALIGNING INSTRUCTIONS

Dummy Antennas

The following dummy antennas are used in aligning and are referred to in the following alignment instructions as "Dummy 1", "Dummy 2", and "Dummy 3".

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.

Dummy 2: (Broadcast)—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Intermediate and Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

Resonance Indicator:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer or by means of an adapter between the plate and cathode terminals of the 5 prong speaker socket. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used.

CAUTION:

No aligning adjustments should be attempted without first thoroughly checking over all other possible causes of trouble, such as poor installations, open or grounded antenna systems, low line voltages, defective tubes, condensers and resistors. In order to properly align this chassis, an oscillator (generator) is absolutely necessary. No aligning adjustments should be attempted with the chassis in the cabinet. To remove the knobs pull them off and to take the chassis out of the cabinet, remove the four bolts by which it is fastened.

ALIGNING I.F. TRANSFORMERS (465 K.C.)

Part No. 108-62 Output I.F. Transformer
Part No. 108-55 Input I.F. Transformer

These I.F. transformers have two adjustments, both of which are accessible from the underside of chassis (see bottom view).

1. With volume control full on, (the extreme right of its rotation), the wave changing switch in the broadcast position, (extreme left of its rotation), the tone control on "Hi" part of the sharp position (as much right rotation as possible without operating the Hi Fidelity switch), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:
   (a) Connect external oscillator set at 465 kilocycles, in series with "Dummy 1", to the control grid cap of the type 6K7 tube, located between the two I.F. transformers, and adjust the output I.F. transformer to resonance.
   (b) With "Dummy 1" still connected, move oscillator output clip from grid of 6K7 to grid cap to 6L7 and adjust input I.F. transformer to resonance.
   (c) With oscillator still connected to 6L7, re-adjust output I.F. transformer.

ALIGNMENT PROCEDURE

The following adjustments to be made after the I.F.'s have been aligned as explained above.

BROADCAST BAND ALIGNMENT:

1. With wave changing switch in the broadcast position, extreme left of its rotation, and with external oscillator set at 600 kilocycles and connected in series with "Dummy 2" to the tan antenna and black ground lead, make the following adjustments:
   (a) Adjust broadcast series pad to resonance with oscillator. Keep set in tune with oscillator by slowly rocking to and fro the variable condenser until maximum output is obtained. Note: This adjustment is accessible from the top of the chassis and is located between the variable condenser and the electrolytic condenser. See top view.
   (b) Re-set external oscillator to 1400 K.C., move dial/pointer to 1400 K.C. and adjust oscillator (adjustment number 3), R.F. (adjustment number 2) and antenna (adjustment number 1) to resonance. See bottom view for location of these adjustments.
   (c) Repeat adjustments "a" and "b" until sensitivity is at its maximum.

NOTE: IT IS EXTREMELY NECESSARY IN MAKING ALL OF THESE ADJUSTMENTS THAT THE FUNDAMENTAL OSCILLATOR SIGNAL BE TUNED IN AND NOT THE IMAGE FREQUENCY WHICH WILL FALL BELOW THE FUNDAMENTAL.

SHORT WAVE BAND ALIGNMENT:

1. With wave changing switch in the short wave position, extreme right of its rotation, and with external oscillator set at 17 megacycles and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:
   (a) Move dial pointer to 17 megacycles and adjust short wave oscillator (adjustment number 8), short wave R.F. (adjustment number 7) and short wave antenna (adjustment number 6) to resonance.
   (b) Re-set external oscillator to 6 megacycles and pick up signal by rotating variable condenser and check for sensitivity.

INTERMEDIATE BAND ALIGNMENT:

1. With wave changing switch in the intermediate wave position, center of its rotation, and with external oscillator set at 1800 K.C. and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:
   (a) Rotate variable condenser to approximately 1800 K.C., tune in oscillator signal and adjust M.W. series pad (see top view) to resonance. Slowly rock condenser to and fro while making this adjustment to be sure maximum output is obtained.
   (b) Set external oscillator at 5 M.C., rotate condenser, pick up signal and adjust intermediate wave R.F. (adjustment number 5), intermediate wave antenna (adjustment number 4) and intermediate wave oscillator (adjustment number 9) to resonance.
   (c) Re-check broadcast alignment and if it is found necessary to re-adjust either R.F. or antenna trimmers, repeat the 17 M.C. short wave and 5 M.C. intermediate wave adjustments.

(2) Grid bias - Measured at genemotor cable socket.

Genemotor Assembly

The genemotor assembly contains all of the parts shown within the dotted lines in Fig. 1. We do not recommend that the genemotor itself be serviced in the field. The filter unit associated with the genemotor may be checked and any defective parts repaired or replaced. However, if the genemotor itself is at fault, it should be sent back to the factory for repair.

SPECIFICATIONS

Power Consumption	9.0 Amperes at 6 Volts	Sensitivity	1.0 Microvolt Absolute
Power Output	5.5 Watts at 6 Volts	Tuning Frequency Range	530 to 1650 KC
	9.0 Watts at 7.5 Volts	Intermediate Frequency	175 KC
Selectivity - 28 KC Broad at 1000 Times Signal (Sharp)		Speaker	8 or 10 Inch Dynamic

Circuit

This model is a 6 tube automobile receiver covering the standard wave band. It has a tuning range as shown in the specifications above. The signal is fed through an antenna transformer with tuned secondary into a 6D6 tube which functions as an R.F. amplifier. The output of this tube is fed through another R.F. transformer with tuned secondary into a 6C6 tube which functions as the first detector and oscillator. The oscillating circuit is tuned by the oscillator section of the gang condenser and is always resonant at a frequency 175 KC above the frequency to which the R.F. circuits are tuned.

One stage of I.F. amplification is employed using a 6D6 tube. The primary and secondary of the first I.F. transformer and the primary of the second I.F. transformer are tuned by small trimmer condensers.

Referring to the 1st I.F. transformer T4 in Fig. 1 it will be noted that there is a coupling winding shown below the primary.

When the expander (selectivity control) is in the sharp position, the coupling winding is open circuited and the loose coupling which exists between the primary and secondary of this transformer results in high selectivity.

When the expander is in the broad position, the coupling winding which is wound under the primary is connected in series with the secondary. This provides overcoupling which results in a greatly widened resonance curve. Passage of a wide range of audio frequencies is thus obtained.

A 6B7 duo diode-pentode tube functions as a diode 2nd detector, A.V.C. tube and a one stage audio amplifier. A.V.C. voltage is applied to the control grid circuits of the 6D6 R.F. and I.F. tubes. The manual volume control varies the audio voltage applied to the grid of the 6B7 tube.

Resistance coupling is used between the 1st audio stage and the driver stage which employs a 41 tube. The latter is transformer coupled to the output stage which uses a 6A6 tube. This tube is a Class "B" power amplifier and combines 2 triodes in one envelope. A dynamic reproducer is used.

Current for the receiver is obtained from the car storage battery. A genemotor supplies the high voltage required for the plate and screen circuits.

Alignment Procedure

I. F. Adjustment

Set the signal generator for a signal of 175 KC.

Connect the output of the signal generator through a .1 mf. condenser to the stator of the interstage section of the tuning condenser—see Fig. 4 for the location of this condenser. This can be done by connecting a lead to the lug on the top of this stator.

Connect the ground lead of the signal generator to the chassis ground.

Short out the oscillator section of the tuning condenser.

Turn the expander to the sharp position and keep it in this position for all adjustments.

Set the volume control at the maximum position.

Attenuate the signal from the signal generator to prevent the levelling-off action of the A.V.C.

Then adjust the three I.F. trimmers until maximum output is obtained. The location of these trimmers is shown in Fig. 4.

1650 KC. Adjustment

Set the signal generator for 1650 KC.

Turn the rotor of the tuning condenser to the full open position.

Connect the shielded antenna lead from the chassis through a 110 mmf. condenser to the antenna post of the signal generator.

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the trimmer of the oscillator section of the three gang condenser until maximum output is obtained—see Fig. 4 for location of this trimmer.

1400 KC. Adjustment

Set the signal generator for 1400 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the interstage and antenna trimmers for maximum output—see Fig. 4.

Do not change the setting of the oscillator trimmer.

Adjusting Antenna Trimmer

After the receiver is installed and the car antenna is connected it will be necessary to adjust the antenna trimmer. Tune in a weak signal between 1200 and 1400 KC. with the volume control about three-fourths on. Remove the cover of the chassis case. The antenna trimmer is on the center tuning condenser section—see Fig. 4. Turn the adjusting screw of this condenser up or down until maximum output is obtained. CAUTION—Do not turn any of the other trimmer adjusting screws for this adjustment.

NOTICE—A change has been made in our parts numbering system. Old parts which are used in new receivers will have a new number assigned to them. For your convenience we are listing below all of the new part numbers and the corresponding old part number, should there be one. **Order by new part number only.**

There is a large letter on the chassis which identifies the set as to major part changes. When ordering parts please be sure to mention the series number and this large letter.

MISCELLANEOUS

INSTALLATION ITEMS

This receiver uses three types of Speaker Mountings. The complete Assembly with Roof Mounting Speaker is the 56Q1; with Flat Dash Mounting 56Q2 and with End Dash Mounting 56Q3. Some of the following parts are common to all three Mountings. Others which are so designated apply only to one or two mountings.

ALIGNMENT PROCEDURE

Correct alignment is of extreme importance in all wave receivers. The receivers are properly aligned at the factory with precision equipment and realignment should not be attempted by the service technician until all other causes of faulty operation are corrected.

In order to properly realign the receiver the following equipment is necessary:

1. A signal generator which will provide an accurately calibrated signal at any frequency from 262 kilocycles to 18 megacycles. The generator should have adjustable signal output.

2. An output audio voltmeter of the low voltage type to be connected across the moving coil of the speaker. This should be capable of providing a readable deflection for relatively low output levels to avoid the effects of overload.

3. An insulated or non-metallic screw driver for the adjustment of trimmers.

IF ALIGNMENT 262.5 KC

1. Connect the output meter (low scale) across the loud speaker voice coil. Turn the wave band switch (outside of tuning knob) to its left hand or counter-clockwise position. This brings the red indicator for broadcast band to the top. Turn the volume control to its maximum position.

2. Connect the test oscillator ground to chassis and the "hot" lead from the test oscillator to the grid of the 6L7 converter tube through a series .1 Mfd. condenser. Set test oscillator to 262.5 kc.

3. Adjust IF alignment screws C13, C14, (see illustration below) of second IF transformer, T2, adjacent to rectifier tube (type 80) to maximum output, reducing output of test oscillator to keep the meter reading on scale as alignment proceeds.

4. Adjust alignment screws C11, C12, of first IF transformer, T1, (directly behind tuning condenser) to maximum output as described above.

5. Readjust these trimmers for accurate alignment. Always use the lowest possible output from the test oscillator to preclude the possibility of automatic volume control action confusing proper adjustment.

ADJUSTMENT OF WAVE TRAP

Connect test oscillator to antenna and ground terminals of the receiver using a .00025 Mfd. condenser in series with the antenna terminal. With oscillator set at 262.5 kc adjust antenna trap alignment screw C4, for minimum signal increasing output of test oscillator as a minimum is reached.

RF ALIGNMENT (Broadcast "A" or "Red" Band)

1. With test oscillator connecting antenna post through .00025 Mfd. as above set signal generator to 1400 kc.

2. Set dial scale, hour and minute hands, to 6 o'clock when gang condenser is fully meshed at maximum capacitance.

3. Set dial to calibration mark 1400 kc using hour hand to indicate frequency (no further attention need be paid to position of minute hand which is used merely for convenience in logging stations by "TIME"). Adjust broadcast oscillator trimmer condenser C15, for maximum output meter reading. If it is found that two peaks occur within the range of the trimmer action use the one in which the trimmer is in its lowest capacitance or counter-clockwise position.

4. Adjust detector input trimmer C8, to a maximum.

5. Adjust the Antenna stage trimmer C5, to a maximum.

6. Set test oscillator to 600 kc and tune in the signal, then adjust broadcast oscillator padder C19, for maximum output. This padder is mounted under the chassis at the side of the RF "deck." Rock the condenser back and forth a degree or two in order to obtain proper maximum.

7. Repeat the 1400 kc adjustments described under 3, 4, 5, for greater accuracy. The output of the test oscillator should always be kept at the lowest output which will allow sufficient meter swing since this assures greater accuracy of adjustment.

Short Wave "B" or "Green" Band

1. Turn the wave band switch to the "B" or "Green" position. Leave the oscillator connected as above but with its output set to 6000 kc and the .00025 Mfd. condenser replaced by a 400 Ohm resistor. Set dial scale to 6 mc on the green or middle band, adjust "B" band oscillator trimmer condenser C16, for maximum output observing as before that the proper point occurs at the minimum or counter-clockwise position of the screw if two points are found.

2. Adjust detector input "B" band trimmer condenser C9, to a maximum while rocking the tuning condenser slightly for maximum response.

3. Adjust Antenna stage "B" band trimmer C6, for maximum output.

4. Set the test oscillator to 2000 kc and tune in the signal. Adjust "B" band oscillator padder condenser C18 for maximum output while rocking tuning condenser as described above.

5. Repeat operations 1, 2, and 3 to assure precise alignment.

Short Wave "C" or "Yellow" Band

1. With test oscillator connected same as for "B" band and set to 18000 kc (18 mc) set dial scale to 18 mc on inner or yellow band.

2. Adjust "C" band oscillator trimming condenser C17, for maximum response. Use lower capacity or counter-clockwise response point.

3. Adjust "C" band detector input trimmer C10, to a maximum, "rocking" tuning adjustment to obtain greatest output.

4. Adjust antenna "C" band trimmer C7, for maximum response.

*The adjustment of the detector input trimmers on the "B" and "C" bands by the procedure outlined above is advisable as contrasted with the usual method of trimming without rocking the tuning adjustment because slight couplings through the tube circuits tend to disturb the oscillator frequency as the detector is tuned. This procedure should be followed on any type of all wave receiver.

See Case Page 7-16, for Dial Drive notes.

In checking the circuit with a continuity or ohmmeter it is wise to follow the schematic diagram in an orderly fashion starting at the antenna and ground connections and proceeding to the speaker circuits.

ALIGNMENT PROCEDURE

Correct alignment is of extreme importance in all wave receivers. The receivers are properly aligned at the factory with precision equipment and realignment should not be attempted by the service technician until all other causes of faulty operation are corrected.

In order to properly realign the receiver the following equipment is necessary:

1. A signal generator which will provide an accurately calibrated signal at any frequency from 262 kilocycles to 18 megacycles. The generator should have adjustable signal output.

2. An output audio voltmeter of the low voltage type to be connected across the moving coil of the speaker. This should be capable of providing a readable deflection for relatively low output levels to avoid the effects of overload.

3. An insulated or non-metallic screw driver for the adjustment of trimmers.

IF ALIGNMENT 262.5 KC

1. Connect the output meter (low scale) across the loud speaker voice coil. Turn the wave band switch (outside of tuning knob) to its left hand or counter-clockwise position. This brings the red indicator for broadcast band to the top. Turn the volume control to its maximum position.

2. Connect the test oscillator ground to chassis and the "hot" lead from the test oscillator to the grid of the 6L7 converter tube through a series .1 Mfd. condenser. Set test oscillator to 262.5 kc.

3. Adjust IF alignment screws C13, C14, (see illustration below) of second IF transformer, T2, adjacent to rectifier tube (type 80) to maximum output, reducing output of test oscillator to keep the meter reading on scale as alignment proceeds.

4. Adjust alignment screws C11, C12, of first IF transformer, T1, (directly behind tuning condenser) to maximum output as described above.

5. Readjust these trimmers for accurate alignment. Always use the lowest possible output from the test oscillator to preclude the possibility of automatic volume control action confusing proper adjustment.

ADJUSTMENT OF WAVE TRAP

Connect test oscillator to antenna and ground terminals of the receiver using a .00025 Mfd. condenser in series with the antenna terminal. With oscillator set at 262.5 kc adjust antenna trap alignment screw C4, for minimum signal increasing output of test oscillator as a minimum is reached.

RF ALIGNMENT (Broadcast "A" or "Red" Band)

1. With test oscillator connecting antenna post through .00025 Mfd. as above set signal generator to 1400 kc.

2. Set dial scale, hour and minute hands, to 6 o'clock when gang condenser is fully meshed at maximum capacitance.

3. Set dial to calibration mark 1400 kc using hour hand to indicate frequency (no further attention need be paid to position of minute hand which is used merely for convenience in logging stations by "TIME"). Adjust broadcast oscillator trimmer condenser C15, for maximum output meter reading. If it is found that two peaks occur within the range of the trimmer action use the one in which the trimmer is in its lowest capacitance or counter-clockwise position.

4. Adjust detector input trimmer C8, to a maximum.

5. Adjust the Antenna stage trimmer C5, to a maximum.

6. Set test oscillator to 600 kc and tune in the signal, then adjust broadcast oscillator padder C19, for maximum output. This padder is mounted under the chassis at the side of the RF "deck." Rock the condenser back and forth a degree or two in order to obtain proper maximum.

MODEL 701 CHASSIS 16 SME

7. Repeat the 1400 kc adjustments described under 3, 4, 5, for greater accuracy. The output of the test oscillator should always be kept at the lowest output which will allow sufficient meter swing since this assures greater accuracy of adjustment.

Short Wave "B" or "Green" Band

1. Turn the wave band switch to the "B" or "Green" position. Leave the oscillator connected as above but with its output set to 6000 kc and the .00025 Mfd. condenser replaced by a 400 Ohm resistor. Set dial scale to 6 mc on the green or middle band, adjust "B" band oscillator trimmer condenser C16, for maximum output observing as before that the proper point occurs at the minimum or counter-clockwise position of the screw if two points are found.

2. Adjust detector input "B" band trimmer condenser C9, to a maximum while rocking the tuning condenser slightly for maximum response.

3. Adjust Antenna stage "B" band trimmer C6, for maximum output.

4. Set the test oscillator to 2000 kc and tune in the signal. Adjust "B" band oscillator padder condenser C18 for maximum output while rocking tuning condenser as described above.

5. Repeat operations 1, 2, and 3 to assure precise alignment.

Short Wave "C" or "Yellow" Band

1. With test oscillator connected same as for "B" band and set to 18000 kc (18 mc) set dial scale to 18 mc on inner or yellow band.

2. Adjust "C" band oscillator trimming condenser C17, for maximum response. Use lower capacity or counter-clockwise response point.

3. Adjust "C" band detector input trimmer C10, to a maximum, *"rocking" tuning adjustment to obtain greatest output.

4. Adjust antenna "C" band trimmer C7, for maximum response.

*The adjustment of the detector input trimmers on the "B" and "C" bands by the procedure outlined above is advisable as contrasted with the usual method of trimming without rocking the tuning adjustment because slight couplings through the tube circuits tend to disturb the oscillator frequency as the detector is tuned. This procedure should be followed on any type of all wave receiver.

In checking the circuit with a continuity or ohmmeter it is wise to follow the schematic diagram in an orderly fashion starting at the antenna and ground connections and proceeding to the speaker circuits.

ALIGNMENT PROCEDURE

Correct alignment is of extreme importance in all wave receivers. The receivers are properly aligned at the factory with precision equipment and realignment should not be attempted by the service technician until all other causes of faulty operation are corrected.

In order to properly realign the receiver the following equipment is necessary:

1. A signal generator which will provide an accurately calibrated signal at any frequency from 262 kilocycles to 18 megacycles. The generator should have adjustable signal output.

2. An output audio voltmeter of the low voltage type to be connected across the moving coil of the speaker. This should be capable of providing a readable deflection for relatively low output levels to avoid the effects of overload.

3. An insulated or non-metallic screw driver for the adjustment of trimmers.

IF ALIGNMENT 262.5 KC

1. Connect the output meter (low scale) across the loud speaker voice coil. Turn the wave band switch (outside of tuning knob) to its left hand or counter-clockwise position. This brings the red indicator for broadcast band to the top. Turn the volume control to its maximum position.

2. Connect the test oscillator ground to chassis and the "hot" lead from the test oscillator to the grid of the 6L7 converter tube through a series .1 Mfd. condenser. Set test oscillator to 262.5 kc.

3. Adjust IF alignment screws C11, C12, (see illustration below) of second IF transformer, T2, adjacent to rectifier tube (type 80) to maximum output, reducing output of test oscillator to keep the meter reading on scale as alignment proceeds.

4. Adjust alignment screws C13, C14, of first IF transformer, T1, (directly behind tuning condenser) to maximum output as described above.

5. Readjust these trimmers for accurate alignment. Always use the lowest possible output from the test oscillator to preclude the possibility of automatic volume control action confusing proper adjustment.

ADJUSTMENT OF WAVE TRAP

Connect test oscillator to antenna and ground terminals of the receiver using a .00025 Mfd. condenser in series with the antenna terminal. With oscillator set at 262.5 kc adjust antenna trap alignment screw C4, for minimum signal increasing output of test oscillator as a minimum is reached.

RF ALIGNMENT (Broadcast "A" or "Red" Band)

1. With test oscillator connecting antenna post through .00025 Mfd. as above set signal generator to 1400 kc.

2. Set dial scale, hour and minute hands, to 6 o'clock when gang condenser is fully meshed at maximum capacitance.

3. Set dial to calibration mark 1400 kc using hour hand to indicate frequency (no further attention need be paid to position of minute hand which is used merely for convenience in logging stations by "TIME"). Adjust broadcast oscillator trimmer condenser C17, for maximum output meter reading. If it is found that two peaks occur within the range of the trimmer action use the one in which the trimmer is in its lowest capacitance or counter-clockwise position.

4. Adjust detector input trimmer C8, to a maximum.

5. Adjust the Antenna stage trimmer C5, to a maximum.

6. Set test oscillator to 600 kc and tune in the signal, then adjust broadcast oscillator padder C15, for maximum output. This padder is mounted under the chassis at the side of the RF "deck." Rock the condenser back and forth a degree or two in order to obtain proper maximum.

7. Repeat the 1400 kc adjustments described under 3, 4, 5, for greater accuracy. The output of the test oscillator should always be kept at the lowest output which will allow sufficient meter swing since this assures greater accuracy of adjustment.

Short Wave "B" or "Green" Band

1. Turn the wave band switch to the "B" or "Green" position. Leave the oscillator connected as above but with its output set to 6000 kc and the .00025 Mfd. condenser replaced by a 400 ohm resistor. Set dial scale to 6 mc on the green or middle band, adjust "B" band oscillator trimmer condenser C18, for maximum output observing as before that the proper point occurs at the minimum or counter-clockwise position of the screw if two points are found.

2. Adjust detector input "B" band trimmer condenser C9, to a maximum while rocking the tuning condenser slightly for maximum response.

3. Adjust Antenna stage "B" band trimmer C6, for maximum output.

4. Set the test oscillator to 2000 kc and tune in the signal. Adjust "B" band oscillator padder condenser C16 for maximum output while rocking tuning condenser as described above.

5. Repeat operations 1, 2, and 3 to assure precise alignment.

Short Wave "C" or "Yellow" Band

1. With test oscillator connected same as for "B" band and set to 18000 kc (18 mc) set dial scale to 18 mc on inner or yellow band.

2. Adjust "C" band oscillator trimming condenser C19, for maximum response. Use lower capacity or counter-clockwise response point.

3. Adjust "C" band detector input trimmer C10, to a maximum, "rocking" tuning adjustment to obtain greatest output.

4. Adjust antenna "C" band trimmer C7, for maximum response.

*The adjustment of the detector input trimmers on the "B" and "C" bands by the procedure outlined above is advisable as contrasted with the usual method of trimming without rocking the tuning adjustment because slight couplings through the tube circuits tend to disturb the oscillator frequency as the detector is tuned. This procedure should be followed on any type of all wave receiver.

In checking the circuit with a continuity or ohmmeter it is wise to follow the schematic diagram in an orderly fashion starting at the antenna and ground connections and proceeding to the speaker circuits.

ALIGNMENT PROCEDURE

Correct alignment is of extreme importance in all wave receivers. The receivers are properly aligned at the factory with precision equipment and realignment should not be attempted by the service technician until all other causes of faulty operation are corrected.

In order to properly realign the receiver the following equipment is necessary:

1. A signal generator which will provide an accurately calibrated signal at any frequency from 262 kilocycles to 18 megacycles. The generator should have adjustable signal output.

2. An output audio voltmeter of the low voltage type to be connected across the moving coil of the speaker. This should be capable of providing a readable deflection for relatively low output levels to avoid the effects of overload.

3. An insulated or non-metallic screw driver for the adjustment of trimmers.

IF ALIGNMENT 262.5 KC

1. Connect the output meter (low scale) across the loud speaker voice coil. Turn the wave band switch (outside of tuning knob) to its left-hand or counter-clockwise position. This brings the red indicator for broadcast band to the top. Turn the volume control to its maximum position.

2. Turn the Variable Selectivity (center bottom knob) to the left or sharpest position. Put tone control on brilliant or clockwise position. With Selectivity Control held all the way to the left or counter-clockwise loosen set screws of collars, which actuate Variable Selectivity coupling and rotate until the drive cables are drawn out as far as possible without forcing. Tighten set screws in the collars. This adjustment assures maximum selectivity and should be checked before IF Alignment is done.

3. Connect the test oscillator ground to chassis and the "hot" lead from the test oscillator to the grid of the 6L7 converter tube through a series .1 Mfd condenser. Set test oscillator to 262.5 kc.

4. With Variable Selectivity Control in sharpest position adjust IF alignment screws, C14, C15, of output transformer, (directly behind tuning condenser) to maximum output reducing output of test oscillator to keep the meter reading on scale as alignment proceeds.

5. Adjust alignment screws, C12, C13, of input transformer T1, (adjacent to electrolytic condenser) to maximum output as described above.

6. Readjust all four alignment screws to insure accurate alignment. Always use the lowest possible output from the test oscillator to preclude the possibility of automatic volume control action confusing proper adjustment.

ADJUSTMENT OF WAVE TRAP

Connect test oscillator to antenna and ground terminals of the receiver using a .00025 Mfd condenser in series with the antenna terminal. With oscillator set at 262.5 kc adjust antenna trap alignment screw C4, for minimum signal increasing output of test oscillator as a minimum is reached.

RF ALIGNMENT (Broadcast "A" or "Red" Band)

1. With test oscillator connecting antenna post through .00025 Mfd as above set signal generator to 1400 kc.

2. Set dial scale, hour and minute hands, to 6 o'clock when gang condenser is fully meshed at maximum capacitance.

3. Set dial to calibration mark 1400 kc using hour hand to indicate frequency (no further attention need be paid to position of minute hand which is used merely for convenience in logging stations by "TIME"). Adjust broadcast oscillator trimmer condenser C16, for maximum output meter reading. If it is found that two peaks occur within the range of the trimmer action use the one in which the trimmer is in its lowest capacitance or counter-clockwise position.

4. Adjust detector input trimmer C9, to a maximum.

In some receivers C9, is a separate trimmer located on the range switch shield under the chassis rather than in the top of the coil can. In these models C8, is a 100 Mmf fixed Mica Condenser instead of the variable trimmer shown on the diagram.

5. Adjust the Antenna stage trimmer C5, to a maximum.

6. Set test oscillator to 600 kc and tune in the signal, then adjust broadcast oscillator padder C20, for maximum output. This padder is mounted under the chassis at the side of the RF "deck." This adjustment is the outer nut of the concentric type padding condenser. Rock the condenser back and forth a degree or two in order to obtain proper maximum.

7. Repeat the 1400 kc adjustments described under 3, 4, 5, for greater accuracy. The output of the test oscillator should always be kept at the lowest output which will allow sufficient meter swing since this assures greater accuracy of adjustment.

Short Wave "B" or "Green" Band

1. Turn the wave band switch to the "B" or "Green" position. Leave the oscillator connected as above but with its output set to 6000 kc and the .00025 Mfd condenser replaced by a 400 Ohm resistor. Set dial scale to 6 mc on the green or middle band, adjust "B" band oscillator trimmer condenser C17, for maximum output observing as before that the proper point occurs at the minimum or counter-clockwise position of the screw if two points are found.

2. Adjust detector input "B" band trimmer condenser C10, to a maximum while rocking the tuning condenser slightly for maximum response.*

3. Adjust Antenna stage "B" band trimmer C6, for maximum output.

4. Set the test oscillator to 2000 kc and tune in the signal. Adjust "B" band oscillator padder condenser C19 for maximum output while rocking tuning condenser as described above. This adjustment is the inner screw of the concentric type padding condenser.

5. Repeat operations 1, 2, and 3 to assure precise alignment.

Short Wave "C" or "Yellow" Band

1. With test oscillator connected same as for "B" band and set to 18000 kc (18 mc) set dial scale to 18 mc on inner or yellow band.

2. Adjust "C" band oscillator trimming condenser C18, for maximum response. Use lower capacity or counter-clockwise response point.

3. Adjust "C" band detector input trimmer C11, to a maximum,* "rocking" tuning adjustment to obtain greatest output.

4. Adjust antenna "C" band trimmer C7, for maximum response.

*The adjustment of the detector input trimmers on the "B" and "C" bands by the procedure outlined above is advisable as contrasted with the usual method of trimming without rocking the tuning adjustment because slight couplings through the tube circuits tend to disturb the oscillator frequency as the detector is tuned. This procedure should be followed on any type of all wave receiver.

Part of the production of Model 19 incorporated certain circuit alterations which are shown in the insert enclosed by dotted lines on the circuit diagram of Page three. The parts placement diagram on Page two is a composite drawing showing the position of parts for both types of receivers. Parts dotted on this diagram refer to those shown in the insert of the schematic diagram. Circuit elements C31 and R17 are not used when dotted connections are employed.

When the variable selectivity control is in "tune" or narrow position certain 6K7 IF tubes may exhibit a tendency toward regeneration or instability due to control grid to plate capacity coupling. This may be "neutralized" by using several turns of twisted hook-up wire connected between the plate of the IF tube and blank lug of the RF socket which is used as a tie point for the AVC return. This is shown on the parts placement diagram.

Excessive hum in this model has been found to be due to defective 6H6 and 6C5 tubes. Replace each tube in turn with a tube known to be normal in this respect.

In checking the circuit with a continuity or ohmmeter it is wise to follow the schematic diagram in orderly fashion starting at the antenna and ground connections and proceeding to the speaker circuits.

ALIGNMENT PROCEDURE

Correct alignment is of extreme importance in all wave receivers. The receivers are properly aligned at the factory with precision equipment and realignment should not be attempted by the service technician until all other causes of faulty operation are corrected.

In order to properly realign the receiver the following equipment is necessary:

1. A signal generator which will provide an accurately calibrated signal at any frequency from 262 kilocycles to 18 megacycles. The generator should have adjustable signal output.

2. An output audio voltmeter of the low voltage type to be connected across the moving coil of the speaker. This should be capable of providing a readable deflection for relatively low output levels to avoid the effects of overload.

3. An insulated or non-metallic screw driver for the adjustment of trimmers.

IF ALIGNMENT 262.5 KC

1. Connect the output meter (low scale) across the loud speaker voice coil. Turn the wave band switch (outside of tuning knob) to its left-hand or counter-clockwise position. This brings the red indicator for broadcast band to the top. Turn the volume control to its maximum position.

2. Turn the Variable Selectivity (center bottom knob) to the left or sharpest position. Put tone control on brilliant or clockwise position. With Selectivity Control held all the way to the left or counter-clockwise loosen set screws of collars, which actuate Variable Selectivity coupling and rotate until the drive cables are drawn out as far as possible without forcing. Tighten set screws in the collars. This adjustment assures maximum selectivity and should be checked before IF Alignment is done.

3. Connect the test oscillator ground to chassis and the "hot" lead from the test oscillator to the grid of the 6L7 converter tube through a series .1 Mfd condenser. Set test oscillator to 262.5 kc.

4. With Variable Selectivity Control in sharpest position adjust IF alignment screws, C14, C15, of output transformer, (directly behind tuning condenser) to maximum output reducing output of test oscillator to keep the meter reading on scale as alignment proceeds.

5. Adjust alignment screws, C12, C13, of input transformer T1, (adjacent to electrolytic condenser) to maximum output as described above.

6. Readjust all four alignment screws to insure accurate alignment. Always use the lowest possible output from the test oscillator to preclude the possibility of automatic volume control action confusing proper adjustment.

RF ALIGNMENT (Broadcast "A" or "Red" Band)

1. With test oscillator connecting antenna post through .00025 Mfd. as above set signal generator to 1400 kc.

2. Set dial scale, hour and minute hands, to 6 o'clock when gang condenser is fully meshed at maximum capacitance.

3. Set dial to calibration mark 1400 kc using hour hand to indicate frequency (no further attention need be paid to position of minute hand which is used merely for convenience in logging stations by "TIME"). Adjust broadcast oscillator trimmer condenser C16, for maximum output meter reading. If it is found that two peaks occur within the range of the trimmer action use the one in which the trimmer is in its lowest capacitance or counter-clockwise position.

4. Adjust detector input trimmer C8, to a maximum.

5. Adjust the antenna stage trimmer C4, to a maximum.

6. Set test oscillator to 600 kc and tune in the signal, then adjust broadcast oscillator padder C20, for maximum output. This padder is mounted under the chassis at the front of receiver. Rock the condenser back and forth a degree or two in order to obtain proper maximum.

7. Repeat the 1400 kc adjustments described under 3, 4, 5, for greater accuracy. The output of the test oscillator should always be kept at the lowest output which will allow sufficient meter swing since this assures greater accuracy of adjustment.

Short Wave "B" or "Green" Band

1. Turn the wave band switch to the "B" or "Green" position. Leave the oscillator connected as above but with its output set to 4000 kc and the .00025 Mfd. Condenser replaced by a 400 Ohm resistor. Set dial scale to 4 mc on the green band, adjust "B" band oscillator trimmer condenser C17, for maximum output observing as before that the proper point occurs at the minimum or counter-clockwise position of the screw if two points are found.

2. Adjust detector input "B" band trimmer condenser C9, to a maximum while rocking the tuning condenser slightly for maximum response.

3. Adjust antenna stage "B" band trimmer C5, for maximum output.

4. Set the test oscillator to 1600 kc and tune in the signal. Adjust "B" band oscillator padder condenser C21, for maximum output while rocking tuning condenser as described above.

5. Repeat operations 1, 2, 3, to assure precise alignment.

Short Wave "C" or "Yellow" Band

1. With test oscillator connected same as for "B" band and set to 9000 kc (9 mc) set dial scale to 9 mc on yellow band.

2. Adjust "C" band oscillator trimming condenser C18, for maximum response. Use lower capacity or counter-clockwise response point.

3. Adjust "C" band detector input trimmer C10, to a maximum, "rocking" tuning adjustment to obtain greatest output.

4. Adjust antenna "C" band trimmer C6, for maximum response.

5. Set test oscillator to 4000 kc (4 mc) and tune in the signal. Adjust "C" band padder condenser C22, for maximum output while rocking tuning condenser as described above.

6. Repeat operations 1, 2, 3, 4, to assure precise alignment.

Short Wave "D" or "Blue" Band

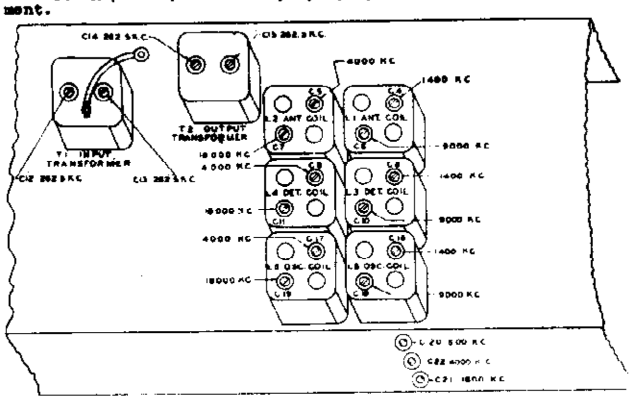
1. With test oscillator connected as for "B" and "C" bands and set to 18000 kc (18 mc) set dial scale to 18 mc on blue band.

2. Adjust "D" band oscillator trimmer C19, for maximum response. Use lower capacity or counter-clockwise response point.

3. Adjust "D" band detector input trimmer C11, to a maximum, "rocking" tuning adjustment to obtain greatest output.

4. Adjust "D" band antenna trimmer C7, for maximum response.

5. Repeat operations 1, 2, 3, 4, to assure precise alignment.



In checking the circuit with a continuity or ohmmeter it is wise to follow the schematic diagram in orderly fashion starting at the antenna and ground connections and proceeding to the speaker circuits.

In checking circuits connected to the electrolytic condensers it is necessary to observe the polarity of the leads of the continuity meter. Use the meter with the positive test terminal on the anode or plus side of the circuit. If the reverse connection is used the electrolytic condenser will become conductive and show a false low resistance reading.

The 10 kc Interchannel Beat Filter L7-C45 is a complete assembly in which the coil inductance is individually adjusted to tune with the condenser. In the event that either part should require replacement it will be necessary to order the complete assembly.

Excessive hum in this model has been found to be due to defective 6H6 and 6C5 tubes. Replace each tube in turn with one known to be normal.

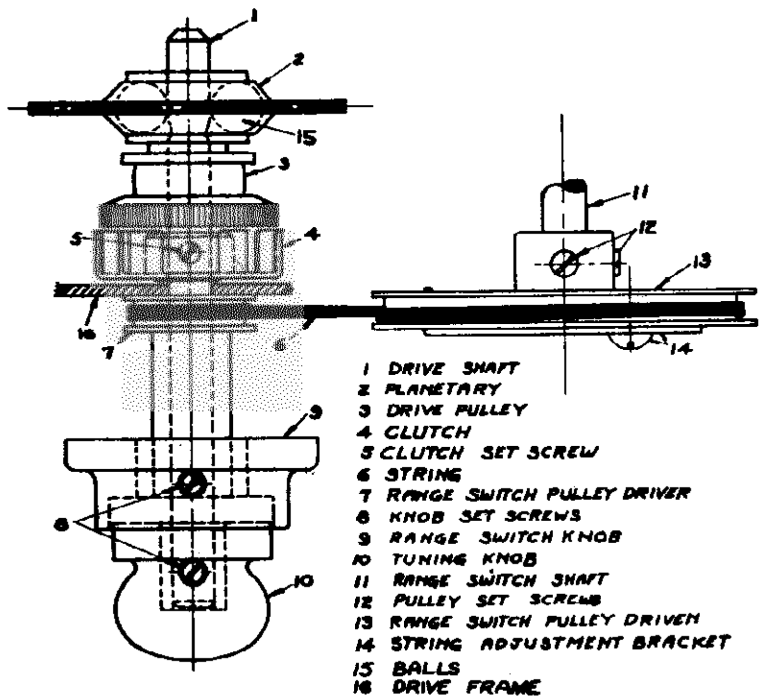
Planetary Drive Assembly, Notes

CASE ELECTRIC CORP.



THE DUAL SPEED PLANETARY DRIVE

In order to make the tuning of short wave broadcast easier, a dual speed drive is provided, giving a ratio of 96 to 1 with the knob, No. 10, in the "OUT" position which is exceptionally good for short wave tuning, a ratio of 16 to 1 is provided with the knob, No. 10, pushed "IN," used for standard broadcast tuning. You can use this drive knob in the position you like best.

The mechanism of this drive is of the planetary type, using ball bearings, No. 15, housed between cantiliver type spring housing, No. 2. When the drive knob, No. 10, is in "OUT" position, the balls, No. 15, operate direct on the drive shaft, No. 1, which gives a reduction in speed on the pointers. When the drive knob, No. 10, is at "IN" position the balls, No. 15, clear the drive shaft, No. 1, and a clutch, No. 4, contacts drive pulley, No. 3, and gives a direct drive on shaft, No. 1.

If drive should ever slip on the "IN" position you will likely find that set screws, No. 5, have become loose in clutch, No. 5. To reset clutch place shaft, No. 1, at "OUT" position. You can tell when it is at "OUT" position by the feel as just after the ball, No. 15, comes up the incline on the shaft, No. 1, it will locate in a very shallow groove on the shaft, No. 1, see that the clutch, No. 4, is against frame, No. 16, and then tighten set screws, No. 5, securely.

If the band switch knob, No. 9, appears to have excessive backlash, you will generally find that it was forced when the switch was at end of its rotation and the set screws, No. 12, are broken loose, tighten these screws and if backlash still appears, loosen screw and adjust bracket and screw, No. 14.

When placing knobs, No. 9 and No. 10, on shafts, be sure knob, No. 9, clears cabinet approximately 3/64 and tighten set screw, No. 8, securely. With shaft, No. 1, at the "IN" position place knob No. 10, on shaft No. 1, until it stops against knob No. 9, then pull to the front 3/64 inch and tighten set screw No. 8, securely.

CASE ELECTRIC CORPORATION--MARION, INDIANA-

SERVICE NOTES

In the event of failure of the receiver, time may often be saved by making a few preliminary checks before removal of the chassis and speaker from the cabinet.

1. Check the antenna and ground connections both at the receiver and also at all points where joints have been made. Noisy operation can often be traced to faults in antenna and ground installation especially when the receiver has been connected to an old antenna.

2. Check the tubes. If a reliable tube checking instrument is not at hand, secure a set of known good tubes and interchange the tubes in the receiver, one at a time, until the defective tube is located. Low sensitivity can often be traced to gas or grid current in an RF, first detector or IF tube. Hum is often due to heater-cathode shorts in any one of the tubes.

If the above checks do not disclose the reason for failure of the receiver remove the chassis and speaker from the cabinet and check the supply voltages as indicated on the chart. To assist in the location of the various tube prongs, the schematic diagram tube symbols have been so drawn as to represent the socket as viewed from the bottom of the chassis.

Hum, motorboating, low volume and low voltage may be due to shorted or defective electrolytic condensers.

Open bypass condensers often cause oscillation or distorted tone. To check for this condition, shunt each condenser with another of similar capacity and of the same voltage rating until the defective unit is located.

Shorted bypass condensers cause low voltage or weak reception. Remove suspected unit and replace by one of correct capacity and rating.

In checking circuits connected to the electrolytic condensers it is necessary to observe the polarity of the leads of the continuity meter. Use the meter with the positive test terminal on the anode or plus side of the circuit. If the reverse connection is used the electrolytic condenser will become conductive and show a false low resistance reading.

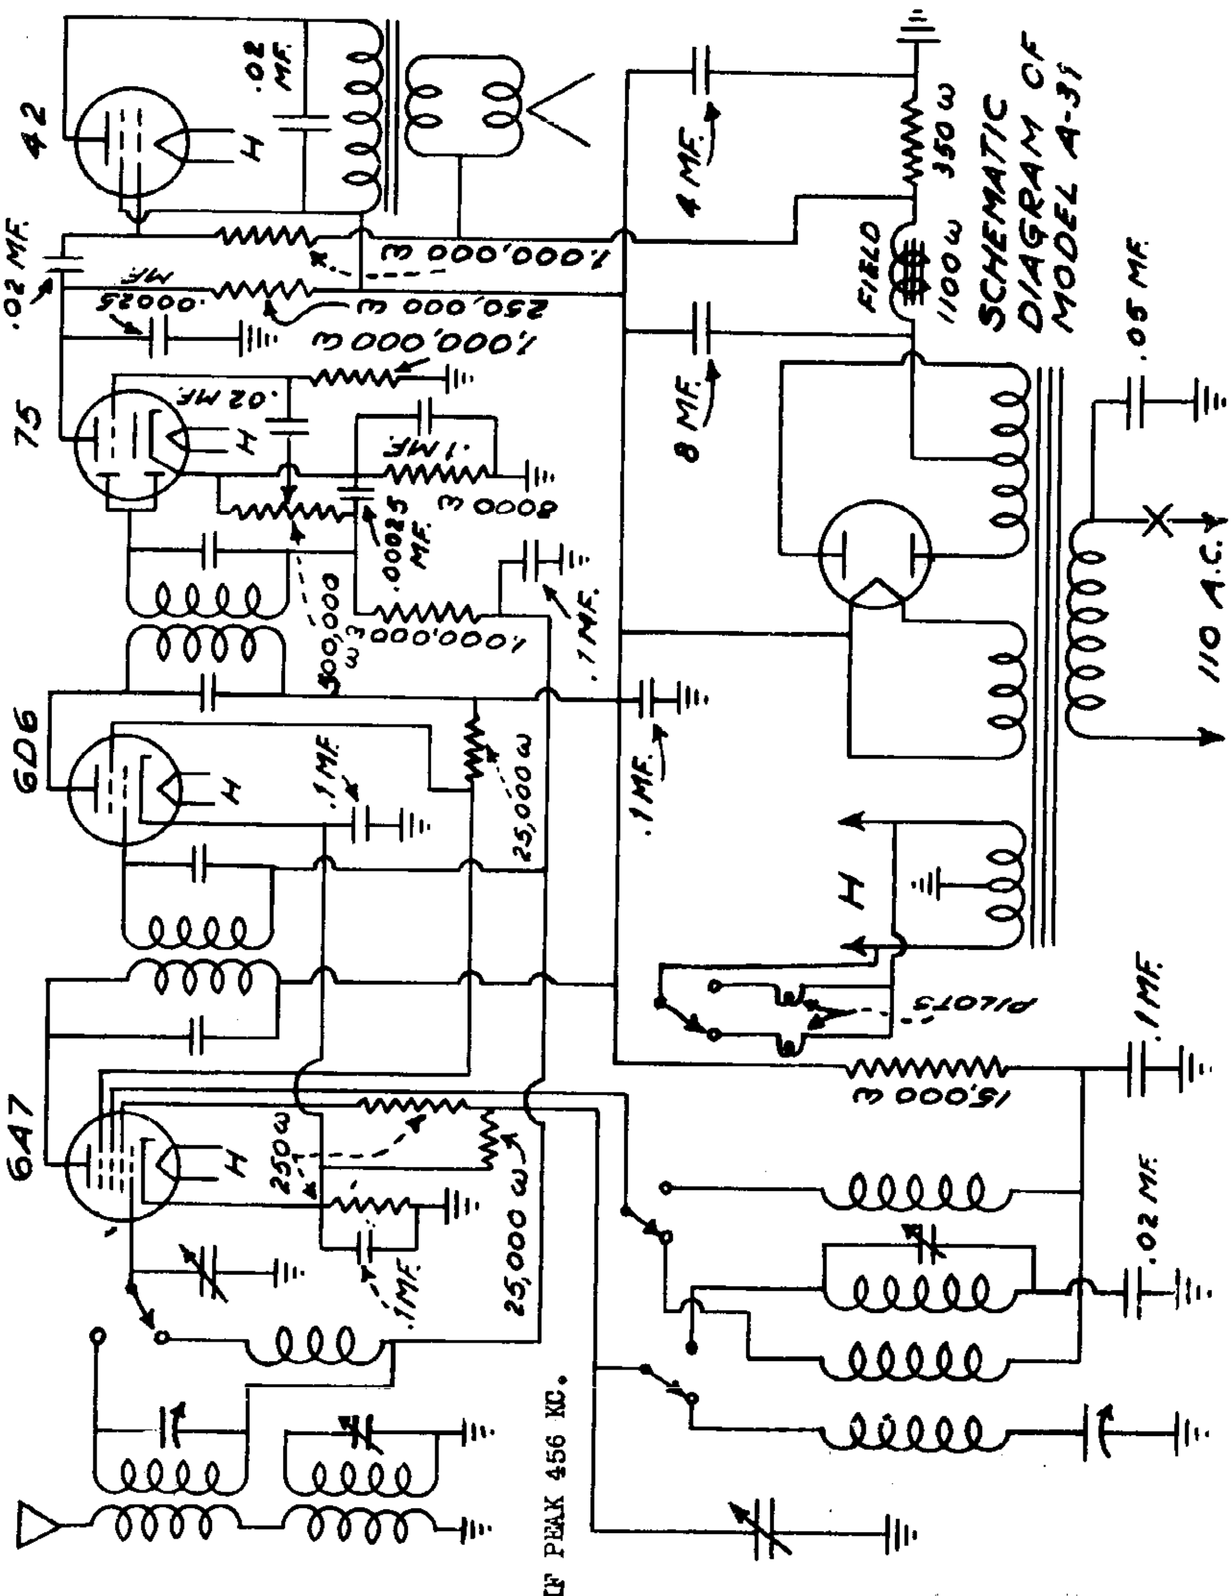
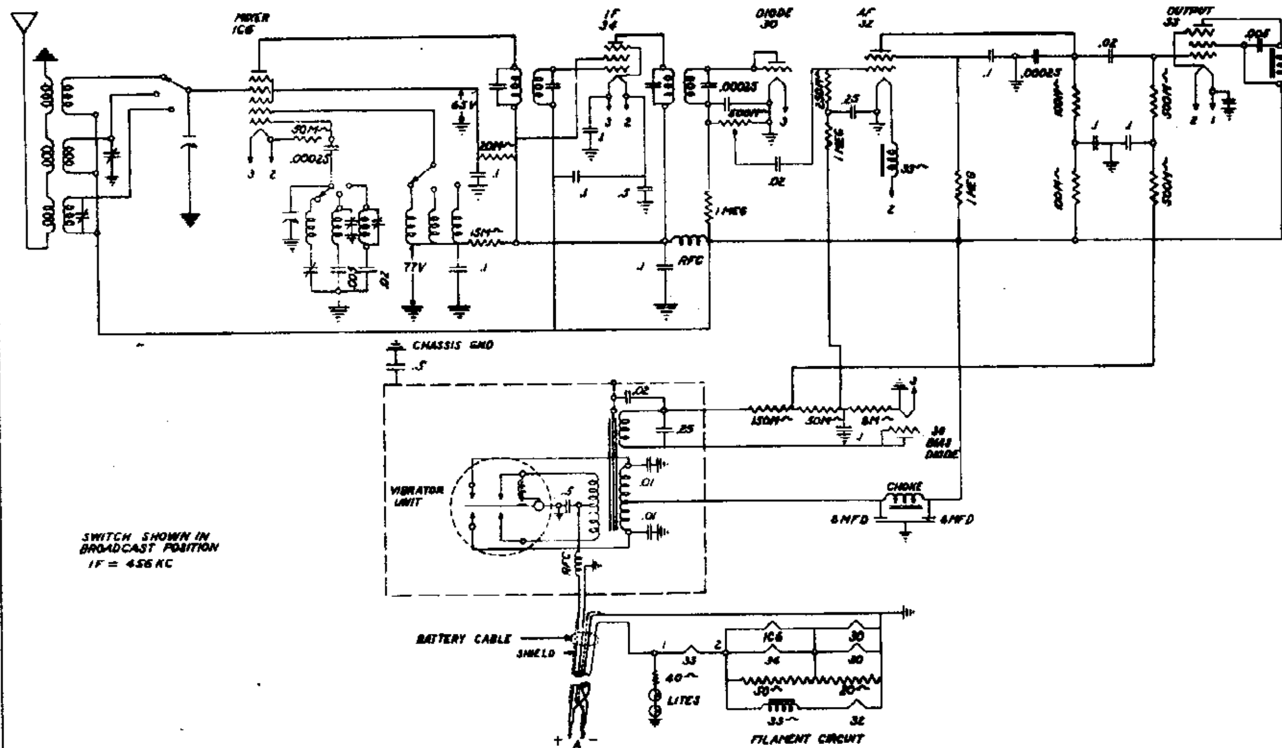
CONTINENTAL RADIO



MODELS X-641, X-741
Schematic, Alignment

CONTINENTAL RADIO & TELEV. CO.



ALIGNMENT DATA

The alignment of this receiver requires the use of a test oscillator that will cover the frequencies of 456, 600, 1400, 3000 and 10,000 K. C. and an output meter to be connected across the speaker terminals.

If possible all alignment should be made with the volume control on maximum and the test oscillator output as low as possible, to prevent the AVC from operating and giving false readings.

I.F. ALIGNMENT Adjust the test oscillator to 1400 K.C. and connect the output to the antenna wire through a .0001 mfd. mica condenser to give the equivalent of an antenna about 60 feet. Set the receiver pointer to 1400 K.C. and adjust the rear gang condenser trimmer to peak. This adjusts the receiver on scale. Then adjust the front or R.F. trimmer to peak.

Next rest the dial pointer on the receiver and test oscillator to 600 K.C. Slowly increase or decrease the oscillator padding condenser, and at the same time continuously tuning back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment seems a little complicated but is the easiest way to adjust the oscillator to the R.F. section. The padding condenser is located on the left hand end of the chassis.

Return to 1400 K.C. and again go over the adjustment at that frequency to be sure they have not been thrown out of adjustment.

SHORT WAVE BANDS

The foreign band of 19 to 49 meters can be adjusted by the two trimmers on the short wave coil located next to the gang condenser. Set the test oscillator to 10 megacycles or 31 meters.

The police and aviation band can be adjusted from a signal set at 3,000 K.C. or 300 on the dial. The oscillator trimmer is located underneath the chassis and the R.F. trimmer is between the 6A7 tube and the wave change switch.

The gang condenser trimmers are not to be used for alignment of either of the short wave bands.

CONTINENTAL RADIO

L5

Seven Tube A. C. All Wave Superheterodyne

This receiver is designed to operate over three tuning ranges: the broadcast range which extends from 540 to 1700 Kilocycles (KC) (175 to 550 meters), Police and Aviation Band which extends from 1700 to 5000 Kilocycles (KC) (52 to 175 Meters) and the International Short Wave Band which extends from 5800 to 15,200 Kilocycles (KC) (18.5 to 52 meters). This latter range is the one which includes the four internationally assigned bands—the 19, 25, 31 and 49 meter bands.

This receiver is designed to operate from a power supply main of 110-120 volts, 60 cycle alternating current (AC). **Never plug into a DC outlet.**

ALIGNMENT DATA AND SERVICING

GENERAL DATA The alignment of this receiver requires the use of a test oscillator that will cover the frequencies of 456, 600, 1400, 1800, 4000, 6000, and 14,000 KC and an output meter to be connected across the primary or secondary of the output transformers. If possible, all alignment should be made with the volume control on maximum and the test oscillator output as low as possible, to prevent the AVC from operating and giving false readings.

CORRECT ALIGNMENT PROCEDURE The intermediate frequency (I.F.) stage should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the Broadcast Band should always be the next procedure; after which, either or both of the Short Wave Bands may be aligned.

I.F. ALIGNMENT Adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tubes (6L7) through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the chassis ground. Align all six I.F. trimmers to peak or maximum reading on the output meter.

BROADCAST BAND ALIGNMENT Adjust the oscillator to 1400 KC and connect the output to the antenna post marked "A" through a .0001 mfd. mica condenser to give the equivalent of an antenna about 60 feet. Set the receiver pointer to 1400 KC and adjust the oscillator trimmer to peak. This trimmer is mounted on the oscillator coil and is located directly under the 6C5 socket. (This adjustment must be made from the bottom of the chassis.) After this has been carefully done, the next step is to adjust the center and rear trimmers of the gang condenser to peak. The center gang section tunes the R.F. or grid coil of the 6L7 tube and the rear condenser section tunes the pre-selector stage circuit.

Next, re-set the dial pointer on the receiver and the test oscillator to 600 KC. Slowly increase or decrease the oscillator padding condenser and at the same time continuously tune back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment seems a little complicated but is the easiest way to adjust the oscillator to the pre-selector or R.F. section. The padding condenser is located in the left end of the chassis. Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 600 KC.

If it is found that in returning to 1400 KC the pointer is accurately on scale, the only readjustments that should be made (in this recheck) are the center and rear trimmers of the gang condenser. If the pointer is found off scale, it may be corrected and put on scale by realignment of the oscillator trimmer. Alignment of the pointer can only be corrected by adjustment of the oscillator trimmer.

This completes the correct sequence of operations in properly aligning the receiver for the Broadcast Band, and **must always be done before** attempting to align the Short Wave Bands.

FOREIGN BAND The Foreign Band of 19 to 49 meters can be adjusted by the two trimmers located on the top of the chassis. The R.F. trimmer is located directly on top of the R.F. or Antenna coil and the oscillator trimmer is mounted on the chassis near the front of the oscillator coil. Set the test oscillator to 14,000 KC. In preparing the test oscillator for alignment of this band, connect a 400 ohm carbon resistor in series with the .0001 mfd. condenser on the output lead of the test oscillator. This resistor is used with the test oscillator only on the Short Wave Bands and should not be used for Broadcast Band alignment. The next operation is to adjust the R.F. and oscillator trimmers for peak at 14,000 KC and as the inherent design of the circuit has been expressly engineered for simplicity in servicing, no other adjustments are necessary for aligning this band.

Note: In order to prevent alignment on the image frequency, it is suggested that alignment be started with the antenna coil trimmer screwed down tightly. To check this adjustment, readjust the pointer to 13100 KC where the image frequency should be found. If properly aligned, the image frequency will be found to be weaker. If, however, the signal at 13100 KC is found to be stronger than the signal at 14000 KC, it signifies that alignment was incorrectly made on the image frequency.

Important: Do not attempt any adjustment of the gang condenser trimmers in aligning the Foreign Band as this will throw the Broadcast Band out of alignment.

POLICE BAND In preparing the test oscillator for alignment of this band, connect a 400 ohm carbon resistor in series with a .0001 mfd. condenser on the output lead of the test oscillator. This resistor is used with the test oscillator only on the Short Wave Bands and should not be used for Broadcast Band alignment.

Set the receiver pointer to 4000 KC (also test oscillator) and adjust the oscillator circuit trimmer to peak.

The oscillator trimmer is mounted on the oscillator coil, which is located underneath the chassis. The oscillator coil is wound with enamel wire and is mounted to the front edge of the chassis. After this has been carefully done, the next step is to adjust the antenna trimmer to peak. The antenna trimmer is attached to the antenna coil; also mounted underneath the chassis and wound with enamel wire. The antenna coil is located nearest the power transformer.

Now reset the dial pointer and the test oscillator to 1800 KC in preparation for adjusting the police band padding condenser. This padding condenser is mounted on the underside of the chassis, directly underneath the gang condenser. Slowly increase or decrease the oscillator padding condenser and at the same time continuously tune back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment seems a little complicated, but is the easiest way to correctly adjust the oscillator to the R.F. or antenna section.

Return to 4000 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made 1800 KC.

If it is found that in returning to 4000 KC the pointer is accurately on scale, the only readjustment that should be made (in this recheck) is the trimmer on the enamel wire antenna coil located underneath the chassis near the power transformer. If the pointer is found off scale, it may be corrected and put on scale by readjustment of the oscillator trimmer. Alignment of the pointer can only be corrected by adjustment of the oscillator trimmer.

Important: There are only three trimmer adjustments necessary for the Police Band. Do not attempt any adjustment of the gang condenser trimmers in aligning the Police Band; otherwise, the Broadcast Band will be thrown out of alignment.

SERVICE DATA FOR ALL BANDS

If it is suspected that the oscillator has stopped but is doubtful due to the presence of the usual amount of noise level, it is suggested that the oscillator plate voltage be checked. An approximate normal minimum oscillating voltage for the plate of the 6C5 (oscillator tube) at 115 volt line potential is as follows:

Broadcast Band	600 KC	124 Volts
	1400 KC	106 Volts
Foreign Band	6000 KC	137 Volts
	14000 KC	140 Volts
Police Band	1700 KC	128 Volts
	4000 KC	110 Volts

Another way of ascertaining whether the tube is oscillating is to ground the grid of the 6C5. If oscillating properly, grounding the grid will cause an appreciable drop in oscillator voltage.

Provisions have been made in this receiver for all types of antennas.

REGULAR ANTENNA Use a standard outside antenna of at least 50 feet including lead-in. Connect to antenna post marked **"A."**

In remote locations that are far away from powerful broadcasting stations, a longer antenna may be used for increased receiving range. Antennas as long as 150 to 200 feet may be employed in "dead spots." (Longer antennas increase sensitivity and decrease selectivity slightly.)

This receiver is designed to operate over three tuning ranges. The broadcast range which extends from 540 to 1700 Kilocycles (KC) (175 to 550 meters), Police and Aviation Band which extends from 1700 to 5000 Kilocycles (KC) (52 to 175 Meters) and the International Short Wave Band which extends from 5800 to 15,200 Kilocycles (KC) (18.5 to 52 meters). This short wave range is the one which includes the four internationally assigned bands—the 19, 25, 31 and 49 meter bands.

ALIGNMENT DATA AND SERVICING

GENERAL DATA The alignment of this receiver requires the use of a test oscillator that will cover the frequencies of 456, 600, 1400, 1800, 4000, 6000, and 14,000 KC and an output meter to be connected across the primary or secondary of the output transformers. If possible, all alignment should be made with the volume control on maximum and the test oscillator output as low as possible, to prevent the AVC from operating and giving false readings.

CORRECT ALIGNMENT PROCEDURE The intermediate frequency (I.F.) stage should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the Broadcast Band should always be the next procedure; after which, either or both of the Short Wave Bands may be aligned.

I.F. ALIGNMENT Adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tubes (6L7) through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the chassis ground. Align all six I.F. trimmers to peak or maximum reading on the output meter.

BROADCAST BAND ALIGNMENT Adjust the oscillator to 1400 KC and connect the output to the antenna post marked "A" through a .0001 mfd. mica condenser to give the equivalent of an antenna about 60 feet. Set the receiver pointer to 1400 KC and adjust the oscillator trimmer to peak. This trimmer is mounted on the oscillator coil and is located directly under the 6C5 socket. (This adjustment must be made from the bottom of the chassis.) After this has been carefully done, the next step is to adjust the center and rear trimmers of the gang condenser to peak. The center gang section tunes the R.F. or grid coil of the 6L7 tube and the rear condenser section tunes the pre-selector stage circuit.

Next, re-set the dial pointer on the receiver and the test oscillator to 600 KC. Slowly increase or decrease the oscillator padding condenser and at the same time continuously tune back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment seems a little complicated but is the easiest way to adjust the oscillator to the pre-selector or R.F. section. The padding condenser is located in the left end of the chassis. Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 600 KC.

This receiver is designed to operate from a power supply main of 110-120 volts, 60 cycle alternating current (AC). Never plug into a DC outlet.

If it is found that in returning to 1400 KC the pointer is accurately on scale, the only readjustments that should be made (in this recheck) are the center and rear trimmers of the gang condenser. If the pointer is found off scale, it may be corrected and put on scale by realignment of the oscillator trimmer. Alignment of the pointer can **only** be corrected by adjustment of the oscillator trimmer.

This completes the correct sequence of operations in properly aligning the receiver for the Broadcast Band, and **must always be done before** attempting to align the Short Wave Bands.

FOREIGN BAND The Foreign Band of 19 to 49 meters can be adjusted by the two trimmers located on the top of the chassis. The R.F. trimmer is located directly on top of the R.F. or Antenna coil and the oscillator trimmer is mounted on the chassis near the front of the oscillator coil. Set the test oscillator to 14,000 KC. In preparing the test oscillator for alignment of this band, connect a 400 ohm carbon resistor in series with the .0001 mfd. condenser on the output lead of the test oscillator. This resistor is used with the test oscillator only on the Short Wave Bands and should not be used for Broadcast Band alignment. The next operation is to adjust the R.F. and oscillator trimmers for peak at 14,000 KC and as the inherent design of the circuit has been expressly engineered for simplicity in servicing, no other adjustments are necessary for aligning this band.

Note: In order to prevent alignment on the image frequency, it is suggested that alignment be started with the antenna coil trimmer screwed down tightly. To check this adjustment, readjust the pointer to 13100 KC where the image frequency should be found. If properly aligned, the image frequency will be found to be weaker. If, however, the signal at 13100 KC is found to be stronger than the signal at 14000 KC, it signifies that alignment was incorrectly made on the image frequency.

Important: Do not attempt any adjustment of the gang condenser trimmers in aligning the Foreign Band as this will throw the Broadcast Band out of alignment.

POLICE BAND In preparing the test oscillator for alignment of this band, connect a 400 ohm carbon resistor in series with a .0001 mfd. condenser on the output lead of the test oscillator. This resistor is used with the test oscillator only on the Short Wave Bands and should not be used for Broadcast Band alignment.

Set the receiver pointer to 4000 KC (also test oscillator) and adjust the oscillator circuit trimmer to peak. The oscillator trimmer is mounted on the oscillator coil, which is located underneath the chassis. The oscillator coil is wound with enamel wire and is mounted to the front edge of the chassis. After this has been carefully done, the next step is to adjust the antenna trimmer to peak. The antenna trimmer is attached to the antenna coil; also mounted underneath the chassis and wound with enamel wire. The antenna coil is located nearest the power transformer. Now reset the dial pointer and the test oscillator to 1800 KC in preparation for adjusting the police band padding condenser. This padding condenser is mounted on the underside of the chassis, directly underneath the gang condenser. Slowly increase or decrease the oscillator padding condenser and at the same time continuously tune back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment seems a little complicated, but is the easiest way to correctly adjust the oscillator to the R.F. or antenna section.

Return to 4000 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made 1800 KC.

If it is found that in returning to 4000 KC the pointer is accurately on scale, the only readjustment that should be made (in this recheck) is the trimmer on the enamel wire antenna coil located underneath the chassis near the power transformer. If the pointer is found off scale, it may be corrected and put on scale by readjustment of the oscillator trimmer. Alignment of the pointer can only be corrected by adjustment of the oscillator trimmer.

Important: There are only three trimmer adjustments necessary for the Police Band. Do not attempt any adjustment of the gang condenser trimmers in aligning the Police Band; otherwise, the Broadcast Band will be thrown out of alignment.

SERVICE DATA FOR ALL BANDS

If it is suspected that the oscillator has stopped but is doubtful due to the presence of the usual amount of noise level, it is suggested that the oscillator plate voltage be checked. An approximate normal minimum oscillating voltage for the plate of the 6C5 (oscillator tube) at 115 volt line potential is as follows:

Broadcast Band	600 KC	125 Volts
	1400 KC	100 Volts
Foreign Band	6000 KC	135 Volts
	14000 KC	140 Volts
Police Band	1700 KC	135 Volts
	4000 KC	110 Volts

Another way of ascertaining whether the tube is oscillating is to ground the grid of the 6C5. If oscillating properly, grounding the grid will cause an appreciable drop in oscillator voltage.

ANTENNA

Provisions have been made in this receiver for all types of antennas.

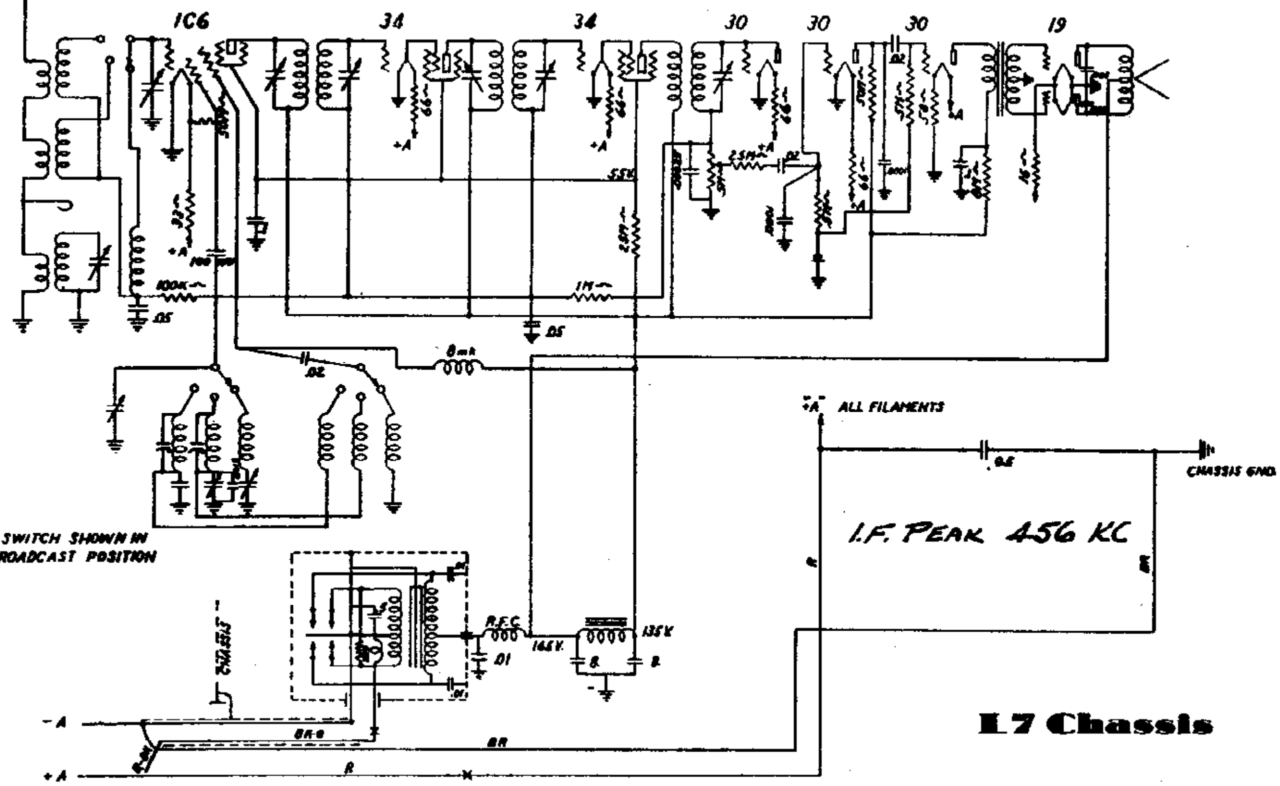
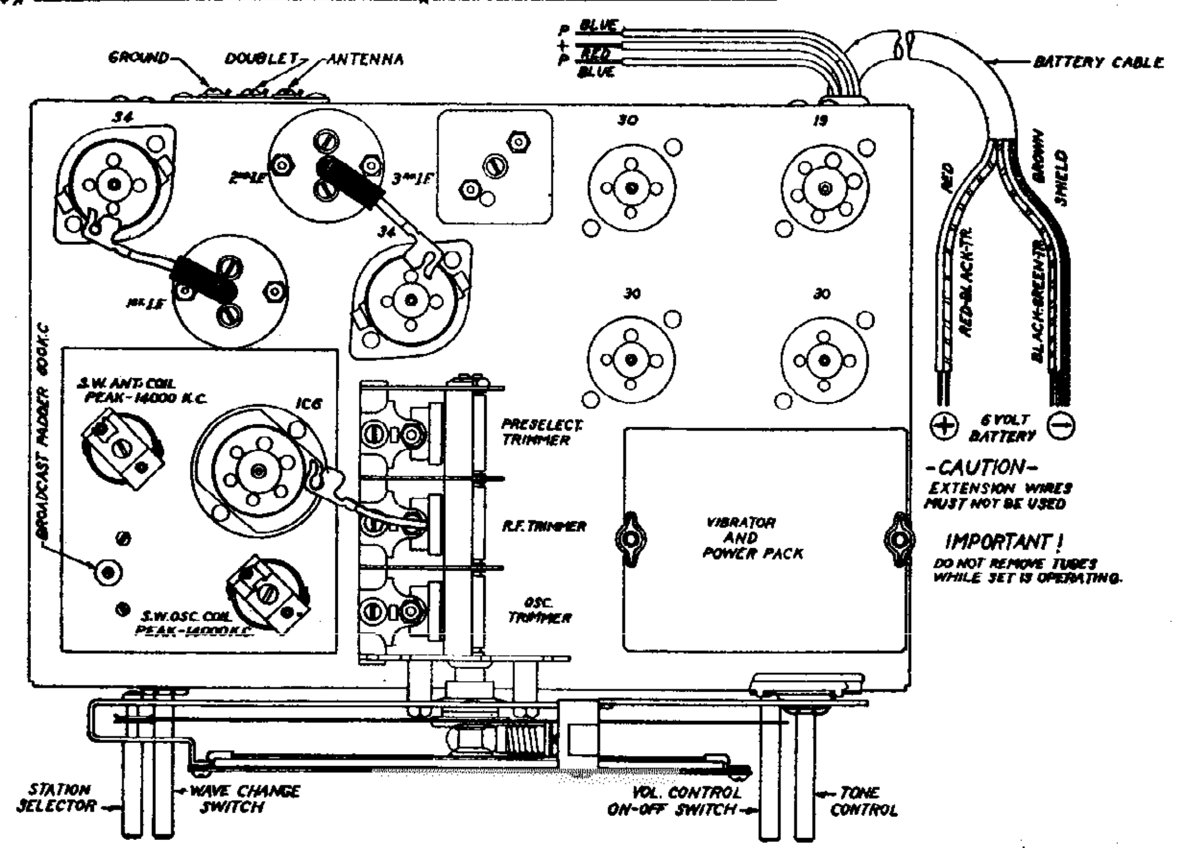
CONTINENTAL RADIO

Seven Tube 6 Volt Battery All Wave Superheterodyne



L 7 Chassis



CONTINENTAL RADIO

L7

Seven Tube 6 Volt Battery All Wave Superheterodyne

This receiver is designed to operate over three tuning ranges: the broadcast range which extends from 540 to 1700 Kilocycles (KC) (175 to 550 meters), Police and Aviation Band which extends from 1700 to 5000 Kilocycles (KC) (52 to 175 Meters) and the International Short Wave Band which extends from 5800 to 15,200 Kilocycles (KC) (18.5 to 52 meters). This latter range is the one which includes the four internationally assigned bands—the 19, 25, 31 and 49 meter bands.

ALIGNMENT DATA AND SERVICING

GENERAL DATA

The alignment of **this receiver requires the use of a test oscillator which will cover the** frequencies of 456, 600, 1400, 1800, 4000, 6000, and 14,000 KC and an output **meter which is to be connected across the primary or secondary** of the output **transformer. If possible, all alignments should be** made **with the volume control on maximum** and the **test oscillator output as low as possible,** to prevent the AVC from operating and giving **false readings.**

CORRECT ALIGNMENT PROCEDURE

The intermediate frequency **(I.F.) stages should be aligned properly as the first step. After the I.F. transformers have been** properly adjusted and **peaked,** the **Broadcast Band should always** be the next procedure; **after which,** either or both of the Short Wave Bands may **be aligned.**

I.F. ALIGNMENT

Adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tube (1C6) through a .05 or .1 mfd. **condenser.** The ground on the test oscillator **can be connected to the chassis ground.** Align all five I.F. trimmers to **peak or maximum** reading on the output meter. **As there are two stages of I.F. in this receiver,** there will be consequently **three I.F. transformers to align.** The I.F. transformer **nearest the type (30) diode detector has only one trimmer,** (single **tuned) and should be the first adjustment. Next** adjust the center **I.F. transformer,** which has two trimmers (double tuned) for **maximum** output; **then adjust the two trimmers on the input** I.F. transformer (double tuned) for **peak.**

BROADCAST BAND ALIGNMENT

Adjust the oscillator to 1400 KC and connect **the output** to the antenna **post marked "A"** through a .0001 mfd. **mica condenser** to give the **equivalent** of an antenna **about 60 feet. Set the receiver pointer** to 1400 **KC** and **adjust** the front **gang condenser** trimmer (oscillator circuit) to **peak. After this has been carefully done, the next step is** to adjust the **center trimmer** of the **gang condenser to peak. The center** condenser **section tunes the** RF or grid circuit of the 1C6 **tube. Next, re-set the dial pointer** on the receiver and the test oscillator to 600 KC. **Slowly** increase or decrease the oscillator **padding** condenser and at the same time continuously tune back and forth **across** the **signal with** the receiver until the maximum **reading is obtained** on the output **meter.** This adjustment **may seem** a **little complicated but is the easiest** way to **adjust** the oscillator to the R.F. **section. The padding** condenser is located on the left hand **side of** the chassis, near the extreme front **left corner.**

Return to 1400 KC and again go **over the adjustments** of this frequency to be certain that **they** were not put **slightly** out of alignment when adjustment was made at 600 KC.

This completes the correct **sequence** of **operations** in properly aligning the receiver for the Broadcast Band, and **must always be done before** attempting to align the Short Wave **Bands.**

FOREIGN BAND ALIGNMENT

The Foreign **Band** of 19 to 49 **meters can be adjusted by the** two trimmers on the short **wave coils located** on the top of the chassis. In preparing the **test oscillator** for **alignment** of this band, connect a 400 **ohm carbon resistor** in **series** with the .0001 mfd. condenser on the output **lead** of the **test oscillator. Set the** receiver pointer to 14,000 KC (also test oscillator). The oscillator coil is located alongside the **oscillator section** of the tuning **condenser** (front section of gang), and the antenna or R.F. **is** the other coil remaining on top of **the chassis. These** two trimmers should be adjusted for **peak** at **14,000 KC** (adjust oscillator trimmer first) and as the inherent design of the circuit has been **expressly** developed for **simplicity in servicing,** no other **adjustments are necessary** for **aligning this band.**

Note: Always **start** this procedure by having the **oscillator** coil **trimmer loose** (out all the way), and the antenna coil trimmer **fairly tight (in all the way); otherwise it is possible** to make a **false alignment on the image frequency. In order to prevent alignment on the image frequency,** it **is suggested** that the following **check be made: Readjust the pointer** to 13,100 KC where the image **frequency should be found. If properly aligned,** the image **frequency will** be found **to be weaker. If, however,** the signal at 13,100 KC **is found to be stronger than the signal** at 14,000 KC, it **signifies** that **alignment was incorrectly** made on the image **frequency.**

IMPORTANT: Do not attempt any **adjustment** of the gang condenser **trimmers in aligning** the Foreign **Band** as this will throw the Broadcast Band **out of alignment.**

POLICE BAND

In **preparing the test oscillator for alignment of this band, connect a 400 ohm carbon resistor in series with a .0001** mfd. condenser on the **output lead of** the test oscillator. This **resistor is used with the test oscillator only** on the Short **Wave Bands and should** not be **used for Broadcast Band alignment.**

Set the receiver pointer to 4000 KC (also test **oscillator) and adjust the oscillator circuit trimmer to peak.** The **oscillator trimmer is mounted** on the **oscillator** coil, **which is** located **underneath the chassis. The oscillator coil is wound with enamel wire and is mounted** to the **front edge of the chassis. This coil can be identified by the use of a layer of yellow cambric** (Empire Cloth) **separating the two windings. After this has been carefully** done, **the next step is to adjust the antenna trimmer to peak.** The antenna **trimmer is attached to the antenna coil; also mounted** underneath the **chassis and wound with enamel wire.** The antenna **coil is mounted at right angles to the oscillator coil and is nearest to the rear of the chassis.**

Now reset the dial pointer and the test oscillator to 1800 KC in preparation for adjusting the police band padding condenser. **This padding condenser is mounted on the underside of the chassis, directly underneath the gang condenser. Slowly** increase or decrease **the oscillator padding condenser** and at the same time **continuously** tune **back and forth across the signal** with the receiver **until the maximum reading is obtained** on the output meter. **This adjustment may seem a little complicated,** but is the **easiest way to correctly adjust** the oscillator to the R.F. or antenna **section. Return to 4000 KC and again** go over the adjustments of this frequency **to be certain** that **they** were not put **slightly** out of alignment **when adjustment was made** 1800 KC.

If it is found that in **returning** to 4000 KC **the pointer is accurately** on scale, the **only readjustment that should be** made (in this recheck) **is the trimmer** on the **enamel wire** antenna coil located underneath the **chassis** near the **power** transformer. If the pointer is found off **scale, it may be** corrected and **put on scale by readjustment** of the **oscillator** trimmer. **Alignment of the pointer can only be** corrected by adjustment of the **oscillator** trimmer.

Important: There are only three trimmer adjustments **necessary** for the Police Band. Do not attempt any adjustment of the gang condenser **trimmers** in aligning the Police Band; **otherwise, the** Broadcast Band **will be** thrown out of alignment.

SERVICE DATA FOR ALL BANDS

If it is **suspected** that the oscillator has stopped but is doubtful due to the **presence** of the usual amount of noise level, it is **suggested that the oscillator** plate **voltage be** checked. To ascertain **whether the tube** is oscillating, ground the oscillator grid of the 1C6 (**short stator** and rotor **plates of** oscillator section on **gang condenser**). **If oscillating properly,** grounding the grid will **cause an appreciable drop in oscillator voltage.**

BATTERY SELECTION

This receiver is designed to operate entirely from a 6 volt storage battery. It requires no other batteries. It will operate from any storage battery having a capacity ranging from 90 to 175 ampere hours. It is suggested, for the sake of greatest economy, that the largest possible capacity battery be used. The following is a schedule giving the number of hours of service on a single charge from batteries of standard capacities. A fully charged battery will provide satisfactory power for the periods specified before requiring additional charge.

90 Ampere Hour Capacity provides **50** to **53** hours use.
100 Ampere Hour Capacity provides **55** to **60** hours use.
110 Ampere Hour Capacity provides **60** to **65** hours use.
120 Ampere Hour Capacity provides **65** to **70** hours use.
150 Ampere Hour Capacity provides **80** to **88** hours use.
170 Ampere Hour Capacity provides **90** to **100** hours use.

Note: The above tabulation is rated very conservatively and in most cases, with new or correctly rated batteries in good condition, many additional hours of service can be obtained from each charge. If, for any reason, the proper hours of service are not obtained, it will be due to the use of an old battery whose condition and rating are no longer up to standard. If a brand new battery fails to give the required hours of service, it is due to the battery being wrongly rated, or defective.

BATTERY CONNECTIONS

At the rear of the receiver there will be found extending from the left end of the chassis, the battery connecting cable. Observation will show that 5 wires are brought out from the braided cable. The **red** and **red with black tracer** wires are joined together and should **both** be securely fastened to the positive (+) terminal of the 6 volt storage battery. The other 3 wires which are **brown, black with green tracer** and **Metallic shield lead** are also joined together and should be securely connected to the negative (—) post of the battery.

WINDCHARGERS

There are many types of windchargers now on the **market which may be** used to advantage for greater economy of **receiver operation.** Such chargers will pay for themselves over a **period of time;** by **saving** the cost of battery recharging; removing the **inconvenience** of taking the battery to a charging station; **non-operation** of the receiver during the charging period.

IMPORTANT NOTE: The battery must never be charged while set is in operation. If a windcharger is used, it should always be disconnected from the battery when the receiver is being used. An inexpensive single pole switch can be used for disconnecting the windcharger from the battery. This will increase the life of the tubes and give additional economy to the use of the receiver. This precaution applies also to gasoline power chargers.

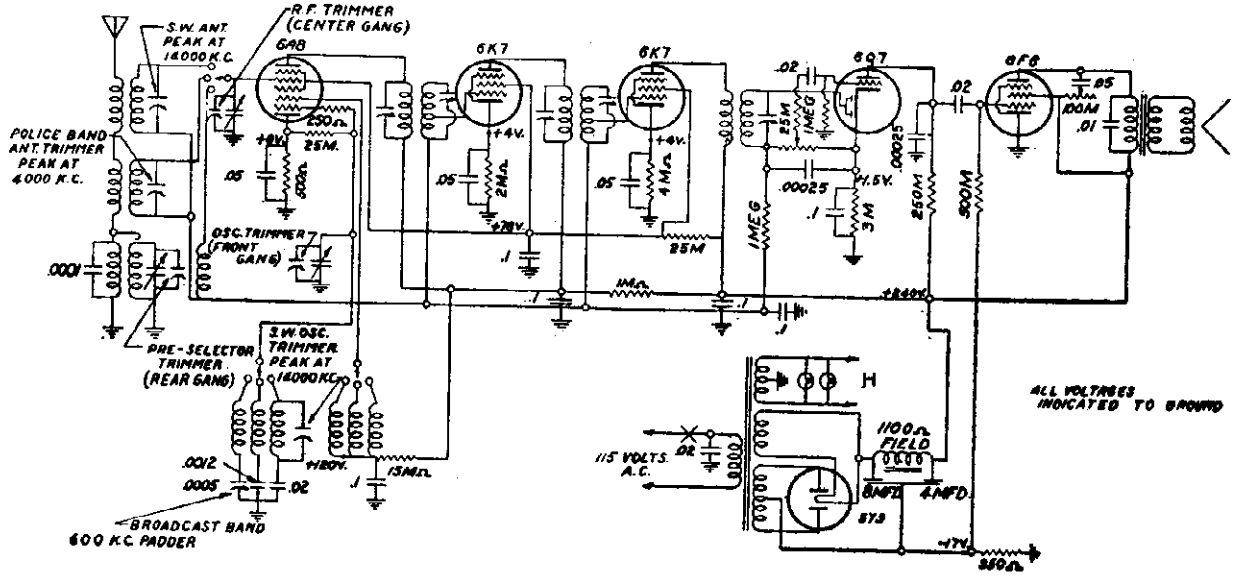
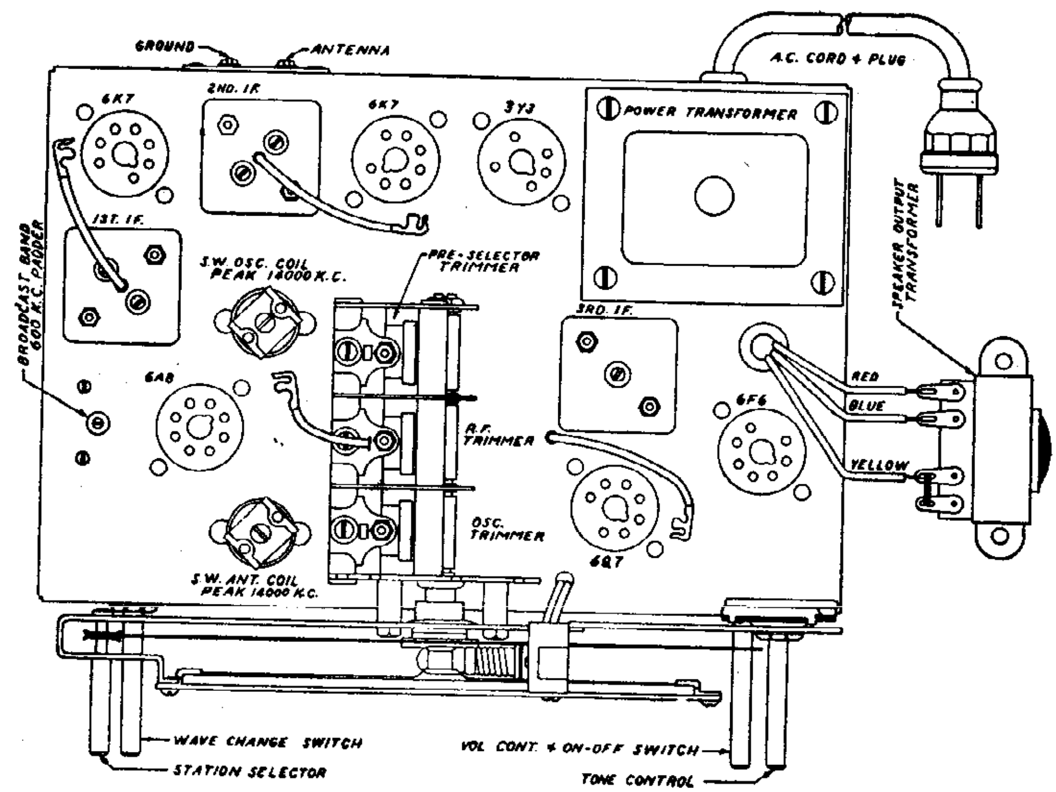
CONTINENTAL RADIO



Six Tube A. C. All Wave Superheterodyne
M1 Chassis



CONTINENTAL RADIO

M1

Six Tube A. C. All Wave Superheterodyne

This receiver is designed to operate over three tuning ranges. The broadcast range which extends from 540 to 1700 Kilocycles (KC) (175 to 550 meters), Police and Aviation Band which extends from 1700 to 5000 Kilocycles (KC) (52 to 175 Meters) and the International Short Wave Band which extends from 5800 to 15,200 Kilocycles (KC) (18.5 to 52 meters). This short wave range is the one which includes the four internationally assigned bands—the 19, 25, 31 and 49 meter bands.

ALIGNMENT DATA AND SERVICING

I.F. ALIGNMENT Adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tubes (6A7) through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the chassis ground. Align all five I.F. trimmers, of the three I.F. transformers, to peak or maximum reading on the output meter.

BROADCAST BAND ALIGNMENT Adjust the oscillator to 1400 KC and connect the output to the antenna post marked "A" through a .0001 mfd. mica condenser to give the equivalent of an antenna about 60 feet. Set the receiver pointer to 1400 KC and adjust the front gang condenser trimmer (oscillator circuit) to peak. After this has been carefully done, the next step is to adjust the center and rear trimmers of the gang condenser to peak. The center gang section tunes the R.F. or grid coil of the 6A8 tube and the front condenser section tunes the pre-selector stage circuit.

Next, re-set the dial pointer on the receiver and the test oscillator to 600 KC. Slowly increase or decrease the oscillator padding condenser and at the same time continuously tune back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment seems a little complicated but is the easiest way to adjust the oscillator to the pre-selector or R.F. section. The padding condenser is located on the left hand side of the chassis, directly to the left of the 6A7 tube and in front of the first I.F. transformer.

Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 600 KC.

This completes the correct sequence of operations in properly aligning the receiver for the Broadcast Band, and **must always be done before** attempting to align the Short Wave Bands.

FOREIGN BAND The Foreign Band of 19 to 49 meters can be adjusted by the two trimmers on the short wave coil located on the top of the chassis. Set the test oscillator to 14,000 KC. The oscillator coil is located near the 1st I.F. Transformer and the antenna or R.F. coil is located directly in front of the Short Wave oscillator coil and about midway between the 1st I.F. Transformer and the 6A7 tube. These two trimmers should be adjusted for peak at 14,000 KC and as the inherent design of the circuit has been expressly designed for simplicity in servicing, no other adjustments are necessary for aligning this band. **Note:** Always start this procedure by having the oscillator coil trimmer loose (out all the way), and the antenna coil trimmer fairly tight (in all the way); otherwise it is possible to make a false alignment on the image frequency.

Important: Do not attempt any adjustment of the gang condenser trimmers in aligning the Foreign Band as this will throw the Broadcast Band out of alignment.

POLICE BAND There is only one adjustment to be made in the alignment of the Police Band. Due to the circuit design and correct matching of the coils, no oscillator adjustment is necessary.

Set the dial pointer to 4000 KC (also the test oscillator) and adjust the antenna coil trimmer to resonance. In preparing the test oscillator for alignment of this band, connect a 400 ohm carbon resistor in series with the .0001 mfd. condenser on the output lead of the test oscillator. This resistor is used with the test oscillator only on the Short Wave Bands and should not be used for Broadcast Band alignment. The two police band coils are under the chassis and the antenna coil trimmer is mounted on the end of the antenna coil.

Important: This is the only adjustment necessary for the Police Band. Do not attempt any adjustment of the gang condenser trimmers in aligning the Police Band, otherwise the Broadcast Band will be thrown out of alignment.

SERVICE DATA FOR ALL BANDS

If it is suspected that the oscillator has stopped but is doubtful due to the presence of the usual amount of noise level, it is suggested that the oscillator plate voltage be checked. To ascertain whether the tube is oscillating, ground the oscillator grid of the 6A8 (short stator and rotor plates of oscillator section on gang condenser). If oscillating properly, grounding the grid will cause an appreciable drop in oscillator voltage.

This receiver is designed to operate from a power supply main of 110-120 volts, 60 cycle alternating current (AC). **Never plug into a DC outlet.**

GENERAL DATA The alignment of this receiver requires the use of a test oscillator that will cover the frequencies of 456, 600, 1400, 1800, 4000, 6000, and 14,000 KC and an output meter to be connected across the primary or secondary of the output transformers. If possible, all alignments should be made with the volume control on maximum and the test oscillator output as low as possible, to prevent the AVC from operating and giving false readings.

CORRECT ALIGNMENT PROCEDURE The intermediate frequency (I.F.) stage should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the Broadcast Band should always be the next procedure; after which, either or both of the Short Wave Bands may be aligned.

This receiver is designed to operate over three tuning ranges. The broadcast range which extends from 540 to 1700 Kilocycles (KC) (175 to 550 meters), Police and Aviation Band which extends from 1700 to 5000 Kilocycles (KC) (52 to 175 Meters) and the International Short Wave Band which extends from 5800 to 15,200 Kilocycles (KC) (18.5 to 52 meters). This short wave range is the one which includes the four internationally assigned bands—the 19, 25, 31 and 49 meter bands.

ALIGNMENT DATA AND SERVICING

BROADCAST BAND ALIGNMENT Adjust the oscillator to 1400 KC and connect the output to the antenna post marked "A" through a .0001 mfd. mica condenser to give the equivalent of an antenna about 60 feet. Set the receiver pointer to 1400 KC and adjust the rear gang condenser trimmer (oscillator circuit) to peak. After this has been carefully done, the next step is to adjust the center and front trimmers of the gang condenser to peak. The center gang section tunes the R.F. or grid coil of the 6A7 tube and the front condenser section tunes the pre-selector stage circuit.

Next, re-set the dial pointer on the receiver and the test oscillator to 600 KC. Slowly increase or decrease the oscillator padding condenser and at the same time continuously tune back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment seems a little complicated but is the easiest way to adjust the oscillator to the pre-selector or R.F. section. The padding condenser is located on the left hand end of the chassis near the 6D6 tube.

Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 600 KC.

This completes the correct sequence of operations in properly aligning the receiver for the Broadcast Band, and **must always be done before** attempting to align the Short Wave Bands.

FOREIGN BAND The Foreign Band of 19 to 49 meters can be adjusted by the two trimmers on the short wave coil located on the top of the chassis. Set the test oscillator to 14,000 KC. The oscillator coil is located near the 1st I.F. Transformer and the antenna or R.F. coil is located directly in front of the Short Wave oscillator coil and about midway between the 1st I.F. Transformer and the 6A7 tube. These two trimmers should be adjusted for peak at 14,000 KC and as the inherent design of the circuit has been expressly designed for simplicity in servicing, no other adjustments are necessary for aligning this band. **Note: Always start** this procedure by having the oscillator coil trimmer loose (out all the way), and the antenna coil trimmer fairly tight (in all the way); otherwise it is possible to make a false alignment on the image frequency.

Important: Do not attempt any adjustment of the gang condenser trimmers in aligning the Foreign Band as this will throw the Broadcast Band out of alignment.

POLICE BAND There is only one adjustment to be made in the alignment of the Police Band. Due to the circuit design and correct matching of the coils, no oscillator adjustment is necessary.

Set the dial pointer to 4000 KC (also the test oscillator) and adjust the antenna coil trimmer to resonance. The two police band coils are under the chassis, but the antenna coil trimmer for this band is on top of the chassis and is located at the left front corner along side of wave band switch.

Important: This is the only adjustment necessary for the Police Band. Do not attempt any adjustment of the gang condenser trimmers in aligning the Police Band, otherwise the Broadcast Band will be thrown out of alignment.

This receiver is designed to operate from a power supply main of 110-120 volts, 60 cycle alternating current (AC). **Never plug into a DC outlet.**

GENERAL DATA The alignment of this receiver requires the use of a test oscillator that will cover the frequencies of 456, 600, 1400, 1800, 4000, 6000, and 14,000 KC and an output meter to be connected across the primary or secondary of the output transformers. If possible, all alignments should be made with the volume control on maximum and the test oscillator ouput as low as possible, to prevent the AVC from operating and giving false readings.

CORRECT ALIGNMENT PROCEDURE The intermediate frequency (I.F.) stage should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the Broadcast Band should always be the next procedure; after which, either or both of the Short Wave Bands may be aligned.

I.F. ALIGNMENT Adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tubes (6A7) through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the chassis ground. Align all four I.F. trimmers to peak or maximum reading on the output meter.

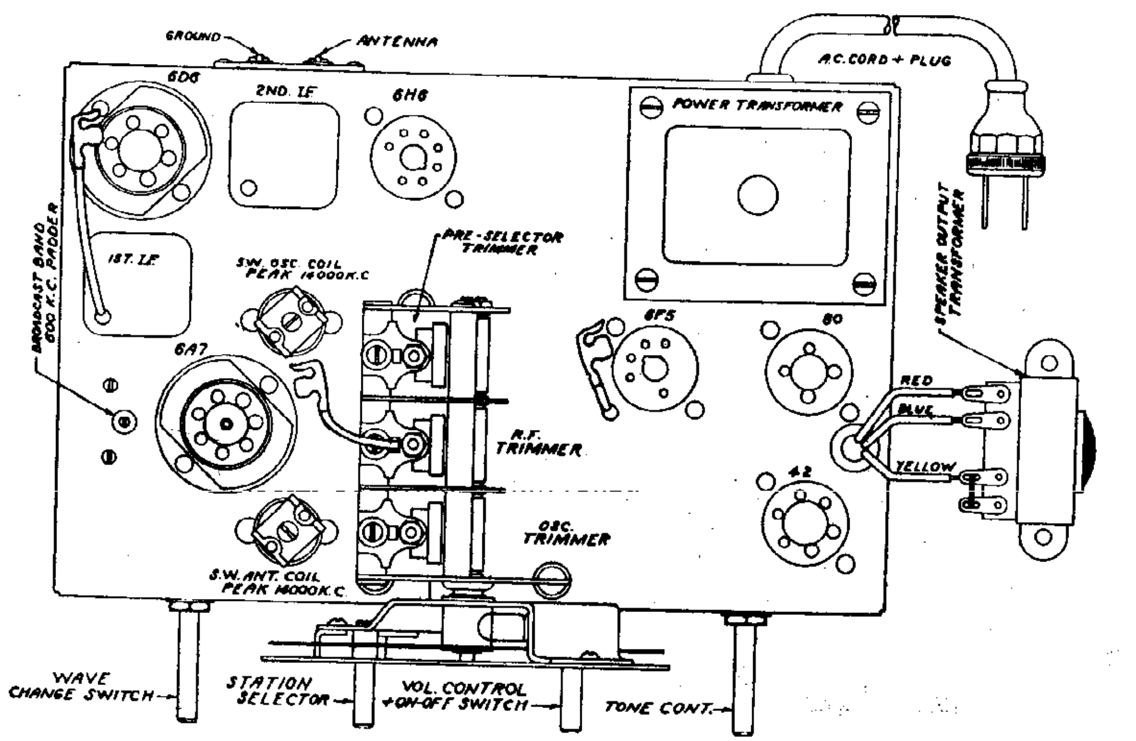
Z2 Chassis



CONTINENTAL RADIO

Z2

This receiver is designed to operate from a power supply main of 110-120 volts, 60 cycle alternating current (AC). **Never plug into a DC outlet.**

Six Tube A.C. All Wave Superheterodyne

This receiver is designed to operate over three tuning ranges. The broadcast range which extends from 540 to 1700 Kilocycles (KC) (175 to 550 meters), Police and Aviation Band which extends from 1700 to 5000 Kilocycles (KC) (52 to 175 Meters) and the International Short Wave Band which extends from 5800 to 15,200 Kilocycles (KC) (18.5 to 52 meters). This short wave range is the one which includes the four internationally assigned bands—the 19, 25, 31 and 49 meter bands.

ALIGNMENT DATA AND SERVICING

I.F. ALIGNMENT Adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tubes (6A7) through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the chassis ground. Align all four I.F. trimmers to peak or maximum reading on the output meter.

BROADCAST BAND ALIGNMENT Adjust the oscillator to 1400 KC and connect the output to the antenna post marked "A" through a .0001 mfd. mica condenser to give the equivalent of an antenna about 60 feet. Set the receiver pointer to 1400 KC and adjust the rear gang condenser trimmer (oscillator circuit) to peak. After this has been carefully done, the next step is to adjust the center and front trimmers of the gang condenser to peak. The center gang section tunes the R.F. or grid coil of the 6A7 tube and the front condenser section tunes the pre-selector stage circuit.

Next, re-set the dial pointer on the receiver and the test oscillator to 600 KC. Slowly increase or decrease the oscillator padding condenser and at the same time continuously tune back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment seems a little complicated but is the easiest way to adjust the oscillator to the pre-selector or R.F. section. The padding condenser is located on the left hand side of the chassis, directly to the left of the 6A7 tube and in front of the first I.F. transformer.

Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 600 KC.

This completes the correct sequence of operations in properly aligning the receiver for the Broadcast Band, and **must always be done before** attempting to align the Short Wave Bands.

FOREIGN BAND The Foreign Band of 19 to 49 meters can be adjusted by the two trimmers on the short wave coil located on the top of the chassis. Set the test oscillator to 14,000 KC. The oscillator coil is located near the 1st I.F. Transformer and the antenna or R.F. coil is located directly in front of the Short Wave oscillator coil and about midway between the 1st I.F. Transformer and the 6A7 tube. These two trimmers should be adjusted for peak at 14,000 KC and as the inherent design of the circuit has been expressly designed for simplicity in servicing, no other adjustments are necessary for aligning this band. **Note: Always start** this procedure by having the oscillator coil trimmer loose (out all the way), and the antenna coil trimmer fairly tight (in all the way); otherwise it is possible to make a false alignment on the image frequency.

Important: Do not attempt any adjustment of the gang condenser trimmers in aligning the Foreign Band as this will throw the Broadcast Band out of alignment.

POLICE BAND There is only one adjustment to be made in the alignment of the Police Band. Due to the circuit design and correct matching of the coils, no oscillator adjustment is necessary.

Set the dial pointer to 4000 KC (also the test oscillator) and adjust the antenna coil trimmer to resonance. In preparing the test oscillator for alignment of this band, connect a 400 ohm carbon resistor in series with the .0001 mfd. condenser on the output lead of the test oscillator. This resistor is used with the test oscillator only on the Short Wave Bands and should not be used for Broadcast Band alignment. The two police band coils are under the chassis and the antenna coil trimmer is mounted on the end of the antenna coil.

Important: This is the only adjustment necessary for the Police Band. Do not attempt any adjustment of the gang condenser trimmers in aligning the Police Band, otherwise the Broadcast Band will be thrown out of alignment.

GENERAL DATA The alignment of this receiver requires the use of a test oscillator that will cover the frequencies of 456, 600, 1400, 1800, 4000, 6000, and 14,000 KC and an output meter to be connected across the primary or secondary of the output transformers. If possible, all alignments should be made with the volume control on maximum and the test oscillator output as low as possible, to prevent the AVC from operating and giving false readings.

CORRECT ALIGNMENT PROCEDURE The intermediate frequency (I.F.) stage should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the Broadcast Band should always be the next procedure; after which, either or both of the Short Wave Bands may be aligned.

Six Tube 6 Volt Battery All Wave Superheterodyne

Z4

This receiver is designed to operate over three tuning ranges: the broadcast range which extends from 540 to 1700 Kilocycles (KC) (175 to 550 meters), Police and Aviation Band which extends from 1700 to 5000 Kilocycles (KC) (52 to 175 Meters) and the International Short Wave Band which extends from 5800 to 15,200 Kilocycles (KC) (18.5 to 52 meters). This latter range is the one which includes the four internationally assigned bands—the 19, 25, 31 and 49 meter bands.

ALIGNMENT DATA AND SERVICING
INFORMATION FOR THE RADIO SERVICE MAN

GENERAL DATA The alignment of this receiver requires the use of a test oscillator which will cover the frequencies of 456, 600, 1400, 1800, 4000, 6000, and 14,000 KC and an output meter which is to be connected across the primary or secondary of the output transformer. If possible, all alignments should be made with the volume control on maximum and the test oscillator output as low as possible, to prevent the AVC from operating and giving false readings.

CORRECT ALIGNMENT PROCEDURE The intermediate frequency (I.F.) stage should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the Broadcast Band should always be the next procedure; after which, either or both of the Short Wave Bands may be aligned.

I.F. ALIGNMENT Adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tube (1C6) through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the chassis ground. Align all four I.F. trimmers to peak or maximum reading on the output meter.

BROADCAST BAND ALIGNMENT Adjust the oscillator to 1400 KC and connect the output to the antenna post marked "A" through a .0001 mfd. mica condenser to give the equivalent of an antenna about 60 feet. Set the receiver pointer to 1400 KC and adjust the rear gang condenser trimmer (oscillator circuit) to peak. After this has been carefully done, the next step is to adjust the front trimmer of the gang condenser to peak. The front condenser section tunes the RF or grid circuit of the 1C6 tube. Next re-set the dial pointer on the receiver and the test oscillator to 600 KC. Slowly increase or decrease the oscillator padding condenser and at the same time continuously tune back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment may seem a little complicated but is the easiest way to adjust the oscillator to the R.F. section. The padding condenser is located on the left hand side of the chassis, directly to the left of the 1C6 tube and in front of the first I.F. transformer. Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 600 KC.

This completes the correct sequence of operations in properly aligning the receiver for the Broadcast Band, and **must always be done before** attempting to align the Short Wave Bands.

FOREIGN BAND ALIGNMENT The Foreign Band of 19 to 49 meters can be adjusted by the two trimmers on the short wave coils located on the top of the chassis. Set the test oscillator to 14,000 KC. In preparing the test oscillator for alignment of this band, connect a 400 ohm carbon resistor in series with the .0001 mfd. condenser on the output lead of the test oscillator. The oscillator coil is located near the 1st I.F. Transformer and the antenna or R.F. coil is located directly in front of the Short Wave oscillator coil and alongside the front section of the gang condenser. These two trimmers should be adjusted for peak at 14,000 KC and as the inherent design of the circuit has been expressly developed for simplicity in servicing, no other adjustments are necessary for aligning this band. **Note:** Always start this procedure by having the oscillator coil trimmer loose (out all the way), and the antenna coil trimmer fairly tight (in all the way); otherwise it is possible to make a false alignment on the image frequency. In order to prevent alignment on the image frequency, it is suggested that the following check be made: Readjust the pointer to 13,100 KC where the image frequency should be found. If properly aligned, the image frequency will be found to be weaker. If, however, the signal at 13,100 KC is found to be stronger than the signal at 14,000 KC, it signifies that alignment was incorrectly made on the image frequency.

IMPORTANT: Do not attempt any adjustment of the gang condenser trimmers in aligning the Foreign Band as this will throw the Broadcast Band out of alignment.

POLICE BAND ALIGNMENT There is only one adjustment to be made in the alignment of the Police Band. Due to the circuit design and correct matching of the coils, no oscillator adjustment is necessary. Set the dial pointer to 4000 KC (also the test oscillator) and adjust the antenna coil trimmer to resonance. In preparing the test oscillator for alignment of this band, connect a 400 ohm carbon resistor in series with the .0001 mfd. condenser on the output lead of the test oscillator. This resistor is used with the test oscillator only on the Short Wave Bands and should not be used for Broadcast Band alignment. The two police band coils are under the chassis and the antenna coil trimmer is mounted on the end of the antenna coil. **Important:** This is the only adjustment necessary for the Police Band. Do not attempt any adjustment of the gang condenser trimmers in aligning the Police Band, otherwise the Broadcast Band will be thrown out of alignment.

SERVICE DATA FOR ALL BANDS

If it is suspected that the oscillator has stopped but is doubtful due to the presence of the usual amount of noise level, it is suggested that the oscillator plate voltage be checked. To ascertain whether the tube is oscillating, ground the oscillator grid of the 1C6 (short stator and rotor plates of oscillator section on gang condenser). If oscillating properly, grounding the grid will cause an appreciable drop in oscillator voltage.

WINDCHARGERS

There are many types of windchargers now on the market which may be used to advantage for greater economy of receiver operation. Such chargers will pay for themselves over a period of time; by saving the cost of battery recharging; removing the inconvenience of taking the battery to a charging station; non-operation of the receiver during the charging period.

IMPORTANT NOTE: The battery must never be charged while set is in operation. If a windcharger is used, it should always be disconnected from the battery when the receiver is being used. An inexpensive single pole switch can be used for disconnecting the windcharger from the battery. This will increase the life of the tubes and give additional economy to the use of the receiver.

BATTERY SELECTION

This receiver is designed to operate entirely from a 6 volt storage battery. It requires no other batteries. It will operate from any storage battery having a capacity ranging from 90 to 175 ampere hours. It is suggested, for the sake of greatest economy, that the largest possible capacity battery be used. The following is a schedule giving the number of hours of service on a single charge from batteries of standard capacities. A fully charged battery will provide satisfactory power for the periods specified before requiring additional charge.

90 Ampere Hour Capacity provides 60 hours use.
100 Ampere Hour Capacity provides 66 hours use.
110 Ampere Hour Capacity provides 73 hours use.
120 Ampere Hour Capacity provides 80 hours use.
150 Ampere Hour Capacity provides 100 hours use.
170 Ampere Hour Capacity provides 113 hours use.

Note: The above tabulation is rated very conservatively and in most cases, with new or correctly rated batteries in good condition, many additional hours of service can be obtained from each charge. If, for any reason, the proper hours of service are not obtained, it will be due to the use of an old battery whose condition and rating are no longer up to standard. If a brand new battery fails to give the required hours of service, it is due to the battery being wrongly rated.

CORONA RADIO & TELEV. CORP.

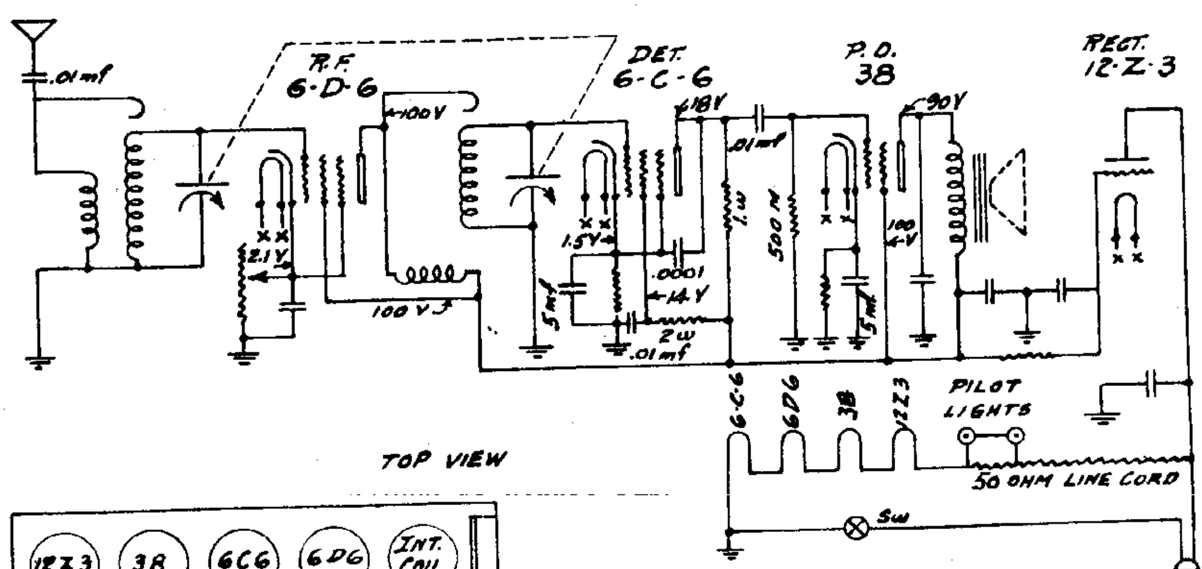
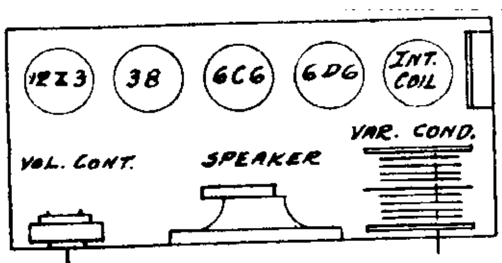
ALIGNMENT PROCEDURE, MODEL 110

Bring Int. frequency circuits in balance by applying a 456 Kc signal to the control grid of the 6A7 tube. Adjust I.F. trimmers for maximum output. Apply a 6 Megacycle note to the antenna and with the band switch on the short wave position, turn gang condenser until the pointer is at 6.00 Mc on the dial. Next, adjust the Osc. trimmer located under the chassis near the electrolytic condenser until the signal is heard. Care should be taken to make certain this trimmer is adjusted to the fundamental rather than the image; this can be checked by tuning in the image near 5.00 Mc. Next, adjust the short wave antenna trimmer, located on top of chassis near dial, for maximum gain. The low frequency padder of short wave band is fixed and no adjustment is necessary. However, check it at 2.5 Mc to determine whether or not it is still oscillating. If not, change 6A7 tube.

Change band switch to broadcast position and turn dial to extreme high frequency end (1720 Kc). Apply a 1720 Kc signal to the antenna and adjust the B.C. oscillator trimmer, located under chassis near outer edge, to 1720 Kc. Bring antenna coil into resonance by adjusting the trimmer on top of chassis near the I.F. transformers. Adjust the low frequency padder for maximum gain at 600 Kc, by applying a 600 Kc signal to the antenna and rocking the gang condenser with each adjustment of the padder until maximum gain is achieved. An output meter is necessary in order to obtain best results in alignment. Recheck 1720 Kc again as it might be thrown off by the adjustment at the low frequency end.



TOP VIEW



NOTE -
UNDER NO CIRCUMSTANCES SHOULD THE CHASSIS BE CONNECTED TO A GROUND, INASMUCH AS A GROUND IS UNNECESSARY.

CROSLEY RADIO CORP.

SPECIFICATIONS

The Crosley Model A-156 auto radio is a single unit, five-tube superheterodyne receiver. The power supply unit is built into a completely shielded compartment and is an integral part of the receiver chassis.

TUBES AND VOLTAGE LIMITS

The following table gives the functions of the tubes used, together with the voltage readings between the tube socket contacts and the receiver chassis. Voltage readings should be taken with a 1000 ohm per volt, 250 volt voltmeter (except filaments) with receiver in operating condition and no signal input. The filament voltages should be measured with an accurate low range D-C voltmeter (approximately 0 to 10 volts). Voltage limits may vary plus or minus 10% of values given.

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and normally should need no further adjustment. However, if it is definitely known that an adjustment is necessary the circuits can be properly aligned ONLY with the use of a modulated signal generator and an output meter.

CONNECTING OUTPUT METER

Connect one terminal of the output meter to the plate and the other terminal to the screen of the 42 Output tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

NOTE: The receiver chassis must be in its case and a speaker similar to the one used with the receiver must be connected to the chassis before making any adjustments. It is also advisable to use a spare control unit for making adjustments of the volume control and tuning condenser. A standard control unit with short cables (6" to 8") makes a very convenient and useful tool. If it is desired to shorten a pair of long cables it will be absolutely necessary to heavily tin the cables before cutting them.

1. Tuning I-F Amplifier To 262 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd., or larger, condenser to the top cap of the 6A7 Osc-Mod tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the receiver chassis frame. KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Adjust the station selector so that the rotor plates of the tuning condenser are completely in mesh.

(c) Turn the volume control of the receiver full on and turn the tone control to the treble position.

(d) Set the signal generator to 262 kilocycles.

(e) Adjust both trimmers located on the 2nd I-F transformer for maximum output. (Fig. 2).

(f) Adjust both trimmers located on the 1st I-F transformer for maximum output.

(g) Repeat operations (e) and (f) for more accurate adjustments.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

2. Aligning R-F Amplifier.

(a) Connect the output lead from the signal generator through a .00025 mfd. condenser to the "ANT" connection of the receiver.

(b) Set the signal generator to 1400 kilocycles.

(c) Adjust the station selector to 140 on the dial.

(d) Adjust the trimmer on the "OSC" section of the tuning condenser for maximum output.

(e) Adjust the trimmer on the "R-F" section of the tuning condenser for maximum output.

(f) Adjust the trimmer on the "ANT" section of the tuning condenser for maximum output.

(g) Readjust the station selector for maximum output. DO NOT READJUST THE OSC. TRIMMER.

(h) Repeat operations (e) and (f) for more accurate adjustments.

3. Adjusting Antenna Compensating Condenser.

(a) Set the signal generator to 600 kilocycles.

(b) Tune in the 600 kilocycle signal with the station selector for maximum output.

(c) Adjust the antenna compensating condenser, Illus. No. 18, Fig. 3, for maximum output.

(d) Repeat operations (b) and (c) alternately until no further improvement in output can be obtained.

(e) Set the signal generator to 1400 kilocycles again.

(f) Tune-in the 1400 kilocycle signal with the station selector for maximum output.

(g) Readjust the trimmer on the "ANT" section of the tuning condenser for maximum output.

It will be necessary to adjust the antenna compensating condenser to the car antenna after the receiver has been installed in the car.

(a) After the installation is complete, tune-in a WEAK station between 55 and 65 on the dial.

(b) Adjust the antenna compensating condenser for maximum volume in the speaker.

MODEL A-166 Socket, Trimmers Chassis, Parts Alignment

CROSLEY RADIO CORP.

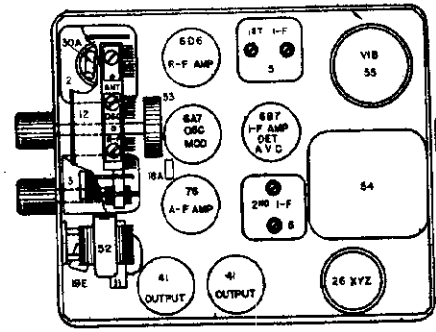

Fig. 2. Top View

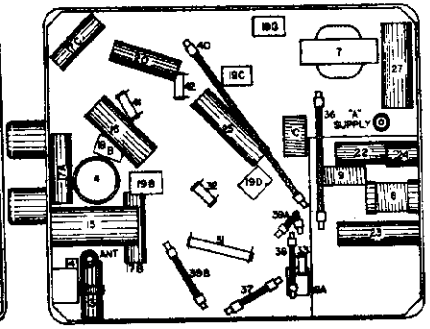

Fig. 3. Bottom View

SPECIFICATIONS

The Crosley Model A-166 auto radio is a two-unit, six-tube superheterodyne receiver with an under-cowl type speaker. The power supply unit is an integral part of the receiver chassis and is completely shielded from the remainder of the receiver.

TUBES AND VOLTAGE LIMITS

The following table gives the functions of the tubes used, together with the voltage readings between the tube socket contacts and the receiver chassis. Voltage readings should be taken with a 1000 ohm per volt, 250 volt voltmeter with receiver in operating condition and no signal input. Voltage limits may vary plus or minus 10% of values given.

PARTS LIST—MODEL A-166

Figures in first column refer to parts in Diagrams.

Item No.	Part No.	Description
1		
2	G83—32000	Ant. Coil
	W —38420	Ant. Coil Shield
	W —32913	Wood Coil Spacer

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and normally should need no further adjustment. However, if it is definitely known that an adjustment is necessary the circuits can be properly aligned ONLY with the use of a modulated signal generator and an output meter.

CONNECTING OUTPUT METER

Connect one terminal of the output meter to the plate of one of the 41 Output tubes and connect the other terminal to the plate of the other Output tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

NOTE: The receiver chassis must be in its case and a speaker similar to the one used with the receiver must be connected to the chassis before making any adjustments. It is also advisable to use a spare control unit for making adjustments of the volume control and tuning condenser. A standard control unit with short cables (6" to 8") makes a very convenient and useful tool. If it is desired to shorten a pair of long cables it will be absolutely necessary to heavily tin the cables before cutting them.

1. Tuning I-F Amplifier to 262 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd., or larger, condenser to the top cap of the 6A7 tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the receiver chassis frame. KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID WIRES OF THE OTHER SCREEN GRID TUBES.

(b) Adjust the station selector so that the rotor plates of the tuning condenser are completely in mesh.

(c) Turn the volume control of the receiver full on and turn the tone control to the treble position.

(d) Set the signal generator to 262 kilocycles.

(e) Adjust both trimmers located on top of the 2nd I-F transformer for maximum output. (Fig. 2).

(f) Adjust both trimmers located on top of the 1st I-F transformer for maximum output.

(g) Repeat operations (e) and (f) for more accurate adjustments.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

2. Aligning R-F Amplifier.

(a) Connect the output lead from the signal generator through a .00025 mfd. condenser to the "ANT" connection of the receiver.

(b) Set the signal generator to 1400 kilocycles.

(c) Adjust the station selector to 140 on the dial.

(d) Adjust the trimmer on the "OSC." section of the tuning condenser for maximum output. (Fig. 2).

(e) Adjust the trimmer on the "R-F" section of the tuning condenser for maximum output.

(f) Adjust the trimmer on the "ANT" section of the tuning condenser for maximum output.

(g) Readjust the station selector for maximum output. DO NOT READJUST THE "OSC" TRIMMER.

(h) Repeat operations (e) and (f) for more accurate adjustments.

3. Adjusting Antenna Compensating Condenser.

(a) Set the signal generator to 600 kilocycles.

(b) Tune-in the 600 kilocycle signal with the station selector for maximum output.

(c) Adjust the antenna compensating condenser, Illus. No. 14, Fig 3, for maximum output.

(d) Repeat operations (b) and (c) alternately until no further improvement in output can be obtained.

(e) Set the signal generator to 1400 kilocycles again.

(f) Tune-in the 1400 kilocycle signal with the station selector for maximum output.

(g) Readjust the trimmer on the "ANT" section of the tuning condenser for maximum output.

It will be necessary to adjust the antenna compensating condenser to the car antenna after the receiver has been installed in the car.

(a) After the installation is complete, tune-in a WEAK station between 55 and 65 on the dial.

(b) Adjust the antenna compensating condenser for maximum volume in the speaker.

Parts

CROSLEY RADIO CORP.

SPECIFICATIONS

The Crosley Model A-266 auto radio is a single unit, six-tube superheterodyne receiver. The power supply unit is built into a completely shielded compartment and is an integral part of the receiver chassis.

TUBES AND VOLTAGE LIMITS

The following table gives the functions of the tubes used, together with the voltage readings between the tube socket contacts and the receiver chassis. Voltage readings should be taken with a 1000 ohm per volt, 250 volt voltmeter (except filaments) with receiver in operating condition and no signal input. The filament voltages should be measured with an accurate low range D-C voltmeter (approximately 0 to 10 volts). Voltage limits may vary plus or minus 10% of values given.

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and normally should need no further adjustment. However, if it is definitely known that an adjustment is necessary the circuits can best be properly aligned with the use of a modulated signal generator and an output meter.

CONNECTING OUTPUT METER

Connect one terminal of the output meter to the plate and the other terminal to the screen of the 42 Output tube. Be sure the meter is protected from D. C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

NOTE: The receiver chassis must be in its case and a speaker similar to one used with the receiver must be connected to the chassis before making any adjustments. It is also advisable to use a spare control unit for making adjustments of the volume control and tuning condenser. A standard control unit with short cables (6" to 8") makes a very convenient and useful tool. If it is desired to shorten a pair of long cables it will be absolutely necessary to heavily tin the cables before cutting them.

1. Tuning I-F Amplifier To 262 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd., or larger, condenser to the top cap of the 6A7 Osc-Mod. tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the receiver chassis frame. KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Adjust the station selector so that the rotor plates of the tuning condenser are completely in mesh.

(c) Turn the volume control of the receiver full on and turn the tone control to the treble position.

(d) Set the signal generator to 262 kilocycles.

(e) Adjust both trimmers located on the 2nd I-F transformer for maximum output. (Fig. 2).

(f) Adjust both trimmers located on the 1st I-F transformer for maximum output.

(g) Repeat operations (e) and (f) for more accurate adjustments.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

2. Aligning R.F Amplifier.

(a) Connect the output lead from the signal generator through a .00025 mfd. condenser to the "ANT" connection of the receiver.

(b) Set the signal generator to 1400 kilocycles.

(c) Adjust the station selector to 140 on the dial.

(d) Adjust the trimmer on the "OSC" section of the tuning condenser for maximum output.

(e) Adjust the trimmer on the "R-F" section of the tuning condenser for maximum output

(f) Adjust the trimmer on the "ANT" section of the tuning condenser for maximum output.

(g) Readjust the station selector for maximum output. DO NOT READJUST THE OSC. TRIMMER.

(h) Repeat operations (e) and (f) for more accurate adjustments.

3. Adjusting Antenna Compensating Condenser.

(a) Set the signal generator to 600 kilocycles.

(b) Tune in the 600 kilocycle signal with the station selector for maximum output.

(c) Adjust the antenna compensating condenser, Illustration No. 10, Fig. 3, for maximum output.

(d) Repeat operations (b) and (c) alternately until no further improvement can be obtained.

(e) Set the signal generator to 1400 kilocycles again.

(f) Tune-in the 1400 kilocycle signal with the station selector for maximum output.

(g) Readjust the trimmer on the "ANT" section of the tuning condenser for maximum output.

It will be necessary to adjust the antenna compensating condenser to the car antenna after the receiver has been installed in the car.

(a) After the installation is complete, tune-in a WEAK station between 55 and 65 on the dial.

(b) Adjust the antenna compensating condenser for maximum volume in the speaker.

MODEL A-366
Socket, Trimmers
Voltage, Alignment

CROSLEY RADIO CORP.

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and normally should need no further adjustment. However, if it is definitely known that an adjustment is necessary the circuits can best be properly aligned with the use of a modulated signal generator and an output meter.

CONNECTING OUTPUT METER

Connect one terminal of the output meter to the plate and the other terminal to the screen of the 42 Output tube. Be sure the meter is protected from D. C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

NOTE: The receiver chassis must be in its case and a speaker similar to one used with the receiver must be connected to the chassis before making any adjustments. It is also advisable to use a spare control unit for making adjustments of the volume control and tuning condenser. A standard control unit with short cables (6" to 8") makes a very convenient and useful tool. If it is desired to shorten a pair of long cables it will be absolutely necessary to heavily tin the cables before cutting them.

1. Tuning I-F Amplifier To 262 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd., or larger, condenser to the top cap of the 6A7 Osc-Mod. tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the receiver chassis frame. KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Adjust the station selector so that the rotor plates of the tuning condenser are completely in mesh.

(c) Turn the volume control of the receiver full on and turn the tone control to the treble position.

(d) Set the signal generator to 262 kilocycles.

(e) Adjust both trimmers located on the 2nd I-F transformer for maximum output. (Fig. 2)

(f) Adjust both trimmers located on the 1st I-F transformer for maximum output.

(g) Repeat operations (e) and (f) for more accurate adjustments.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

2. Aligning R.F Amplifier.

(a) Connect the output lead from the signal generator through a .00025 mfd. condenser to the "ANT" connection of the receiver.

(b) Set the signal generator to 1400 kilocycles.

(c) Adjust the station selector to 140 on the dial.

(d) Adjust the trimmer on the "OSC" section of the tuning condenser for maximum output.

(e) Adjust the trimmer on the "R-F" section of the tuning condenser for maximum output.

(f) Adjust the trimmer on the "ANT" section of the tuning condenser for maximum output.

(g) Readjust the station selector for maximum output. DO NOT READJUST THE OSC. TRIMMER.

(h) Repeat operations (e) and (f) for more accurate adjustments.

3. Adjusting Antenna Compensating Condenser.

(a) Set the signal generator to 600 kilocycles.

(b) Tune in the 600 kilocycle signal with the station selector for maximum output.

(c) Adjust the antenna compensating condenser, Illustration No. 14, Fig. 3, for maximum output.

(d) Repeat operations (b) and (c) alternately until no further improvement can be obtained.

(e) Set the signal generator to 1400 kilocycles again.

(f) Tune-in the 1400 kilocycle signal with the station selector for maximum output.

(g) Readjust the trimmer on the "ANT" section of the tuning condenser for maximum output.

It will be necessary to adjust the antenna compensating condenser to the car antenna after the receiver has been installed in the car.

(a) After the installation is complete, tune-in a WEAK station between 55 and 65 on the dial.

(b) Adjust the antenna compensating condenser for maximum volume in the speaker.

TUBE SOCKET VOLTAGE READINGS

Tube	Function	H	P	S	G	K	Ga	Go
6D6	R-F Amplifier	6.0	220	100	0	5.7	—	—
6A7	Osc.-Mod.	6.0	220	100	0	5.7	130	-5 to -10
6B7	I-F Amp. & Diode Detector	6.0	220	100	0	6.8	—	—
76	1st A-F Amp.	6.0	130	—	0	8.0	—	—
41	(2) Output	6.0	210	—	0	18.0	—	—

Power Output Approximately 3 Watts.
Battery Drain Approximately 6.2 Amperes at 6 Volts.

TUBES AND VOLTAGE LIMITS

The following table gives the functions of the tubes used, together with the voltage readings between the tube socket contacts and the receiver chassis. Voltage readings should be taken with a 1000 ohm per volt, 250 volt voltmeter (except filaments) with receiver in operating condition and no signal input. Voltage limits may vary plus or minus 10% of voltages given.

CROSLEY RADIO CORP.

SPECIFICATIONS

The Crosley Model 415 radio is a four-tube superheterodyne receiver designed for operation from batteries. The method of connecting the battery cable to the batteries is shown on the Wiring Diagram. The batteries required are: one two-volt storage battery or an air cell battery, three "plug-in type" 45 volt "B" batteries and one "plug-in type" 22½ volt "C" battery.

TUBES AND VOLTAGE LIMITS

The following table gives the functions of the tubes used, together with the voltage readings between the tube socket contacts and B—. Voltage readings should be taken with a 1000 ohm per volt, 250 volt voltmeter (except filaments) with receiver in operating condition and no signal input. The filament voltages should be measured with an accurate low range D-C voltmeter (approximately 0-10 volts). Voltage limits may vary plus or minus 10% of values given.

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and normally should need no further adjustment. However, if it is definitely known that an adjustment is necessary the circuits can be properly aligned ONLY with the use of a modulated signal generator and an output meter.

CONNECTING OUTPUT METER

Connect one terminal of the output meter to the plate and the other terminal to the screen of the 33 Output tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier To 450 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd. condenser to the top cap of the 1A6 Osc-Mod tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the ground wire (BLACK) at the rear of the chassis. KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Set the tuning condenser so that the plates are completely out of mesh and turn the volume control to the right (ON).

(c) Set the signal generator to 450 kilocycles.

(d) Adjust the trimmer condenser for the 2nd I-F transformer, Fig. 3, Illustration No. 31, for maximum output.

(e) Adjust both trimmer condensers, located on top of the 1st I-F transformer, for maximum output.

(f) Check operations (d) and (e) for more accurate adjustments.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

2. Aligning R-F Amplifier.

(a) Connect the output lead from the signal generator through a .00025 mfd. condenser to the antenna wire (BLUE) at the rear of the chassis.

(b) Set the signal generator to 1400 kilocycles.

(c) Place the chassis in the cabinet and adjust the station selector to 140 on the dial.

(d) Remove the chassis from the cabinet and adjust the "OSC" trimmer, 12Y, located on the tuning condenser, for maximum output. (Fig. 2).

(e) Adjust the "ANT" trimmer, 12Z, located on the tuning condenser, for maximum output.

(f) Tune-in the generator signal with the station selector for maximum output.

(g) Repeat operation (e) for more accurate adjustment.

CONNECTING OUTPUT METER

Connect one terminal of the output meter to the plate and the other terminal to the screen of the 43 Output tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier To 450 Kilocycles.

(a) Connect the output of the signal generator through a .02 condenser to the top cap of the 78 tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator through a .05 mfd., or larger, condenser to the receiver chassis. KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE 6F7 TUBE.

(b) Set the station selector condenser so that the plates are completely out of mesh and turn the volume control to the right (ON).

(c) Set the signal generator to 450 kilocycles.

(d) Adjust the trimmer condenser for the 2nd I-F transformer, Fig. 3, Illustration No. 17, for maximum output.

(e) Adjust both trimmer condensers for the 1st I-F transformer, Fig. 3, Illustration Nos. 16Y and 16Z, for maximum output.

(f) Check operations (d) and (e) for more accurate adjustments.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

2. Aligning R-F Amplifier.

(a) Connect the output lead from the signal generator through a .00025 mfd. condenser to the antenna condenser at the point where the antenna wire is connected.

(b) Set the signal generator to 1400 kilocycles.

(c) Place the chassis in the cabinet and adjust the station selector to 140 on the dial.

(d) Remove the chassis from the cabinet and adjust the "OSC" trimmer, located on the station selector condenser, for maximum output. (Fig. 2.)

(e) Adjust the "ANT" trimmer, located on the station selector condenser, for maximum output.

(f) Repeat operations (d) and (e) for more accurate adjustments.

CROSLEY RADIO CORP.

SPECIFICATIONS

The Crosley Model 435 radio is a four-tube superheterodyne receiver designed for operation from a six-volt storage battery. It contains a completely shielded, built-in power supply unit which employs a self-rectifying type vibrator.

Connect one terminal of the output meter to the plate and the other terminal to the screen of the 38 Output tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier to 450 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd. condenser to the top cap of the 6A7 tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the "Gnd" terminal of the receiver. KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Adjust the station selector so that the plates of the condenser gang are completely out of mesh and turn the volume control to the right (ON).

(c) Set the signal generator to 450 kilocycles.

(d) Adjust both trimmers located on top of the 2nd. I-F Transformer for maximum output. (Fig. 2).

(e) Adjust both trimmers located on top of the 1st. I-F Transformer for maximum output.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

2. Aligning R-F Amplifier.

(a) Connect the output lead from the signal generator through a .00025 mfd. condenser to the "ANT" terminal of the receiver.

(b) Set the signal generator to 1400 kilocycles.

(c) Adjust the station selector to 140 on the dial.

(d) Adjust the trimmer on the "OSC" section of the condenser gang for maximum output. (Fig. 3.)

(e) Adjust the trimmer on the "ANT" section of the condenser gang for maximum output.

(f) Repeat operations (d) and (e) for more accurate adjustments.

Alignment

CROSLEY RADIO CORP.

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and normally should need no further adjustment. However, if it is definitely known that an adjustment is necessary the circuits can best be properly aligned with the use of a modulated signal generator and an output meter.

CONNECTING OUTPUT METER

Connect the output meter to P, and P2 of the 6N6 Output Tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier to 450 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd. condenser to the top cap of the 6A8 tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the "GND" terminal of the receiver. KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Set the station selector so that the tuning condenser plates are completely out of mesh. Turn the volume control knob to the right (ON) and turn the tone control knob to the left (TREBLE).

(c) Turn the band selector switch to the right (High Frequency).

(d) Set the signal generator to 450 kilocycles.

(e) Adjust both trimmers located on top of the 2nd I-F Transformer for maximum output. (Fig. 2).

(f) Adjust both trimmers located on top of the 1st I-F Transformer for maximum output.

(g) Check operations (e) and (f) for more accurate adjustments.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

2. Aligning R-F Amplifier.

(a) When aligning the R-F Amplifier the output lead from the signal generator should be connected through a dummy antenna to the "ANT" terminal of the receiver. For the broadcast band the dummy antenna should be a .00025 mfd. condenser and for the high frequency band this condenser should be replaced by a 400 ohm (Non Inductive) carbon resistor.

Each band should be shunt aligned, series aligned and then shunt aligned again in the order given. The band selector switch should be set for the band being aligned and the signal generator should be set to the frequency indicated below for each adjustment.

Adjust the "OSC" and "ANT" shunt trimmers (shunt alignment. See Fig. 3) in the order given for maximum output. Tune the station selector to the generator signal for maximum output and then check the adjustment of the "ANT" trimmer. NOTE: When aligning the high frequency band care should be exercised so that the circuits will be aligned on the fundamental frequency rather than on the image frequency which is approximately 900 kilocycles less than the fundamental. To check on this, increase the output of the signal generator approximately 10 times and try to tune-in the signal both at the generator frequency as indicated on the station selector dial and at approximately 900 kilocycles below the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct dial setting.

To adjust the "series" trimmers (Fig. 3) set the signal generator to the frequency indicated below and then tune-in this signal with the station selector for maximum output. Adjust the series trimmer, while rocking the tuning condenser back and forth slightly, until no further improvement in output can be obtained.

(b) Signal Generator Frequencies.

	Shunt Alignment	Series Alignment
High Frequency Band	1400 Kc.	600 Kc.
Broadcast Band	6000 Kc.	1500 Kc.

SPECIFICATIONS

The Crosley Radio Models 526 and 5526 are companion models employing the same circuit. The Model 526 is supplied in a mantle cabinet having the speaker mounted on the chassis and the Model 5526 is a console type having the speaker mounted in the cabinet.

This receiver is designed to use either metal tubes or the equivalent glass tubes with octal bases. If glass tubes are replaced with metal tubes or metal tubes are replaced with glass tubes it will be necessary to completely realign the circuits of the receiver. The frequency ranges covered are from 540 to 1710 kilocycles in the broadcast band and from 2350 to approximately 7500 kilocycles in the high frequency band.

TUBES AND VOLTAGE LIMITS

The following table gives the functions of the tubes used, together with the voltage readings between tube socket contacts and chassis. Voltage readings should be taken with a 1000 ohm per volt, 500 volt voltmeter (except filaments) with receiver in operating condition and no signal input. The filament voltages should be measured with an accurate low range A-C voltmeter (Approximately 0 to 10 volts). Voltage limits may vary plus or minus 10% of values given.

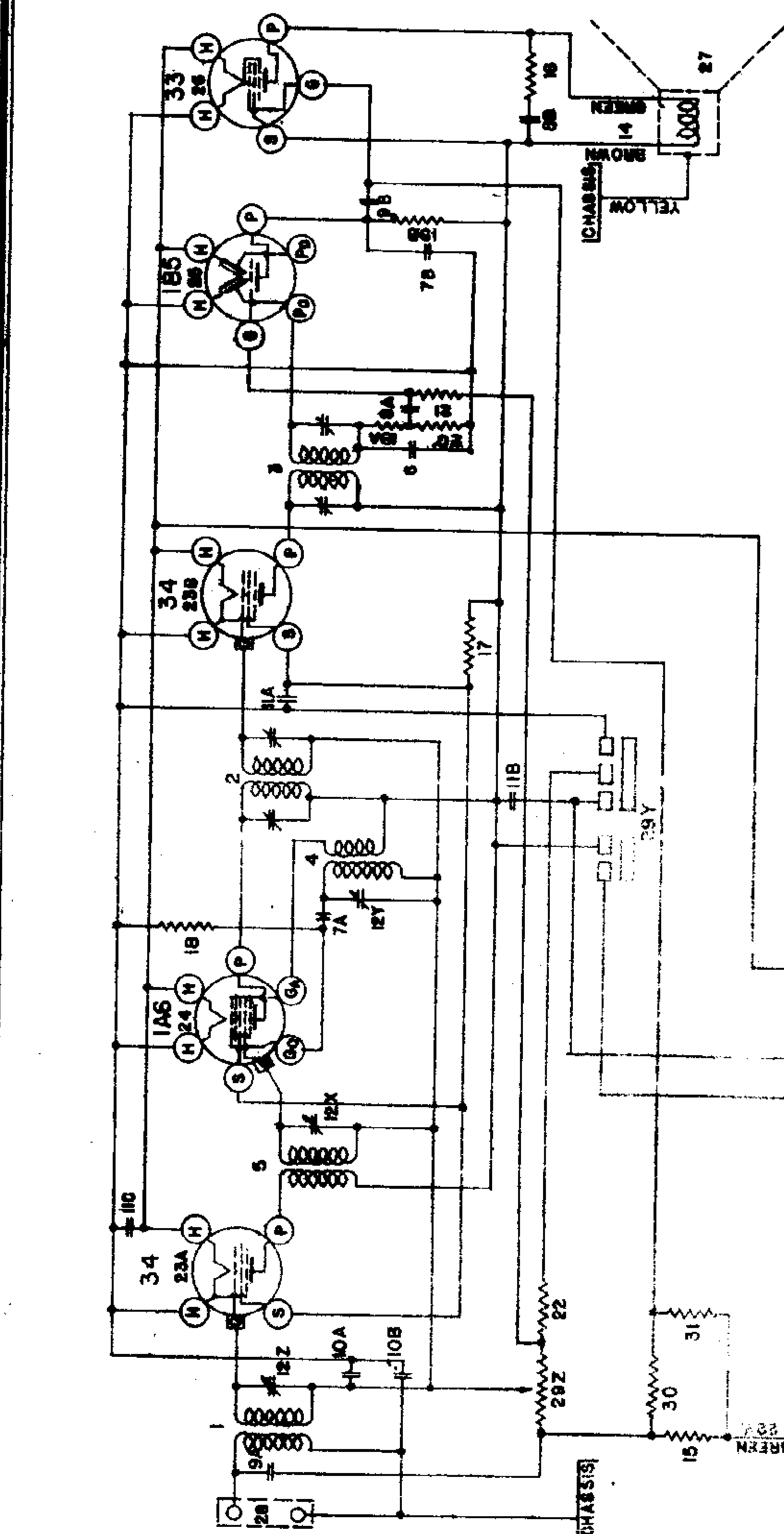
MODEL 535
Schematic, Socket Voltage

CROSLEY RADIO CORP.



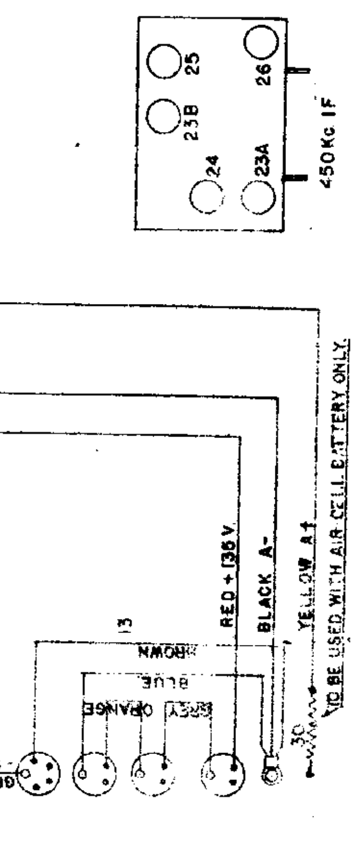


FIG. 1—WIRING DIAGRAM

SPECIFICATIONS

The Crosley Model 535 radio is a five-tube, single band superheterodyne receiver designed for operation from batteries. The method of connecting the battery cables to the batteries is shown on the wiring diagram. The batteries required are: one two-volt storage battery or an air cell battery, three plug-in type 45 volt "B" batteries and one plug-in type 22½ volt "C" battery.

TUBES AND VOLTAGE LIMITS

The following table gives the functions of the tubes used, together with the voltage readings between the tube socket and "A"—. Voltage readings should be taken with a 1000 ohm per volt, 250 volt voltmeter (except filaments) with receiver in operating condition and no signal input. Filament voltages should be measured with an accurate low range D.C. voltmeter (0 to 10 volts). Voltage limits may vary plus or minus 10% of values given.

Alignment

CROSLEY RADIO CORP.

Connect one terminal of the output meter to the plate and the other terminal to the screen of the 33 Output tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier to 450 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd. condenser to the top cap of the 1A6 Osc-Mod tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the "GND" terminal of the receiver. KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID WIRES OF THE OTHER SCREEN GRID TUBES.

(b) Set the station selector condenser so that the plates are completely out of mesh and turn the volume control to the right (ON).

(c) Set the signal generator to 450 kilocycles.

(d) Adjust the trimmer condensers located on top of the 2nd I-F transformer for maximum output. (Fig. 2).

(e) Adjust the trimmer condensers located on top of the 1st I-F transformer for maximum output.

(f) Repeat operations (d) and (e) for more accurate adjustments.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

2. Aligning R-F Amplifier.

(a) Connect the output lead from the signal generator through a .00025 mfd. condenser to the "ANT" terminal of the receiver.

(b) Set the signal generator to 1400 kilocycles.

(c) Adjust the station selector to 140 on the dial.

(d) Adjust the trimmer located on the "OSC" section of the condenser gang for maximum output. (Fig. 3.)

(e) Adjust the trimmer located on the "R-F" section of the condenser gang for maximum output.

(f) Adjust the trimmer located on the "ANT" section of the condenser gang for maximum output.

(g) Repeat operations (d), (e) and (f) for more accurate adjustments.

CONNECTING OUTPUT METER

Connect one terminal of the output meter to the plate and the other terminal to the screen of the 25A6 Output tube. Be sure the meter is protected from D. C. by connecting a condenser (.1 mfd. or larger—non-electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier to 450 Kilocycles.

(a) Connect the output of the signal generator through a .02 condenser to the top cap of the 6K7 Oscillator-Modulator tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator through a .05 mfd., or larger, condenser to the receiver chassis. KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Set the station selector so that the plates of the condenser gang are completely out of mesh, turn the band selector switch to the right (High Frequency Position) and turn the volume control to the right (ON).

(c) Set the signal generator to 450 kilocycles.

(d) Adjust the 2nd I-F trimmer condenser, Illus. No. 17—Fig. 3, located on the rear of the chassis for maximum output.

(e) Adjust the 1st I-F trimmer condensers, Illus. Nos. 16Z and 16Y, located on the rear of the chassis for maximum output.

(f) Check operations (d) and (e) for more accurate adjustments.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

2. Aligning R-F Amplifier.

(a) Connect the output lead from the signal generator through a .00025 mfd. condenser to the antenna condenser at the point where the antenna wire is connected.

(b) Set the signal generator to 1400 kilocycles.

(c) Adjust the station selector to 140 on the dial.

(d) Adjust the trimmer (18-Y Fig. 3) located on the "OSC" section of the condenser gang for maximum output.

(e) Adjust the trimmer (18-Z) located on the "ANT" section of the condenser gang for maximum output.

(f) Readjust the tuning condenser slightly for maximum output.

(g) Repeat operation (e) for more accurate adjustment.

NOTE: The locations of the speaker and electrolytic condenser (Illus. No. 8) are interchanged on Models 536 and 5536. The dial used on Model 5536 is larger than the dial used on Model 536 and replacement parts are clearly indicated in the Parts List.

SPECIFICATIONS

The Crosley Models 536 and 5536 are five-tube superheterodyne receivers designed for operation on a 110 volt power supply, either AC or DC.

The tuning range of the receiver is from 540-1550 kilocycles (555-195 Meters) in the Broadcast Band and from 1500-3450 Kilocycles (200-87 Meters) in the High Frequency Band.

TUBES AND VOLTAGE LIMITS

The following table gives the functions of the tubes used, together with the voltage readings between the tube socket contacts and one of the terminals of the 25Z6 tube. Voltage readings should be taken with a 1000 ohm per volt, 250 volt voltmeter (except filaments) with volume control full on and no signal input. The filament voltages should be measured with an accurate low range voltmeter. Voltage limits may vary plus or minus 10% of values given.

MODEL 54
Schemati
Voltage

CROSLEY RADIO CORP.

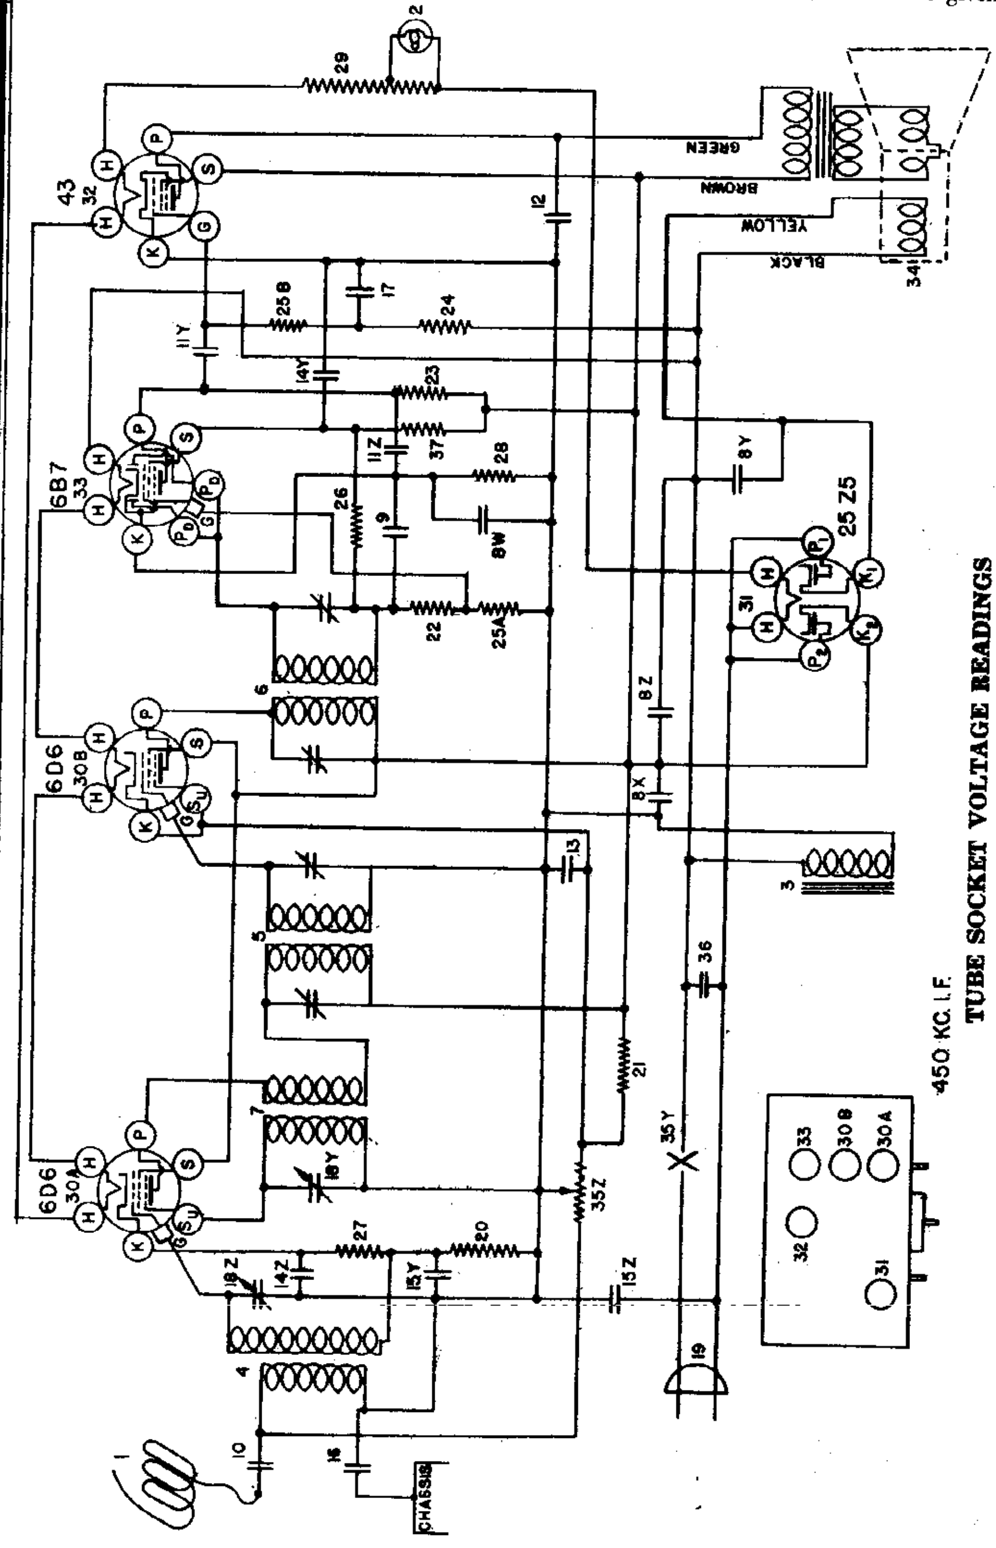
SPECIFICATIONS

The Crosley Model 545 radio is a five-tube single band superheterodyne receiver designed for operation on a 110 volt power supply, either AC or DC.

The frequency range covered is from 530 Kc. to 1710 Kc.

TUBES AND VOLTAGE LIMITS

The following table gives the functions of the tubes used, together with the voltage readings between the tube socket contacts and one of the terminals of the 25Z5 tube. Voltage readings should be taken with a 1000 ohm per volt, 250 volt voltmeter (except filaments) with volume control full on and no signal input. The filament voltages should be measured with an accurate low range D-C voltmeter. Voltage limits may vary plus or minus 10% of values given.



TUBE SOCKET VOLTAGE READINGS

Tube	Where Used	H	P	S	Su	G	K
6D6	Osc.-Mod.	6.5	105	105	0	−17	20
6D6	I-F Amplifier	6.5	105	105	3.5	0	3.5
6B7	Diode Detector & A-F Amplifier	6.5	25	20	—	0	1.5
43	Output	25.2	100	105	—	−20	0
25Z5	Rectifier	25.2	117.5 A.C.				

Power Consumption Approximately 55 Watts at 120 Volts.

Voltage Reading Approximately 10% Lower on 120 V., D.C.

CONNECTING OUTPUT METER

Connect one terminal of the output meter to the plate and the other terminal to the screen of the 43 Ouput tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier to 450 Kilocycles.

(a) Connect the output of the signal generator through a .02 condenser to the top cap of the 6D6 Oscillator-Modulator tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator through a .05 mfd., or larger, condenser to the receiver chassis. KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Set the station selector so that the plates of the condenser gang are completely out of mesh and turn the volume control to the right (ON).

(c) Set the signal generator to 450 kilocycles.

(d) Adjust both trimmers located on top of the 2nd I-F transformer for maximum output. Fig. 2.

(e) Adjust both trimmers located on top of the 1st I-F transformer for maximum output.

(f) Check operations (d) and (e) for more accurate adjustments.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

2. Aligning R-F Amplifier.

(a) Connect the output lead from the signal generator through a .00025 mfd. condenser to the antenna condenser at the point where the antenna wire is connected.

(b) Set the signal generator to 1400 kilocycles.

(c) Adjust the station selector to 140 on the dial.

(d) Adjust the trimmer (18-Y Fig 3) located on the "OSC" section of the condenser gang for maximum output.

(e) Adjust the trimmer (18-Z) located on the "ANT" section of the condenser gang for maximum output.

(f) Readjust the tuning condenser slightly for maximum output.

(g) Repeat operation (e) for more accurate adjustment.

Alignment

CROSLEY RADIO CORP.

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and normally should need no further adjustment. However, if it is definitely known that an adjustment is necessary the circuits can best be properly aligned with the use of a modulated signal generator and an output meter.

CONNECTING OUTPUT METER

Connect one terminal of the output meter to the plate and the other terminal to the screen of the 38 Output tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier To 450 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd. condenser to the top cap of the 6A7 tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the "GND" terminal of the receiver. KEEP THE GENERATOR OUTPUT LEAD AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Set the station selector so that the tuning condenser plates are completely out of mesh. Turn the volume control knob to the right (ON) and turn the tone control knob to the left (TREBLE).

(c) Turn the band selector switch to the right (High Frequency Band).

(d) Set the signal generator to 450 kilocycles.

(e) Adjust both trimmers located on top of the 2nd I-F transformer for maximum output.

(f) Adjust both trimmers located on top of the 1st I-F transformer for maximum output.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

2. Aligning R-F Amplifier.

When aligning the R-F amplifier the output lead from the signal generator is connected to the antenna ("A-1") terminal of the receiver through a .00025 mfd. condenser.

Each band should first be shunt aligned and then series aligned. The band selector switch should be set for the band being aligned and the signal generator should be set to the frequency indicated for each adjustment.

Adjust the "OSC", "R-F" and "ANT" shunt trimmers in the order given for maximum output. Tune the station selector to the signal generator for maximum output and then check the adjustments of the "R-F" and "ANT" trimmers in the order given. Do not readjust the "OSC" trimmer. NOTE: When aligning the High Frequency Band care must be exercised so that the circuits will be aligned on the fundamental frequency rather than on the image frequency which is approximately 900 kilocycles less than the fundamental. To check on this, increase the output of the signal generator approximately ten times and try to tune-in the signal at both the generator frequency as indicated on the station selector dial and at approximately 900 kilocycles below the correct frequency. If the circuits have been properly aligned the signal can be tuned in at both positions but much stronger at the correct position.

To adjust the "series" trimmers set the signal generator to the frequency indicated and then tune-in this signal with the station selector for maximum output. Adjust the "series" trimmer while rocking the tuning condenser back and forth slightly, until no further improvement in output can be obtained.

SIGNAL INPUT FREQUENCIES

		Shunt Alignment	Series Alignment
American Broadcast Band	(BLUE)	1400 Kc.	600 Kc.
High Frequency Band	(RED)	6000 Kc.	2500 Kc.

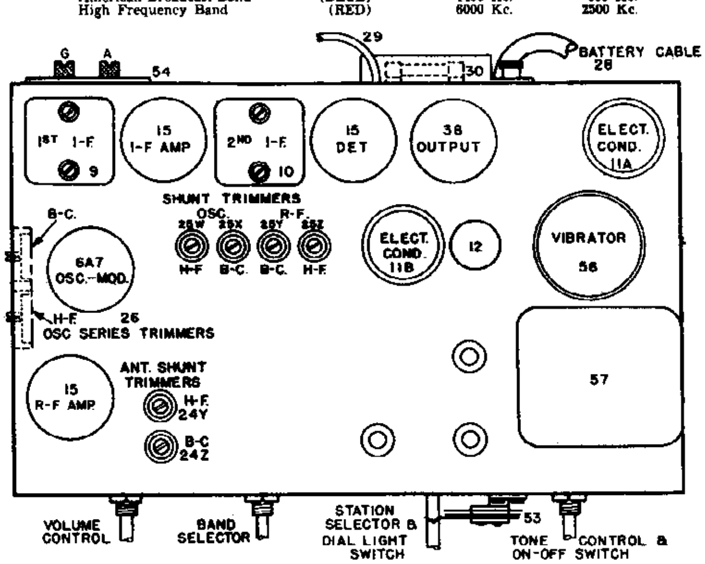

Fig. 2. Top View

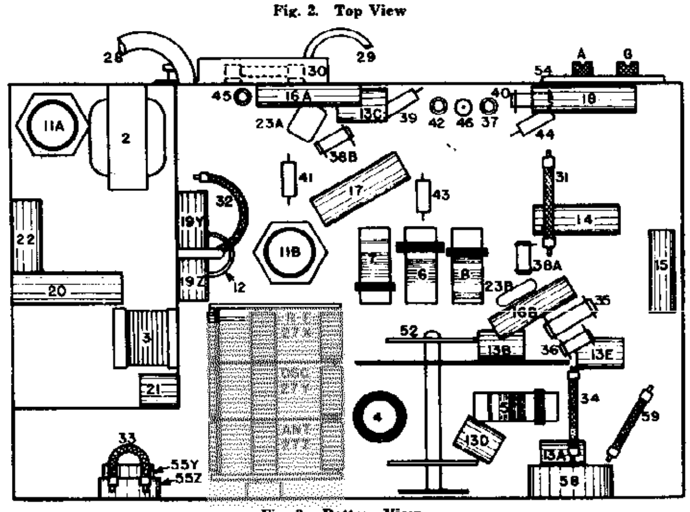

Fig. 3. Bottom View

TUBES AND VOLTAGE LIMITS

The following table gives the functions of the tubes used, together with the voltage readings between the tube socket contacts and the chassis. Voltage readings should be taken with a 1000 ohm per volt, 250 volt

power supply unit which employs a self-rectifying type vibrator.

The tuning range of the receiver is from 540 to 7000 kilocycles and is divided into two bands as follows:

(American Broadcast Band)
(High Frequency Band).

voltmeter (except filaments) with the volume control full on and no signal input. The filament voltages should be measured with an accurate low range D-C voltmeter (approximately 0 to 10 volts). Voltage limits may vary plus or minus 10% of values given.

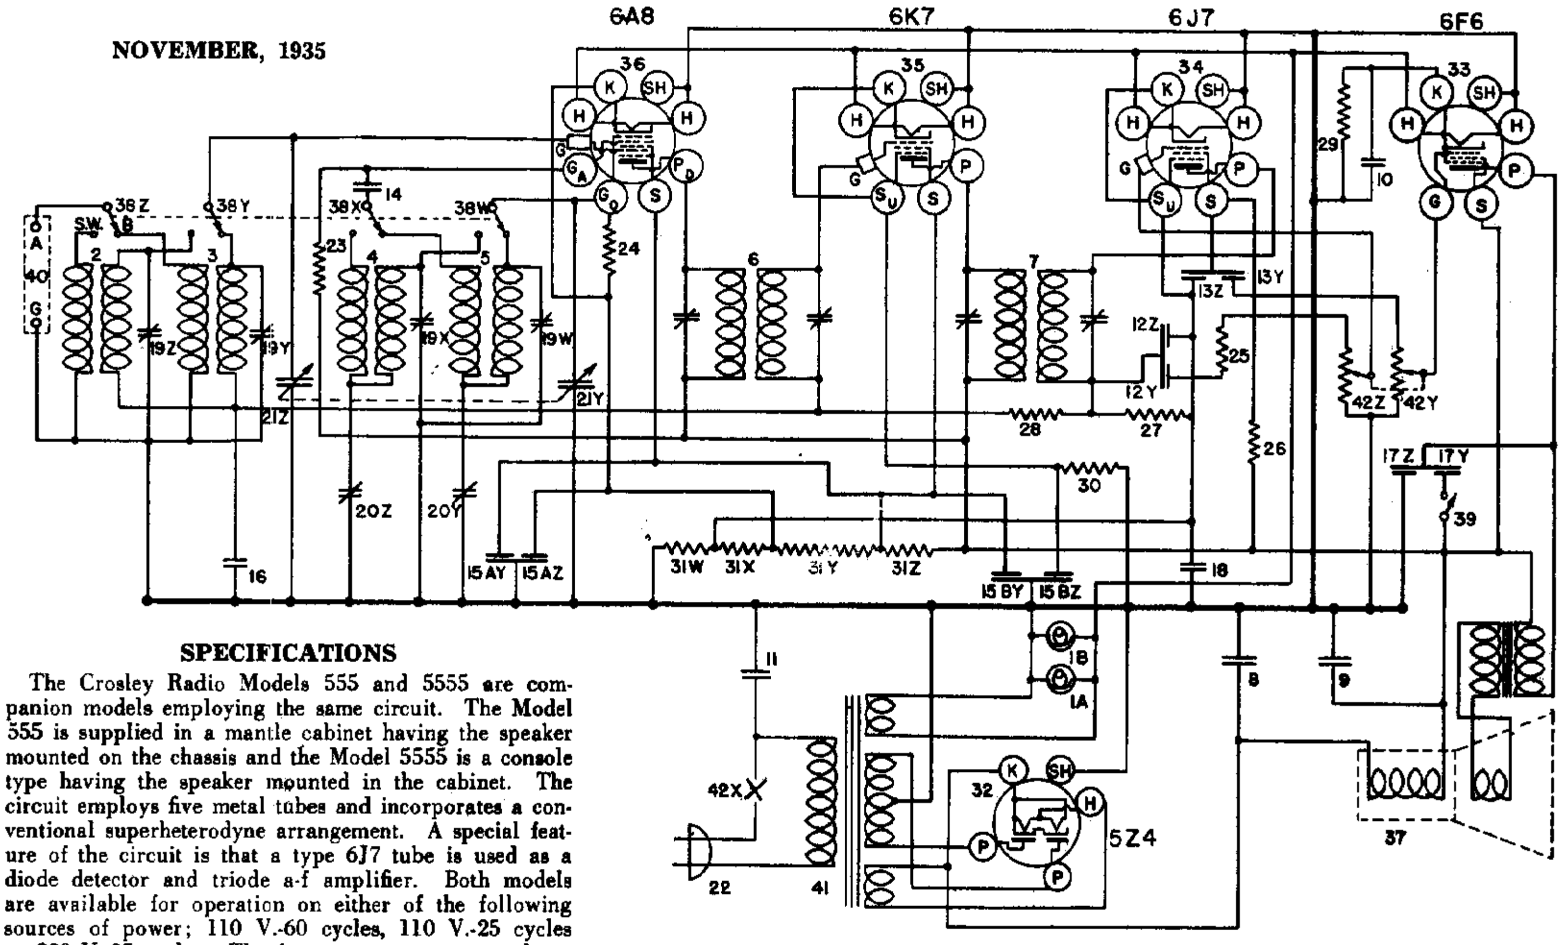
CROSLEY RADIO CORP.

NOVEMBER, 1935



SPECIFICATIONS

The Crosley Radio Models 555 and 5555 are companion models employing the same circuit. The Model 555 is supplied in a mantle cabinet having the speaker mounted on the chassis and the Model 5555 is a console type having the speaker mounted in the cabinet. The circuit employs five metal tubes and incorporates a conventional superheterodyne arrangement. A special feature of the circuit is that a type 6J7 tube is used as a diode detector and triode a-f amplifier. Both models are available for operation on either of the following sources of power; 110 V.-60 cycles, 110 V.-25 cycles or 220 V.-25 cycles. The frequency ranges covered are from 540 to 1710 kilocycles in the broadcast band and from 2350 to approximately 7500 kilocycles in the high frequency band.

Power Output Approximately 3 Watts. Power Consumption Approximately 85 Watts at 117.5 Volts.

MODELS 555,5555
Socket, Trimmers
Chassis, Parts
Alignment

CROSLEY RADIO CORP.

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and normally should need no further adjustment. However, if it is definitely known that an adjustment is necessary the circuits can be properly aligned ONLY with the use of a modulated signal generator and an output meter.

CONNECTING OUTPUT METER

Connect one terminal of the output to the plate and the other terminal to the screen of the 6F6 Output Tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier to 450 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd. condenser to the top cap of the 6A8 tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the "GND" terminal of the receiver. KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Set the station selector so that the tuning condenser plates are completely out of mesh. Turn the volume control knob to the right (ON) and turn the tone control knob to the left (TREBLE).

(c) Turn the band selector switch to the right (High Frequency).

(d) Set the signal generator to 450 kilocycles.

(e) Adjust both trimmers located on top of the 2nd I-F Transformer for maximum output. (Fig. 2A or 2B).

(f) Adjust both trimmers located on top of the 1st I-F Transformer for maximum output.

(g) Check operations (e) and (f) for more accurate adjustments.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

2. Aligning R-F Amplifier.

(a) When aligning the R-F Amplifier the output lead from the signal generator should be connected through a dummy antenna to the "ANT" terminal of the receiver. *For the broadcast band the dummy antenna should be a .00025 mfd. condenser and for the high frequency band this condenser should be replaced by a 400 ohm carbon resistor (* Non Inductive).

Each band should be shunt aligned, series aligned and then shunt aligned again in the order given. The band selector switch should be set for the band being aligned and the signal generator should be set to the frequency indicated below for each adjustment.

Adjust the "OSC" and "ANT" parallel trimmers (shunt alignment. See Fig. 3) in the order given for maximum output. Tune the station selector to the generator signal for maximum output and then check the the adjustment of the "ANT" trimmer. NOTE: When aligning the high frequency band care should be exercised so that the circuits will be aligned on the fundamental frequency rather than on the image frequency which is approximately 900 kilocycles less than the fundamental. To check on this, increase the output of the signal generator approximately 10 times and try to tune-in the signal both at the generator frequency as indicated on the station selector dial and at approximately 900 kilocycles below the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct dial setting.

To adjust the "series" trimmers (Fig. 2A or 2B) set the signal generator to the frequency indicated below and then tune-in this signal with the station selector for maximum output. Adjust the series trimmer while rocking the tuning condenser back and forth slightly, until no further improvement in output can be obtained.

(b) Signal Generator Frequencies.

	Shunt Alignment	Series Alignment
Broadcast Band	1400 Kc.	600 Kc.
High Frequency Band	6000 Kc.	1500 Kc.

CROSLEY RADIO CORP.

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and normally should need no further adjustment. However, if it is definitely known that an adjustment is necessary the circuits can best be properly aligned with the use of a modulated signal generator and an output meter.

CONNECTING OUTPUT METER

Connect one terminal of the output meter to the plate and the other terminal to the screen of the 33 Output tube. Be sure the meter is protected from D.C. by connecting a condenser .1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier to 450 Kilocycles.

(a) Connect the output of the signal generator through a .02, or larger, mfd. condenser to the top cap of the 1A6 Osc-Mod tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the "GND" terminal of the receiver. KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Set the station selector so that the tuning condenser plates are completely out of mesh. Turn the volume control knob to the right (ON).

(c) Turn the band selector switch to the left (High Frequency).

(d) Set the signal generator to 450 kilocycles.

(e) Adjust both trimmers located on top of the 2nd I-F transformer for maximum output. Fig. 2.

(f) Adjust both trimmers located on top of the 1st I-F transformer for maximum output.

(g) Check operations (e) and (f) for more accurate adjustments.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

2. Aligning R-F Amplifier.

(a) Connect the output lead from the signal generator through a .00025 mfd. condenser to the "ANT" terminal of the receiver.

(b) Set the signal generator to 1400 kilocycles.

(c) Turn the band selector switch to the right (Broadcast Band).

(d) Adjust the station selector to 140 on the dial.

(e) Adjust the trimmer located on the "OSC" section of the condenser gang for maximum output. Fig. 3.

(f) Adjust the trimmer located on the "R-F" section of the condenser gang for maximum output.

(g) Adjust the trimmer located on the "ANT" section of the condenser gang for maximum output.

(h) Tune the station selector to the generator signal for maximum output.

(i) Repeat operations (f) and (g) for more accurate adjustments.

TUBES AND VOLTAGE LIMITS

The following table gives the functions of the tubes used, together with the voltage readings between the tube socket contacts and the negative side of the "A" battery circuit. Voltage readings should be taken with a 1000 ohm per volt, 250 volt voltmeter (except filaments) with receiver in operating condition and the volume control full on and no signal input. The filament voltages should be measured with an accurate low range D-C voltmeter (Approximately 0 to 10 volts). Voltage limits may vary plus or minus 10% of values given.

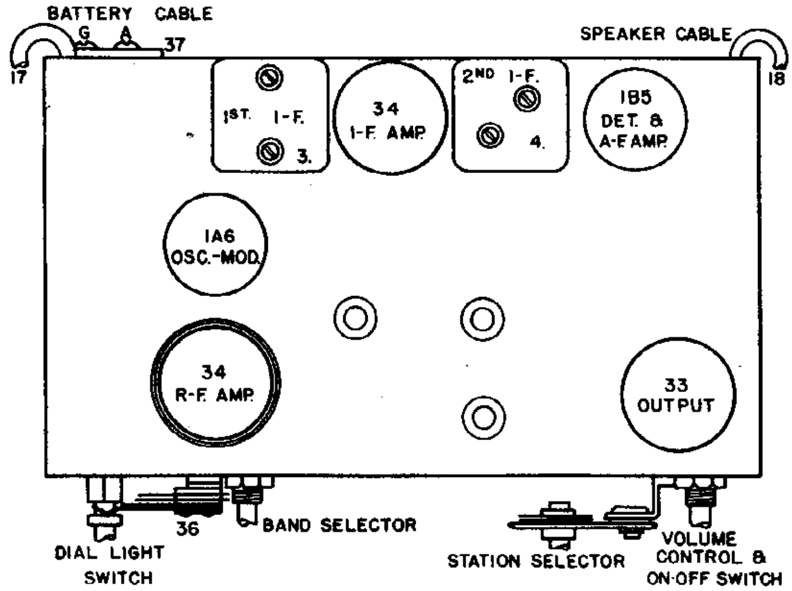

Fig. 2. Top View 556

SPECIFICATIONS

The method of connecting the battery cable to the batteries is shown on the Wiring Diagram. The batteries required are: one two-volt storage battery or air cell battery, three plug-in type 45 volt "B" batteries and one plug-in type 22½ volt "C" battery.

MODEL 605
Schematic
Voltage

NOVEMBER, 1935

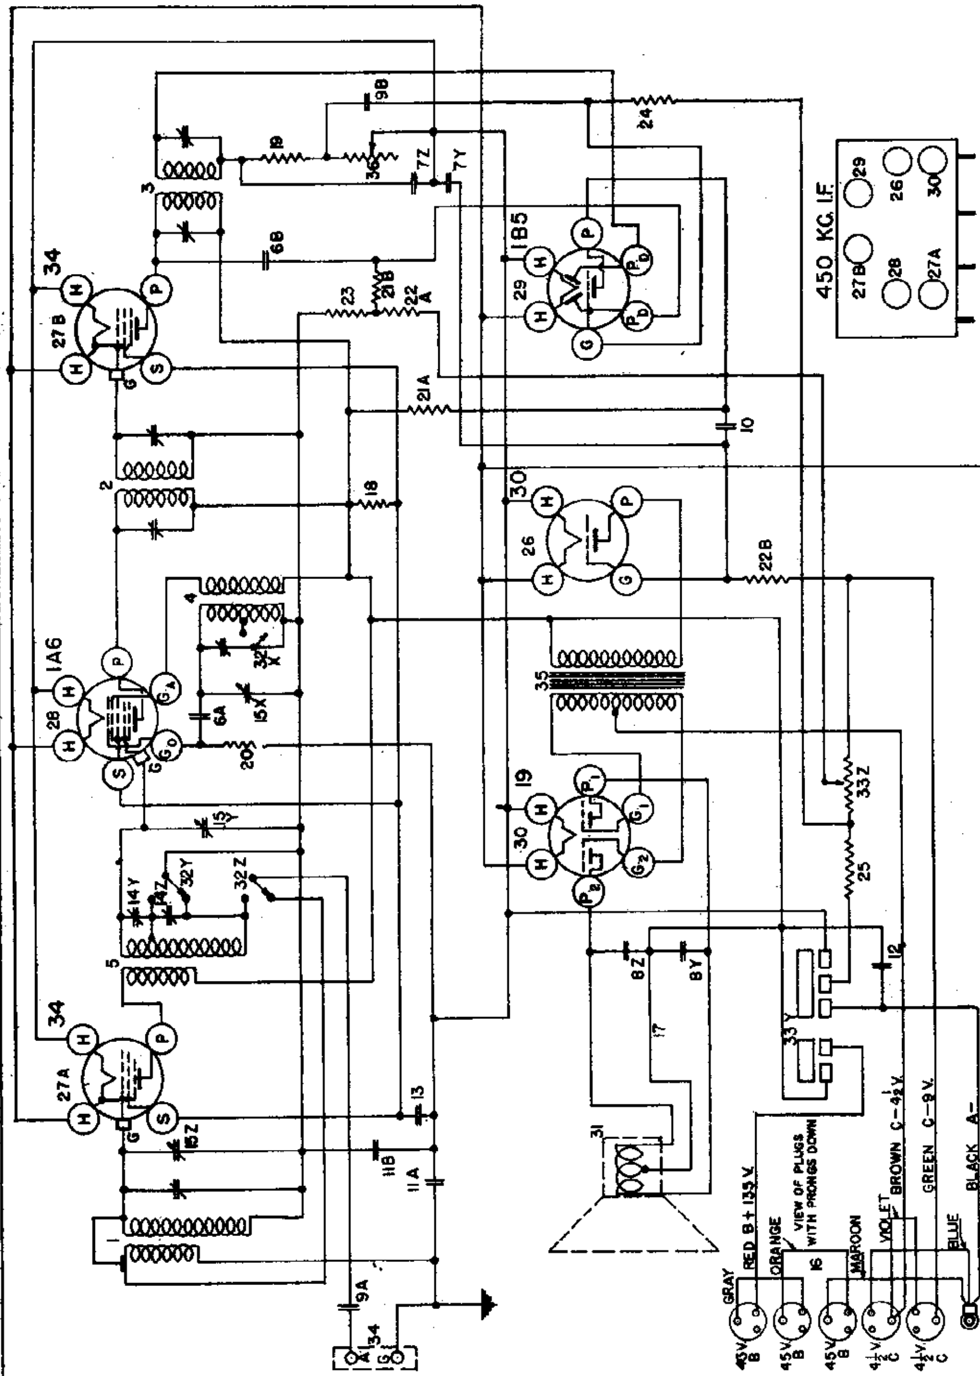

FIG. 1—WIRING DIAGRAM—MODEL 605

SPECIFICATIONS

The Crosley Model 605 radio is a six-tube superheterodyne receiver designed for operation from batteries. The method of connecting the battery cable to the batteries is shown on the Wiring Diagram. The batteries required are: one two-volt storage battery or air cell battery, three plug-in type 45 volt "B" batteries and two plug-in type 4½ volt "C" batteries. The sensitivity control will enable the operator to control the sensitivity and apparent selectivity of the receiver. When tuning for weak stations turn the control to the right. When the control is turned toward the left it will decrease the sensitivity, increase the apparent selectivity and decrease the "B" battery drain.

The frequency ranges covered are from 540 to 1575 kilocycles in the broadcast band and from 1565 to 3800 kilocycles in the high frequency band.

CONNECTING OUTPUT METER

Connect the two terminals of the output meter to the two plates of the 19 Output tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier to 450 Kilocycles.

(a) Connect the output of the signal generator through a .02, or larger, mfd. condenser to the top cap of the 1A6 Osc-Mod tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the "GND" terminal of the receiver. KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Set the station selector so that the tuning condenser plates are completely out of mesh. Turn the volume control and the sensitivity control knobs to the right (ON).

(c) Turn the band selector switch to the left (High Frequency).

(d) Set the signal generator to 450 kilocycles.

(e) Adjust both trimmers located on top of the 2nd I-F transformer for maximum output. Fig. 2.

(f) Adjust both trimmers located on top of the 1st I-F transformer for maximum output.

(g) Check operations (e) and (f) for more accurate adjustments.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

2. Aligning R-F Amplifier.

(a) Connect the output lead from the signal generator through a .00025 mfd. condenser to the "ANT" terminal of the receiver.

(b) Set the signal generator to 1400 kilocycles.

(c) Turn the band selector switch to the right (Broadcast Band).

(d) Adjust the station selector to 140 on the dial.

(e) Adjust the trimmer located on the "OSC" section of the condenser gang for maximum output. Fig. 3.

(f) Adjust the "R-F" trimmer condenser, No. 14Z, Fig. 2, for maximum output.

(g) Adjust the trimmer located on the "ANT" section of the condenser gang for maximum output.

(h) Tune the station selector to the generator signal for maximum output.

(i) Repeat operations (f) and (g) for more accurate adjustments.

(j) Turn the band selector switch to the left (High Frequency Band).

(k) Set the signal generator to 3500 kilocycles.

(l) Adjust the station selector ot 3.5 on the dial.

(m) Adjust the "R-F" trimmer condenser, No. 14Y. Fig. 2, for maximum output.

Measured on 117.5 Volt A. C. Line.

Power Consumption Approximately 60 Watts.

ALIGNMENT PROCEDURE

All the circuits in the receiver are very accurately adjusted at the factory and should need no further adjustment. However, if it is definitely known that an adjustment is necessary the circuits can be properly aligned only with the use of a modulated signal generator and an output meter.

Connecting Output Meter.

Connect one terminal of the output meter to the plate and the other terminal to the screen of the 43 output tube. Looking at the bottom of the tube with the filament prongs toward you the plate prong will be the first to the left of the filaments and the screen prong will be next to the plate prong. Be sure the meter is protected from D. C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Peaking I. F. Stages at 450 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd. condenser to the grid cap of the 6A7 tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the receiver chassis. KEEP THE GENERATOR OUTPUT LEAD AS FAR AS POSSIBLE FROM THE OTHER S. G. TUBES.

(b) Turn the tuning condenser rotor plates until they are completely meshed.

(c) Turn the band selector switch to the short wave band (extreme left hand position).

(d) Set the signal generator to 450 kilocycles.

(e) Adjust the trimmer for the 3rd I. F. transformer (Item No. 27, Fig 2) for maximum output.

(f) Adjust both trimmers located on top of the 2nd I. F. transformer for maximum output.

(g) Adjust both trimmers located on top of the 1st I. F. transformer for maximum output.

(h) Using the lowest signal generator output that will give a reasonable scale deflection on the output meter repeat operations (e) (f) and (g) as many times as necessary to obtain the maximum output.

2. Peaking R. F. Circuits—Broadcast Band (540 to 1700 K. C.)

(a) Connect the output of the signal generator through a .00025 mfd. condenser to the "Ant" terminal of the receiver.

(b) Turn the tuning condenser rotor plates until they are COMPLETELY OUT OF MESH.

(c) Turn the band selector switch to the broadcast band (extreme right hand position).

(d) Set the signal generator at 1720 kilocycles.

(e) Adjust the oscillator parallel trimmer (broadcast band) for maximum output. (Fig. 2).

(f) Set the signal generator at 1400 kilocycles.

(g) Tune-in the 1400 kilocycles signal with the station selector.

(h) Adjust the antenna parallel trimmer (broadcast band) for maximum output.

(i) Using the lowest signal generator output that will give a reasonable output meter reading, repeat operations (g) and (h) until no further increase in output can be obtained.

(j) Set the signal generator to 600 kilocycles.

(k) Tune-in the 600 kilocycle signal with the station selector in the region of 60 on the dial, for maximum reading on the output meter.

(l) Adjust the oscillator series trimmer, (Fig. 2) while rocking the condenser gang plates back and forth slightly, until no further increase in output can be obtained.

(m) Repeat operations (g) and (h) for more accurate adjustments.

3. Peaking R. F. Circuits—Police Band (1650 to 4750 K. C.)

(a) Turn the band selector switch to the police band (middle position).

(b) Set the signal generator to 4000 kilocycles. (4.0 megacycles).

(c) Turn the station selector to 4 on the police band.

(d) Adjust the oscillator parallel trimmer (P. Band) for maximum output.

(e) Adjust the antenna parallel trimmer (P. Band) for maximum output.

4. Peaking R. F. Circuits—Short Wave Band (5.3 to 15 Meg.)

(a) Replace the .00025 mfd. condenser which is being used in series with the output lead of the signal generator with a 400 ohm carbon resistor.

(b) Turn the band selector switch to the short wave band (left hand position).

(c) Set the signal generator to 15 megacycles.

(d) Close the Oscillator parallel trimmer (S-W Band) and then open three turns.

(e) Close the Antenna parallel trimmer (S-W Band) and then open ½ turn.

(f) Turn the station selector to 15 on the dial (S-W Band).

(g) Peak the oscillator parallel trimmer (S-W Band) on the FIRST signal heard when closing the condenser. In making this adjustment care should be taken not to use too much output from the signal generator to avoid setting the oscillator circuit on the wrong frequency.

NOTE: Check on the adjustment of the S-W Band oscillator parallel trimmer as follows:

1. Increase the signal generator output not more than ten times.

2. Try to tune-in the 15 megacycles signal with the station selector at approximately 14 on the dial.

3. If the 15 megacycle signal can be heard at approximately 14 and 15 both on the dial the oscillator parallel trimmer has been aligned on the correct frequency. It should be noted, however, that the signal tuned in at 15 on the dial should be much stronger than the signal heard at 14. If this condition is not found it will be necessary to repeat operation (g).

(h) Reduce the output of the signal generator to the previous output and retune the station selector to 15 megacycles at 15 on the dial.

(i) Adjust the antenna parallel trimmer (S-W Band) for maximum output, then retune the station selector for maximum output.

(j) Repeat the two operations in (i) as many times as necessary to obtain the maximum output.

Alignment

CROSLEY RADIO CORP.

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and normally should need no further adjustment. However, if it is definitely known that an adjustment is necessary the circuits can best be properly aligned with the use of a modulated signal generator and an output meter.

CONNECTING OUTPUT METER

Connect the output meter to the two plates of the 6N6 Output Tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier to 450 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd. condenser to the top cap of the 6A8 tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the "GND" terminal of the receiver. KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Set the station selector so that the tuning condenser plates are completely out of mesh. Turn the volume control knob to the right (ON) and turn the tone control knob to the left (TREBLE).

(c) Turn the band selector switch to the High Frequency Band.

(d) Set the signal generator to 450 kilocycles.

(e) Adjust both trimmers located on top of the 2nd I-F Transformer for maximum output.

(f) Adjust both trimmers located on top of the 1st I-F Transformer for maximum output.

(g) Check operations (e) and (f) for more accurate adjustments.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

Aligning R-F Amplifier.

When aligning the R-F Amplifier the output lead of the signal generator is connected to the "ANT" terminal of the receiver. For the BLUE and RED bands a .00025 mfd. condenser must be connected in series with the output lead of the signal generator and for the high-frequency band a 400 ohm carbon resistor should be used in place of the condenser.

Each band should first be shunt aligned and then series aligned, where provision is made for series alignment (BLUE band). The band selector switch should be set for the band being aligned and the station selector and signal generator should be set to the frequency indicated (c) for each adjustment.

(a) Adjust the "Osc" and "ANT" shunt trimmers in the order given for maximum output. Readjust the station selector slightly so that the generator signal is tuned-in with maximum output and then check the adjustments of the "ANT" trimmers. DO NOT READJUST the "OSC" TRIMMER.

NOTE: When shunt aligning the RED and GREEN bands care must be exercised so that the circuits will be aligned on the correct frequency rather than on the image frequency which is approximately 900 kilocycles less than the fundamental. To check on this, increase the output of the signal generator ten times, or more, and try to tune-in the signal both at the generator frequency as indicated on the station selector dial and at approximately 900 kilocycles less than the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct position.

(b) To align the series trimmer (Item 21, Fig. 2) set the signal generator to the frequency indicated (c) and then tune-in this signal with the station selector for maximum output. To obtain the best adjustment for the series trimmer it will be necessary to rotate the station selector back and forth slightly while adjusting the trimmer for maximum output.

(c) Signal Input Frequencies:

	Shunt Alignment	Series Alignment
American Broadcast Band (BLUE)	1700 Kilocycles	600 Kilocycles
Police Band (RED)	6000 Kilocycles	....
High-Frequency Band (GREEN)	18000 Kilocycles	....

SPECIFICATIONS

The Crosley Radio Model 616 is a six tube superheterodyne receiver designed to operate on an ALTERNATING CURRENT power supply. It is designed to use either metal tubes or the equivalent glass tubes with octal bases. If glass tubes are replaced with metal tubes or metal tubes are replaced with glass tubes it will be necessary to completely realign the circuits of the receiver.

It is a three band receiver and the dial is divided into three sections as follows:

BLUE	540-1800 Kilocycles	(American Broadcast Band)
RED	1.8- 6.0 Megacycles	(Police and Amateurs).
GREEN	6.0- 18.0 Megacycles	(High Frequency Bands).

SOCKET VOLTAGES

The tube socket voltages are measured from the tube socket contacts to the chassis with a 1000 ohm per volt, 500 volt D.C. voltmeter (except filaments) with the receiver in operating condition and no signal input. The filament voltages should be measured with an accurate low range A-C voltmeter (Approximately 0-10 volts). Readings may vary plus or minus 10% of values given.

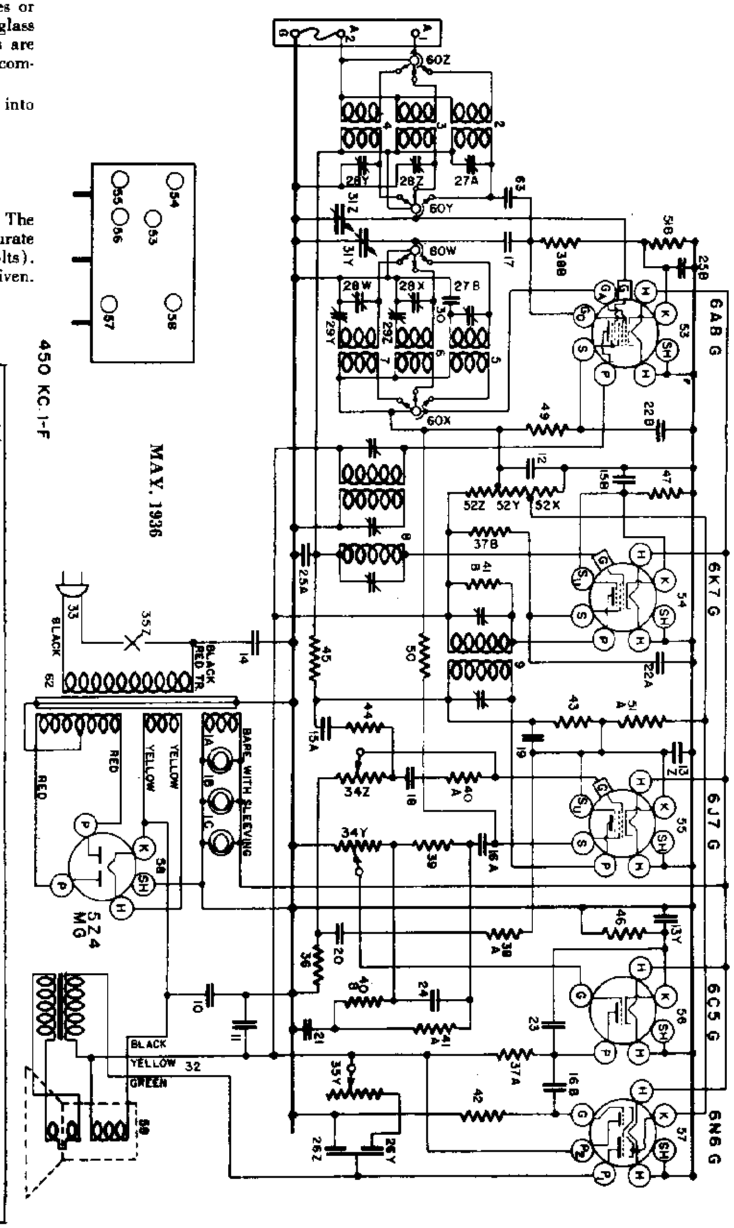
Schematic
Parts

CROSLEY RADIO CORP.



SPECIFICATIONS

The Crosley Model 626 radio is a six-tube superheterodyne receiver designed to operate on an ALTERNATING CURRENT power supply. It is available with either of the following types of power transformers: 110 volt—60 cycles, 110 volt—25 cycles or 220 volts—25 cycles.

This receiver is designed to use either metal tubes or the equivalent glass tubes with octal bases. If glass tubes are replaced with metal tubes or metal tubes are replaced with glass tubes it will be necessary to completely realign the circuits of the receiver.

It is a three band receiver and the dial is divided into three sections as follows:

BLUE	540- 1800 Kilocycles	(American Broadcast Band)
RED	1800- 6000 Kilocycles	(Police and Amateurs)
GREEN	5800-18500 Kilocycles	(High Frequency Band)

SOCKET VOLTAGES

The tube socket voltages are measured from the tube socket contacts to the chassis with a 1000 ohm per volt, 500 volt D.C. voltmeter (except filaments) with the receiver in operating condition and no signal input. The filament voltages should be measured with an accurate low range A-C voltmeter (Approximately 0-10 volts). Readings may vary plus or minus 10% of values given.

PARTS LIST—MODEL 626

Figures in first column refer to parts in Diagrams.

Item	Part No.	Description

ALIGNMENT PROCEDURE

CONNECTING OUTPUT METER

Connect the two terminals of the output meter to the two plates of the 6N6 Output tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

Tuning I-F Amplifier to 450 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd. condenser to the top cap of the 6K7 I-F Amplifier tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the receiver chassis. KEEP THE GENERATOR OUTPUT LEAD AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Turn the band selector switch to the Broadcast Band and rotate the station selector to approximately 60 on the dial. Turn the volume knob to the right (ON) and turn the tone control knob to the left (TREBLE).

(c) Set the signal generator to 450 kilocycles.

(d) Adjust the trimmer condensers located on top of the 2nd. I-F transformer for maximum output (Fig. 2).

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

(e) Transfer the output lead of the signal generator from the 6K7 tube to the top cap of the 6A8 Oscillator-Modulator tube, leaving the tube's grid clip in place.

(f) Close the middle trimmer (Tert. Fig. 4) on the 1st I-F transformer so that it is moderately tight. (Do not force adjusting screw).

(g) Adjust the top trimmer on the 1st. I-F transformer for maximum output.

(h) Adjust the bottom trimmer on the 1st I-F transformer for maximum output.

(i) Transfer the signal generator output lead from the 6A8 tube to the "ANT" terminal of the receiver and increase the output of the signal generator if necessary.

(j) Check the adjustment of the bottom trimmer of the 1st I-F transformer. DO NOT READJUST THE TOP TRIMMER.

(k) Adjust the middle trimmer of the 1st I-F transformer by opening condenser until maximum output is obtained. DO NOT READJUST THE TOP AND BOTTOM TRIMMERS.

Aligning R-F Amplifier.

When aligning the R-F Amplifier the output lead of the signal generator is connected to the "ANT" terminal of the receiver. For the BLUE and RED bands a .00025 mfd. condenser must be connected in series with the output lead of the signal generator and for the high-frequency band a 400 ohm carbon resistor should be used in place of the condenser.

Each band should first be shunt aligned and then series aligned, where provision is made for series alignment (BLUE and RED bands). The band selector switch should be set for the band being aligned and the station selector and signal generator should be set to the frequency indicated (c) for each adjustment.

(a) Adjust the "OSC" and "ANT" shunt trimmers in the order given for maximum output. Readjust the station selector slightly so that the generator signal is tuned-in with maximum output and then check the adjustments of the "ANT" trimmers. DO NOT READJUST the "OSC" TRIMMER.

NOTE: When shunt aligning the RED and GREEN bands care must be exercised so that the circuits will be aligned on the correct frequency rather than on the image frequency which is approximately 900 kilocycles less than the fundamental. To check on this, increase the output of the signal generator ten times or more and try to tune-in the signal both at the generator frequency as indicated on the station selector dial and at approximately 900 kilocycles less than the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct position.

(b) To align the series trimmers (29Y-29Z Fig. 4) set the signal generator to the frequency indicated (c) and then tune-in this signal with the station selector for maximum output. To obtain the best adjustment for each series trimmer it will be necessary to rotate the station selector back and forth slightly while adjusting the trimmer for maximum output.

(c) Signal Input Frequencies:

	Shunt Alignment	Series Align
American Broadcast Band (BLUE)	1700 Kilocycles	600 Kilocy
Police Band (RED)	6000 Kilocycles	2500 Kilocy
High-Frequency Band (GREEN)	18000 Kilocycles	....

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and normally should need no further adjustment. However, if it is definitely known that an adjustment is necessary the circuits can best be properly aligned with the use of a modulated signal generator and an output meter.

CONNECTING OUTPUT METER

Connect one terminal of the output meter to P1 and the other terminal to P2 of the 19 Output tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier To 450 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd. condenser to the top cap of the 6A7 tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the "GND" terminal of the receiver. KEEP THE GENERATOR OUTPUT LEAD AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Set the station selector so that the tuning condenser plates are completely out of mesh. Turn the volume control knob to the right (ON) and turn the tone control knob to the left (TREBLE).

(c) Turn the band selector switch to the right (High Frequency Band).

(d) Set the signal generator to 450 kilocycles.

(e) Adjust the trimmers located on top of the 2nd I-F transformer for maximum output. Fig. 2.

(f) Adjust the trimmers located on top of the 1st I-F transformer for maximum output.

(g) Repeat operations (e) and (f) for more accurate adjustments.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

2. Aligning R-F Amplifier.

When aligning the R-F amplifier the output lead from the signal generator is connected to the antenna ("A-1") terminal of the receiver through a .00025 mfd. condenser.

Each band should first be shunt aligned and then series aligned. The band selector switch should be set for the band being aligned and the signal generator should be set to the frequency indicated for each adjustment.

Adjust the "OSC", "R-F" and "ANT" shunt trimmers in the order given for maximum output. Tune the station selector to the signal generator for maximum output and then check the adjustments of the "R-F" and "ANT" trimmers in the order given. Do not readjust the "OSC" trimmer. NOTE: When aligning the High Frequency Band care must be exercised so that the circuits will be aligned on the fundamental frequency rather than on the image frequency which is approximately 900 kilocycles less than the fundamental. To check on this, increase the output of the signal generator approximately ten times and try to tune-in the signal at both the generator frequency as indicated on the station selector dial and at approximately 900 kilocycles below the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct position.

To adjust the "series" trimmers (Illus. Nos. 68, 28Z and 28Y top view, Fig. 2) set the signal generator to the frequency indicated and then tune-in this signal with the station selector for maximum output. Adjust the "series" trimmer while rocking the tuning condenser back and forth slightly, until no further improvement in output can be obtained.

SIGNAL INPUT FREQUENCIES

		Shunt Alignment	Series Alignment
BLUE	(American Broadcast)	1700 Kc.	600 Kc.
RED	Police and Amateur)	6.0 Mc.	2.0 Mc.
GREEN	(High Frequency)	18.0 Mc.	6.0 Mc.

SPECIFICATIONS

The Crosley Model 635 is a six-tube superheterodyne receiver designed for operation from a six-volt storage battery. It contains a completely shielded, built-in

BLUE	540-1800 Kc. or 555-167 Meters
RED	1.8-6.0 Mc. or 167-50 Meters
GREEN	6.0-18.0 Mc. or 50-17 Meters

TUBES AND VOLTAGE LIMITS

The following table gives the functions of the tubes used, together with the voltage readings between the tube socket contacts and the chassis. Voltage readings should be taken with a 1000 ohm per volt, 250 volt power supply unit which employs a self-rectifying type vibrator.

The tuning range of this receiver is from 540 to 18000 kilocycles and is divided into three bands as follows:

(American Broadcast Band)
(Police and Amateur Band)
(High Frequency or Short Wave Band)

voltmeter (except filaments) with the volume control full or and no signal input. The filament voltages should be measured with an accurate low range D-C voltmeter (approximately 0 to 10 volts). Voltage limits may vary plus or minus 10% of values given.

TUBE SOCKET VOLTAGE READINGS

Tube	Function	H	P	S	Su	G	Go	Ga	K
6D6	R-F Amp.	6.3	31.5	32	0	0	—	—	0
6A7	Osc.-Mod.	6.3	32.0	20	—	0	2	32	0
6D6	I-F Amp.	6.3	32.0	32	0	0	—	—	0
85	Det. & A-F Amp.	6.3	32.0	—	—	0	—	—	0
48	Output	25.0	31.5	32	—	0	—	—	5.7
48	Output	25.0	31.5	32	—	0	—	—	5.7

Measured on 32 Volt D-C Line. Current Drain Approximately 1.35 Amperes at 32 Volts.

SENSITIVITY CONTROL

The sensitivity control, Illus. No. 35, is a low resistance potentiometer. One end is connected through a condenser to the antenna lead and the other end is connected to the cathodes of the R-F and Osc-Mod tubes. The moving arm is connected to the chassis. When the knob is turned toward the left it simultaneously decreases the resistance across the primary of the antenna coil and increases the grid bias on the R-F and Osc-Mod tubes. This has the effect of decreasing the sensitivity of the receiver and increasing the selectivity. Since the sensitivity of the R-F and I-F amplifiers is simultaneously decreased, it serves as a control of overall oscillations which sometimes develop with abnormally high line voltage.

GROUND CIRCUIT

DO NOT ground the chassis except through the use of the "Gnd" terminal. This terminal is separated from the chassis by a series condenser in order to prevent a short circuit when operating the receiver on a 32 volt line with the positive side grounded.

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and should need no further adjustment. However, if an adjustment is found necessary the circuits can be properly aligned only with the use of a modulated signal generator and an output meter.

CONNECTING OUTPUT METER

Connect one terminal of the output meter to the plate of one of the type 48 output tubes and connect the other terminal to the plate of the other 48 tube. Looking at the bottom of the tube with the filament prongs toward you the plate prong will be the first prong to the left of the filament prongs. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Peaking I-F Stages at 450 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd. condenser to the grid cap of the 6A7 tube, leaving the tube's grid clip in place. KEEP THE OUTPUT LEAD FROM THE SIGNAL GENERATOR AS FAR AS POSSIBLE FROM THE OTHER SCREEN GRID TUBES.

(b) Connect the ground terminal of the signal generator to the ground terminal of the receiver.

(c) Set the signal generator to exactly 450 kilocycles.

(d) Rotate the receiver tuning condenser until the rotor plates are completely meshed.

(e) Turn the band selector switch to the left. (Short Wave).

(f) Adjust the line voltage to 32 volts.

(g) Turn the volume control and the sensitivity control all the way to the right.

(h) With the signal generator set to the lowest usable output level adjust the I-F trimmer condensers for maximum signal output.

NOTE: The I-F trimmers are located on top of the I-F transformers, Fig. 2, and may be adjusted with an insulated screw driver. Always make the adjustments very carefully, going over them several times to insure that the final setting is at resonant frequency.

2. Aligning R-F Circuits—Broadcast Band (540-1570 K. C.)

(a) Turn the band selector switch to the right hand position. (Broadcast Band).

(b) Rotate the tuning condenser until the rotor plates are completely out of mesh.

(c) Connect the antenna terminal of the signal generator to the receiver antenna terminal through a .00025 mfd., mica, series condenser.

(d) Connect the ground terminal of the signal generator to the ground terminal of the receiver.

(e) Set the signal generator to approximately 1575 kilocycles.

(f) Adjust the "Osc." section (rear section) of the tuning condenser gang for maximum signal output. (Fig. 2.)

(g) Set the signal generator to 1400 kilocycles.

NOTE: If electrical interference causes an excessive reading on the output meter, making alignment difficult, it can be reduced by connecting a 5 to 10 mfd., paper, condenser between the ground terminal of the receiver and the chassis frame.

(h) Tune in the 1400 kilocycle signal with station selector for maximum output.

NOTE: Do not disturb the setting of the oscillator trimmer (rear section) as this is adjusted at 1575 kilocycles only and any further adjustment at this point would affect both the tuning range of the receiver and the tracking of its circuits.

(i) Adjust the "R-F" parallel trimmer of the condenser gang for maximum output.

(j) Adjust the "Ant." parallel trimmer of the condenser gang for maximum output.

(k) Repeat operations (h), (i) and (j) until no further improvement in output can be made.

3. Aligning R-F Circuits—Short Wave (1570-4000 K. C.)

(a) Set the signal generator to 2500 kilocycles.

(b) Turn the band selector switch to the left. (Short Wave).

(c) Tune in the 2500 kilocycle signal with the tuning condenser for maximum output.

(d) Adjust the R-F short wave padding condenser, Illus. No. 15Y for maximum output.

(e) Adjust the Ant. short wave padding condenser, Illus. No. 15Z for maximum output.

Chassis, Parts
Alignment

CROSLEY RADIO CORP.

SPECIFICATIONS

The Crosley Model 646 radio is a six-tube superheterodyne receiver designed for operation from batteries. The method of connecting the battery cable is shown on the Wiring Diagram, Fig. 1. The batteries required are: one two volt storage battery or air cell battery, three plug-in type 45 volt "B" batteries and two plug-in type 4½ volt "C" batteries.

ALIGNMENT PROCEDURE

CONNECTING OUTPUT METER

Connect the two terminals of the output meter to the two plates of the 19 Output tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier to 450 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd. or larger, condenser to the top cap of the 1C6 Osc-Mod tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the "GND" terminal of the receiver. KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Set the station selector so that the tuning condenser plates are completely out of mesh. Turn the volume control knob to the right (ON).

(c) Turn the band selector switch to the "H-F" position.

(d) Set the signal generator to 450 kilocycles.

(e) Adjust both trimmers located on top of the 2nd I-F transformer for maximum output. Fig. 2.

(f) Adjust both trimmers located on top of the 1st I-F transformer for maximum output.

(g) Check operations (e) and (f) for more accurate adjustments.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

2. Aligning R-F Amplifier.

When aligning the R-F amplifier the output lead from the signal generator is connected to the "ANT" (A1) terminal of the receiver through a .00025 mfd. condenser.

Each band should first be shunt aligned and then series aligned. The band selector switch should be set for the band being aligned and the signal generator should be set to the frequency indicated for each adjustment.

Adjust the "OSC," "R-F" (Fig. 4), and "ANT" (Fig. 2), shunt trimmers in the order given, for maximum output. Tune the station selector to the generator signal for maximum output and then check the adjustments of the "R-F" and "ANT" trimmers in the order given. Do not readjust the "OSC" trimmer. NOTE: When aligning the High Frequency Band care must be exercised so that the circuits will be aligned on the fundamental frequency rather than on the image frequency which is approximately 900 kilocycles less than the fundamental. To check on this, increase the output of the signal generator approximately ten times and try to tune-in the signal both at the generator frequency as indicated on the station selector dial and at approximately 900 kilocycles below the correct frequency.

To adjust the "series" trimmers, Illus. Nos. 52, 26Z and 26Y—Fig. 2, set the signal generator to the frequency indicated and then tune-in the signal with the station selector for maximum output. While adjusting each "series" trimmer rock the tuning condenser back and forth slightly, until no further improvement in output can be obtained.

	Shunt Alignment	Series Alignment
American Broadcast Band (BLUE)	1700 Kilocycles	600 Kilocycles
Police and Amateur Band (RED)	6000 Kilocycles	
High Frequency Band (GREEN)	18 Megacycles

MODEL 655, Olympia
Alignment, Parts

CROSLEY RADIO CORP.

SPECIFICATIONS

The Crosley Model 655 radio is a six-tube superheterodyne receiver using all metal tubes and is available or adaptable for operation on A-C lines as follows: 110 V—60 cycles, 110 V—25 cycles and 220 V—25 cycles. It is a three band receiver tuning from 540 to 1700 kilocycles in the broadcast band, 1700 to 5200 kilocycles in the police and amateur band and 5400 to 15,300 kilocycles in the high frequency band.

The tubes used are: 6A8 Oscillator-Modulator, 6K7 I-F Amplifier, 6H6 Detector and AVC, 6K7 A-F Amplifier, 6F6 Output and type 5Z4 Rectifier.

SOCKET VOLTAGES

The tube socket voltages are measured from the socket contacts to the chassis with a 1000 ohm per volt, 250 volt voltmeter (except filaments) with the receiver in operating condition and no signal input. Readings may vary plus or minus 10% of values given.

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and should need no further adjustment. However, if it is definitely known that an adjustment is necessary the circuits can be properly aligned only with the use of a modulated signal generator and an output meter.

CONNECTING OUTPUT METER

Connect one terminal of the output meter to the plate and the other terminal to the screen of the 6F6 output tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Tuning I. F. Amplifier to 450 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd. condenser to the grid cap of the 6A8 tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the receiver chassis. KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID WIRES OF THE OTHER S. G. TUBES.

(b) Turn the tuning condenser rotor plates until they are completely meshed.

(c) Turn the band selector switch to the short wave band (extreme left hand position).

(d) Set the signal generator to 450 kilocycles.

(e) Adjust both trimmers located on top of the 2nd I. F. transformer for maximum output. (Fig 2).

(f) Adjust both trimmers located on top of the 1st I. F. transformer for maximum output.

(g) Using the lowest signal generator output that will give a reasonable scale deflection on the output meter repeat operations (e) and (f) as many times as necessary to obtain the maximum output.

2. Aligning R. F. Amplifier—Broadcast Band (540 to 1700 Kc.)

(a) Connect the output of the signal generator through a .00025 mfd. condenser to the "Ant" terminal of the receiver.

(b) Turn the tuning condenser rotor plates until they are COMPLETELY OUT OF MESH.

(c) Turn the band selector switch to the broadcast band (extreme right hand position).

(d) Set the signal generator at 1720 kilocycles.

(e) Adjust the oscillator parallel trimmer (broadcast band) for maximum output.

(f) Set the signal generator at 1400 kilocycles.

(g) Tune-in the 1400 kilocycle signal with the station selector.

(h) Adjust the antenna parallel trimmer (broadcast band) for maximum output.

(i) Using the lowest signal generator output that will give a reasonable output meter reading, repeat operations (g) and (h) until no further increase in output can be obtained.

(j) Set the signal generator to 600 kilocycles.

(k) Tune-in the 600 kilocycle signal with the station selector in the region of 60 on the dial, for maximum reading on the output meter.

(l) Adjust the oscillator series trimmer. (Fig. 2) while rocking the condenser gang plates back and forth slightly, until no further increase in output can be obtained.

(m) Repeat operations (g) and (h) for more accurate adjustments.

3. Aligning R. F. Amplifier—Police Band 1700 to 5200 Kc.)

(a) Turn the band selector switch to the police band (middle position).

(b) Set the signal generator to 5000 kilocycles. (5.0 megacycles).

(c) Turn the station selector to 5 on the police band.

(d) Adjust the oscillator parallel trimmer (P. Band) for maximum output. (Fig. 4).

(e) Adjust the antenna parallel trimmer (P. Band) for maximum output.

4. Aligning R. F. Amplifier—Short Wave Band 5.4 to 15 Meg.)

(a) Replace the .00025 mfd. condenser which is being used in series with the output lead of the signal generator with a 400 ohm carbon resistor.

(b) Turn the band selector switch to the short wave band (left hand position).

(c) Set the signal generator to 15 megacycles.

(d) Close the Oscillator parallel trimmer (S-W Band) and then open three turns.

(e) Close the Antenna parallel trimmer (S-W Band) and then open ½ turn.

(f) Turn the station selector to 15 on the dial (S-W Band.)

(g) Peak the oscillator parallel trimmer (S-W Band) on the FIRST signal heard when closing the condenser. In making this adjustment care should be taken not to use too much output from the signal generator to avoid setting the oscillator circuit on the wrong frequency.

NOTE: Check on the adjustment of the S-W Band oscillator parallel trimmer as follows:

1. Increase the signal generator output not more than ten times.
2. Try to tune-in the 15 megacycles signal with the station selector at approximately 14 on the dial.
3. If the 15 megacycle signal can be heard at approximately 14 and 15 both on the dial the oscillator parallel trimmer has been aligned on the correct frequency. It should be noted, however, that the signal tuned in at 15 on the dial should be much stronger than the signal heard at 14. If this condition is not found it will be necessary to repeat operation (g).

(h) Reduce the output of the signal generator to the previous output and retune the station selector to 15 megacycles at 15 on the dial.

(i) Adjust the antenna parallel trimmer (S-W Band) for maximum output, then re-tune the station selector for maximum output.

(j) Repeat the two operations in (i) as many times as necessary to obtain the maximum output.

NOTE: On the band selector switch there is a small eyelet soldered to one of the connecting lugs. This eyelet, item No. 23, is used as a small condenser the capacity of which is formed by inserting an insulated wire into the sleeve of the eyelet. If a new band selector switch is installed care should be taken to see that the "capacity wire" is inserted into the sleeve of the eyelet. This insulated wire should be passed through the eyelet and a slight hook made in the end to prevent it from pulling out. (See Fig. 3).

CROSLEY RADIO CORP.

SPECIFICATIONS

The Crosley Model 725 radio is a seven-tube superheterodyne receiver and is available or adaptable for operation on A-C lines as follows: 110 V—60 cycles, 110 V—25 cycles and 220 V—25 cycles.

It is a five band receiver and the dial is divided into five sections as follows:

ORANGE—	150- 400 kilocycles	(Weather Band)
BLACK —	540- 1,555 kilocycles	(American Broadcast Band)
GREEN —	1,500- 4,200 kilocycles	(Police and Amateur Band)
RED —	3,900-10,400 kilocycles	(Night High Frequency Band)
VIOLET —	9,800-22,000 kilocycles	(Day High Frequency Band)

The positions on the band selector switch are in the above order, reading from right to left.

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and should need no further adjustment. However, if it is definitely known that an adjustment is necessary the circuits can be properly aligned only with the use of a modulated signal generator and an output meter.

CONNECTING OUTPUT METER

Connect one terminal of the output meter to the plate and the other terminal to the screen of the 42 output tube. Looking at the bottom of the tube with the filament prongs toward you the plate prong will be the first to the left of the filament prongs and the screen prong will be next to the plate prong. Be sure the meter is protected from D. C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. **Tuning I-F Amplifier to 450 Kilocycles.**

(a) Connect the output of the signal generator through a .02 mfd. condenser to the top cap of the 6A7 tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the receiver chassis. KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID WIRES OF THE OTHER SCREEN GRID TUBES.

(b) Set the station selector so that the tuning condenser plates are open. Turn the volume control knob to the right (ON) and turn the tone control knob to the left (TREBLE).

(c) Turn the band selector switch all the way to the left.

(d) Set the signal generator to 450 kilocycles.

(e) Close the middle trimmer condenser on the 1st. I-F transformer.

(f) Adjust the trimmers located on top of the 2nd. I-F transformer for maximum output.

(g) Adjust the top and bottom trimmers of the 1st. I-F transformer for maximum output.

(h) Repeat operations (f) and (g) for more accurate adjustments.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

(i) Reduce the output of the signal generator and adjust the middle trimmer on the 1st. I-F transformer for maximum output. DO NOT READJUST THE OTHER TRIMMERS.

2. **Aligning R-F Amplifier.**

(a) When aligning the R-F amplifier the output lead from the signal generator is connected to the "Ant" terminal of the receiver. For the ORANGE, BLACK and GREEN bands a .00025 mfd. condenser must be connected in series with the output lead from the signal generator and for the two high frequency bands a 400 ohm carbon resistor should be used in place of the condenser.

Each band should first be shunt aligned and then series aligned where provision is made for series alignment (Weather Band and Broadcast Band). The band selector switch should be set for the band being aligned and the signal generator should be set to the frequency indicated for each adjustment.

Adjust the "Osc", "R-F" and "Ant" trimmers in the order given for maximum output and then check the adjustments in the same order. NOTE: When aligning the Police and High Frequency Bands care must be exercised so that the circuits will be aligned on the fundamental frequency rather than on the image frequency which is always approximately 900 kilocycles less than the fundamental. To check on this, increase the output of the signal generator approximately ten times and try to tune-in the signal both at the generator frequency as with the station selector for maximum output. Adjust the "series" trimmer while rocking the tuning condenser back and forth slightly, until no further improvement in output can be obtained.

After the "series" alignment of any band has been completed it will be necessary to repeat the "shunt" alignment of that band.
indicated on the station selector dial and at approximately 900 kilocycles below the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct position.

To align the "series" trimmer, set the signal generator to the frequency indicated and then tune-in this signal

(b) Signal Input Frequencies.

	Shunt Alignment	Series Alignment
Weather Band (ORANGE)	400 Kc.	150 Kc.
American Broadcast Band (BLACK)	1400 Kc.	600 Kc.
Police and Amateur Band (GREEN)	4000 Kc.	—
Night H-F Band (RED)	10 Megacycles	—
Day H-F Band (VIOLET)	21 Megacycles	—

SOCKET VOLTAGES

The tube socket voltages are measured from the tube socket contacts to the chassis with a 1000 ohm per volt, 500 volt voltmeter (except filaments) with the receiver in operating condition and no signal input. Readings may vary plus or minus 10% of values given.

CROSLEY RADIO CORP.

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and normally should need no further adjustment. However, if it is definitely known that an adjustment is necessary the circuits can be properly aligned ONLY with the use of a modulated signal generator and an output meter.

CONNECTING OUTPUT METER

Connect the two terminals of the output meter to the two plates of the 19 Output tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. **Tuning I-F Amplifier to 450 Kilocycles.**

(a) Connect the output of the signal generator through a .02 mfd. condenser to the top cap of the 1C6 Oscillator-Modulator tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the "GND" terminal of the receiver. KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID WIRES OF THE OTHER SCREEN GRID TUBES.

(b) Set the station selector so that the tuning condenser plates are completely out of mesh. Turn the volume control knob to the right (ON).

(c) Turn the band selector switch to the left (High Frequency).

(d) Set the signal generator to 450 kilocycles.

(e) Adjust both trimmers located on top of the 3rd I-F transformer for maximum output. (Screw and nut).

(f) Adjust both trimmers located on top of the 2nd I-F transformer for maximum output.

(g) Adjust both trimmers for the 1st I-F transformer (26Y and 26Z located on end of chassis) for maximum on the station selector dial and at approximately 900 kilocycles below the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct dial setting.

To adjust the "series" trimmers 25Z—Broadcast and output.

(h) Repeat operations (e), (f) and (g) for more accurate adjustments.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

2. **Aligning R-F Amplifier.**

(a) When aligning the R-F Amplifier the output lead from the signal generator should be connected through a dummy antenna to the "ANT" terminal of the receiver. For the broadcast band the dummy antenna should be a .00025 mfd. condenser and for the high frequency band this condenser should be replaced by a 400 ohm carbon resistor (Non-Inductive).

Each band should be shunt aligned, series aligned and then shunt aligned again in order given. The band selector switch should be set for the band being aligned and the signal generator should be set to the frequency indicated below for each adjustment.

Adjust the "OSC" (24), "R-F" (23) and "ANT" (22) shunt trimmers, Z—Broadcast and Y—High Frequency Bands, in the order given for maximum output. Return the station selector to the generator signal for maximum output. Readjust the "R-F" and "Ant" trimmers for maximum output. Do not readjust the "OSC" shunt trimmer.

NOTE: When aligning the high frequency band care should be exercised so that the circuits will be aligned on the fundamental rather than on the image frequency which is approximately 900 kilocycles less than the fundamental. To check on this, increase the output of the signal generator approximately 10 times and try to tune-in the signal both at the generator frequency as indicated 25Y—High Frequency Bands, set the signal generator to the frequency indicated below and then tune-in this signal with the station selector for maximum output. Adjust the series trimmer while rocking the tuning condenser back and forth slightly, until no further improvement in output can be obtained.

(b) Signal Generator Frequencies.

	Shunt Alignment	Shunt Alignment
High Frequency Band	1400 Kc.	600 Kc.
Broadcast Band	15000 Kc.	6000 Kc.

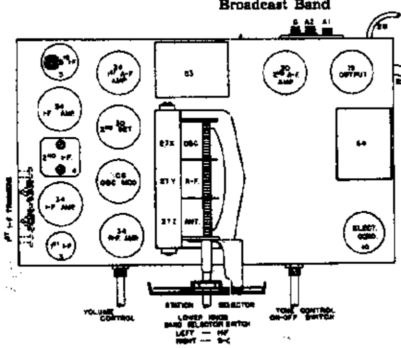

Fig. 2. Top View 815

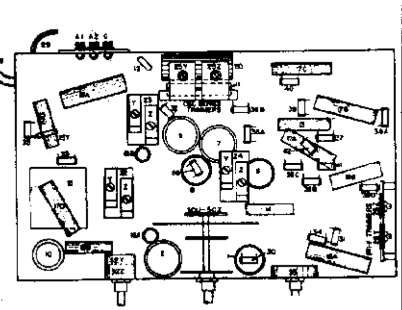

Fig. 3. Bottom View 815

SPECIFICATIONS

The Crosley Model 815 radio is an eight-tube superheterodyne receiver designed for operation from batteries. The method of connecting the battery cable to the batteries is shown on the wiring diagram. The batteries required are: one two-volt storage battery or an air cell battery, three plug-in type 45-volt "B" batteries and two 4½-volt "C" batteries. The frequency ranges covered are from 540 to 1710 kilocycles in the broadcast band and from 5800 to 15,300 kilocycles in the high frequency band.

TUBES AND VOLTAGE LIMITS

The following table gives the functions of the tubes used, together with the voltage readings between the tube socket contacts and "A"—. Voltage readings should be taken with a 1000 ohm per volt, 250 volt voltmeter (except filaments) with volume control full on and no signal input. Filament voltages should be measured with an accurate low range D.C. voltmeter (0 to 10 volts). Voltage limits may vary plus or minus 10% of values given.

TUBE SOCKET VOLTAGE READINGS

Tube	Where Used	H	P	S	G	Ga	Go
34	R. F. Amplifier	2.0	135	67.5	—	—	—
1C6	Osc.-Mod.	2.0	135	67.5	—	85	-5 to -10
34	1st I-F Amplifier	2.0	135	67.5	-3	—	—
34	2nd I-F Amplifier	2.0	135	67.5	-3	—	—
30	Diode Detector	2.0	—	—	—	—	—
30	A-F Amplifier	2.0	70	—	-3	—	—
30	A-F Driver	2.0	135	—	-9	—	—
19	Double Triode Output	2.0	135	—	-1.5	—	—

POWER OUTPUT APPROXIMATELY 2.5 WATTS.
"A" BATTERY DRAIN APPROXIMATELY .74 AMPERES AT 2 VOLTS.
"B" BATTERY DRAIN 20 TO 35 MILLIAMPERES—DEPENDING UPON VOLUME CONTROL ADJUSTMENT.

PARTS LIST—MODEL 815

MODEL 816
Socket, Trimmers
Voltage, Chassis
Alignment

CROSLEY RADIO CORP.

SPECIFICATIONS

The Crosley Model 816 radio is an eight-tube superheterodyne receiver and uses either glass or metal tubes, except the Phantom Conductor (Auto-Expressionator) tube which is always glass and the 5Z4 rectifier which should always be the MG type. • NOTE: If glass tubes are replaced with metal tubes or metal tubes replaced with glass tubes it will be necessary to completely re-align the circuits of the receiver because of the difference in inter-electrode capacities. Chassis are available either with a standard 110 Volt—60 Cycle, 110 Volt—25 Cycle or 220 Volt—25 Cycle Power Transformer.

The tuning range of the receiver is from 540 to 19000 Kilocycles and is divided into three bands as follows:

BLUE	540-1900 Kc. or 555-158 Meters (Standard American Broadcast)
RED	1.9- 6.5 Mc. or 158- 46 Meters (Police and Amateurs)
GREEN	6.0- 19.0 Mc. or 50- 16 Meters (High Frequency)

SOCKET VOLTAGES

The tube socket voltages are measured from the tube socket contacts to the chassis with a 1000 ohm per volt, 500 volt D. C. voltmeter (except filaments) with the receiver in operating condition and no signal input. The filaments should be measured with an accurate low range A. C. voltmeter. Readings may vary plus or minus 10% of values given.

PANTOM CONDUCTOR (Auto Expressionator)

The Phantom Conductor tube, Illustration No. 49, is connected across the voice coil of the speaker. When operating its resistance varies so as to increase the volume of loud tones, thus giving a wider volume range to reproduced music which tends to compensate for the electrical limitations of broadcasting equipment.

PHONOGRAPH PICKUP

Chassis equipped with a 25 cycle power transformer also have three terminals on the back for connecting a phonograph pickup. These terminals are marked P C S and the pickup is connected through a double pole single throw switch to these terminals as shown in Fig. 7.

ALIGNMENT PROCEDURE

This is a High Fidelity receiver and in order to secure maximum performance the alignment of its circuits should be done with precision instruments.

Tuning I-F Amplifier to 450 Kilocycles.

The I-F amplifier employs two triple-tuned I-F transformers and under no condition should their trimmer condensers be readjusted just to determine if they are properly tuned. Fig. 5 shows the selectivity curve of a receiver whose I-F amplifier was slightly mis-tuned while Fig. 6 shows a curve made from actual measurements of a receiver which was properly aligned with the use of an oscilloscope. (See Note 3, next page).

1. Conventional Method—

(a) Connect one terminal of the output meter to P2 of one of the 6N6 Output tubes and the other terminal through a .1 mf., or larger, condenser—Not Electrolytic —to P2 of the other Output tube.

(b) Connect the output of the signal generator through a .02 mf. condenser, to the top cap of the 6K7 I-F Amp. tube; leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the GND. terminal of the receiver chassis. KEEP THE GENERATOR OUTPUT LEAD AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(c) Set the band selector switch to the Broadcast Band and rotate the station selector to approximately 60 on the dial. Turn the volume control knob to the right (ON), turn the tone control knob to the left (TREBLE), and turn the Phantom Control Switch to the left (OFF).

(d) Set the signal generator to 450 Kilocycles.

(e) Adjust the trimmer condensers on the top of the 2nd. I-F transformer for maximum output. Fig. 2 (Item 12).

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE READING ON THE OUTPUT METER.

(f) Transfer the output lead of the signal generator from the 6K7 tube to the top cap of the 6A8 Osc.-Mod. tube, leaving the tube's grid clip in place.

(g) Close the middle trimmer condenser on the 1st. I-F transformer (Tert. Fig. 4) so that it is moderately tight. (DO NOT FORCE ADJUSTING SCREW).

(h) Adjust the top (Sec) and then the bottom (Pri) trimmers of the 1st. I-F transformer for maximum output.

(i) Transfer the lead of the signal generator from the 6A8 tube to the "ANT" terminal of the receiver and increase the output of the signal generator if necessary.

(j) Check the adjustment of the bottom (Pri) trimmer of the 1st. I-F transformer. Then adjust the middle trimmer by opening until maximum output is obtained. DO NOT READJUST TOP OR BOTTOM TRIMMERS AFTER THE MIDDLE TRIMMER HAS BEEN ADJUSTED.

2. Oscilloscope Method.

(a) Connect the output of the signal generator through a .02 mf. condenser to the top cap of the 6K7 I-F amplifier tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the receiver chassis. KEEP THE GENERATOR OUTPUT LEAD AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Connect the vertical plates of the cathode ray oscilloscope to the receiver as follows: The binding post marked "GND" should be connected to the receiver chassis and the other binding post should be connected to the plate terminal of the 6R7 tube. (Be sure the oscilloscope is protected from D. C. by connecting a condenser, 0.1 to .05 mf., in series with the lead to the plate of the 6R7 tube).

(c) Set the band selector switch to the Broadcast Band and rotate the station selector to approximately 60 on the dial. The exact setting should be at a position where no broadcast signal will be received. Turn the volume control to the right (ON), turn the tone control to the left (TREBLE) and turn the Phantom Conductor switch to the left (OFF).

(d) Set the signal generator to 450 kilocycles. See Instructions supplied with signal generator and oscilloscope.

(e) Adjust the trimmer condensers located on top of the 2nd. I-F transformer for maximum amplitude and symmetry of the selectivity curve on the resonance line (R).

NOTE: Keep the signal generator output as low as possible in order to prevent AVC action in the receiver.

(f) *Transfer the output lead of the signal generator from the 6K7 tube to the top cap of the 6A8 oscillator-modulator tube, leaving the tube's grid clip in place.

(g) Close the middle trimmer (TERT) of the 1st. I-F transformer so that it is moderately tight. (Do not force adjustment screw).

(h) Increase the output of the signal generator and adjust the top trimmer (Sec) of the 1st. I-F transformer for maximum symmetry and amplitude.

(i) Adjust the bottom trimmer (Pri) of the 1st. I-F transformer for maximum amplitude.

(j) Reduce the output of the signal generator and adjust the middle trimmer of the 1st. I-F transformer for maximum symmetry and amplitude.

Aligning R-F Amplifier.

The R-F amplifier can best be aligned in the conventional manner, using a modulated signal generator and output meter.

When aligning the R-F amplifier the output lead of the signal generator is connected to the antenna terminal of the receiver. For the BLUE and RED bands a .00025 mf. condenser must be in series with the output lead of the signal generator and for the high-frequency band a 400 Ohm carbon resistor should be used in place of the condenser.

Each band should be shunt aligned and then series aligned, where provision is made for series alignment (BLUE band). The band selector switch should be set for the band being aligned and the signal generator should be set to the frequency indicated (c) for each adjustment.

(a) Adjust the "Osc.," "R-F" (Fig. 4) and "Ant." (Fig. 2) shunt trimmers in the order given for maximum output. Readjust the station selector slightly so that the generator signal is tuned-in with maximum output and then check the adjustments of the "R-F" and "Ant." trimmers in the order given. DO NOT READJUST THE "OSC" TRIMMER.

NOTE: When shunt aligning the RED and GREEN bands care must be exercised so that the circuits will be aligned on the fundamental frequency rather than on the image frequency which is approximately 900 Kilocycles less than the fundamental frequency. To check on this, increase the output of the signal generator ten times or more and try to tune-in the signal both at the generator frequency as indicated on the station selector dial and at approximately 900 Kilocycles less than the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct position.

(b) To align the B-C "OSC" series trimmert, Illus. 27, Fig. 4, set the signal generator to 600 Kilocycles and then tune-in this signal with the station selector for maximum output. While the series trimmer is being adjusted rotate the station selector back and forth slightly until no further improvement in output can be obtained.

(C) SIGNAL INPUT FREQUENCIES

		Shunt Aligned	Series Aligned
American Broadcast	(BLUE)	1700 Kc.	600 Kc.
Pol. & Amateur	(RED)	6000 Kc.	
High-Frequency	(GREEN)	18000 Kc.	

NOTE 3: The high frequency oscillator on this receiver is neutralized by the addition of some small capacity coupling between the oscillator grid and the R-F grid of the 6A8 tube. This is accomplished by loosely wrapping a piece of insulated hook-up wire around the R-F grid lug and connecting it to the oscillator grid lug on the band selector switch.

It is necessary on some sets to adjust or even remove this coupling, in which case the wire should be unwrapped and threaded through the extra hole in the grid end of the R-F coil.

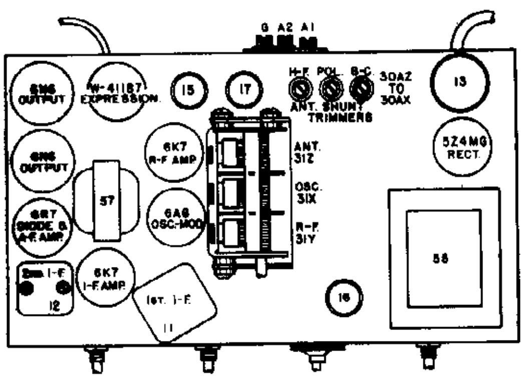

Fig. 2. Top View

Voltage, Socket

SPECIFICATIONS

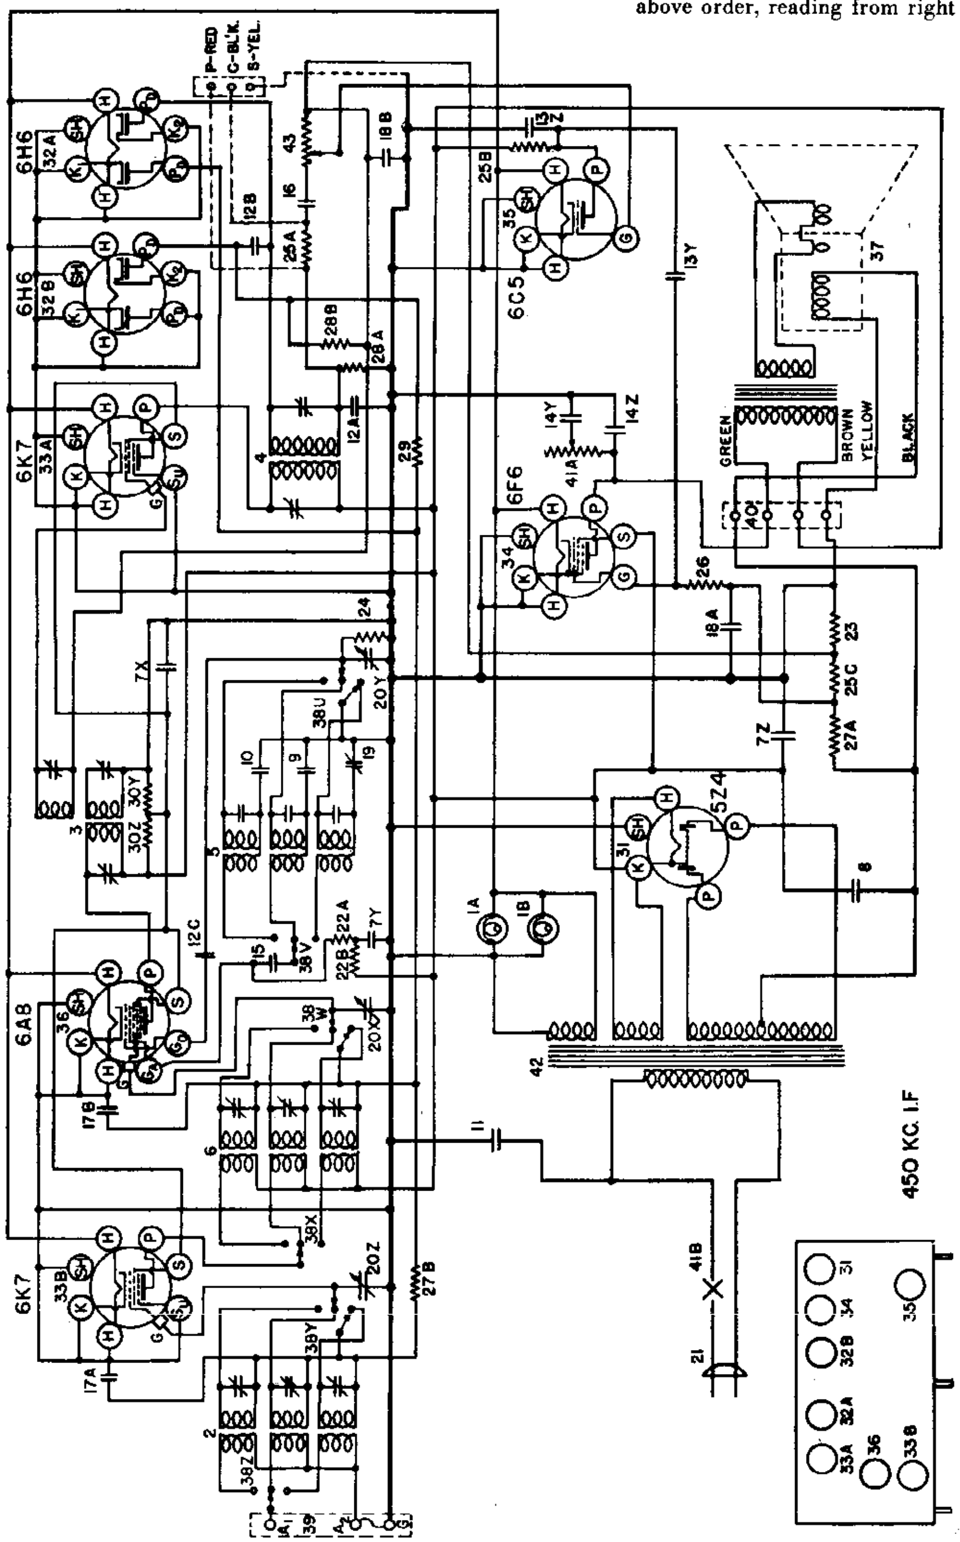
The Crosley Model 855 radio is an eight-tube superheterodyne receiver using all metal tubes. It is available or adaptable for operation on A-C lines as follows: 110 V—60 cycles, 110 V—25 cycles and 220 V—25 cycles.

It is a three band receiver and the dial is divided into three sections as follows:

BLACK— 540- 1,625 kilocycles
GREEN—1,625- 4,700 kilocycles
RED —5,250-15,300 kilocycles

The positions on the band selector switch are in the above order, reading from right to left.

NOVEMBER, 1935



TUBE SOCKET VOLTAGE READINGS

Tube	Function	H	P	S	Su	G	K	Go	Ga
6K7	R-F Amplifier	6.3	245	110	0	-3	0	—	—
6A8	Osc.-Mod.	6.3	245	110	—	-3	0	-5 to -15	175
6K7	I-F Amplifier	6.3	245	110	0	-3	0	—	—
6H6	Detector	6.3	—	—	—	—	0	—	—
6H6	AVC	6.3	—	—	—	—	0	—	—

Chassis, Parts
Alignment

CROSLEY RADIO CORP.

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and should need no further adjustment. However, if it is definitely known that an adjustment is necessary the circuits can be properly aligned only with the use of a modulated signal generator and an output meter.

CONNECTING OUTPUT METER

Connect one terminal of the output meter to the plate and the other terminal to the screen of the 6F6 output tube. Be sure the meter is protected from D.C. by connecting a condenser .1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier to 450 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd. condenser to the top cap of the 6A8 tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the receiver chassis. KEEP THE GENERATOR OUTPUT LEAD AS FAR AS POSSIBLE FROM THE OTHER SCREEN GRID TUBES.

(b) Set the station selector so that the tuning condenser plates are open. Turn the volume control knob to the right (ON) and turn the tone control knob to the left (TREBLE).

(c) Turn the band selector swich all the way to the left.

(d) Set the signal generator to 450 kilocycles.

(e) Close the middle trimmer condenser on the 1st. I-F transformer.

(f) Adjust the trimmers located on top of the 2nd. I-F transformer for maximum output.

(g) Adjust the top and bottom trimmers of the 1st. I-F transformer for maximum output.

(h) Repeat operations (f) and (g) for more accurate adjustments.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

(i) Reduce the output of the signal generator and adjust the middle trimmer on the 1st. I-F transformer for maximum output. DO NOT READJUST THE OTHER TRIMMERS.

2. Aligning R-F Amplifier.

(a) When aligning the R-F amplifier the output lead from the signal generator is connected to the "Ant" terminal of the receiver. For the BLACK and GREEN bands a .00025 mfd. condenser must be connected in series with the output lead from the signal generator and for the high frequency band a 400 ohm carbon resistor should be used in place of the condenser.

Each band should first be shunt aligned and then series aligned where provision is made for series alignment (Broadcast band). The band selector switch should be set for the band being aligned and the signal generator should be set to the frequency indicated for each adjustment.

Adjust the "Osc", "R-F" and "Ant" trimmers in the order given for maximum output and then check the adjustments in the same order. NOTE: When aligning the Police and High Frequency Band care must be exercised so that the circuits will be aligned on the fundamental frequency rather than on the image frequency which is approximately 900 kilocycles less than the fundamental. To check on this increase the output of the signal generator approximately ten times and try to tune-in the signal both at the generator frequency as indicated on the station selector dial and at approximately 900 kilocycles below the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct position.

To align the "series" trimmer set the signal generator to the frequency indicated and then tune-in this signal with the station selector for maximum output. Adjust the "series" trimmer while rocking the tuning condenser back and forth slightly, until no further improvement in output can be obtained.

After the "series" alignment of the broadcast band has been completed it will be necessary to check the "shunt" alignment of that band.

(b) Signal Input Frequencies.

	Shunt Alignment	Series Alignment
American Broadcast Band (BLACK)	1400 Kc.	600 Kc.
Police and Amateur Band (GREEN)	4000 Kc.	—
Night H-F Band (RED)	10 Megacycles	—

SOCKET VOLTAGES

The tube socket voltages are measured from the tube socket contacts to the chassis with a 1000 ohm per volt, 500 volt voltmeter (except filaments) with the receiver in operating condition and no signal input. Readings may vary plus or minus 10% of values given.

CONNECTING OUTPUT METER

Connect one terminal of the output meter to the plate and the other terminal to the screen of the 6F6 output tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier to 450 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd. condenser to the top cap of the 6A8 tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the receiver chassis. KEEP THE GENERATOR OUTPUT LEAD AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Set the station selector so that the tuning condenser plates are open. Turn the volume control knob to the right (ON) and turn the tone control knob to the left (TREBLE).

(c) Turn the band selector switch all the way to the left.

(d) Set the signal generator to 450 kilocycles.

(e) Close the middle trimmer condenser (SEC) on the 1st I-F transformer. (Fig. 2).

(f) Adjust the trimmers located on top of the 2nd I-F transformer for maximum output.

(g) Adjust the top and bottom trimmers (TERT and PRI) of the 1st I-F transformer for maximum output.

(h) Repeat operations (f) and (g) for more accurate adjustments.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

(i) Reduce the output of the signal generator and adjust the middle trimmer on the 1st I-F transformer for maximum output. DO NOT READJUST THE OTHER TRIMMERS.

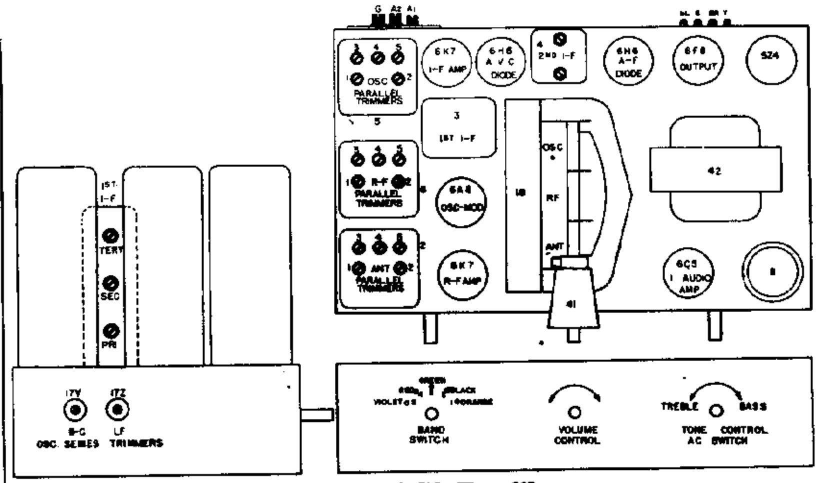

Fig. 2. Top & Side Views 865

2. Aligning R-F Amplifier.

(a) **When aligning the R-F amplifier the output lead** from the signal generator is connected to the "Ant" terminal of the receiver. For the ORANGE, BLACK and GREEN bands a .00025 mfd. condenser must be connected in series with the output lead from the signal generator and for the two high frequency bands a 400 ohm carbon resistor should be used in place of the condenser.

Each band should first be shunt aligned and then series aligned where provision is made for series alignment (Orange and Black Bands). The band selector switch should be set for the band being aligned and the signal generator should be set to the frequency indicated for each adjustment.

Adjust the "Osc", "R-F" and "Ant" parallel trimmers in the order given for maximum output. Tune the station selector to the generator signal for maximum output and then check the adjustments of the "R-F" and "Ant" trimmers in the order given. Do not readjust the "Osc" trimmer. NOTE: When aligning the Police and High Frequency Bands care must be exercised so that the circuits will be aligned on the fundamental frequency rather than on the image frequency which is always approximately 900 kilocycles less than the fundamental. To check on this, increase the output of the signal generator approximately ten times and try to tune-in the signal both at the generator frequency as indicated on the station selector dial and at approximately 900 kilocycles below the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct position.

To align the "series" trimmer (17Y and 17Z, Fig. 2) set the signal generator to the frequency indicated and then tune-in this signal with the station selector for maximum output. Adjust the "series" trimmer while rocking the tuning condenser back and forth slightly, until no further improvement in output can be obtained.

CROSLEY RADIO CORP.

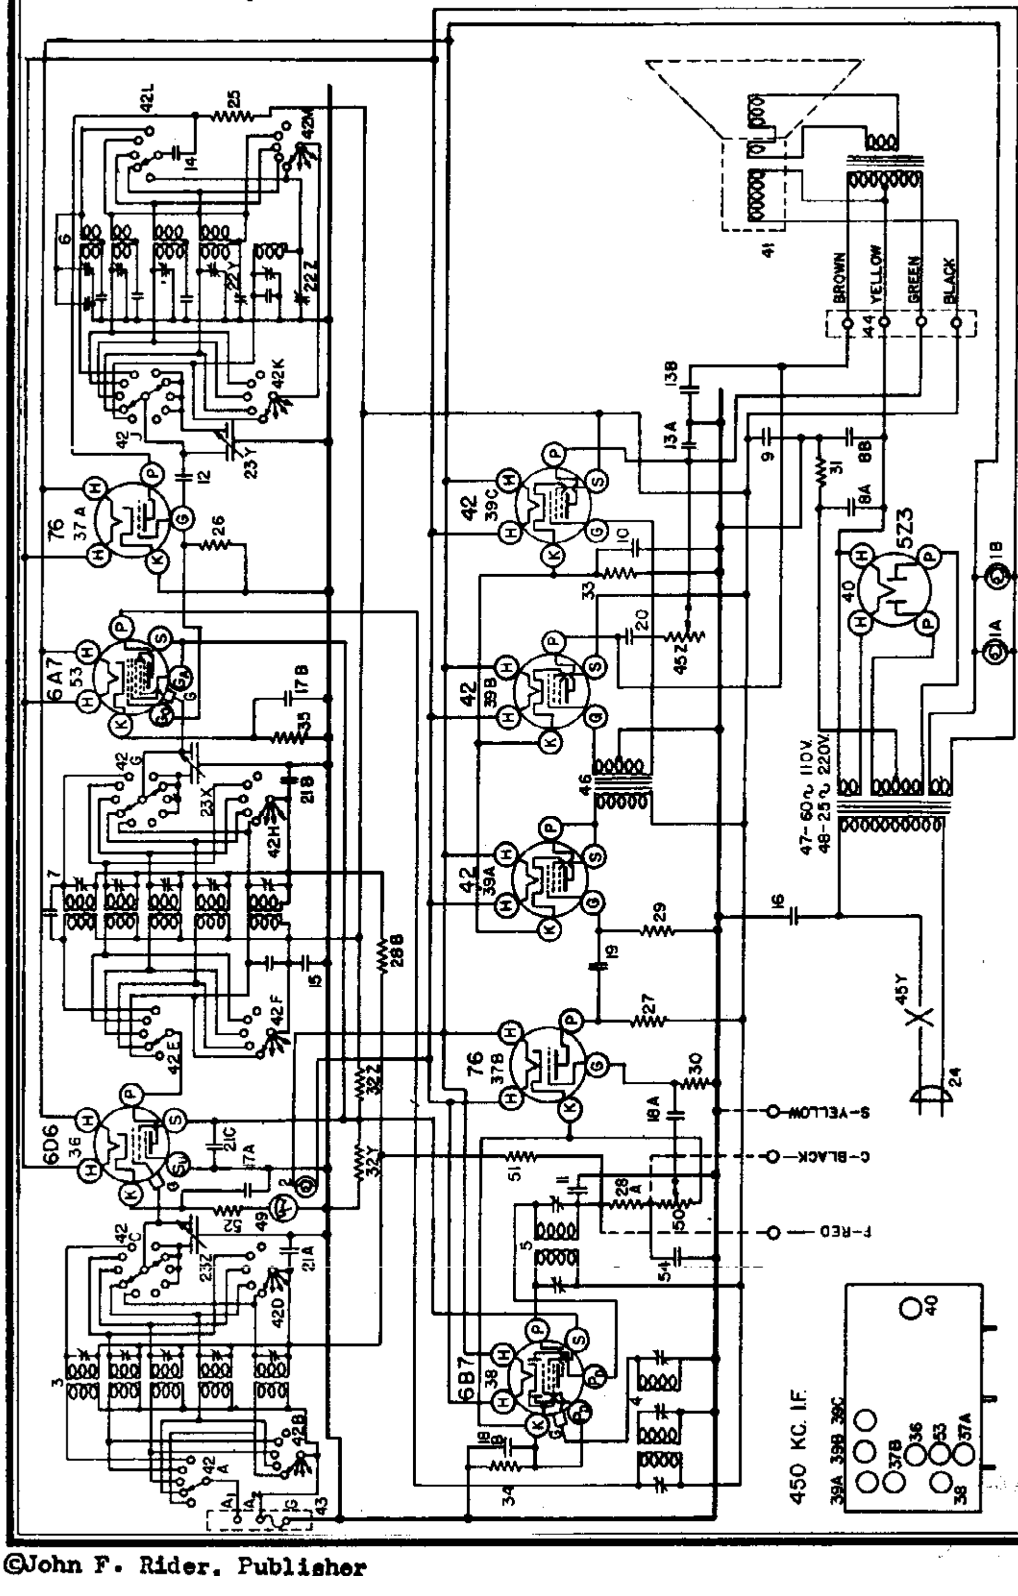
SPECIFICATIONS

The Crosley Model 915 radio is a nine-tube superheterodyne receiver and is available either with a standard 110 volt—60 cycle power transformer or with a universal power transformer which can be adapted to A-C lines from 95 to 267 volts and any frequency.

It is a five band receiver and the dial is divided into five sections as follows:

ORANGE—	150- 400	kilocycles	(Weather Band)
BLACK —	540- 1,500	kilocycles	(American Broadcast Band)
GREEN —	1,500- 4,000	kilocycles	(Police and Amateur Band)
RED —	4,000-10,000	kilocycles	(Night High Frequency Band)
VIOLET —	10,000-21,000	kilocycles	(Day High Frequency Band)

The positions on the band selector switch are in the above order, reading from left to right.



TUBE SOCKET VOLTAGE READINGS

Tube	Function	H	P	S	Su	G	K	Go	Ga

UNIVERSAL POWER TRANSFORMER

The Model 915 chassis for use on other than 110 volts, 60 cycles, is supplied with a universal power transformer designed to operate on 25 cycles and up. When leaving the factory it is wired for the voltage indicated on the license plate. It is possible, however, by a slight change in the power transformer wiring to adapt the set to a different voltage anywhere from 95 to 267 volts. To adapt the set to a different line voltage it is necessary to remove the chassis from the cabinet, remove the bottom from the chassis and locate the terminal strip on the bottom of the power transformer, Fig. 3. After careful measurement of the maximum values of line voltage, unsolder the wire of the A-C line cord from the terminal strip and solder it to the correct terminal. The correct terminal will be the one marked so as to cover or nearly cover the maximum line voltage. THE MAXIMUM VOLTAGE SHOULD NOT EXCEED THE HIGHEST RATING STAMPED ON THE TERMINAL BOARD BESIDE THE TERMINAL TO BE USED BY MORE THAN 3%.

PHONOGRAPH PICKUP

Chasses equipped with a universal power transformer also have three terminals on the back for connecting a phonograph pickup. These terminals are marked P C S and the pickup is connected through a double pole—single throw switch to these terminals as shown in Fig. 4.

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and should need no further adjustments. However, if it is definitely known that an adjustment is necessary the circuits can be properly aligned only with the use of a modulated signal generator and an output meter.

CONNECTING OUTPUT METER

Connect one terminal of the output meter to the plate of one of the type 42 output tubes and connect the other terminal to the plate of the other 42 output tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier to 450 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd. condenser to the top cap of the 6A7 tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the receiver chassis. KEEP THE GENERATOR OUTPUT LEAD AS FAR AS POSSIBLE FROM THE OTHER SCREEN GRID TUBES.

(b) Set the station selector so that the tuning condenser plates are open. Turn the volume control knob to the right (ON) and turn the tone control knob to the left (TREBLE).

(c) Turn the band selector switch all the way to the right.

(d) Set the signal generator to 450 kilocycles.

(e) Close the middle trimmer condenser on the 1st. I-F transformer.

(f) Adjust the trimmers located on top of the 2nd. I-F transformer for maximum output.

(g) Adjust the top and bottom trimmers of the 1st. I-F transformer for maximum output.

(h) Repeat operations (f) and (g) for more accurate adjustments.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

(i) Reduce the output of the signal generator and adjust the middle trimmer on the 1st. I-F transformer for maximum output. DO NOT READJUST THE OTHER TRIMMERS.

2. Aligning R-F Amplifier.

(a) When aligning the R-F amplifier the output lead from the signal generator is connected to the "Ant" terminal of the receiver. For the ORANGE, BLACK and GREEN bands a .00025 mfd. condenser must be connected in series with the output lead from the signal generator and for the two high frequency bands a 400 ohm resistor should be used in place of the condenser.

Each band should first be shunt aligned and then series aligned where provision is made for series alignment (Weather band and Broadcast band). The band selector switch should be set for the band being aligned and the signal generator should be set to the frequency indicated for each adjustment.

Adjust the "Osc", "R-F" and "Ant" trimmers in the order given for maximum output and then check the adjustments in the same order. NOTE: When aligning the Police and High Frequency Bands care must be exercised so that the circuits will be aligned on the fundamental frequency rather than on the image frequency which is always approximately 900 kilocycles less than the fundamental. To check on this, increase the output of the signal generator approximately 10 times and try to tune-in the signal both at the generator frequency as indicated on the station selector dial and at approximately 900 kilocycles below the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct frequency.

To align the "series" trimmer, set the signal generator to the frequency indicated and then tune-in this signal with the station selector for maximum output. Adjust the "series" trimmer while rocking the tuning condenser back and forth slightly, until no improvement in output can be obtained.

After the "series" alignment of any band has been completed it will be necessary to repeat the "shunt" alignment of that band.

(b) Signal Input Frequencies.

	Shunt Alignment	Series Alignment
Weather Band (ORANGE)	400 Kc.	150 Kc.
American Broadcast Band (BLACK)	1400 Kc.	600 Kc.
Police & Amateur Band (GREEN)	4000 Kc.	—
Night H-F Band (RED)	10 Megacycles	—
Day H-F Band (VIOLET)	21 Megacycles	—

SOCKET VOLTAGES

The tube socket voltages are measured from the tube socket contacts to the chassis with a 1000 ohm per volt 500 volt voltmeter (except filaments) with the receiver in operating condition and no signal input. Readings may vary plus or minus 10% of values given.

PARTS LIST—MODEL 915

Figures in first column refer to parts shown in diagrams.

Item No.	Part No.	Description
1A	—36504	Dial Light Socket Assm.

Alignment

CROSLEY RADIO CORP.

SPECIFICATIONS

The Crosley Model 916 radio is a nine-tube superheterodyne receiver and is available either with a standard 110 volt—60 cycle power transformer or with a universal power transformer.

The tubes used are 6K7 R-F Amplifier, 6A8 Oscillator-Modulator, 6K7 I-F Amplifier, 6R7 Detector and 1st Audio Amplifier, 6C5 2nd Audio Amplifier, two 6N6 Output, 5Z4 Rectifier and the newly developed Phantom Conductor or Volume Expander tube.

The tuning range of the receiver is from 540 to 19000 Kilocycles and is divided into three bands as follows:

BLUE	540-1900 Kc.	or	555 –158 Meters (American Broadcast Band)
RED	1.9 –6.5 Megacycles	or	158 – 46 Meters (Police & Amateurs)
GREEN	6.0 –19 Megacycles	or	50 – 16 Meters (High Frequency Band)

PHANTOM CONDUCTOR (Auto Expressionator)

The Phantom Conductor tube, Illustration No. 65, is connected across the voice coil of the speaker. When it is operating its resistance varies so as to increase the volume of loud tones, thus giving a wider volume range to reproduced music which tends to compensate for the electrical limitations of broadcasting equipment.

SOCKET VOLTAGES

The tube socket voltages are measured from the tube socket contacts to the chassis with a 1000 ohm per volt, 500 volt D.-C. voltmeter (except filaments) with the receiver in operating condition and no signal input. The filament voltages should be measured with an accurate low range A.-C. voltmeter. Readings may vary plus or minus 10% of values given.

TUBE SOCKET VOLTAGE READINGS

Tube.	Function	H	P	P_2	S	Su	G	K	Ga
6K7	R-F Amplifier	6.3	221	—	98	4	0	4	—
6A8	Osc-Mod	6.3	221	—	180	—	0	4.5	136
6K7	I-F Amplifier	6.3	200	—	138	5	0	5	—
6R7	Detector & 1st A-F Amplifier	6.3	130	—	—	—	0	6.5	—
6C5	2nd A-F Amplifier	6.3	150	—	—	—	0	6.5	—
6N6	(2) Output	6.3	285	278	—	—	0	3.2	—
5Z4	Rectifier	4.5	357	—	—	—	—	—	—
Phantom Conductor Tube (W41187)				Varies with power output.					

Voltage drop across speaker field 73 volts.
Power Output approximately 9 Watts.
Power Consumptoin approximately 117 Watts.
All readings taken on 117.5 volt power supply.

UNIVERSAL POWER TRANSFORMER

The Model 916 chassis for use on other than 110 volts—60 cycles, is supplied with a universal power transformer designed to operate on a power supply of from 95 to 267 volts and any commercial frequency of 25 cycles or above. To adapt the set to a different line voltage it is necessary to remove the chassis from the cabinet, remove the bottom from the chassis, locate the terminal strip on the bottom of the power transformer and locate the wire leading from the power switch to the terminal strip. After careful measurement of the maximum values of line voltage, unsolder the wire described above, from the lug on the terminal strip and solder it to the correct lug. The correct lug will be the one marked so as to cover or nearly cover the maximum line voltage. THE MAXIMUM LINE VOLTAGE SHOULD NOT EXCEED THE HIGHEST VOLTAGE STAMPED ON THE TERMINAL STRIP BESIDE THE LUG TO BE USED BY MORE THAN 3%.

PHONOGRAPH PICKUP

Chasses equipped with a universal power transformer also have three terminals on the back for connecting a phonograph pickup. These terminals are marked P C S and the pickup is connected through a double pole—single throw switch to these terminals as shown in Fig. 7.

ALIGNMENT PROCEDURE

This is a High Fidelity receiver and in order to secure maximum performance the alignment of its circuits should be done with precision instruments.

Tuning I-F Amplifier to 450 Kilocycles.

The I-F amplifier employs two triple-tuned I-F transformers and under no condition should their trimmer condensers be readjusted just to determine if they are properly tuned. Fig. 5 shows the selectivity curve of a receiver whose I-F amplifier was slightly mis-tuned while Fig. 6 shows a curve made from actual measurements of a receiver which was properly aligned with the use of an oscilloscope.

I. Conventional Method—

(a) Connect one terminal of the output meter to P2 of one of the 6N6 Output tubes and the other terminal through a .1 mf., or larger, condenser—not electrolytic—to P2 of the other 6N6 Output tube.

(b) Connect the output of the signal generator through a .02 mf. condenser to the top cap of the 6K7 I-F Amplifier tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the "GND" terminal of the receiver chassis. KEEP THE GENERATOR OUTPUT LEAD AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(c) Set the band selector switch to the Broadcast Band and rotate the station selector to approximately 60 on the dial. Turn the volume control knob to the right (ON), turn the tone control knob to the left (TREBLE) and turn the Multivox control knob to the Auditorium Position (Third position in the clockwise direction).

(d) Set the signal generator to 450 kilocycles.

(e) Close the middle trimmer condenser on the 2nd. I-F transformer (Tert. Fig. 4) so that it is moderately tight. (Do not force the adjustment screw).

(f) Adjust the top trimmer and then the bottom trimmer (Sec. & Pri) of the 2nd. I-F transformer for maximum output. ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE READING ON THE OUTPUT METER.

(g) Transfer the output lead of the signal generator from the 6K7 tube to the top cap of the 6A8 Osc.-Mod. tube, leaving the tube's grid clip in place.

(h) Open the middle trimmer of the 1st I-F transformer three or four turns from the closed position. (Care should be taken that the adjustment screw does not become dislodged from the nut).

(i) Adjust the top trimmer and then the bottom trimmer of the 1st I-F transformer for maximum output.

(j) Transfer the output lead of the signal generator from the 6A8 tube to the "ANT" terminal of the receiver and increase the output of the signal generator, if necessary.

(k) Adjust the middle trimmer of the 2nd. I-F transformer by opening until maximum output is obtained. DO NOT READJUST THE TOP AND BOTTOM TRIMMERS.

(l) Adjust the middle trimmer of the 1st. I-F transformer by closing until maximum output is obtained. DO NOT READJUST TOP AND BOTTOM TRIMMERS.

II. Oscilloscope Method—

(a) Connect the output of the signal generator through a .02 mf. condenser to the top cap of the 6K7 I-F amplifier tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the receiver chassis. KEEP THE GENERATOR OUTPUT LEAD AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Connect the vertical plates of the cathode ray oscilloscope to the receiver as follows: The binding post marked "GND" should be connected to the receiver chassis and the other binding post should be connected to the terminal marked "P" of the 6R7 tube. (Be sure the oscilloscope is protected from D. C. by connecting a condenser, .1 to .05 mf., in series with the lead connected to the plate of the 6R7 tube).

(c) Set the band selector switch to the Broadcast Band and rotate the station selector to approximately 60 on the dial. The exact setting should be at a position where no broadcast signal will be received. Turn the volume control knob to the right (ON), turn the tone control knob to the left (TREBLE) and turn the Multivox control knob to the Auditorium Position (Third position in the clockwise direction).

(d) Set the signal generator to 450 kilocycles. See Instructions supplied with signal generator and oscilloscope.

(e) Close the middle trimmer condenser on the 2nd. I-F transformer (Tert. Fig. 4) so that it is moderately tight. (Do not force adjustment screw).

(f) Adjust the top trimmer (Sec) of the 2nd. I-F transformer so that the nose of the selectivity curves is centered on the resonance axis (R) of the transparent scale supplied with the oscilloscope.

(g) Adjust the bottom trimmer (Pri) of the 2nd. I-F transformer for maximum amplitude of the selectivity curve on resonance line (R).

(h) Reduce the output of the signal generator and adjust the middle trimmer of the 2nd. I-F transformer for maximum amplitude and symmetry of the selectivity curve about the resonance line.

NOTE: Keep the base of the selectivity curve centered on the transparent scale from −15 to +15 and keep the signal generator output as low as possible in order to prevent AVC action in the receiver.

(i) Readjust the bottom trimmer of the 2nd. I-F transformer for maximum symmetry and amplitude.

(j) Transfer the output lead of the signal generator from the 6K7 tube to the top cap of the 6A8 Modulator tube, leaving the tube's grid clip in place.

(k) Open the middle trimmer of the 1st. I-F transformer three or four turns from the closed position. Care should be taken that the adjustment screw does not become dislodged from the nut).

(l) Increase the output of the signal generator and adjust the top trimmer (Sec) of the 1st. I-F transformer for maximum symmetry and amplitude.

(m) Adjust the bottom trimmer of the 1st. I-F transformer for maximum amplitude.

(n) Reduce the output of the signal generator and adjust the middle trimmer of the 1st. I-F transformer for maximum symmetry and amplitude.

(o) Carefully repeat operations (h), (i) and (n) for more accurate adjustments.

Aligning R-F Amplifier.

The R-F amplifier can best be aligned in the conventional manner, using a modulated signal generator and output meter.

When aligning the R-F amplifier the output lead of the signal generator is connected to the antenna terminal of the receiver. For the BLUE and RED bands a .00025 mfd. condenser must be connected in series with the output lead of the signal generator and for the high-frequency band a 400 ohm carbon resistor should be used in place of the condenser.

Each band should first be shunt aligned and then series aligned, where provision is made for series alignment (BLUE and RED bands). The band selector switch should be set for the band being aligned and the signal generator should be set to the frequency indicated (c) for each adjustment.

(a) Adjust the "OSC", "R-F" and "ANT" shunt trimmers in the order given for maximum output. Readjust the station selector slightly so that the generator signal is tuned-in with maximum output and then check the adjustments of the "R-F" and "ANT" trimmers in the order given. DO NOT READJUST THE "OSC" TRIMMER.

NOTE: When shunt aligning the RED and GREEN bands care must be exercised so that the circuits will be aligned on the fundamental frequency rather than on the image frequency which is approximately 900 kilocycles less than the fundamental. To check on this, increase the output of the signal generator ten times or more and try to tune-in the signal both at the generator frequency as indicated on the station selector dial and at approximately 900 kilocycles less than the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct position.

(b) To align the series trimmers, 32Y and 32Z Fig. 2, set the signal generator to the frequency indicated below and then tune-in this signal with the station selector for maximum output. At the time that any series trimmer is being adjusted rotate the station selector back and forth slightly until no further improvement in output can be obtained.

(c) Signal Input Frequencies:

	Shunt Aligned	Series Aligned
American Broadcast Band (BLUE)	1700 Kc.	600 Kc.
Police Band (RED)	6000 Kc.	2000 Kc.
High-Frequency Band (GREEN)	18000 Kc.	———

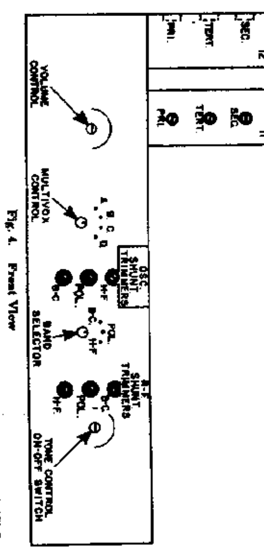

Fig. 4. Front View

AUTO EXPRESSIONATOR

The auto-expressionator circuit, Items numbered 2A, 2B, 29, 43A, 43B, 60 and 67, reduces the volume of soft tones and sustains the volume of loud tones. This gives a wider volume range to reproduced music and tends to compensate for the electrical limitations of broadcasting equipment. The condenser and transformer, Items 29 and 67, provide bass compensation by preventing normal suppression of low frequency tones.

VOLTAGE DROP ACROSS SPEAKER FIELD 80 VOLTS. POWER OUTPUT APPROXIMATELY 10 WATTS.
POWER CONSUMPTION APPROXIMATELY 125 WATTS.
ALL READINGS TAKEN ON 117.5 VOLT POWER SUPPLY.

UNIVERSAL POWER TRANSFORMER

The Model 955 chassis for use on other than 110 volts—60 cycles, is supplied with a universal power transformer designed to operate on a power supply of from 95 to 267 volts and any commercial frequency of 25 cycles or above. To adapt the set to a different line voltage it is necessary to remove the chassis from the cabinet, remove the bottom from the chassis, locate the terminal strip on the bottom of the power transformer and locate the wire leading from the power switch to the terminal strip. After careful measurement of the maximum values of line voltage, unsolder the wire described above, from the lug on the terminal strip and solder it to the correct lug. The correct lug will be the one marked so as to cover or nearly cover the maximum line voltage. THE MAXIMUM LINE VOLTAGE SHOULD NOT EXCEED THE HIGHEST VOLTAGE STAMPED ON THE TERMINAL STRIP BESIDE THE LUG TO BE USED BY MORE THAN 3%.

PHONOGRAPH PICKUP

Chasses equipped with a universal power transformer also have three terminals on the back for connecting a phonograph pickup. These terminals are marked P C S and the pickup is connected through a double pole—single throw switch to these terminals as shown in Fig. 7.

ALIGNMENT PROCEDURE

This is a high fidelity receiver and in order to secure maximum performance the alignment of its circuits should be done with the use of precision instruments.

Tuning I-F Amplifier to 450 Kilocycles.

The I-F amplifier employs a triple-tuned I-F transformer in conjunction with a double-tuned I-F transformer in order to secure flat top tuning. The trimmer condensers in these transformers are very accurately adjusted at the factory and should not be readjusted unless it is definitely known that the circuits are mis-aligned or after new parts have been installed. The graphic representation in Fig. 5, shows the selectivity curve of a receiver whose I-F amplifier is slightly mis-tuned. This is only one of hundreds of curves that were obtained through mis-alignment. Fig. 6, shows a curve made from actual measurements of a receiver which was properly aligned with the use of an oscilloscope.

The circuits of this receiver may be most accurately aligned with the aid of an oscilloscope. However, if an oscilloscope is not available a good alignment may be obtained by means of a signal generator and an output meter provided the following procedure is carefully observed.

(a) Connecting Output Meter: Connect one terminal of the output meter to the plate of one of the 6F6 Output tubes and the other terminal through a .1 mfd., or larger, condenser—not electrolytic—to the plate of the other 6F6 Output tube.

(b) Connect the output of the signal generator through a .02 mfd. condenser to the top cap of the 6K7 I-F amplifier tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the ground terminal of the receiver chassis.

(c) Set the band selector switch to the broadcast band and rotate the station selector to approximately 60 on the dial. Turn the volume control knob to the right (ON), turn the tone control knob to the left (TREBLE) and turn the expressionator switch OFF.

(d) Set the signal generator to 450 kilocycles.

(e) Adjust the trimmer condensers located on top of the 2nd. I-F transformer for maximum output. (7 Fig. 2).

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

(f) Transfer the output lead of the signal generator from the 6K7 tube to the top cap of the 6L7 modulator tube, leaving the tube's grid clip in place.

(g) Close the middle trimmer condenser on the 1st. I-F transformer (Tert. Fig. 4) so that it is moderately tight. (Do not force adjusting screw).

(h) Adjust the top and then the bottom trimmer of the 1st I-F transformer for maximum output.

(i) Transfer the output lead of the signal generator from the 6L7 tube to the "ANT" terminal of the receiver and increase the output of the signal generator, if necessary.

(j) Adjust the middle trimmer of the 1st I-F transformer by opening condenser until maximum output is obtained. (DO NOT READJUST THE TOP AND BOTTOM TRIMMERS).

Aligning R-F Amplifier.

When aligning the R-F amplifier the output lead of the signal generator is connected to the antenna terminal of the receiver. For the BLUE and RED bands a .00025 mfd. condenser must be connected in series with the output lead of the signal generator and for the high-frequency band a 400 ohm carbon resistor should be used in place of the condenser.

Each band should first be shunt aligned and then series aligned, where provision is made for series alignment (BLUE and RED bands). The band selector switch should be set for the band being aligned and the signal generator should be set to the frequency indicated (c) for each adjustment.

(a) Adjust the "OSC", "R-F" and "ANT" shunt trimmers in the order given for maximum output. Readjust the station selector slightly so that the generator signal is tuned-in with maximum output and then check the adjustments of the "R-F" and "ANT" trimmers in the order given. DO NOT READJUST THE "OSC" TRIMMER.

NOTE: When shunt aligning the RED and GREEN bands care must be exercised so that the circuits will be aligned on the fundamental frequency rather than on the image frequency which is approximately 900 kilocycles less than the fundamental. To check on this, increase the output of the signal generator ten times or more and try to tune-in the signal both at the generator frequency as indicated on the station selector dial and at approximately 900 kilocycles less than the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct position.

(b) To align the series trimmers, 30Y and 30Z Fig. 2, set the signal generator to the frequency indicated (c) and then tune-in this signal with the station selector for maximum output. At the same time that any series trimmer is being adjusted rotate the station selector back and forth slightly until no further improvement in output can be obtained.

(c) Signal Input Frequencies:

	Shunt Aligned	Series Aligned
American Broadcast Band (BLUE)	1700 Kc.	600 Kc.
Police Band (RED)	6000 Kc.	2500 Kc.
High-Frequency Band (GREEN)	18000 Kc.	....

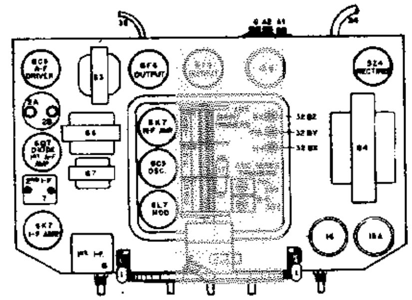

Fig. 2. Top View

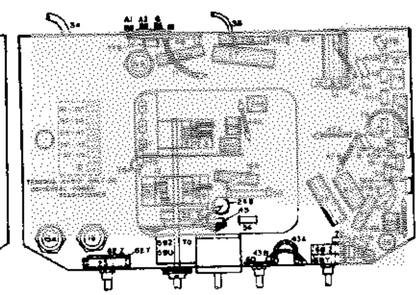

Fig. 3. Bottom View

SPECIFICATIONS

The Crosley Model 955 radio is a nine-tube superheterodyne receiver and uses all metal tubes. It is available either with a standard 110 volt—60 cycle power transformer or with a universal power transformer.

The tubes used are 6K7 R-F Amplifier, 6L7 Modulator, 6C5 Oscillator, 6K7 I-F Amplifier, 6Q7 Diode Detector and A-F Amplifier, 6C5 Output Driver, two 6F6 Output tubes and 5Z4 Rectifier tube.

It is a three band receiver and the dial is divided into three sections as follows:

BLUE	540- 1900 Kilocycles	(American Broadcast Band)
RED	1900- 6500 Kilocycles	(Police and Amateurs)
GREEN	6000-19000 Kilocycles	(High Frequency Band)

Alignment
Voltage, Parts

CROSLEY RADIO CORP.

PHANTOM CONDUCTOR (Auto Expressionator)

The Phantom Conductor tube, Illustration No. 65, is connected across the voice coil of the speaker. When it is operating its resistance varies so as to increase the volume of loud tones, thus giving a wider volume range to reproduced music which tends to compensate for the electrical limitations of broadcasting equipment.

SOCKET VOLTAGES

The tube socket voltages are measured from the tube socket contacts to the chassis with a 1000 ohm per volt 500 volt D.-C. voltmeter (except filaments) with the receiver in operating condition and no signal input. The filament voltages should be measured with an accurate low range A.-C. voltmeter. Readings may vary plus or minus 10% of values given.

UNIVERSAL POWER TRANSFORMER

The Model 1016 chassis for use on other than 110 volts —60 cycles, is supplied with a universal power transformer designed to operate on a power supply of from 95 to 267 volts and any commercial frequency of 25 cycles or above. To adapt the set to a different line voltage it is necessary to remove the chassis from the cabinet, remove the bottom from the chassis, locate the terminal strip on the bottom of the power transformer and locate the wire leading from the power switch to the terminal strip. After careful measurement of the maximum values of line voltage, unsolder the wire described above, from the lug on the terminal strip and solder it to the correct lug. The correct lug will be the one marked so as to cover or nearly cover the maximum line voltage. THE MAXIMUM LINE VOLTAGE SHOULD NOT EXCEED THE HIGHEST VOLTAGE STAMPED ON THE TERMINAL STRIP BESIDE THE LUG TO BE USED BY MORE THAN 3%.

PHONOGRAPH PICKUP

Chassis equipped with a universal power transformer also have three terminals on the back for connecting a phonograph pickup. These terminals are marked P C S and the pickup is connected through a double pole—single throw switch to these terminals as shown in Fig. 7.

ALIGNMENT PROCEDURE

This is a High Fidelity receiver and in order to secure maximum performance the alignment of its circuits should be done with precision instruments.

Tuning I-F Amplifier to 450 Kilocycles.

The I-F amplifier employs two triple-tuned I-F transformers and under no condition should their trimmer condensers be readjusted just to determine if they are properly tuned. Fig. 5 shows the selectivity curve of a receiver whose I-F amplifier was slightly mis-tuned while Fig. 6 shows a curve made from actual measurements of a receiver which was properly aligned with the use of an oscilloscope.

I. Conventional Method—

(a) Connect one terminal of the output meter to P2 of one of the 6N6 Output tubes and the other terminal through a .1 mf., or larger, condenser—not electrolytic —to P2 of the other 6N6 Output tube.

(b) Connect the output of the signal generator through a .02 mf. condenser to the top cap of the 6K7 I-F Amplifier tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the "GND" terminal of the receiver chassis. KEEP THE GENERATOR OUTPUT LEAD AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(c) Set the band selector switch to the Broadcast Band and rotate the station selector to approximately 60 on the dial. Turn the volume control knob to the right (ON), turn the tone control knob to the left (TREBLE) and turn the Multivox control knob to the Auditorium Position (Third position in the clockwise direction).

(d) Set the signal generator to 450 kilocycles.

(e) Close the middle trimmer condenser on the 2nd. I-F transformer (Tert. Fig. 4) so that it is moderately tight. (Do not force the adjustment screw).

(f) Adjust the top trimmer and then the bottom trimmer (Sec. & Pri) of the 2nd. I-F transformer for maximum output. ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE READING ON THE OUTPUT METER.

(g) Transfer the output lead of the signal generator from the 6K7 tube to the top cap of the 6A8 Modulator tube, leaving the tube's grid clip in place.

(h) Open the middle trimmer of the 1st. I-F transformer three or four turns from the closed position. (Care should be taken that the adjustment screw does not become dislodged from the nut).

(i) Adjust the top trimmer and then the bottom trimmer of the 1st I-F transformer for maximum output.

(j) Transfer the output lead of the signal generator from the 6A8 tube to the "ANT" terminal of the receiver and increase the output of the signal generator, if necessary.

(k) Adjust the middle trimmer of the 2nd. I-F transformer by opening until maximum output is obtained. DO NOT READJUST THE TOP AND BOTTOM TRIMMERS.

(l) Adjust the middle trimmer of the 1st. I-F transformer by closing until maximum output is obtained. DO NOT READJUST TOP AND BOTTOM TRIMMERS.

II. Oscilloscope Method—

(a) Connect the output of the signal generator through a .02 mf. condenser to the top cap of the 6K7 I-F amplifier tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the receiver chassis. KEEP THE GENERATOR OUTPUT LEAD AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Connect the vertical plates of the cathode ray oscilloscope to the receiver as follows: The binding post marked "GND" should be connected to the receiver chassis and the other binding post should be connected to the terminal marked "P" of the 6R7 tube. (Be sure the oscilloscope is protected from D. C. by connecting a condenser, .1 to .05 mf., in series with the lead connected to the plate of the 6R7 tube).

(c) Set the band selector switch to the Broadcast Band and rotate the station selector to approximately 60 on the dial. The exact setting should be at a position where no broadcast signal will be received. Turn the volume control knob to the right (ON), turn the tone control knob to the left (TREBLE) and turn the Multivox control knob to the Auditorium Position (Third position in the clockwise direction).

(d) Set the signal generator to 450 kilocycles. See Instructions supplied with signal generator and oscilloscope.

(e) Close the middle trimmer condenser on the 2nd. I-F transformer (Tert. Fig. 4) so that it is moderately tight. (Do not force adjustment screw).

(f) Adjust the top trimmer (Sec) of the 2nd. I-F transformer so that the nose of the selectivity curves is centered on the resonance axis (R) of the transparent scale supplied with the oscilloscope.

(g) Adjust the bottom trimmer (Pri) of the 2nd. I-F transformer for maximum amplitude of the selectivity curve on resonance line (R).

(h) Reduce the output of the signal generator and adjust the middle trimmer of the 2nd. I-F transformer for maximum amplitude and symmetry of the selectivity curve about the resonance line.

NOTE: Keep the base of the selectivity curve centered on the transparent scale from —15 to +15 and keep the signal generator output as low as possible in order to prevent AVC action in the receiver.

(i) Readjust the bottom trimmer of the 2nd. I-F transformer for maximum symmetry and amplitude.

(j) Transfer the output lead of the signal generator from the 6K7 tube to the top cap of the 6A8 Modulator tube, leaving the tube's grid clip in place.

(k) Open the middle trimmer of the 1st. I-F transformer three or four turns from the closed position. (Care should be taken that the adjustment screw does not become dislodged from the nut).

(l) Increase the output of the signal generator and adjust the top trimmer (Sec) of the 1st. I-F transformer for maximum symmetry and amplitude.

(m) Adjust the bottom trimmer of the 1st. I-F transformer for maximum amplitude.

(n) Reduce the output of the signal generator and adjust the middle trimmer of the 1st. I-F transformer for maximum symmetry and amplitude.

(o) Carefully repeat operations (h), (i) and (n) for more accurate adjustments.

Aligning R-F Amplifier.

The R-F amplifier can best be aligned in the conventional manner, using a modulated signal generator and output meter.

When aligning the R-F amplifier the output lead of the signal generator is connected to the antenna terminal of the receiver. For the BLUE and RED bands a .00025 mfd. condenser must be connected in series with the output lead of the signal generator and for the high-frequency band a 400 ohm carbon resistor should be used in place of the condenser.

Each band should first be shunt aligned and then series aligned, where provision is made for series alignment (BLUE and RED bands). The band selector switch should be set for the band being aligned and the signal generator should be set to the frequency indicated (c) for each adjustment.

(a) Adjust the "OSC", "R-F" and "ANT" shunt trimmers in the order given for maximum output. Readjust the station selector slightly so that the generator signal is tuned-in with maximum output and then check the adjustments of the "R-F" and "ANT" trimmers in the order given. DO NOT READJUST THE "OSC" TRIMMER.

NOTE: When about aligning the RED and GREEN bands care must be exercised so that the circuits will be aligned on the fundamental frequency rather than on the image frequency which is approximately 900 kilocycles less than the fundamental. To check on this, increase the output of the signal generator ten times or more and try to tune-in the signal both at the generator frequency as indicated on the station selector dial and at approximately 900 kilocycles less than the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct position.

(b) To align the series trimmers, 32Y and 32Z Fig. 2, set the signal generator to the frequency indicated below and then tune-in this signal with the station selector for maximum output. At the time that any series trimmer is being adjusted rotate the station selector back and forth slightly until no further improvement in output can be obtained.

(c) Signal Input Frequencies:

	Shunt Aligned	Series Aligned
American Broadcast Band (BLUE)	1700 Kc.	600 Kc.
Police Band (RED)	6000 Kc.	3800 Kc.
High-Frequency Band (GREEN)	18000 Kc.	———

SPECIFICATIONS

The Crosley Model 1016 radio is a ten-tube superheterodyne receiver and is available either with a standard 110 volt—60 cycle power transformer or with a universal power transformer.

The tubes used are 6K7 R-F Amplifier, 6A8 Modulator, 6C5 Oscillator, 6K7 I-F Amplifier, 6R7 Detector and 1st Audio Amplifier, 6C5 2nd Audio Amplifier, two 6N6 Output, 5Z4 Rectifier and the newly developed Phantom Conductor or Volume Expander tube.

The tuning range of the receiver is from 540 to 19000 Kilocycles and is divided into three bands as follows:

BLUE	540—1600 Kc.	or	555 —188 Meters	(American Broadcast Band)
RED	1.9 —6.5 Megacycles	or	158 — 46 Meters	(Police & Amateurs)
GREEN	6.0 —19 Megacycles	or	50 — 16 Meters	(High Frequency Band)

CROSLEY RADIO CORP.

SPECIFICATIONS

The Crosley Model 1055 radio is a ten-tube superheterodyne receiver and is available either with a standard 110 volt-60 cycle power transformer or with a universal power transformer which can be adapted to A-C lines from 95 to 267 volts and any frequency.

The tubes used are 6K7 R-F Amplifier, 6A8 Modulator, 6C5 Oscillator, 6K7 I-F Amplifier, 6H6 Detector, 6C5 1st. A-F Amplifier, 6F6 2nd. A-F Amplifier, two type 6F6 Output tubes and type 5Z4 Rectifier.

It is a five band receiver and the dial is divided into five sections as follows:

ORANGE—	150- 400 kilocycles	(Weather Band)
BLACK —	540- 1,500 kilocycles	(American Broadcast Band)
GREEN —	1,500- 4,000 kilocycles	(Police and Amateur Band)
RED —	4,000-10,000 kilocycles	(Night High Frequency Band)
VIOLET —	10,000-21,000 kilocycles	(Day High Frequency Band)

The positions on the band selector switch are in the above order, reading from left to right.

SOCKET VOLTAGES

The tube socket voltages are measured from the tube socket contacts to the chassis with a 1000 ohm per volt, 500 voltmeter (except filaments) with the receiver in operating condition and no signal input. Readings may vary plus or minus 10% of values given.

UNIVERSAL POWER TRANSFORMER

The Model 1055 chassis for use on other than 110 volts, 60 cycles, is supplied with a universal power transformer designed to operate on 25 cycles and up. When leaving the factory it is wired for the voltage indicated on the license plate. It is possible, however, by a slight change in the power transformer wiring to adapt the set to a different voltage anywhere from 95 to 267 volts. To adapt the set to a different line voltage it is necessary to remove the chassis from the cabinet, remove the bottom from the chassis and locate the terminal strip on the bottom of the power transformer, Fig. 3. After careful measurement of the maximum values of line voltage, unsolder the wire of the A-C line cord from the terminal strip and solder it to the correct terminal. The correct terminal will be the one marked so as to cover or nearly cover the maximum line voltage. THE MAXIMUM VOLTAGE SHOULD NOT EXCEED THE HIGHEST RATING STAMPED ON THE TERMINAL BOARD BESIDE THE TERMINAL TO BE USED BY MORE THAN 3%.

PHONOGRAPH PICKUP

Chasses equipped with a universal power transformer also have three terminals on the back for connecting a phonograph pickup. These terminals are marked P C S and the pickup is connected through a double pole—single throw switch to these terminals as shown in Fig. 4.

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and should need no further adjustment. However, if it is definitely known that an adjustment is necessary the circuits can be properly aligned only with the use of a modulated signal generator and an output meter.

CONNECTING OUTPUT METER

Connect one terminal of the output meter to the plate of one of the type 6F6 output tubes and connect the other terminal to the plate of the other type 6F6 output tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. **Tuning I-F Amplifier to 450 Kilocycles.**

(a) Connect the output of the signal generator through a .02 mfd. condenser to the top cap of the 6A8 tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the receiver chassis. KEEP THE GENERATOR OUTPUT LEAD AS FAR AS POSSIBLE FROM THE OTHER SCREEN GRID TUBES.

(b) Set the station selector so that the tuning condenser plates are open. Turn the volume control knob to the right (ON) and turn the tone control knob to the left (TREBLE).

(c) Turn the band selector switch all the way to the right.

(d) Set the signal generator to 450 kilocycles.

(e) Close the middle (tert.) trimmer condenser on the 1st I-F transformer. (Fig. 2.)

(f) Adjust the trimmers located on top of the 2nd. I-F transformer for maximum output.

(g) Adjust the top and bottom trimmers of the 1st. I-F transformer for maximum output.

(h) Repeat operations (f) and (g) for more accurate adjustments.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

(i) Reduce the output of hte signal generator and adjust the middle (tert.) trimmer on the 1st. I-F transformer for maximum output. DO NOT READJUST THE OTHER TRIMMERS.

2. **Aligning R-F Amplifier.**

(a) When aligning the R-F amplifier the output lead from the signal generator is connected to the "Ant" terminal of the receiver. For the ORANGE, BLACK and GREEN bands a .00025 mfd. condenser must be connected in series with the output lead from the signal generator and for the two high frequency bands a 400 ohm carbon resistor should be used in place of the condenser.

Each band should first be shunt aligned and then series aligned where provision is made for series alignment (Weather Band and Broadcast Band). The band selector switch should be set for the band being aligned and the signal generator should be set to the frequency indicated for each adjustment.

Adjust the "Osc," "R-F" and "Ant" trimmers in the order given for maximum output and then check the adjustments in the same order. NOTE: When aligning the Police and High Frequency Bands care must be exercised so that the circuits will be aligned on the fundamental frequency rather than on the image frequency which is always approximately 900 kilocycles less than the fundamental. To check on this, increase the output of the signal generator approximately 10 times and try to tune-in the signal both at the generator frequency as indicated on the station selector dial and at approximately 900 kilocycles below the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct frequency.

To align the "series" trimmer, set the signal generator to the frequency indicated and then tune-in this signal with the station selector for maximum output. Adjust the "series" trimmer while rocking the tuning condenser back and forth slightly, until no improvement in output can be obtained.

After the "series" alignment of any band has been completed it will be necessary to repeat the "shunt" alignment of that band.

PARTS LIST—MODEL 1055

Figures in first column refer to parts shown in diagrams.

Item No.	Part No.	Description
1A	36504	Dial Light Socket Assm.
1B	36504	Dial Light Socket Assm.
2	W —36557	Tuning Meter Bulb.
3	G63 —32000	Ant. Coil Assm. Complete
	G64 —32000	Ant. Coil only 150-400 Kc. (W. B.)
	G68 —32000	Ant. Coil only 540-1500 Kc. (B. B.)
	G65 —32000	Ant. Coil only 1500-4000 Kc. (P.B.)
	G67 —32000	Ant. Coil only 4-10 Mc. (S. W. B.)
	G66 —32000	Ant. Coil only 10-22 Mc. (S. W. B.)

VOLTAGE DROP ACROSS SPEAKER FIELD 125 VOLTS. POWER OUTPUT APPROXIMATELY 15.5 WATTS. POWER CONSUMPTION APPROXIMATELY 140 WATTS. ALL READINGS TAKEN ON 117.5 VOLT POWER SUPPLY.

UNIVERSAL POWER TRANSFORMER

The Model 1155 chassis for use on other than 110 volts—60 cycles, is supplied with a universal power transformer designed to operate on a power supply of from 95 to 267 volts and any commercial frequency of 25 cycle or above. To adapt the set to a different line voltage it is necessary to remove the chassis from the cabinet, remove the bottom from the chassis and locate the terminal strip on the bottom of the power transformer. After careful measurement of the maximum values of line voltage, unsolder the wire leading from the power switch from the terminal strip and solder it to the correct terminal. The correct terminal will be the one marked so as to cover or nearly cover the maximum line voltage. THE MAXIMUM VOLTAGE SHOULD NOT EXCEED THE HIGHEST RATING STAMPED ON THE TERMINAL BOARD BESIDE THE TERMINAL TO BE USED BY MORE THAN 3%.

PHONOGRAPH PICKUP

Chassis equipped with a universal power transformer also have three terminals on the back for connecting a phonograph pickup. These terminals are marked P C S and the pickup is connected through a double pole —single throw switch to these terminals as shown in Fig. 7.

ALIGNMENT PROCEDURE

This is a high fidelity receiver and in order to secure maximum performance the alignment of its circuits should be done with the use of precision instruments. The I-F amplifier employs two triple-tuned I-F transformers and under no condition should their trimmer condensers be readjusted just to determine if they are properly tuned. The graphic representation in Fig. 5, shows the selectivity curve of a receiver whose I-F amplifier is slightly mis-tuned. This is only one of hundreds of curves that were obtained through mis-alignment. Fig. 6, shows a curve made from actual measurements of a receiver which was properly aligned with the use of an oscilloscope.

Poor quality, loss of high frequency response and poor selectivity are likely results of an improperly tuned I-F amplifier.

The circuits of this receiver may be most accurately aligned with the aid of an oscilloscope. However, if an oscilloscope is not available a good alignment may be obtained by means of a signal generator and output meter, provided the following procedure is carefully observed.

Connecting Output Meter.

Connect one terminal of the output meter to the plate of one of the 6F6 Output tubes and the other terminal through a .1 mfd., or larger, condenser—not electrolytic—to the plate of the other 6F6 Output tube.

Tuning I-F Amplifier to 450 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd. condenser to the top cap of the 6K7 I-F amplifier tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the ground terminal of the receiver chassis. KEEP THE GENERATOR OUTPUT LEAD AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Set the band selector switch to the broadcast band and rotate the station selector to 60 on the Broadcast Band. Turn the volume control knob to the right (ON), turn the tone control knob to the left (TREBLE), and turn the expressionator control knob to the left (OFF).

(c) Set the signal generator to 450 kilocycles.

(d) Close the middle trimmer condenser on the 2nd I-F transformer (Terl. Fig 4) so that it is moderately tight. (Do not force adjusting screw).

(e) Adjust the top and then the bottom trimmers (Sec. and Pri.) of the 2nd I-F transformer for maximum output.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

(f) Transfer the output lead of the signal generator from the 6K7 tube to the top cap of the 6L7 modulator tube leaving the tube's grid clip in place.

(g) Open the middle trimmer of the 1st I-F transformer three or four turns from the closed position. (Care should be taken that the screw does not become dislodged from the nut).

(h) Adjust the top and then the bottom trimmers of the 1st I-F transformer for maximum output.

(i) Transfer the output lead of the signal generator from the 6L7 tube to the "ANT" terminal of the receiver and increase the output of the signal generator, if necessary.

(j) Adjust the middle trimmer of the 2nd I-F transformer by opening condenser until maximum output is obtained. (DO NOT READJUST THE TOP AND BOTTOM TRIMMERS).

(k) Adjust the middle trimmer of the 1st I-F transformer by closing condenser until maximum output is obtained. (DO NOT READJUST THE TOP AND BOTTOM TRIMMERRS).

Aligning R-F Amplifier.

When aligning the R-F amplifier the output lead of the signal generator is connected to the "ANT" terminal of the receiver. For the BLUE, RED and GREEN, bands a .00025 mfd. condenser must be connected in series with the output lead of the signal generator and for the high-frequency band a 400 ohm carbon resistor should be used in place of the condenser.

Each band should first be shunt aligned and then series aligned where provision is made for series alignment (BLUE, RED and GREEN bands). The band selector switch should be set for the band being aligned and the signal generator should be set to the frequency indicated (c) for each adjustment.

(a) Adjust the "OSC", "R-F" and "ANT" parallel trimmers (Fig. 4 and 2) in the order given for maximum put. Tune the station selector slightly to the generator signal for maximum output and then check the adjustments of the "R-F" (Fig. 4) and "ANT" trimmers (Fig. 2) in the order given. DO NOT READJUST THE "OSC" TRIMMER.

NOTE: When shunt aligning the GREEN and VIOLET bands care must be exercised so that the circuits will be aligned on the fundamental frequency rather than on the image frequency which is approximately 900 kilocycles less than the fundamental. To check on this, increase the output of the signal generator approximately ten times and try to tune-in the signal both at the generator frequency as indicated on the station selector dial and at approximately 900 kilocycles below the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct position.

(b) To align the "series" trimmers (Fig. 2) set the signal generator to the frequency indicated (c) and then tune-in this signal with the station selector for maximum output. Tune the station selector slightly to the generator output. Adjust the series trimmer while rotating the station selector back and forth slightly until no further improvement in output can be obtained.

(c) Signal Input Frequencies for Aligament:

	Shunt Alignment	Series Alignment
Weather Band (BLUE)	400 Kc	150 Kc
American Broadcast Band (RED)	1700 Kc	600 Kc
Police Band (GREEN)	6000 Kc	2500 Kc
High Frequency Band (VIOLET)	18000 Kc	———

AUTO-EXPRESSIONATOR

The auto-expressionator circuit, items numbered 2A, 2B, 36, 54A, 54B, 74 and 79, reduces the volume of soft tones and sustains the volume of loud tones. This gives a wider volume range to reproduced music and tends to compensate for the electrical limitations of broadcasting equipment. The transformer and condenser, items No. 79 and 36, provide bass compensation by preventing the normal suppression of low frequency tones.

MODEL 6615
Socket, Chassis
Trimmers, Voltage
Alignment

CROSLEY RADIO CORP.

SPECIFICATIONS

The Crosley Model 6615 radio is a six-tube superheterodyne receiver designed for operation from a six-volt storage battery. It contains a completely shielded, built-in power supply unit which employs a self-rectifying type vibrator.

It is a three band receiver and the dial is divided into three sections as follows:

ORANGE— 150- 400 kilocycles (Weather Band)
BLACK — 540-1700 kilocycles (American Broadcast Band)
GREEN —2350-7300 kilocycles (High Frequency Band)

TUBES AND VOLTAGE LIMITS

The following table gives the functions of the tubes used, together with the voltage readings between the tube socket contacts and the chassis. Voltage readings should be taken with a 1000 ohm per volt, 250 volt voltmeter (except filaments) with the volume control full on and no signal input. The filament voltages should be measured with an accurate low range D-C voltmeter (approximately 0 to 10 volts). Voltage limits may vary plus or minus 10% of values given.

TUBE SOCKET VOLTAGE READINGS

Tube	Function	H	P	S	G	K	Ga	Ge
15	R-F Amplifier	2.0	150	85	−2	0	—	—
6A7	Osc.-Modulator	5.8	150	85	−2	0	120	−5 to −15
6B7	I-F Amp. & Detector	5.8	180	85	−2	0	—	—
15	A-F Amplifier	2.0	70	15	−2	0	—	—
38	Output	5.8	145	150	0	12	—	—
31	AVC Diode	2.0	—	—	—	—	—	—

"A" Battery Drain Approximately 2.5 Amperes.

Power Output Approximately .9 Watt.

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and normally should need no further adjustment. However, if it is definitely known that an adjustment is necessary the circuits can be properly aligned ONLY with the use of a modulated signal generator and an output meter.

CONNECTING OUTPUT METER

Connect one terminal of the output meter to the plate and the other terminal to the screen of the 38 Output tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier To 450 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd. condenser to the top cap of the 6A7 tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the "GND" terminal of the receiver. KEEP THE GENERATOR OUTPUT LEAD AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Set the station selector so that the tuning condenser plates are completely out of mesh. Turn the volume control knob to the right (ON) and turn the tone control knob to the left (TREBLE).

(c) Turn the band selector switch all the way to the left (High Frequency Band).

(d) Set the signal generator to 450 kilocycles.

(e) Close the middle trimmer condenser (SEC) on the 1st I-F transformer. (Fig. 2).

(f) Adjust the trimmers located on top of the 2nd I-F transformer for maximum output.

(g) Adjust the top and bottom trimmers (TERT and PRI) of the 1st I-F transformer for maximum output.

(h) Repeat operations (f) and (g) for more accurate adjustments.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

(i). Reduce the output of the signal generator and adjust the middle trimmer on the 1st I-F transformer for maximum output. DO NOT READJUST THE OTHER TRIMMERS.

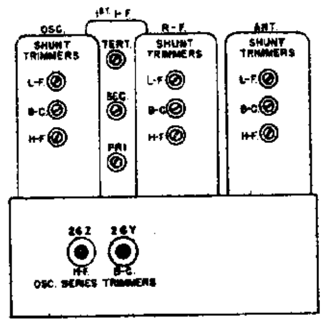
2. Aligning R-F Amplifier.

When aligning the R-F amplifier the output lead from the signal generator is connected to the antenna ("A-1") terminal of the receiver through a .00025 mfd. condenser.

Each band should first be shunt aligned and then series aligned. The band selector switch should be set for the band being aligned and the signal generator should be set to the frequency indicated for each adjustment.

Adjust the "OSC", "R-F" and "ANT" shunt trimmers in the order given for maximum output. Tune the station selector to the signal generator for maximum output and then check the adjustments of the "R-F" and "ANT" trimmers in the order given. Do not readjust the "OSC" trimmer. NOTE: When aligning the High Frequency Band care must be exercised so that the circuits will be aligned on the fundamental frequency rather than on the image frequency which is approximately 900 kilocycles less than the fundamental. To check on this, increase the output of the signal generator approximately ten times and try to tune-in the signal both at the generator frequency as indicated on the station selector dial and at approximately 900 kilocycles below the Correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct position.

To adjust the "series" trimmers (Illus. Nos. 53 top view, 26Z and 26Y side view, Fig. 2) set the signal generator to the frequency indicated and then tune-in this signal with the station selector for maximum output. Adjust the "series" trimmer while rocking the tuning condenser back and forth slightly, until no further improvement in output can be obtained.



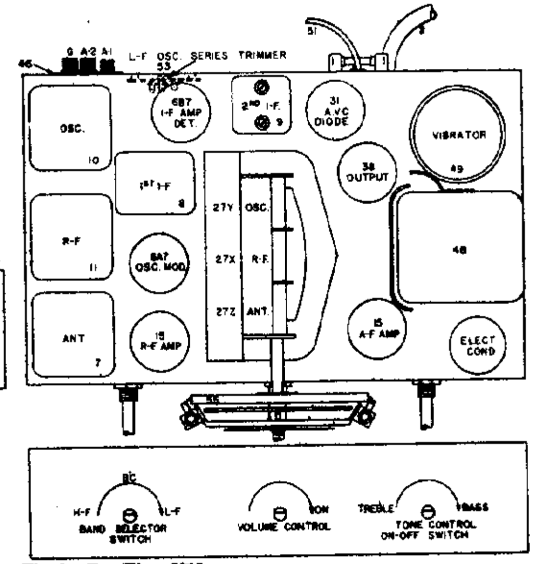


Fig. 2. Top View 6615

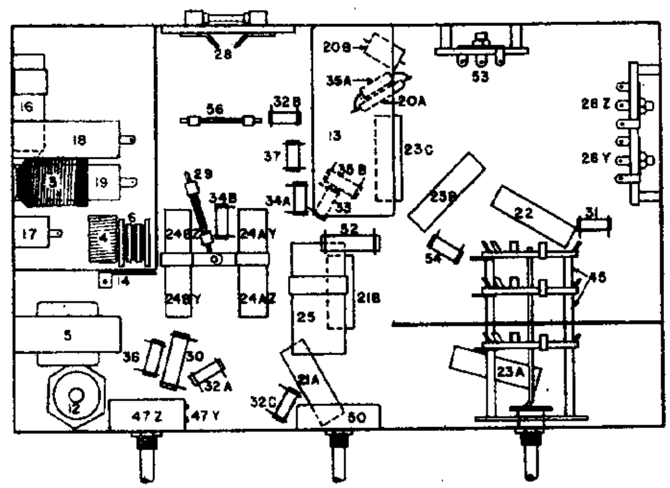

Fig. 3. Bottom View

SIGNAL INPUT FREQUENCIES

	Shunt Alignment	Series Alignment
Weather Band (ORANGE)	400 Kc.	150 Kc.
American Broadcast Band (BLACK)	1400 Kc.	600 Kc.
High Frequency Band (GREEN)	6000 Kc.	2500 Kc.

CROSLEY RADIO CORP.

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and normally should need no further adjustment. If it is definitely known that readjustment is necessary the circuits may be most accurately aligned with the aid of an oscilloscope. However, if an oscilloscope is not available a good alignment may be obtained by means of a signal generator and an output meter provided the following procedure is carefully observed.

CONNECTING OUTPUT METER

Connect the two terminals of the output meter to the two plates of the 6B5 Output tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

Tuning I-F Amplifier to 450 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd. condenser to the top cap of the 6D6 I-F Amplifier tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the receiver chassis. KEEP THE GENERATOR OUTPUT LEAD AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Turn the band selector switch to the Broadcast Band and rotate the station selector to approximately 60 on the dial. Turn the volume knob to the right (ON) and turn the tone control knob to the left (TREBLE).

(c) Set the signal generator to 450 kilocycles.

(d) Adjust the trimmer condensers located on top of the 2nd. I-F transformer for maximum output (Fig. 2.)

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

(e) Transfer the output lead of the signal generator from the 6D6 tube to the top cap of the 6A7 Oscillator-Modulator tube, leaving the tube's grid clip in place.

(f) Close the middle trimmer (Tert. Fig. 4) on the 1st I-F transformer so that it is moderately tight. (Do not force adjusting screw).

(g) Adjust the top trimmer on the 1st. I-F transformer for maximum output.

(h) Adjust the bottom trimmer on the 1st. I-F transformer for maximum output.

(i) Transfer the signal generator output lead from the 6A7 tube to the "ANT" terminal of the receiver and increase the output of the signal generator if necessary.

(j) Check the adjustment of the bottom trimmer of the 1st. I-F transformer. DO NOT READJUST THE TOP TRIMMER.

(k) Adjust the middle trimmer of the 1st. I-F transformer by opening condenser until maximum output is obtained. DO NOT READJUST THE TOP AND BOTTOM TRIMMERS.

Aligning R-F Amplifier

When aligning the R-F Amplifier the output lead of the signal generator is connected to the "ANT" terminal of the receiver. For the BLUE and RED bands a .00025 mfd. condenser must be connected in series with the output lead of the signal generator and for the high-frequency band a 400 ohm carbon resistor should be used in place of the condenser.

Each band should first be shunt aligned and then series aligned, where provision is made for series alignment (BLUE and RED bands). The band selector switch should be set for the band being aligned and the station selector and signal generator should be set to the frequency indicated (c) for each adjustment.

(a) Adjust the "OSC" and "ANT" shunt trimmers in the order given for maximum output. Readjust the station selector slightly so that the generator signal is tuned-in with maximum output and then check the adjustments of the "ANT" trimmers. DO NOT READJUST THE "OSC" TRIMMER

NOTE: When shunt aligning the RED and GREEN bands care must be exercised so that the circuits will be aligned on the correct frequency rather than on the image frequency which is approximately 900 kilocycles less than the fundamental. To check on this, increase the output of the signal generator ten times or more and try to tune-in the signal both at the generator frequency as indicated on the station selector dial and at approximately 900 kilocycles less than the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct position.

(b) To align the series trimmers (29Y-29Z Fig. 4) set the signal generator to the frequency indicated (c) and then tune in this signal with the station selector for maximum output. To obtain the best adjustment for each series trimmer it will be necessary to rotate the station selector back and forth slightly while adjusting the trimmer for maximum output.

(c) Signal Input Frequencies:

	Shunt Alignment	Series Alignment
American Broadcast Band (BLUE)	1700 Kilocycles	600 Kilocycles
Police Band (RED)	6000 Kilocycles	2500 Kilocycles
High-Frequency Band (GREEN)	18000 Kilocycles	....

MEASURED ON 117.5 VOLT—60 CYCLE POWER SUPPLY.
POWER CONSUMPTION APPROXIMATELY 80 WATTS.
POWER OUTPUT APPROXIMATELY 3 WATTS.

SPECIFICATIONS

The Crosley Model 6625 radio is a six-tube superheterodyne receiver designed to operate on an ALTERNATING CURRENT power supply. It is available with either of the following types of power transformers: 110 volt—60 cycles, 110 volt—25 cycles or 220 volts—25 cycles.

The tubes used are 6A7 Oscillator-Modulator, 6D6 I-F Amplifier, 6C6 Detector and A-F Amplifier, 76 2nd A-F Amplifier, 6B5 Output and type 80 Rectifier.

It is a three band receiver and the dial is divided into three sections as follows:

BLUE 540- 1800 Kilocycles (American Broadcast Band)
RED 1800- 6000 Kilocycles (Police and Amateurs)
GREEN 5800-18500 Kilocycles (High Frequency Band)

SHUNT TRIMMERS

	Ant.	Osc.	
High-Frequency	27A	27B	High-Frequency
Police	28Z	28X	Police
Broadcast	28Y	28W	Broadcast

SOCKET VOLTAGES

The tube socket voltages are measured from the tube socket contacts to the chassis with a 1000 ohm per volt, 500 volt D.C. voltmeter (except filaments) with the receiver in operating condition and no signal input. The filament voltages should be measured with an accurate low range A-C voltmeter (Approximately 0-10 volts). Readings may vary plus or minus 10% of values given.

INSTRUCTIONS FOR R-F. AND I-F. ALIGNMENT OF 6ZM AND 7ZM RECEIVERS

R-F. and I-F. Alignment

The trimmers on the tuning condensers and the intermediate stages are very accurately adjusted before the receiver leaves the factory, and should need little or no attentio To check adjustments, the following procedure should be followed:

Set wave band switch in broadcast position and turn volume control to extreme right (full on). Adjust test oscillator to 370 kc. and couple to control grid of 6A8G tube. Adjust four trimmers located in top of i-f. units for maximum output.

R-F. Alignment

1. Couple oscillator to antenna terminal, leaving band switch in broadcast position; set dial pointer and test oscillator to 1400 kc.; adjust oscillator trimmer located on top of tuning condenser for maximum output.

2. Turn band switch to "F" band and set dial pointer and test oscillator to 15 mc. Adjust antenna and r-f. trimmers located on top of tuning condenser for maximum output.

3. Reset band switch to broadcast position and set dial pointer and test oscillator to 140 kc.; adjust antenna and r-f. trimmers located on top of antenna and r-f. coils for maximum output.

4. Set dial pointer and test oscillator to 600 kc. Adjust padding condenser located in bottom of chassis, near 6A8G tube socket, for maximum output. Reset dial pointer and test oscillator to 1400 kc. and readjust oscillator trimmer located on top of tuning condenser for maximum output. This completes all adjustments.

INSTRUCTIONS FOR R-F. AND I-F. ALIGNMENT OF 10ZM RECEIVER

R-F. and I-F. Alignment

The trimmers on the tuning condenser and intermediate stages are very accurately adjusted before the receiver leaves the factory, and should need little or no attention. To check and adjust, the following procedure should be followed:

Set wave band switch in broadcast position and turn volume control to extreme right (full on); adjust test oscillator to 456 kc. and couple to control grid of 6A8G tube; adjust six trimmers located in top of i-f. units for maximum output.

R-F. Alignment

1. Couple oscillator to antenna terminal, leaving band switch in broadcast position. Set dial pointer and test oscillator to 1400 kc.; adjust oscillator trimmer on top of tuning condenser for maximum output.

2. Turn band switch to "F" band and set dial and test oscillator to 15 mc. Adjust antenna on r-f. trimmer located on top of tuning condenser for maximum output.

3. Reset band switch to broadcast position and set dial pointer and test oscillator to 600 kc.; adjust padding condenser located near long wave oscillator coil for maximum output. Rock tuning condenser back and forth slowly when making this adjustment.

4. Reset dial pointer and test oscillator to 1400 kc. and readjust oscillator trimmer on top of tuning condenser for maximum output.

5. Turn band switch to "1" band and set dial pointer and test oscillator to 160 kc. Adjust long wave padding condenser located near oscillator coil shield for maximum output. Rock tuning condenser back and forth slowly when making this adjustment. This completes all necessary adjustments.

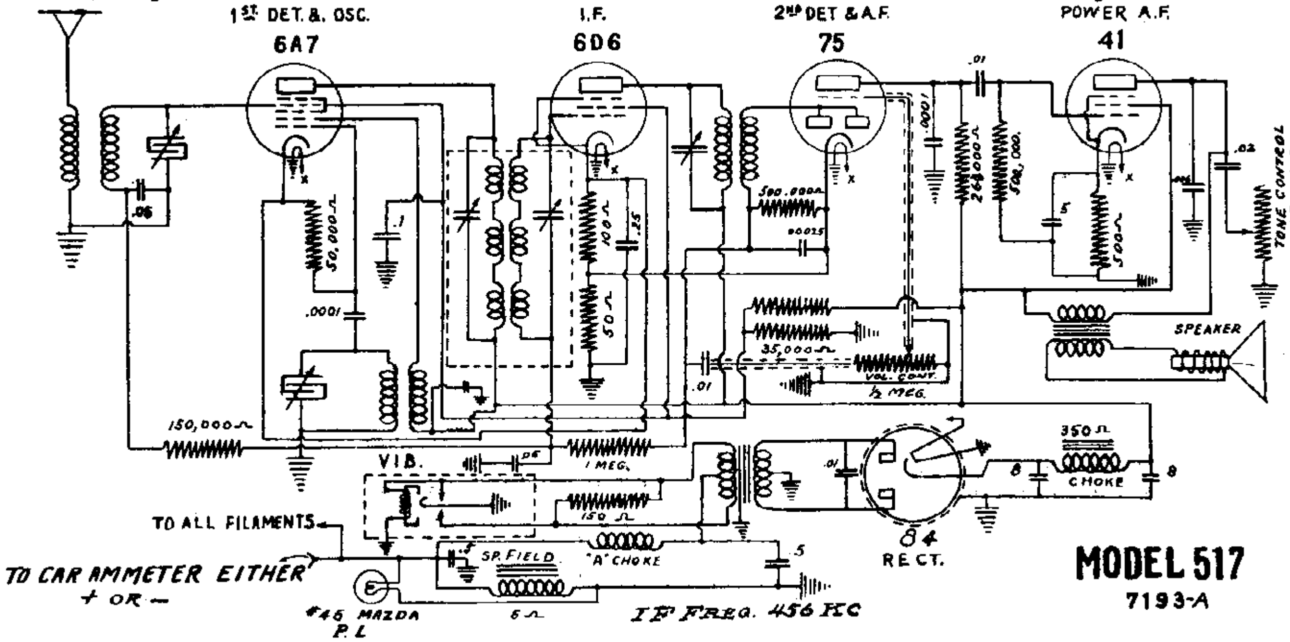
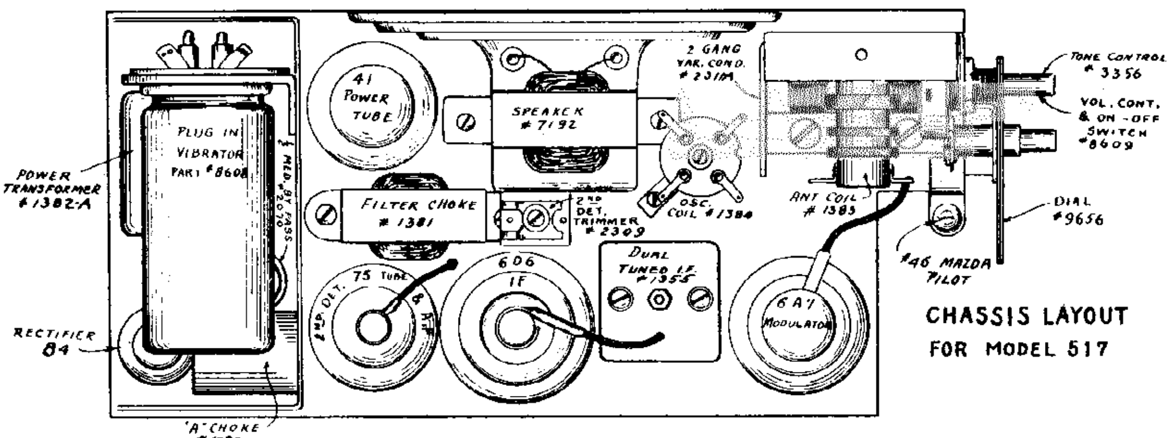
MODEL 517
Schematic, Socket

DeWALD RADIO

Trimmers, Alignment
Notes, Parts





CHASSIS LAYOUT
FOR MODEL 517

CALIBRATION INSTRUCTIONS Connect test Oscillator, Hot lead to the grid of the 6-A-7 tube and the "Cold" lead to the receiver chassis, short circuit the Receiver's variable condenser, cut Oscillator section. Peak - I.F. two trimmers in the top of the aluminum shield and trimmer in rear of speaker to 456-K.C. - After the I.F. has been Peaked, remove short from the variable condenser stator and connect test Oscillator "Hot lead" to the antenna Lead-in of the Receiver. Set test Oscillator and Receiver to 1500 K.C. and adjust variable condenser trimmers for max. signal.

Antenna Lead: A Shielded Antenna lead is connected to the set. If any connections, extensions or alterations are made to this lead care should be taken to see that the lead is well shielded to a point without the field of interference. It is also necessary to ground the "far" end of the Antenna lead-in shield.

Battery: The battery should be kept in a well charged condition and the terminals cleaned of corrosion. Check generator charging rate to keep battery in charged condition.

Ignition Coil: In cases where noise is originating from the ignition coil, it may be overcome by placing a copper shield around the coil and grounding same.

Battery Cables: May be corroded at the battery and are making imperfect contact. Keep all battery cables and wires away from the high tension system. It may also be of advantage to place a choke coil of about 50 turns of #16 wire in series with the main battery lead to the set.

Wires under Car: Where wires run along chassis or other metal parts below the car they should be inspected for quality of insulation and general condition. It may be well to place a condenser at the stop light switch and at the tail light.

Distributor: Points may be burned or improperly adjusted. Rotor arm may be making poor contact with cap.

Distributor Cables: Cables may be "leaking" due to poor or burned insulation. In some installations it may be necessary to shield the high tension leads with copper braid. If ignition cables are insulated with plain rubber insulation it is not advisable to place shielding directly over the wire. In this case the wire should be first covered with a varnished composition covering or loom. The battery lead from the ammeter to the distributor coil and the battery lead to the generator should be shielded.

Dome Light Wire: If dome light wire is radiating, it may be necessary to shield this wire. A .5 Mfd. condenser or a choke in series with this lead by-passed at either side of choke to chassis may help considerably. These connections should be made at the point where the dome light enters the upright post.

Bonding: Although metal joints on the car, such as dash panel to side of car etc., may appear to be solid they may not be making good electrical contact and are causing noise. Paint and other material may get into seams and cause poor or intermittent contacts and for this reason it may be necessary to bond certain parts of the car. The brake rods, drive shaft tubes and parts around the motor should be bonded.

For Realligning Receiver See Circuit Diagram.

Model 606 and Early Production of Model 617 use a padder condenser instead of a cut-plate oscillator section.

MODELS 606, 617 (Early and Late)

DEWALD RADIO

Socket, Trimmers, Alignment

Is a six tube superheterodyne receiver with full automatic volume control operating on all three radio frequency tubes. The speaker and eliminator are assembled in the same case as the receiver, permitting simple installation. Tone modulation is obtained by turning knob on right side of receiver cover.

BATTERY VOLTAGE — The set operates on a 6 to 8 volt battery with either POSITIVE or NEGATIVE ground.

TUBES — 6D6, 6A7, 6D6, 75, 41 and 84 (6Z4)

ANTENNA — The Antenna may be either the copper mesh or built in type furnished as standard equipment on some cars, or in the case of the new metal roof, or "Turret Top" cars it may be a plate type or balanced Hairpin type Antenna mounted under the running board.

INSTALLATION (See fig. #1) — Connect ammeter condenser to spring clip at end of wire in which the fuse holder is located. Use the self tapping screw provided. Compress the clip and slide it on battery side of ammeter. Ground other terminal of ammeter condenser to any convenient point. Plug antenna lead into connection on right side of set by pushing in and turning to the right. Attach "lead-in" to car antenna. Install the generator condenser by connecting the lead to the generator terminal and grounding the case of the condenser.

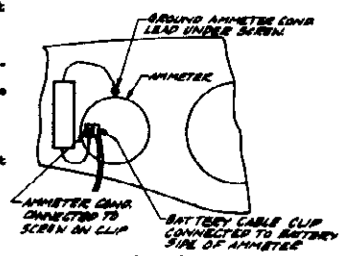

FIG 5

FUSE — The fuse is located in a metal retainer in the wire that connects to the ammeter. A standard automobile type 15 ampere fuse should be used for replacement, being sure to use fibre cover. Do not use anything else in place of fuse as guarantee will be invalidated.

REMOTE CONTROL — The remote control unit is furnished with drive cables attached. It may be well to examine the set screws holding the cables in place to see that they have not become loosened in shipping. Locate the unit on the steering column and fasten same by means of control clamp.

After the unit has been mounted, looking at the front of unit, the larger knob is the tuning control and the smaller one is the key, switch and volume control.

The remote control cables should now be connected to the receiver by inserting them into cable bushings located on the left side of the set. The drive cable (tongue end) should be inserted into the bushing at the rear of the set and the volume control cable (slotted end) into the one nearer the front. After the cables have been inserted the knobs on the remote control unit should be turned back and forth several times to be sure that the cables are engaged. The cable bushing set screws should now be tightened to hold them firmly in place.

To adjust pointer on remote control dial, turn larger knob as far to right as it will go, then with a small screw driver turn the adjusting screw in the rear of the remote control unit until the pointer is on the first dial mark on the right side of the dial. (below 150) The tuning of the set will then agree with the dial calibration.

LIST OF ACCESSORY PARTS

1 Mounting Stud
1 Mounting Washer
1 Mounting Nut
1 Lock Nut
1 Remote Control Unit
1 Drive Sheath and Cable
1 Volume Control Sheath and Cable
1 Mazda Pilot Lamp #55, 6-8 Volts
1 Antenna Plug and Lead-In
1 Generator Condenser
1 Ammeter Condenser
1 Key Knob

NOISE SUPPRESSION

This receiver has been designed to operate without the use of either spark plug or distributor suppressors. If the ignition system is faulty, or if the set is installed in an old model car where the ignition system radiates badly, it may be necessary to place a suppressor at the distributor in series with the main high tension lead. If spark plug interference is still noticed it may also be necessary to place a suppressor on each plug.

It is important that all items and connections in the electrical system of the car be in good condition. If excessive noises are present it may be well to examine the following points.

1. Antenna Lead: A Shielded Antenna lead is furnished with the set. If any connections, extensions or alterations are made to this lead care should be taken to see that the lead is well shielded to a point without the field of interference. It is also necessary to ground the "far" end of the Antenna lead-in shield.

2. Battery: The battery should be kept in a well charged condition and the terminals cleaned of corrosion. Check generator charging rate to keep battery in charged condition.

3. Ignition Coil: In cases where noise is originating from the ignition coil, it may be overcome by placing a copper shield around the coil and grounding same (See fig. #4).

4. Battery Cables: May be corroded at the battery and are making imperfect contact. Keep all battery cables and wires away from the high tension system. It may also be of advantage to place a choke coil of about 50 turns of #15 wire in series with the main battery lead to the set.

5. Wires under Car: Where wires run along chassis or other metal parts below the car they should be inspected for quality of insulation and general condition. It may be well to place a condenser at the stop light switch and at the tail light.

6. Distributor: Points may be burned or improperly adjusted. Rotor arm may be making poor contact with cap.

7. Distributor Cables: Cables may be "leaking" due to poor or burned insulation. In some installations it may be necessary to shield the high tension leads with copper braid. If ignition cables are insulated with plain rubber insulation it is not advisable to place shielding directly over the wire. In this case the wire should be first covered with a varnished composition covering or loom. The battery lead from the ammeter to the distributor coil and the battery lead to the generator should be shielded. (See fig. #4)

8. Dome Light Wire: If dome light wire is radiating it may be necessary to shield this wire. A single .5 mfd. condenser or a double condenser and choke as shown in fig. #3 connected at the point where the dome light wire enters the upright post will clear up this trouble.

9. Bonding: Although metal joints on the car, such as dash panel to side of car etc., may appear to be solid they may not be making good electrical contact and are causing noise. Paint and other material may get into seams and cause poor or intermittent contacts and for this reason it may be necessary to bond certain parts of the car. The brake rods, drive shaft tubes and parts around the motor should be bonded.

SERVICE NOTES

INT. FREQ. ALIGNMENT — Intermediate frequency peaked at 175 K.C. Connect test oscillator to grid of 6A7 and ground. (Ground stator of oscillator condenser during this operation)

R.F. ALIGNMENT — Connect test oscillator to antenna and ground. Set dial to 1500 K.C. and align trimmer condensers on variable condensers for maximum signal. All other frequencies will automatically be aligned because of cut section oscillator condenser.

(Model 606 and Early Model 617 use a padding condenser)

MOUNTING INSTRUCTIONS

1- SCREW UNSLOTTED END OF MOUNTING BOLT TIGHTLY (UP TO THE NICKS) INTO LARGE THREADED HOLE IN REAR OF RECEIVER CASE.
2- DETERMINE LOCATION OF RECEIVER AND DRILL 1/2 INCH HOLE IN FIRE BOARD TO PASS THE MOUNTING BOLT.
3- SCREW ON THE MOUNTING NUT SO THAT RECEIVER IS HELD FIRMLY IN PLACE. SCREW ON LOCK NUT FIRMLY OVER MOUNTING NUT.

SERVICE NOTES

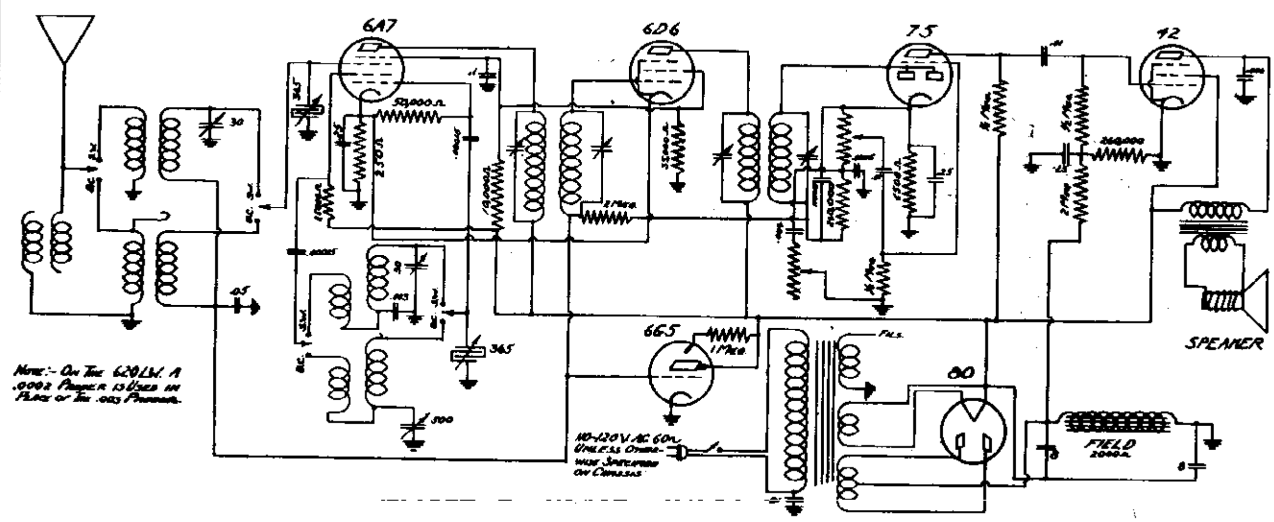
I.F. ALIGNMENT- Intermediate Frequency Peaked At 456 K.C. Connect Test Oscillator To Grid of 6A7 And Chassis. Short Circuit Stator of Front Section of Variable Condenser During This Operation. Then Peak I.F. Trimmers For Maximum Signal.

R.F. ALIGNMENT- Remove Short From Stator of Variable Condenser. Turn Wave Band Switch To Broadcast. Connect Test Oscillator To Antenna And Chassis. Set Test Oscillator And Radio Dial To 1500 K.C. And Peak Var. Cond. Trimmers For Maximum Signal. Set Test Oscil. At 600 K.C. And Adjust Padder Condenser in Front of Chassis For Max. Signal. During This Operation The Var. Cond. Must Be Rocked. Readjust 1500 K.C.

POLICE BAND ALIGNMENT- Turn Wave Band Switch To Police Band Set Test Osc. And Radio Dial To 4000 K.C. And Peak 2 Trimmers Near Front Of Chassis For Max. Sig. The Low Freq. Setting is Automatically Adjusted By A Fixed Calibrated Padder. If Receiver Has Long Waves Instead of Police Band Calibrate Same Trimming Cond. As on Police Band But Set Oscillator And Receiver At 300 K.C. For Alignment.

SHORT WAVE ALIGNMENT- Turn W.B. Switch To Short Wave. Set Test Osc. And Radio Dial To 15 Megacycles And Peak Trimmers Near Center of Chassis For Max. Sig. Low Freq. Setting is Automatically Taken Care Of By Short Wave Coils Which Are Carefully Matched For This Setting By A Fixed Calibrated Padder.

MODEL-618



Note:- On The 620LW. A .0002 Padder Is Used in Place of The .003 Padder.

SERVICE NOTES

I.F. ALIGNMENT- Intermediate Frequency Peaked At 456 K.C. Connect Test Osc. To Grid of 6A7 And Chassis. Short Circuit Stator of Front Section of Var. Cond. During This Operation. Then Peak I.F. Trimmers For Minimum Signal.

R.F. ALIGNMENT- Remove Short From Stator of Var. Cond. Turn Wave Band Switch To Broadcast. Connect Test Osc. To Antenna And Chassis. Set Test Oscil. And Radio Dial To 1500 K.C. And Peak Var. Cond. Trimmers For Max. Signal. Set Test Oscil. At 600 KC. And Adjust Padder Cond. on Top of Chassis For Max Signal. During This Operation The Var. Cond. Must Be Rocked. Readjust 1500 KC.

SHORT WAVE ALIGNMENT- Turn W.B. Switch To Short Wave Set Test Oscil. And Radio Dial To 15 Megacycles And Peak Trimmers Near Center of Chassis For Max. Signal. Low Frequency Setting is Automatically Taken Care of By Short Wave Coils Which Are Carefully Matched For This Setting By A Fixed Calibrated Padder.

L.W. ALIGNMENT- Turn W.B. Switch To L.W. Set Osc. And Radio At 300 KC And Peak The L.W. Trimmers Then Set Osc. And Radio To 175 KC And Adjust Padder Cond. Recheck 300 KC.

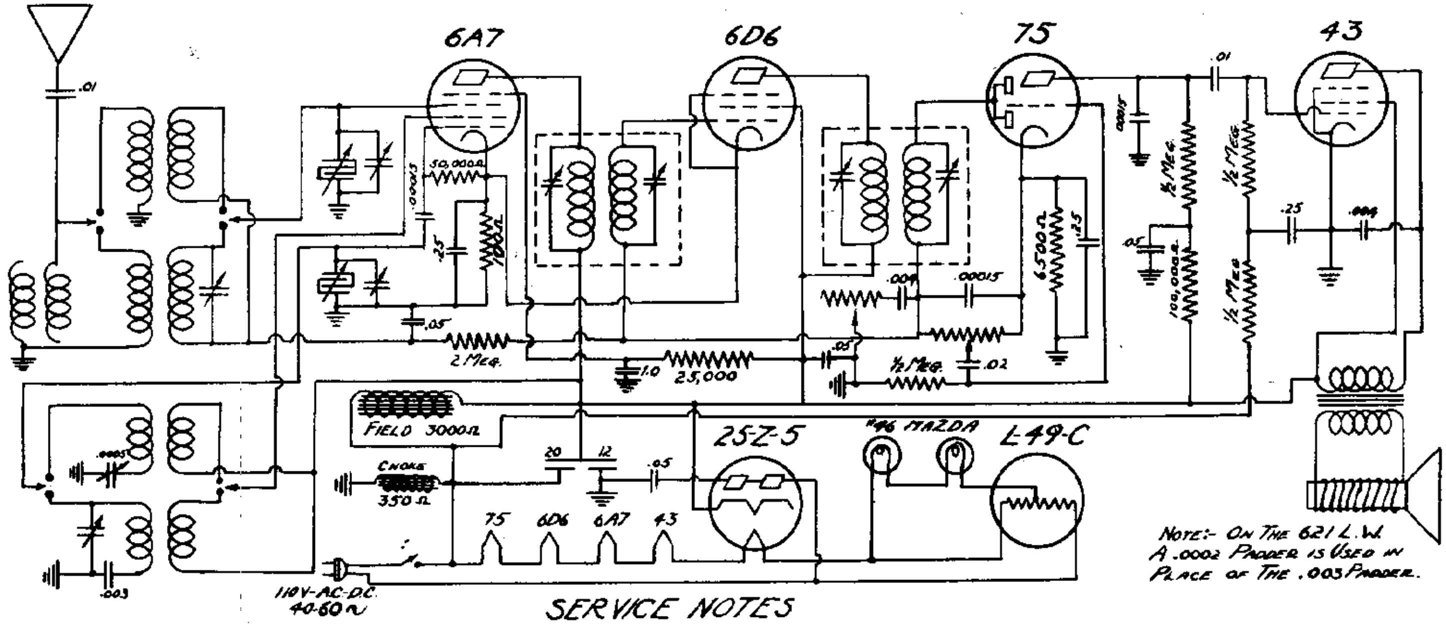
Schematic
Alignment, Notes

DeWALD RADIO

SHORT WAVE TUNING — In tuning stations on the short waves, great care must be exercised in tuning as the receiver acts very selectively. A station may be tuned in and out within a fraction of a degree on the dial and for this reason it is necessary that the receiver be tuned carefully. An example of the care required may be obtained when one considers that in one dial division there may be as many as five stations.



MODEL 621 621-L.W.
PART # 7208

SERVICE NOTES

I.F. ALIGNMENT- INTERMEDIATE FREQUENCY PEAKED AT 456 K.C. CONNECT TEST OSCILLATOR TO GRID OF 6A7 AND CHASSIS. SHORT CIRCUIT STATOR OF FRONT SECTION OF VAR. COND. DURING THIS OPERATION. THEN PEAK I.F. TRIMMERS FOR MAXIMUM SIGNAL.

R.F. ALIGNMENT- REMOVE SHORT FROM STATOR OF VAR. COND. TURN WAVE BAND SWITCH TO BROADCAST. CONNECT TEST OSCILLATOR TO ANTENNA AND CHASSIS. SET TEST OSCILLATOR AND RADIO DIAL TO 1500 KC. AND PEAK VAR. COND. TRIMMERS FOR MAXIMUM SIGNAL. SET TEST OSCIL. AT 600 KC. AND ADJUST PADDER CONDENSER ON TOP OF CHASSIS FOR MAX. SIGNAL. DURING THIS OPERATION THE VAR. COND. MUST BE ROCKED. READJUST 1500 K.C.

SHORT WAVE ALIGNMENT- TURN W.B. SWITCH TO SHORT WAVE. SET TEST OSC. AND RADIO DIAL TO 15 MEGACYCLES AND PEAK TRIMMERS NEAR CENTER OF CHASSIS FOR MAX. SIGNAL. LOW FREQ. SETTING IS AUTOMATICALLY TAKEN CARE OF BY SHORT WAVE COILS WHICH ARE CAREFULLY MATCHED FOR THIS SETTING BY A FIXED CALIBRATED PADDER.

L.W. ALIGNMENT- TURN W.B. SWITCH TO L.W. SET OSC. AND RADIO AT 300 KC. AND PEAK THE L.W. TRIMMERS. THEN SET OSC AND RADIO TO 175 K.C. AND ADJUST PADDER COND. RECHECK 300 K.C.

These receivers are six tube dual wave superheterodyne with full automatic volume control on both wave bands. They are designed to operate on 110-120 volts 40-60 cycles alternating current or direct current, unless otherwise specified on rear of chassis.

RANGES: The Model 621 has the following ranges:
550-1700 K.C. (550-178 meters) and
17 - 55 M.C. (18-55 meters)
The Model 621 L.W. has the following ranges:
550-1700 K.C. (550-178 meters and 140-350 K.C.)

ANTENNA — An Antenna of 50 to 100 feet should be connected to the red lead extending from rear of chassis. The antenna should be kept as far away as possible from obstructions, such as electric power lines, telephone lines, or other antenna. For best results it is necessary to have a secure ground connection made to a water or other grounded pipe.

BROADCAST OPERATION — Turn the radio on by rotating the left hand knob toward the right. The volume of the radio is adjusted by this same knob. Turn the lower center knob to the right and tune the receiver by manipulating the top knob and making use of the outer figures on the dial scale.

SHORT WAVE OPERATION — Turn the lower center knob to the left. On this band, the center figures on the dial scale should be noticed. Due to the sharpness of tuning on short wave it is necessary to tune slowly and have the volume control turned on "full" to avoid passing over stations.

LONG WAVE RECEPTION — The 621 L.W. has Long Wave in place of Short Wave band. Follow the same instructions as for Short Wave reception but use inner row of Figures.

TONE CONTROL — The tone control is the knob to the right. Various degrees of tone can be obtained by merely adjusting this control.

DeWALD RADIO

Alignment, Socket Trimmers, Data

DEWALD RADIO

The Models 804 and 805 are all wave superheterodyne receivers designed to operate on 110-120 or 210-230 volts, alternating current, 50-60 cycles only. The primary tap on top of the power transformer must be connected properly for the voltage to be used.

Before plugging into the power line, make sure that the line voltage and current frequency agree with the above. If doubt exists regarding the exact power line conditions, consult your local power Company.

Check the tubes to be certain that they are securely pushed into their respective sockets, and that the grid clips on top of the tubes are firmly in place. Also check the speaker plug to see that it is securely pushed into its socket at the rear of the Chassis.

<u>TUBES</u> 2-58a, 1-2A7, 1-2A6, 1-2A5, 2-45s, 1-80

<u>INSTALLATION</u> This receiver is arranged for a "Doublet" Antenna system, or an ordinary single wire system. For connections of either type see Fig. #3a & 3B. A good Antenna is essential for the correct operation of this receiver, especially where distant reception is expected. The flat top portion of the Antenna should be placed as high as possible above the ground and surrounding objects. No. 14 solid or stranded wire may be used for the flat top portion and well insulated semi-flexible wire for the lead-in section. The Antenna should be equipped with good insulators wherever they are required. Material such as pyrex, glass, Bakelite, and high grade porcelain are well suited for radio installations. The lead-in wire should be kept away from all nearby wires and should be run at right angles to power or trolley lines wherever possible. It should be brought into the house at the nearest point convenient to the receiver in order to avoid picking up noise from home electrical devices. The ground wire should be as short as possible and must be a good connection to water or other grounded pipe.

<u>BAND SWITCH</u> This switch is located on the left side of front panel and its position is indicated by the letters engraved into the knob. (A-B-C-D)

<u>BAND "A"</u> Standard Domestic Broadcast band. Frequency range from 540 to 1800 K.C.

<u>BAND "B"</u> Intermediate Short wave Band. Broadcast Frequency range from 1600 K.C. to 5500 K.C. Services operating on this band are: Police, Aeroplane, Television, and Amateur. Reception on this band is reliable for moderate distances during both day and night, but for distances greater than 1000 miles the area must be in darkness.

<u>BAND "C"</u> Short Wave Band. Frequency range 5.4 to 18 megacycles. Services operating on this band include: Domestic and Foreign Short wave Broadcasting, Aeroplane, Amateur, Commercial Code and Telephone, and Experimental. Stations in the vicinity of 18 to 12 Megacycles are best received when the distance between transmitter and receiver is greater than 1500 miles and the area between is in Daylight. This same holds true for stations about 10 to 12 Megacycles except that signals are often heard in the early hours of darkness. Stations operating on frequencies between 10 and 7 megacycles offer reliable reception both day and night, especially when the distance is greater than 700 miles. Reliable reception on frequencies below 7 megacycles, when the distance exceeds 1500 miles, may be expected when the area between receiver and transmitter is in darkness.

<u>BAND "D"</u> Long wave Band. Frequency range 140 K.C. to 400 K. C. (Model 805 only) This band includes the European long wave Broadcast band, (Heard in Europe only) Domestic Aviation Beacons, weather Reports and Commercial Code.

<u>BAND SPREAD DIAL</u> This receiver is provided with a dual station selector drive, to permit micrometer tuning which is especially valuable on the short waves where band spreading or its equivalent, high ratio tuning, becomes necessary for easy and rapid registering of foreign programs.
The large knob of the main selector drive is the low ratio control with a normal ratio of 24 to 1 in 360°. The small knob on the same shaft controls the high ratio control with a tuning ratio of 125 to 1 in 360°. Bands "A" and "B" are calibrated in kilocycles and Band "C" in megacycles. The Small Band Spread Indicator may be used to make fine adjustments not obtainable from the larger scale.

<u>PHONOGRAPH PICKUP</u> It is also possible to use this receiver with an electric phono pickup attachment for the reproduction of disc. recordings. For this purpose, a Phono Jack is located at the rear of the Chassis. The volume Control will control the strength of signals for phonograph reproduction (any high impedance pickup of high quality may be used with this receiver.)

SERVICE NOTES

<u>REALIGNMENT</u> The procedure outlined below should be followed should the receiver require realignment. For location aligning trimmers and padders, see Fig. 2.

<u>I. F. ALIGNMENT</u> To align the Intermediate Frequency stages, first place the wave Band Switch in Pos. "A" and Short Circuit the Oscillator Section of the Variable Condenser. Set the test Oscillator to 456 K.C. and connect its output through A .00025 MFD fixed Condenser to the grid cap of the 2A7 Tube and chassis ground. Adjust the six I. F. Compensators (Three on each I.F. Transformer) for Max Signal. (Volume Control must be in maximum position during all adjustments. Use the least possibe input to the receiver to prevent broadening of the resonance peaks.)

<u>BAND "A" (BROADCAST) ALIGNMENT</u> After the Intermediate Frequency stages have been completely aligned, connect external test oscillator to the Antenna and Ground binding posts of the set. See Fig. 3-4. Set the band switch to "A" position. Set test Oscillator to 1500 K.C. and adjust the three band A Compensators for maximum gain. Next, set dial at 600 K.C. and adjust Band "A" Paddler for maximum signal, rocking Variable Condenser at the same time. Now repeat repeaking operation at 1500 K. C.

<u>BAND "B" ALIGNMENT</u> Turn wave Band Switch to "B" Position and set Variable Condenser to 5000 K. C. Adjust test oscillator to this frequency and adjust 3 Band "B" Trimmers for maximum gain. Next set dial at 1900 K. C. and adjust band "B" Paddler for maximum signal. Now repeat repeaking operation at 5000 K. C.

<u>BAND "C" (SHORT WAVE) ALIGNMENT</u> Turn Wave Band Switch to "C" position and set Variable Condenser to 16 megacycles. Adjust test oscillator to this frequency and adjust three band "C" Trimmers.

<u>BAND "D" (LONG WAVE) ALIGNMENT</u> Turn wave Band Switch to "D" position and align Trimmers on long wave coils at 375 K.C. Adjust Band "D" Padder at 160 K. C.

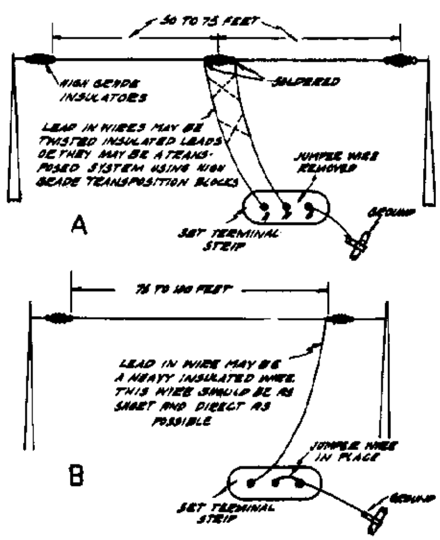

FIG. 3

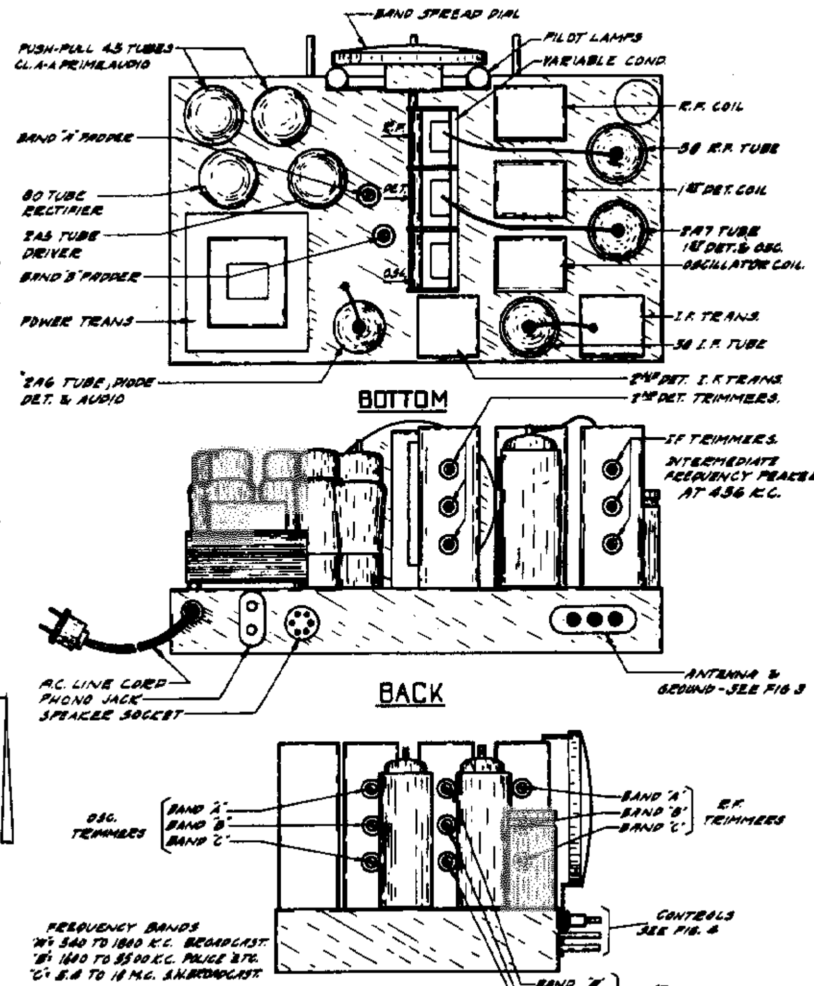

FIG. 2

<u>TONE CONTROL</u> The Tone Control Knob is located directly below the main Tuning Knob. By adjusting this knob the user may select any tone shading desired from mellow to brilliant. The Tone Control may also be used to reduce background noise on signals that are accompanied by excessive disturbances such as static and local electrical noise.

<u>VOLUME CONTROL AND ON-OFF SWITCH</u> To place receiver in operation turn the "Volume Control Knob" to the right. To increase volume rotate to the right; to decrease rotate to the left. The receiver is also equipped with an automatic volume control feature which tends to maintain all reception at a constant level, thereby reducing fading effects and blasting of strong signals.

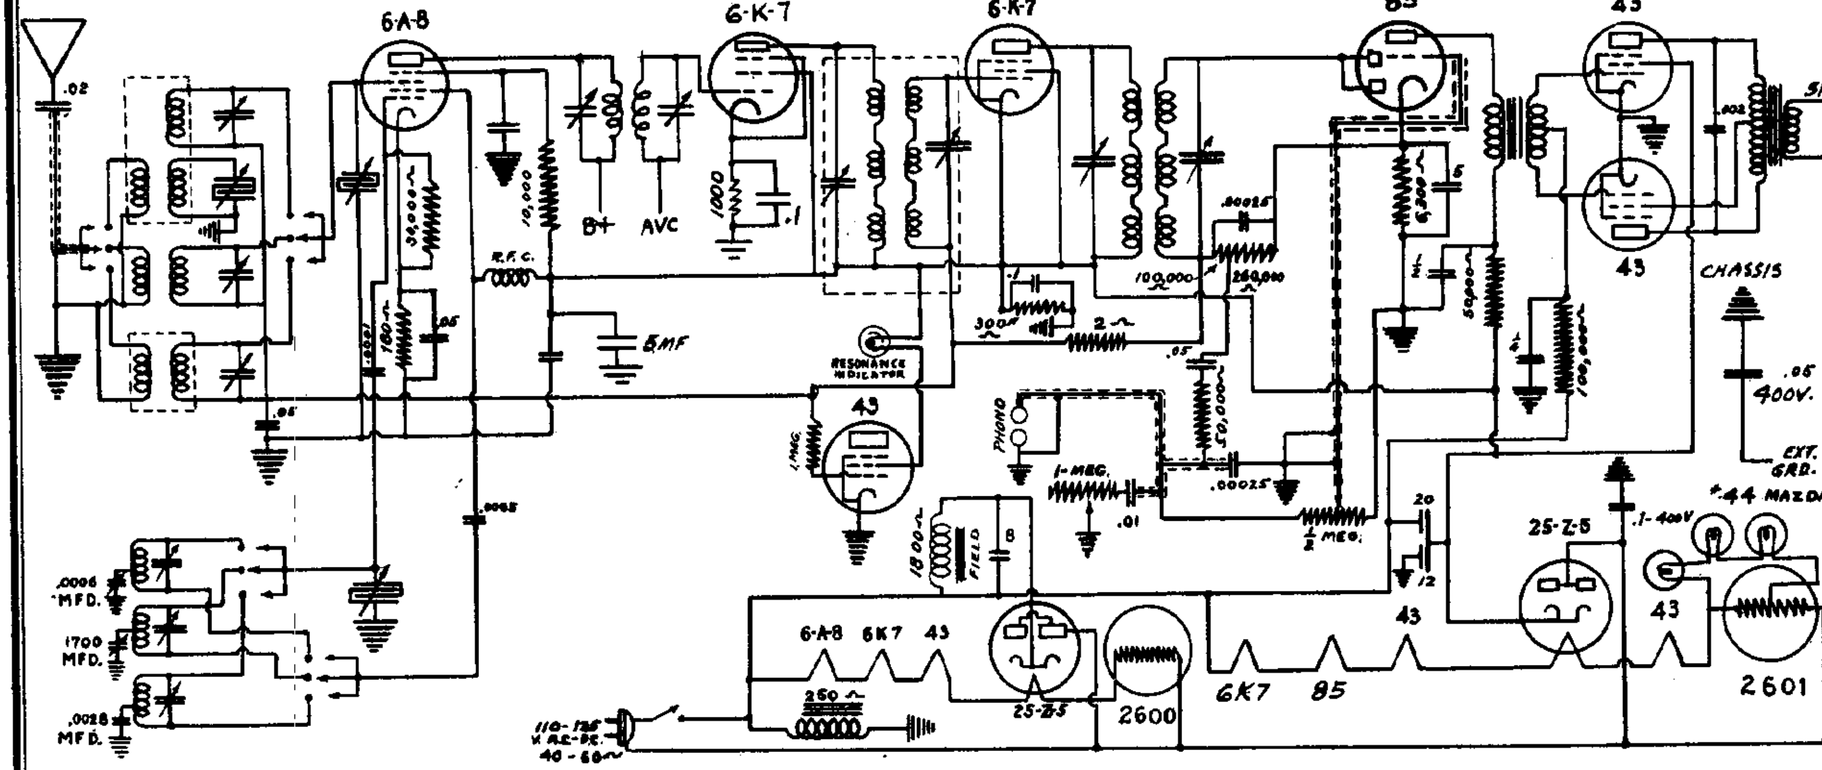
Schematic Data

DeWALD RADIO



I.F. FREQUENCY 456 K.C.

ANTENNA AND GROUND CONNECTIONS — An Antenna from 50 to 100 feet long should be connected to the post in rear of chassis. It should be as far as possible from obstructions, such as electric light, telephone lines, or other buildings. For quiet and stable service it is necessary to have a secure ground connection made to a water pipe or radiator with a good ground clamp. Connect ground to black wire in rear of chassis.

GREEN BROADCASTING OPERATION — To receive stations on the broadcasting band, turn wave band-switch knob (located on the lower left side of front panel) to the right (Green position) band position. Turn set on by rotating combination switch and volume control knob (located on the lower right hand side of front panel) to the right. Tune receiver to the desired station, which may be located on the top dial scale (green figures) and adjust volume control for desired volume.

WHITE SHORT WAVE OPERATION — For reception of stations on the short wave band, (5.5 to 15.5) megacycles) turn wave band switch to the left, (White position), and tune carefully noting the white scale. Due to the sharpness of the tuning on the short wave it is usually necessary to turn up the volume control in order to avoid passing over stations.

WHITE SHORT WAVE TUNING NOTE — In tuning stations on the short wave, great care must be exercised in tuning as the receiver acts very selectively. A station may be tuned in and out within a fraction of a degree on the dial and for this reason it is necessary that the receiver be tuned carefully. An example of the care required may be obtained when one considers that in one dial division there may be as many as five stations.

RED BAND OPERATION — This band covers the frequency range between 1600 to 4600 K.C., in the Model 1100, or 150 to 410 K.C. in the Model 1100 IN. When tuning on these ranges, the wave band switch is in the center position and the red scale is in use.

RESONANCE INDICATOR — Green spot in the lower right hand side of dial is the Resonance Indicator. When tuning receiver watch this spot until the glow is at a minimum. At this point the receiver is tuned exactly on the station desired.

TONE CONTROL — The Tone Control Knob is located in the upper left hand side of the receiver. By adjusting this knob the user may select any tone shading desired from mellow to brilliant. The Tone Control may also be used to reduce background noise on signals that are accompanied by excessive distrubences such as static and local electrical noise.

PHONOGRAPH PICKUP — It is also possible to use this receiver with an electric phono pickup attachment for the reproduction of disc. recordings. For this purpose, a Phono Jack is located at the rear of the Chassis. The Volume Control will control the strength of signals for phonograph reproduction (any high impedance pickup of high quality may be used with this receiver)

ADJUSTMENTS

An oscillator with frequencies of 456, 600, 1600 and 15,000 kc is required.

In aligning the broadcast coils use, as a dummy antenna, a .0002 condenser in series with the test oscillator antenna lead. In aligning the short-wave coils a non-inductive 400 ohm resistor should be used as a dummy antenna.

An output meter should be used across the voice coil or output transformer for observing maximum response.

Location of Coils and Trimmer Adjustments

The two i-f transformers are located on top of the chassis deck. The first i-f is the one closer to the front.

The broadcast and short-wave antenna coils are wound on one form and mounted vertically on top of the chassis deck, directly in front of the first i-f transformer. The trimmers for these two coils are mounted on a strip which is attached to the coil tubing. The lower trimmer is for the short-wave antenna coil and the upper trimmer is for the broadcast antenna coil.

The broadcast and short-wave oscillator coils are wound on one form and mounted with the trimmer assembly against the inside of the right-hand chassis wall. The trimmer screws are accessible through two holes in the chassis. The trimmer closer to the front is for the short-wave oscillator coil. The trimmer closer to the rear is for the broadcast oscillator coil.

The adjustable 456 kc wave trap is also mounted on the inside of the right-hand chassis wall. The trimmer for this wave trap is accessible through a hole in the rear wall of the chassis.

The broadcast series padder is mounted on the inside of the front chassis wall with the adjusting screw accessible through a hole in the chassis. There is no adjustable padder for the short-wave band.

I-f and Wave-trap Alignment

Rotate the wave-band switch (extreme right-hand control) to the broadcast position, clockwise. Rotate the variable condenser to the minimum capacity position and feed 456 kc to the grid cap of the 6A7 tube. Adjust the four i-f trimmers (at the tops of the cans) for maximum response. Feed 456 kc through the antenna and adjust the wave trap (through hole in rear of chassis) for *minimum response.*

Broadcast Alignment

With the wave-band switch in the broadcast position, set the dial pointer to 600, feed 600 kc to the antenna through a dummy antenna and adjust the broadcast series padder (on front wall) for maximum response. Move the pointer to 1600, feed 1600 kc to the antenna and adjust the broadcast oscillator trimmer (on right wall, closer to rear) for maximum response and then adjust the broadcast antenna trimmer (top trimmer on antenna coil) for maximum response. Return pointer to 600, feed 600 kc and readjust the broadcast series padder, rocking the variable condenser (rotate condenser shaft back and forth through small arc) for maximum response. Return to 1600 kc again and check the alignment.

Short-wave Alignment

Rotate the wave-band switch to the short-wave position, counter-clockwise. Set the dial pointer a little below 16 and feed 15,000 kc to the antenna, using a 400 ohm dummy antenna. Adjust the short-wave oscillator trimmer (closer to front on right wall) for maximum response, choosing the *minimum capacity* peak, and then adjust the short-wave antenna trimmer (lower trimmer on antenna coil) for maximum response, choosing the *maximum capacity* peak. (See General Instructions below.)

GENERAL INSTRUCTIONS

The set's oscillator is higher in frequency than the signal, so images should be observed on the low frequency side of the signals.

Always choose the minimum capacity peak on oscillator trimmers and maximum capacity peaks on antenna trimmers. The last motion in adjusting trimmers should always be a tightening one, not a loosening one.

Never leave a trimmer with the outside plate so loose that there is no tension on the screw. Either bend the plate up or remove the screw entirely. Loose screws are a sure source of noise and drifting.

In aligning antenna trimmers on the high frequency signals there is always a tendency for the oscillator to drift, due to interlocking. To compensate for this always keep tuning the variable condenser as you adjust the trimmers.

Always use as weak a test signal as possible during alignment.

VOLTAGE ANALYSIS

Readings should be taken with a 1000 ohms-per-volt meter. Voltages listed below are from point indicated to ground (chassis) with volume control turned on full and no signal. The battery voltage for these readings was 6.1 volts.

Tube	*Plate*	*Screen*	*Cathode*	*Osc. Plate*	*Fil.*
6A7	95	63	3.0	95	6
15	157	63	1.8	—	2
15	114	63	1.8	—	2
85	53	—	5.5	—	6
76	150	—	5.7	—	6
19	153	—	—	—	2

Voltage from each control grid of the 19 tube to ground—4 volts.

With an input of 6.0 volts and 1.6 amperes the output of the power pack should be approximately 140 volts at .040 amperes.

GENERAL NOTES

The large, oblong metal box on the top of the chassis deck contains the power pack. The function of this power pack is to convert the 6 volt direct current from the storage battery into 140 volt direct current. The vibrator used is of the synchronous type.

*Item number locates article on schematic diagram.

It is important to observe the proper polarity in connecting the battery to the receiver. The heavy red lead should be attached to the positive side of the battery. If the connections are reversed the vibrator and electrolytic condenser in the power pack will be seriously damaged.

The color coding of the leads of the i-f transformers is as follows:

Grid—green
Grid return—black
Plate—blue
B plus—red

With few exceptions the color coding of the general wiring is as follows:

Plate—blue
B plus—red
Screen—brown
Cathode—white or yellow
Grid—green
Filament and ground—black

The color coding of the leads of the power pack is as follows:

A plus—yellow
B plus—red

The chassis is common negative for both the A and B supply.

MODEL 101U
Chassis U68
Alignment, Voltage Notes, Parts List

EMERSON RADIO & PHONO. CORP.

ADJUSTMENTS

An oscillator with frequencies of 456, 600, 1600, 1700, 4500 and 15,000 kc should be used. In addition, an output meter should be used across the voice coil or output transformer for observing maximum response.

I-f Alignment

The i-f transformers XXT-188A and XXT-189A are located on the top of the chassis. The four trimmers, two for each i-f transformer, are located at the tops of the cans. Set the wave-band switch to broadcast (extreme clockwise position) and rotate variable condenser to minimum. Feed 456 kc to grid of the 6A8 tube and adjust the four i-f trimmers for *maximum response*. Then feed 456 kc through the antenna and adjust the wave-trap trimmer for *minimum response*. The trimmer is on the wave-trap, which is located on top of the chassis behind the antenna coil.

Location of Coils

The antenna coils for the three bands are wound on one form and mounted on top of the chassis to the right of the variable condenser. The three trimmers for these coils are mounted on a bakelite strip above the tubing. The trimmer nearest the front of the chassis is for the broadcast antenna coil. The central trimmer is for the police antenna coil and the trimmer furthest from the front of the chassis is for the short-wave antenna coil.

The oscillator coils for the three bands are wound on one form and mounted underneath the chassis deck directly behind the tone control. The three trimmers for these coils are mounted on a bakelite strip between the coil tubing and the chassis. The trimmers are accessible through three holes in the top of the chassis. The trimmer nearest the front of the chassis is for the short-wave oscillator coil. The central trimmer is for the police oscillator coil and the trimmer furthest from the front of the chassis is for the broadcast oscillator coil.

The dual adjustable padder is mounted underneath the chassis between the oscillator coil and the variable condenser with the adjusting screws accessible through two holes in the top of the chassis. The screw closer to the front is for the police band and the other screw is for the broadcast band. The short-wave band has no adjustable padder.

Broadcast Alignment

Set the wave-band switch to broadcast position (extreme clockwise) and dial pointer to 600. Feed 600 kc through antenna lead and adjust broadcast padder (on dual padder, closer to back of chassis) for maximum response. Set pointer to 1600, feed 1600 kc and adjust the broadcast-oscillator trimmer (to left of variable, furthest from front of chassis) for maximum response, and then the broadcast antenna trimmer (on antenna coil, nearest front of chassis). Return pointer to 600 and rock the variable condenser (rotate condenser back and forth through small arc) while adjusting the broadcast padder for maximum response. If a readjustment is necessary return to 1600 and realign the antenna and oscillator trimmers.

Police Alignment

Set the wave-band switch to police (central position), pointer to 1700 and feed 1700 kc through antenna lead. Adjust police band padder (on dual padder, closer to front) for maximum response. Set pointer to 4500 and feed 4500 kc. Adjust police band oscillator trimmer (to left of variable, central trimmer) for maximum response. If two peaks are heard, select the one of minimum capacity (see General Instructions below), then adjust police band antenna trimmer (central one on antenna coil) for maximum response, selecting the peak of maximum capacity. Again feed 1700 kc, with pointer at 1700, rock variable condenser and adjust police band padder for maximum response. Realign at 4500 if necessary.

Short-Wave Alignment

Set wave-band switch to counter-clockwise (short-wave) position and pointer at 15 megacycles. Feed 15,000 kc through antenna. Adjust short-wave oscillator trimmer (to left of variable, closest to front) for maximum response. If two peaks are obtained, select the one of minimum capacity.

Check all three bands for dead spots or incorrect alignment.

General Instructions

The set's oscillator is higher in frequency than the signal on all three bands. Images, therefore, should be observed on the low-frequency side of the signals.

Always choose the minimum capacity peak on oscillator trimmers and maximum capacity peaks on antenna trimmers. The last motion in adjusting trimmers should always be a tightening one.

Never leave a trimmer with the outside plate so loose that there is no tension on the screw. Either bend the plate up or remove the screw entirely. Loose screws are a source of noise, frequency drift and microphonism.

In aligning antenna trimmers on the high-frequency signals there is usually a tendency for the oscillator to drift, due to interlocking. To compensate for this, always keep re-tuning the variable condenser.

VOLTAGE ANALYSIS

Readings should be taken with a 1000 ohms-per-volt meter. Voltages listed below are from point indicated to ground (chassis). Line voltage for these readings was 117.5 volts, 60 cycles, a.c.

Tube	*Plate*	*Screen*	*Cathode*	*Osc. Plate*	*Fil.*
6A8	105	50	1.25	90	6
6K7 1st i-f	105	105	3.5	—	6
6K7 2nd i-f	62	50	3.5	—	6
75	57	—	0	—	6
43	92	105	0	—	24

GENERAL NOTES

1. Bias for the grid of the audio section of the 75 tube is obtained by means of a very small one-volt battery (bias cell). The cell assembly is mounted on a bakelite strip on the inside of the right-hand chassis wall. Do not put a voltmeter across this bias cell. If the set distorts, check the cell by temporarily replacing with a new cell, or some other one-volt source, and noting results. To remove the bias cell, simply pull up on the spring clip and lift the cell from its cup. On replacing it be sure the clip makes good contact.
2. Pilot lights may be replaced by slipping the push-on sockets off the dial and unscrewing the bulbs. It is not necessary to remove either the dial or chassis from cabinet.
3. One side of the power line is directly grounded to the chassis base. Under no circumstances, therefore, should a ground wire be permitted to come in contact with any metal part of this receiver.
4. If replacements are made or the wiring disturbed in the r-f section of the circuit, the receiver should be carefully realigned.
5. In operating the receiver on d.c. it may be necessary to reverse the line plug for correct polarity.
6. The color coding of the i-f transformer leads is as follows:
   Grid—green
   Grid return—black
   Plate—blue
   B plus—red

NOTES ON REVISED MODEL

In later production receivers a 6E5 cathode ray tube was added to the chassis to be used as a tuning indicator. The circuit revision is indicated in the schematic diagram. The entire 6E5 circuit is blocked off in the lower left hand corner of the diagram. It should be noted that the original circuit is not changed. The revision of these models involves only the addition of the 6E5 circuit.

The extra parts required for the addition of the 6E5 tube are listed under Replacement Parts below. Revisions in the main circuit and parts list are indicated under Production Changes.

ADJUSTMENTS

An oscillator with frequencies of 456, 600, 1600, 1800, 5500, 6000 and 17000 kc should be used.

An output meter should be used across the voice coil or speaker output transformer for observing maximum response.

I-f Alignment

The i-f transformers NNT-153 and NNT-154 are located on extreme left side of chassis. Set wave-band switch at position A (clockwise) and condenser at minimum. Feed 456 kc to grid of 6A8 tube. Adjust the five i-f trimmers carefully for maximum response. Feed 456 kc through antenna and adjust 456 kc wave-trap for minimum response. This wave-trap is located at bottom rear of set, directly under the antenna binding post.

Broadcast Alignment

The three broadcast coils are in separate cans on top of tuner unit. (The tuner unit is the separate chassis section floated on rubber in center of chassis base). All trimmers for these coils are located at bottoms of cans and are available from bottom of chassis. NNT-150 is antenna coil, NNT-151 is detector coil and NNT-152 is oscillator coil. The oscillator coil has two adjusting screws; the one painted red is the series padder and the other is the trimmer. The antenna and detector coils have one trimmer each.

Set switch at A and pointer to 600 on dial. Feed 600 kc to antenna and adjust broadcast oscillator padder (red screw at bottom front of tuner unit, left-hand corner) for maximum response. Set pointer at 1600, feed 1600 kc to antenna and adjust oscillator trimmer beside red padder for maximum response, and then adjust r-f trimmer (through hole at about center of tuner unit), and antenna trimmer (through hole at rear of unit). Reset the pointer to 600, feed 600 kc to antenna and rock the variable condenser while resetting the oscillator padder for maximum response. Return to 1600, and check alignment. If readjustment is necessary, return to 600 and repeat entire procedure.

Police Alignment

The three police-band coils are the smaller ones located on the bottom side of the tuner unit, in row at left of wave-band switch (same side of switch as antenna binding post). The antenna coil is the one furthest from front of chassis, detector coil in center, and oscillator coil nearest front of chassis. The dual padder mounted on bottom, right-hand side of tuner unit has one padder for police-band oscillator coil and one for short-wave oscillator coil. The padder nearest wave-band switch is for the police band. Each of the three trimmers for the police-band coils is located on top of its respective coil.

Set switch at B (central position) and pointer to 1800 (2 divisions below 200 mark). Feed 1800 kc to antenna. Adjust oscillator series padder nearest to switch in right-hand corner for maximum response. Set pointer to 5500 and feed 5500 kc to antenna. First adjust oscillator trimmer (front one on row of smaller coils) for maximum response. If two peaks are obtained, select the minimum capacity peak. (See General Instructions below). Then adjust the antenna (rear) and detector (center) trimmers for maximum response. If two peaks are obtained, select the maximum capacity peak. Reset pointer to 1800, feed 1800 kc to antenna, and rock variable condenser while adjusting police band oscillator padder for maximum response. Return to 5500 and check alignment. If a readjustment is necessary return to 1800 and repeat entire procedure.

Short-Wave Alignment

The three short-wave coils are the larger ones located on bottom side of tuner unit in row at right of wave-band switch. The antenna coil is the one furthest from front of chassis, detector coil in center and oscillator coil nearest front of chassis. On dual padding condenser the padder furthest from wave-band switch is for short-wave oscillator coil. Each of the three trimmers for the short-wave coils is located on top of its respective coil.

Set switch at C (counter-clockwise) and pointer at 6 megacycles. Feed 6000 kc to antenna. Adjust short-wave oscillator padder (furthest from switch on dual unit) for maximum response. Set pointer to 17 megacycles and feed 17000 kc to antenna. First adjust oscillator trimmer (front) for maximum response. If two peaks are obtained, select the minimum capacity peak. Then adjust the antenna (rear) and detector (center) trimmers for maximum response. If two peaks are obtained, select the maximum capacity peak. Return pointer to 6 mc, feed 6000 kc to antenna and rock variable condenser while adjusting the oscillator padder for maximum response. Return to 17 mc. Feed 17000 kc to antenna and check alignment.

Check the receiver on all three bands for dead spots which indicate incorrect alignment.

General Instructions

The set's oscillator is higher in frequency than the signal on all three bands. Images, therefore, should be observed on the low-frequency side of the signals.

Always choose the minimum capacity peak on oscillator trimmers and maximum capacity peaks on antenna and r-f trimmers. The last motion in adjusting trimmers should always be a tightening one.

Never leave a trimmer with the outside plate so loose that there is no tension on the screw. Either bend the plate up or remove the screw entirely. Loose screws are a source of noise, frequency drift and microphonism.

In aligning antenna trimmers on the high-frequency signals there is usually a tendency for the oscillator to drift, due to interlocking. To compensate for this always keep re-tuning the variable condenser as you align.

A jack is provided at the rear of the chassis for a phonograph attachment. The pickup to be used should be of the high impedance type. A separate potentiometer type volume control is required, the overall resistance to be determined by the type of pickup chosen. The pickup leads should be connected to the two outside terminals of the volume control with the ground lead of the pickup on the right-hand terminal (looking at front with terminals at top) of the control. A lead from this terminal should be plugged into the hole in the phone jack nearest the center of the chassis. A lead from the center terminal of the volume control should be plugged into the other hole in the jack (grid side of jack). Ends of leads to be plugged in jack should be fitted with tips. The volume control in the receiver should be turned to the extreme counter-clockwise (low) position when operating phonograph. Since the phono jack is of the shorting type signals cannot be received by the set when the leads are plugged into the jack. The leads should be removed before attempting to receive broadcast stations.

In replacing chassis in cabinet do not tighten mounting screws so much that chassis will not float freely, and do not allow any part of the dial assembly to touch the cabinet. Do not push control knobs on so far that they touch the cabinet front panel. If these precautions are not observed the receiver may become microphonic.

The color coding of the power transformer leads is as follows:

Primary—two green leads	6.3 v. sec.—two heavy blue leads
High voltage sec.—two black leads	6.3 center tap—thin blue lead
High voltage center tap—yellow lead	5 v. sec.—two heavy red leads

VOLTAGE ANALYSIS

Readings should be taken with a 1000 ohms-per-volt meter. Voltages listed below are from point indicated to ground, with no signal. Line voltage for these readings was 117.5 volts, 60 cycles.

Tube	Plate	Screen	Cathode	Osc. Plate	Fil.
6K7 (r-f)	250	107	4.0	—	6.3 a.c.
6A8	250	100	3.5	190	6.3 a.c.
6K7 (i-f)	250	107	5.5	—	6.3 a.c.
75	100	—	0.9	—	6.3 a.c.
6C5	135	—	4.7	—	6.3 a.c.
6F6	245	250	15.5	—	6.3 a.c.
6F6	245	250	15.5	—	6.3 a.c.

Voltage across speaker field—100 volts.
B plus at 80 filament—350 volts.

(Revised Model) - PRODUCTION CHANGES

To facilitate production of later receivers, tubular condensers were substituted for the seven-section condenser block, part no. NNC-157. Relative to these condensers, the revised parts list should read as follows:

Item No.	Part No.	Description	Price
C16	BBC-132	0.1 mf, 400 volt tubular condenser	$.16
C17	AC-6	0.1 mf, 200 volt tubular condenser	.16
C20	BC-12	0.05 mf, 200 volt tubular condenser	.16
C25	AAC-112	0.25 mf, 400 volt tubular condenser	.15
C27,C28	KC-58	0.01 mf, 400 volt tubular condenser	.15
C33	NNC-245	0.9 mf, 400 volt tubular condenser	.60

The dial was changed from part no. NND-23 to part no. NND-23A.

Previous to the above changes, C41, 8 mf-450 volt tubular electrolytic condenser (part no. NNC-226), was added.

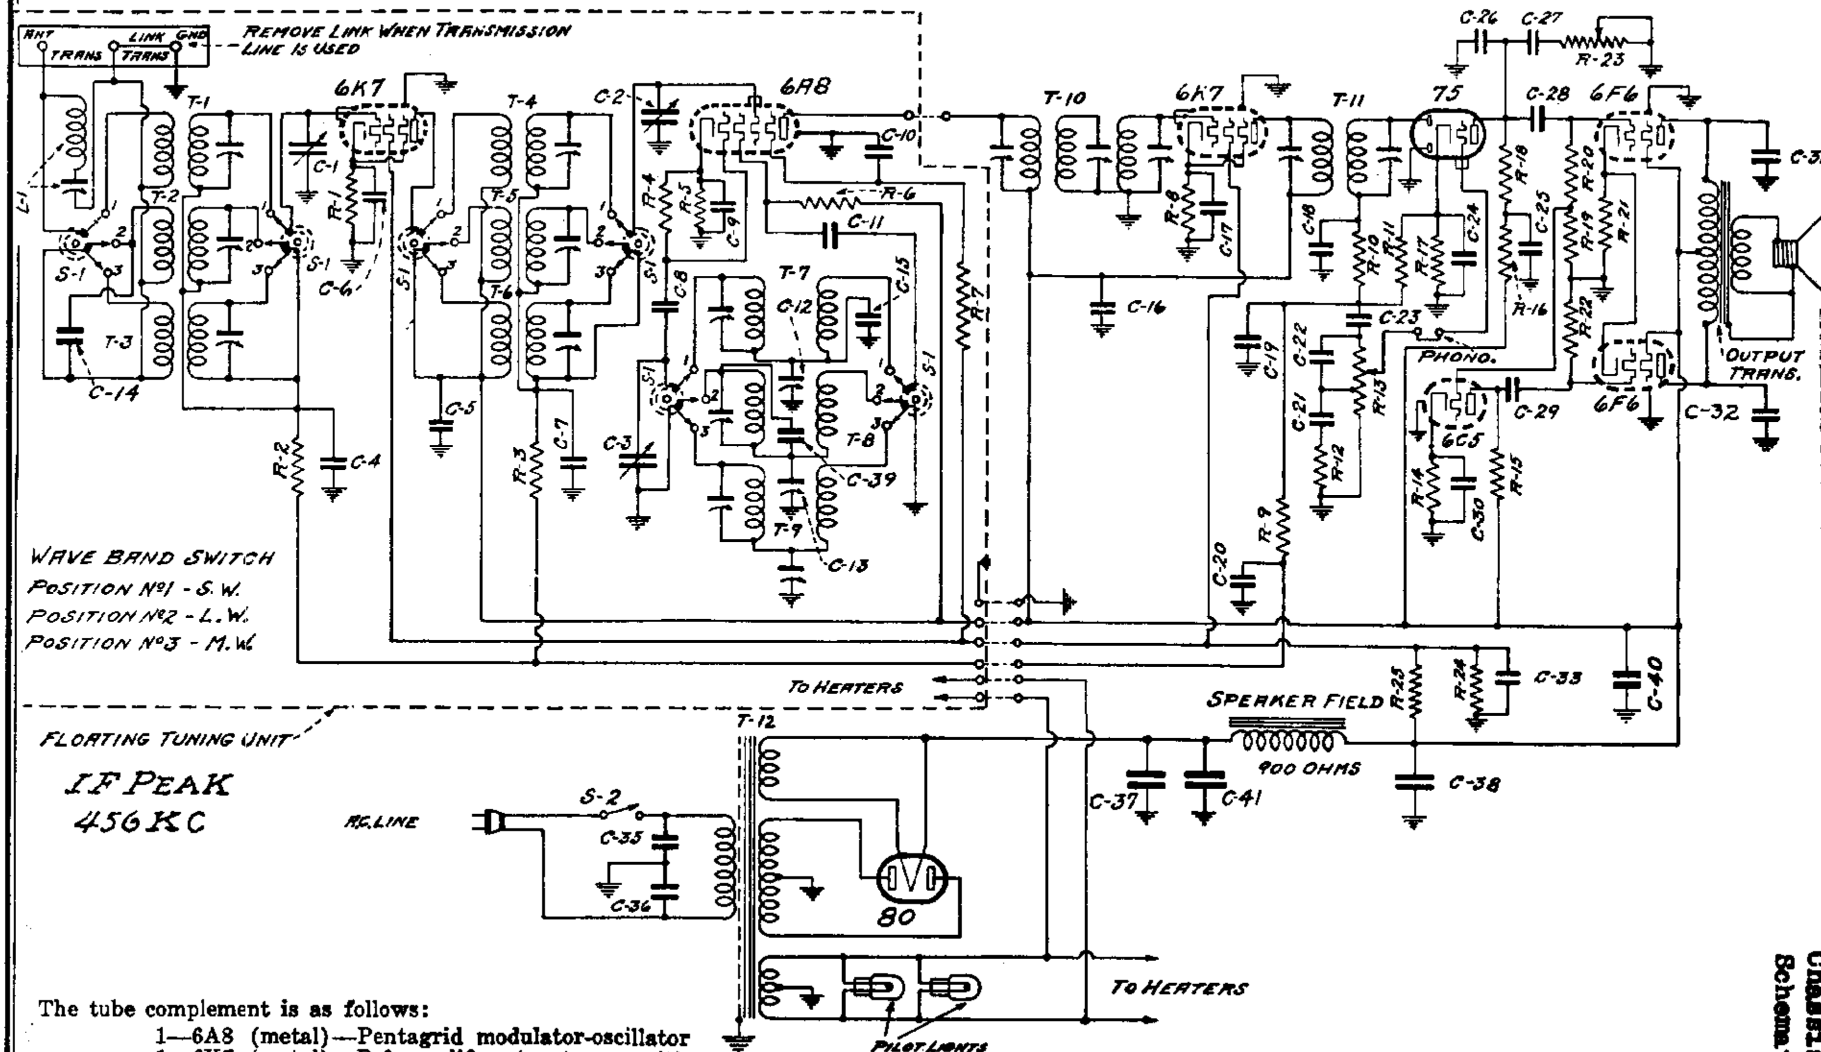
EMERSON RADIO & PHONO. CORP.



The tube complement is as follows:

1—6A8 (metal)—Pentagrid modulator-oscillator
1—6K7 (metal)—R-f amplifier (on tuner unit)
1—6K7 (metal)—I-f amplifier
1—75 (glass)—Second detector—a-f amplifier
1—6C5 (metal)—Phase inverter
2—6F6 (metal)—Push-pull output
1—80 (glass)—Full-wave rectifier.

Voltage rating .... 110-120 volts, a.c. (unless otherwise specified).
Current drain .... .73 amps., a.c. (at 117.5 volts).
Frequency ranges .... 135 to 375 kc, 540 to 1800 kc, 5.5 to 19.0 megacycles.

EMERSON RADIO & PHONO. CORP.

ADJUSTMENTS

An oscillator with frequencies of 150, 345, 456, 600, 1600, 6000 and 17000 kc should be used.

An output meter should be used across the voice coil or speaker output transformer for observing maximum response.

I-f Alignment

The i-f transformers NNT-153 and NNT-154 are located on extreme left side of chassis. Set wave-band switch at position A (clockwise) and condenser at minimum. Feed 456 kc to grid of 6A8 tube. Adjust the five i-f trimmers carefully for maximum response. Feed 456 kc through antenna and adjust 456 kc wave-trap for *minimum response*. This wave-trap is located at bottom rear of set, directly under the antenna binding post.

Medium-Wave Alignment

The three medium-wave coils are in separate cans on top of tuner unit. (The tuner unit is the separate chassis section floated on rubber in center of chassis base). All trimmers for these coils are located at bottoms of cans and are available from bottom of chassis. NNT-150 is antenna coil, NNT-151 is detector coil and NNT-152 is oscillator coil. The oscillator coil has two adjusting screws; the one painted red is the series padder and the other is the trimmer. The antenna and detector coils have one trimmer each.

Set switch at A and pointer to 600 on dial. Feed 600 kc to antenna and adjust medium-wave oscillator padder (red screw at bottom front of tuner unit, left-hand corner) for maximum response. Set pointer at 1600, feed 1600 kc to antenna and adjust oscillator trimmer beside red padder for maximum response, and then adjust r-f trimmer (through hole at about center of tuner unit), and antenna trimmer (through hole at rear of unit). Reset the pointer to 600, feed 600 kc to antenna and rock the variable condenser while resetting the oscillator padder for maximum response. Return to 1600, and check alignment. If readjustment is necessary, return to 600 and repeat entire procedure.

Long-Wave Alignment

The three long-wave coils are the coils with the large number of turns located on the bottom side of the tuner unit, in row at left of wave-band switch (same side of switch as antenna binding post). The antenna coil is the one furthest from front of chassis, detector coil in center, and oscillator coil nearest front of chassis. The dual padder mounted on bottom, right-hand side of tuner unit has one padder for the long-wave oscillator coil and one for the short-wave oscillator coil. The padder nearest the wave-band switch is for the long-wave band. Each of the three trimmers for the long-wave coils is located on top of its respective coil.

Set switch at B (central position) and pointer to 150. Feed 150 kc to antenna. Adjust oscillator series padder (nearest to switch in right-hand corner) for maximum response. Set pointer to 345 and feed 345 kc to antenna. First adjust oscillator trimmer (front one on row of long-wave coils) for maximum response. Then adjust the antenna (rear) and detector (center) trimmers for maximum response. Return pointer to 150, feed 150 kc to antenna, and rock variable condenser while adjusting long-wave oscillator padder for maximum response. Return to 345 and check alignment. If a readjustment is necessary return to 150 and repeat entire procedure.

Short-Wave Alignment

The three short-wave coils are the ones with the heavy wire turns located on bottom side of tuner unit, in row at right of wave-band switch. The antenna coil is the one furthest from front of chassis, detector coil in center and oscillator coil nearest front of chassis. On dual padding condenser the padder furthest from wave-band switch is for short-wave oscillator coil. Each of the three trimmers for the short-wave coils is located on top of its respective coil.

Set switch at C (counter-clockwise) and pointer at 6 megacycles. Feed 6000 kc to antenna. Adjust short-wave oscillator padder (furthest from switch on dual unit) for maximum response. Set pointer to 17 megacycles and feed 17000 kc to antenna. First adjust oscillator trimmer (front) for maximum response. If two peaks are obtained, select the *minimum capacity* peak. Then adjust the antenna (rear) and detector (center) trimmers for maximum response. If two peaks are obtained, select the *maximum capacity* peak. Return pointer to 6 mc, feed 6000 kc to antenna and rock variable condenser while adjusting the oscillator padder for maximum response. Return to 17 mc. Feed 17000 kc to antenna and check alignment.

Check the receiver on all three bands for dead spots which indicate incorrect alignment.

General Instructions

The set's oscillator is higher in frequency than the signal on all three bands. Images, therefore, should be observed on the low-frequency side of the signals.

Always choose the minimum capacity peak on oscillator trimmers and maximum capacity peaks on antenna and r-f trimmers. The last motion in adjusting trimmers should always be a tightening one.

Never leave a trimmer with the outside plate so loose that there is no tension on the screw. Either bend the plate up or remove the screw entirely. Loose screws are a source of noise, frequency drift and microphonism.

In aligning antenna trimmers on the high-frequency signals there is usually a tendency for the oscillator to drift, due to interlocking. To compensate for this always keep re-tuning the variable condenser as you align.

GENERAL NOTES

1. A jack is provided at the rear of the chassis for a phonograph attachment. The pickup to be used should be of the high impedance type. A separate potentiometer type volume control is required, the overall resistance to be determined by the type of pickup chosen. The pickup leads should be connected to the two outside terminals of the volume control with the ground lead of the pickup on the right-hand terminal (looking at front with terminals at top) of the control. A lead from this terminal should be plugged into the hole in the phono jack nearest the center of the chassis. A lead from the center terminal of the volume control should be plugged into the other hole in the jack (grid side of jack). Ends of leads to be plugged in jack should be fitted with tips. The volume control in the receiver should be turned to the extreme counter-clockwise (low) position when operating phonograph. The pickup leads should be removed before attempting to receive broadcast stations.
2. The receiver should never be turned on with the speaker plug or the 6F6 tubes out of their sockets, since the rapid rise in rectifier voltage would damage the electrolytic condenser.
3. Pilot lights may be replaced by slipping the push-on sockets off the dial and unscrewing the bulbs. It is not necessary to remove either the dial or chassis from cabinet.
4. In replacing chassis in cabinet do not tighten mounting screws so much that chassis will not float freely, and do not allow any part of the dial assembly to touch the cabinet. Do not push control knobs on so far that they touch the cabinet front panel. If these precautions are not observed the receiver may become microphonic.
5. The color coding of the power transformer leads is as follows:

Primary—two green leads	6.3 v. sec.—two heavy blue leads
High voltage sec.—two black leads	6.3 center tap—thin blue lead
High voltage center tap—yellow lead	5 v. sec.—two heavy red leads.

6. If the dial is of the type which has four small screws spaced circularly about the main knob shaft it may be adjusted to prevent slipping by carefully tightening up on these screws. Extreme care should be exercised to tighten the screws only enough to cure the slipping; excessive pressure will damage the internal mechanism.

VOLTAGE ANALYSIS

Readings should be taken with a 1000 ohms-per-volt meter. Voltages listed below are from point indicated to ground, with no signal. Line voltage for these readings was 117.5 volts, 60 cycles.

EMERSON RADIO & PHONO. CORP.

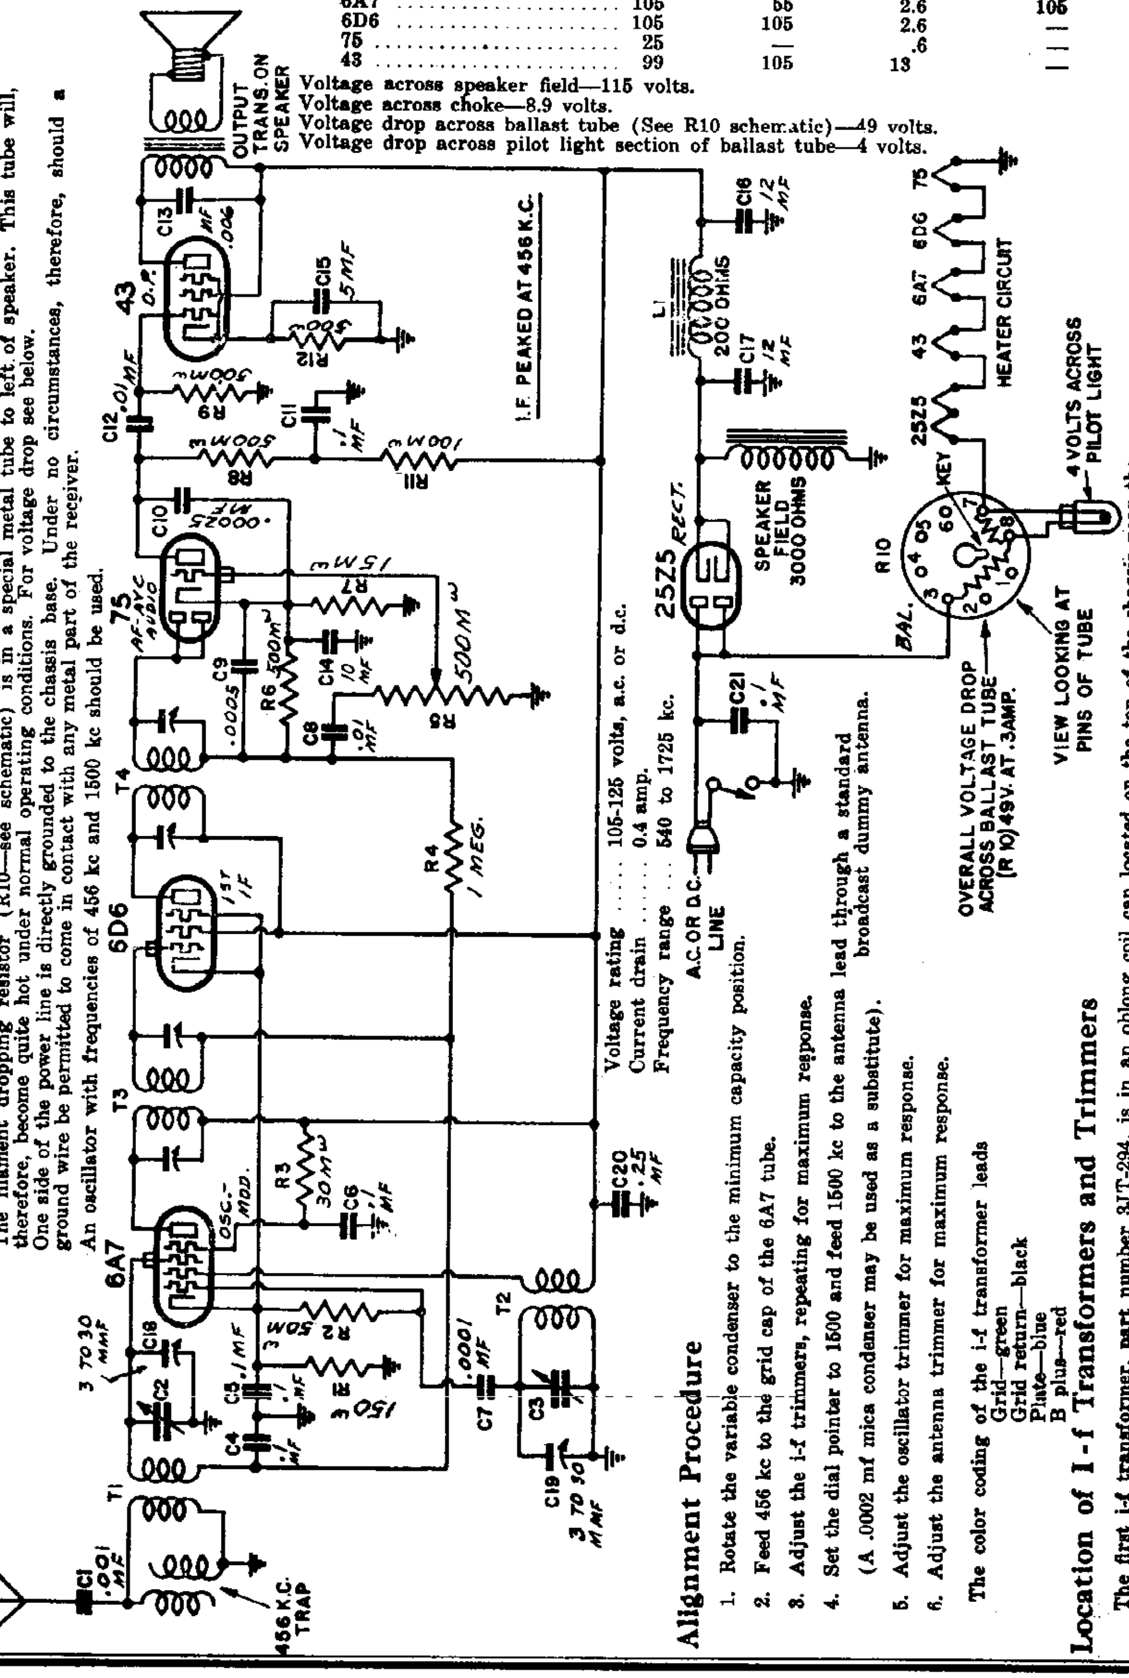
MODEL J106
Chassis J
Schematic, Voltage
Alignment, Data

Readings should be taken with a 1000 ohms-per-volt meter. Voltages listed below are from point indicated to ground (chassis) with the volume control turned on full and no signal. Line voltage for these readings was 117.5 volts, 60 cycles, a.c.

Tube	*Plate*	*Screen*	*Cathode*	*Osc. Plate*	*Fil.*
6A7	105	55	2.6	105	6.3
6D6	105	105	2.6	—	6.3
75	25	—	.6	—	6.3
43	99	105	13	—	25

Voltage across speaker field—115 volts.
Voltage across choke—8.9 volts.
Voltage drop across ballast tube (See R10 schematic)—49 volts.
Voltage drop across pilot light section of ballast tube—4 volts.

The filament dropping resistor (R10—see schematic) is in a special metal tube to left of speaker. This tube will, therefore, become quite hot under normal operating conditions. For voltage drop see below.
One side of the power line is directly grounded to the chassis base. Under no circumstances, therefore, should a ground wire be permitted to come in contact with any metal part of the receiver.
An oscillator with frequencies of 456 kc and 1500 kc should be used.



Voltage rating ..... 105-125 volts, a.c. or d.c.
Current drain ..... 0.4 amp.
Frequency range ... 540 to 1725 kc.

Alignment Procedure

1. Rotate the variable condenser to the minimum capacity position.
2. Feed 456 kc to the grid cap of the 6A7 tube.
3. Adjust the i-f trimmers, repeating for maximum response.
4. Set the dial pointer to 1500 and feed 1500 kc to the antenna lead through a standard broadcast dummy antenna.
   (A .0002 mf mica condenser may be used as a substitute).
5. Adjust the oscillator trimmer for maximum response.
6. Adjust the antenna trimmer for maximum response.

The color coding of the i-f transformer leads
Grid—green
Grid return—black
Plate—blue
B plus—red

Location of I-f Transformers and Trimmers

The first i-f transformer, part number 3JT-294, is in an oblong coil can located on the top of the chassis near the right-hand end. The two trimmers for this i-f are accessible through holes in the top of the coil can.

The second i-f transformer, part number 3JT-295, is in an oblong coil can located on the top of the chassis directly behind the speaker. The two trimmers for this i-f are accessible through holes in the top of the coil can.

The oscillator and antenna trimmers are on a bakelite strip, mounted underneath the chassis on the right-hand wall. The two adjusting screws are available through holes in the chassis wall. The trimmer nearest the rear is the oscillator trimmer and the trimmer farthest from the rear is the antenna trimmer.

VOLTAGE ANALYSIS

Readings should be taken with a 1000 ohms-per-volt meter. Voltages listed below are from point indicated to cathode of the 43 tube (B minus). Line voltage for these readings was 117.5 volts, 60 cycles, a.c.

Tube	*Plate*	*Screen*	*Cathode*	*Osc. Plate*	*Fil.*
6A7	99	43	1.1	80	6.3
6K7	99	80	1.8	—	6.3
6H6	—	—	0	—	6.3
6F5	50	—	0	—	6.3
43	87	99	0	—	24

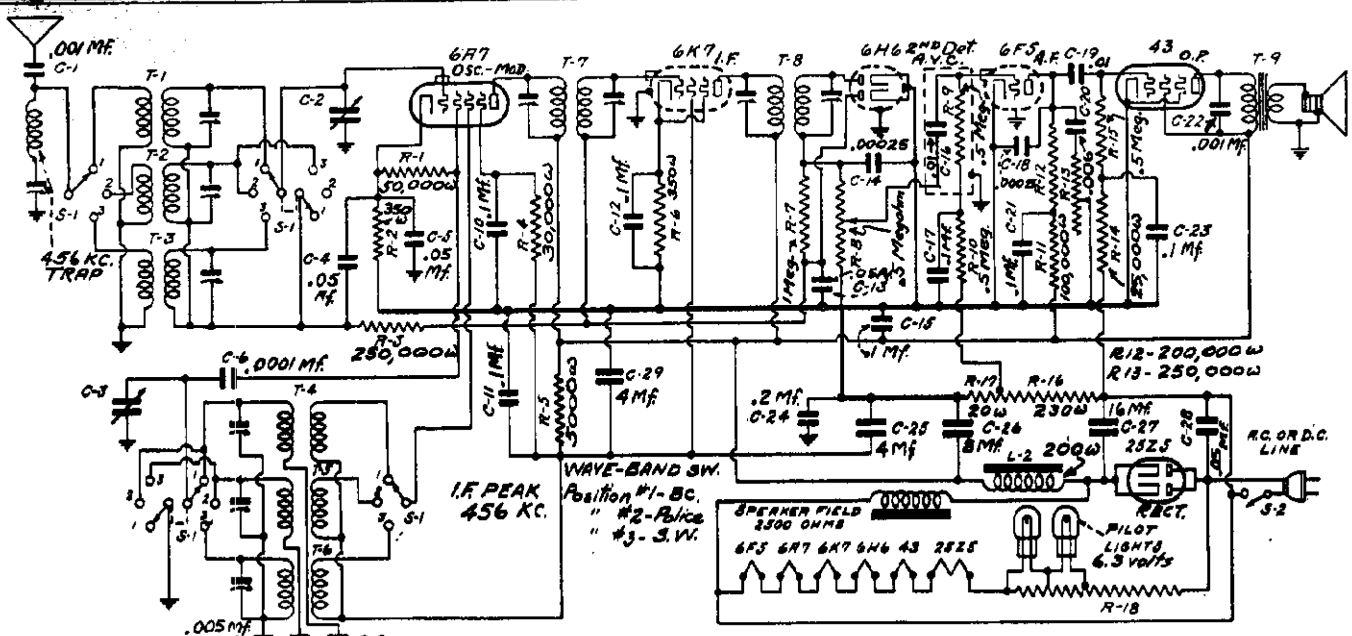
Voltage across speaker field (black and yellow leads)—120

Voltage across filter choke—9.5

The 250 ohm bias resistor, R16 and R17 on schematic diagram, is located underneath the chassis deck near volume control.

Voltage across the two outside terminals of this resistor—11.5

Voltage from cathode of 43 tube to central terminal of resistor—1.0



Schematic of Emerson chassis U6F used in Models 107, 111.

The schematic diagram of the receiver bearing these model numbers, shown on *Emerson page 6-15 of Rider's Volume VI*, is for Chassis U6A. A note on that page makes reference to chassis U6F that carries the same model numbers, 107 and 111. This chassis is different and its schematic is shown in the accompanying illustration.

The filament dropping resistor (Part No. 2LR-212) is of the cylindrical plug-in type and is located on top of the chassis between the 6H6 and 25Z5 tubes. The output transformer (Part No. 2LT-221 and T-9 on the diagram) and the filter choke (Part No. 2CT-207A and L-2 on the diagram) are located in the square can on top of the chassis to the left of the speaker.

The voltage across the speaker field (black and yellow leads)—120, and the voltage across the filter choke—9.5. Voltage across two outside terminals of the 250-ohm bias resistor (R-16 and R-17, located underneath the chassis deck near the volume control)—11.5 and the voltage from the cathode of the 43 tube to central terminal of resistor—1.0.

The various paragraphs under the heading "Adjustments" on Emerson page 6-16 applies to this chassis also, with the exception of the locations of the trimmers for the antenna coils. These are as follows: Short-wave coil, upper trimmer; police band, central trimmer, and that for the broadcast band is the lower trimmer. While adjusting the short-wave antenna trimmer (the upper one) for maximum response, rock the variable condenser.

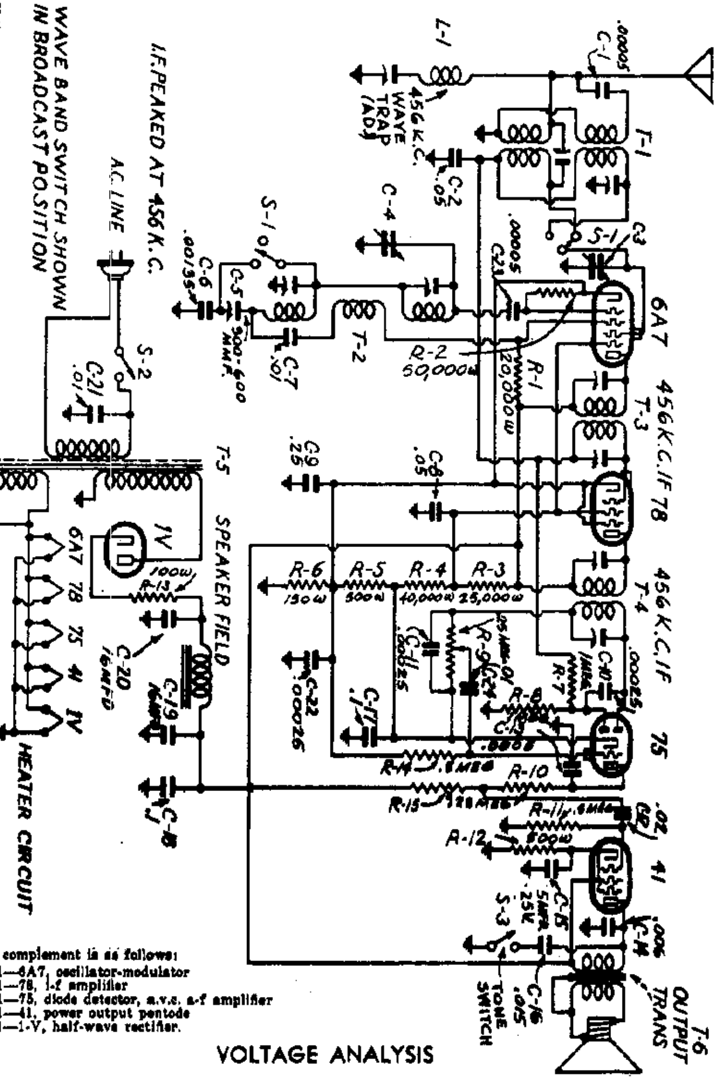
Voltage rating .... 105-130 volts ac-dc
Current drain ..... 0.43 amps.

The filament dropping resistor, part number 2LR-212, is of the cylindrical plug-in type and is located on top of the chassis between the 6H6 and 25Z5 tubes.

The output transformer, part no. 2LT-221 (T9 on schematic diagram) and the filter choke, part no. 2CT-207A (L2 on schematic diagram) are located in the square can on top of the chassis to the left of the speaker.

MODELS 107AC,114
Chassis E5
Schematic,Voltage
Alignment,Changes

EMERSON RADIO & PHONO. CORP.



Voltage rating .... 105 to 125 volts
Current drain .... 0.4 amps
Frequency range .... 540 to 1750 kc, 2200 to 7500 kc.

The tube complement is as follows:
1—6A7, oscillator-modulator
1—78, i-f amplifier
1—75, diode detector, a.v.c. a-f amplifier
1—41, power output pentode
1—1-V, half-wave rectifier.

VOLTAGE ANALYSIS

Readings should be taken with a 1000 ohms-per-volt meter. Voltages listed below are from point indicated to ground, with volume control turned on full and no signal. Line voltage for these readings was 117.5 volts, 60 cycles, a.c.

Tube	Plate	Screen	Cathode	Osc. Plate	Fil.
6A7	219	74	2.3	150	6.3 a.c.
78	219	74	2.3	—	6.3 a.c.
75	75	—	3.2	—	6.3 a.c.
41	206	219	13.6	—	6.3 a.c.

B plus at cathode of 1-V tube—271 volts.
Voltage across the speaker field—60 volts.

ADJUSTMENTS

An oscillator with frequencies of 456, 600, 1600, 6000 and 7500 should be used.
An output meter should be used across the voice coil or output transformer for observing maximum response.

Location of Coils and Trimmer Adjustments:

The two i-f transformers are located on the top of the chassis deck. The second i-f is the one directly behind the 6A7 tube. The four trimmers, two for each transformer, are accessible through holes in the tops of the cans.

The 456 kc wave trap is located on top of the chassis deck beside the antenna coil.

The adjustable padding condenser for the broadcast band is mounted underneath the chassis deck (in the corner near the antenna coil) with the screw adjustment accessible through a hole in the front of the chassis.

The antenna coils for the broadcast and short-wave bands are wound on one form and mounted on bracket on top of chassis deck. The trimmers for these coils are accessible through holes in the bracket. The trimmer nearest the chassis is the short-wave antenna trimmer. The trimmer nearest the top of the bracket is the broadcast antenna trimmer.

The oscillator coil for the broadcast and short-wave bands are wound on one form and mounted underneath the chassis deck. The trimmers for these coils are accessible through holes in the right-hand wall of the chassis. The trimmer nearest the front of the chassis is for the short-wave oscillator coil, and the trimmer farthest from the front is for the broadcast oscillator coil.

Short-Wave Alignment:

Use a 400 ohm dummy antenna (a 400 ohm resistor in series with the test oscillator lead) in aligning the short-wave coils. Rotate the wave-band switch to the short-wave position (counter-clockwise) and set the variable condenser at minimum capacity. Feed 7500 kc and adjust the short-wave oscillator trimmer (closest to front on right-hand chassis wall) for maximum response. Then feed 6000 kc and rotate the variable condenser until the signal is picked up, and adjust the short-wave antenna trimmer (lower one on upright bracket on right side of chassis) for maximum response. Be very careful to choose the minimum capacity peak on the oscillator trimmer. (See General Instructions below).

Broadcast Alignment:

Use a standard dummy antenna in aligning the broadcast coils. (A .0002 condenser may be used as a substitute). Rotate the wave-band switch to the broadcast position, clockwise. Set the dial pointer at 600 and feed 600 kc. Adjust the broadcast series padder (in front under antenna coil) for maximum response. Move pointer to 1600 and feed 1600 kc and adjust the broadcast oscillator trimmer (farthest from front on right-hand chassis wall) for maximum response. Then adjust the antenna trimmer (nearest top on unpright bracket) for maximum response. Return to 600, feed 600 kc and readjust the broadcast series padder, rocking the variable condenser (rotate the variable condenser shaft back and forth through a small arc) for maximum response.

The set's oscillator is higher in frequency than the signal, so images should be observed on the low frequency side of the signals.

Always choose the minimum capacity peak on oscillator trimmers and maximum capacity peaks on antenna trimmers. The last motion in adjusting trimmers should always be a tightening one, not a loosening one.

Never leave a trimmer with the outside plate so loose that there is no tension on the screw. Either bend the plate up or remove the screw entirely.

Always use as weak a test signal as possible during alignment.

1. The receiver should never be turned on with the 41 tube out of its socket, since the rapid rise in rectifier voltage may damage the electrolytic condenser.
2. When replacing the chassis in the cabinet take precautions to keep any part of the dial and condenser assembly from touching the cabinet, otherwise microphonism will result.
3. The color-coding of the i-f transformers is as follows:
   Grid—green | Grid return—black
   B plus—red | Plate—blue
4. The color-coding of the power transformer is as follows:
   Primary—two black leads | 6.3 volt secondary—two green leads
   High-voltage secondary—two red leads | Electrostatic shield—bare stranded wire
5. The adjustable padding condenser for the broadcast band is mounted underneath the chassis (in the corner near the wave-band switch) with the screw adjustment accessible through a hole in the front of the chassis. The short-wave band has a fixed padder which is a 1850 mmf molded mica condenser. (Note that this condenser is coded 1800 mmf). When replacing this fixed padder be careful to use a condenser which has a capacity within 3% of 1850 mmf, otherwise the short-wave coils may not track.
6. With a few exceptions, the color-coding of the general wiring is as follows:
   Plate—blue | Cathode—white or yellow
   B plus—red | Grid—green
   Screen—brown | Filament and ground—black

PRODUCTION CHANGES

On early production:

a. Trimmer across secondary of broadcast antenna coil had rotor returned to ground.
b. Trimmer across secondary of short-wave oscillator coil had rotor returned to ground.
c. In very early sets 85 tube was used in place of 75, and .02 mf coupling condenser went directly to plate. One 100,000 ohm plate resistor was used in place of two resistors R-10 and R-15 shown in plate circuit. The control grid of the 85 in these receivers was connected directly to movable arm on the volume control, and R-14 and C-24 were not in the circuit.
d. Model 114 had 6D6, first i-f tube in place of 78. All production changes above also apply to model 114.
e. The second electrolytic condenser C19 was of the regulating type, part no. 2NC-247A.
f. The 456 kc wave-trap was originally part no. MMT-149.

SCHEMATIC DIAGRAM

VOLTAGE ANALYSIS

Readings should be taken with a 1000 ohms-per-volt meter. Voltages listed below are from point indicated to ground (chassis) with volume control turned on full and no signal. The line voltage for these readings was 117.5 volts, 60 cycles, a-c.

Tube	*Plate*	*Screen*	*Cathode*	*Fil.*
6D6	100	102	3	6.3
6C6	30	21	2	6.3
43	95	101	18	25.0

Voltage across speaker field (25Z5 cathode to chassis)—118 volts.
Voltage across choke (25Z5 cathode to 43 screen)—16.5 volts.
The line voltage dropping resistor, part no. 2VR-215, is of the plug-in type and resembles a metal tube. The overall voltage drop of this resistor is 55 volts.

ALIGNMENT PROCEDURE

An oscillator with a frequency of 1425 kc is required.
The dial pointer should be at the extreme low-frequency end of the dial calibration when the variable condenser is at the maximum capacity position.
Set the dial pointer at 1425, feed 1425 kc to the antenna and adjust both trimmers on the variable condenser for maximum response. Use as weak a test signal as possible.

Range: The receiver is designed to operate over the broadcast range from 540 to 1650 kilocycles. This range covers all of the standard American broadcast stations and some of the low-frequency police transmitters.

The tubes used are as follows:
1—6D6, r-f amplifier.
1—6C6, biased detector.
1—43, power output pentode.
1—25Z5, dual half-wave rectifier.

Voltage rating	105 to 130 volts a-c or d-c
Current drain	0.38 amps.
Frequency range	540 to 1650 kc.

WHEN ORDERING REPLACEMENT PARTS SPECIFY PART NUMBERS

PRODUCTION CHANGES

Receivers bearing serial numbers up to about 708,040 did not have a resistor connected from the cathode of the 6D6 tube to B plus. (This resistor is R8 on schematic diagram.)

In receivers bearing serial numbers up to 712,500 the variable condenser was part no. 2VC-238. The variable condenser now indicated in the parts listed above was used in receivers bearing serial numbers above 712,500. (The part no. is stamped on the end plate of the condenser.)

In receivers bearing serial numbers up to 720,250, R4 was a 500,000 ohm ¼ watt carbon resistor.

EMERSON PRODUCTION CHANGES AS OF 4/29/36,
NOT ALREADY NOTED IN SERVICE NOTES.

Chassis Model U4B; Cabinet Models 118 and 126

Receivers bearing serial numbers lower than 740,750:
C-8, .01 output condenser, was originally across 43 plate and ground, instead of to screen.

THE RECEIVER WAS DESIGNED TO OPERATE WITHOUT A GROUND. UNDER NO CIRCUMSTANCES SHOULD A GROUND WIRE BE PERMITTED TO COME IN CONTACT WITH ANY METAL PART OF THE RECEIVER.

Power Supply: The power supply for this receiver should be either a. c. 50 to 60 cycles, or d. c., of any voltage between 105 and 130 volts. With special external line cord ballast resistors this receiver may be operated on higher voltages.

ADJUSTMENTS

An oscillator with frequencies of 150, 345, 456, 600 and 1600 and 15,000 kc should be used. An output meter should be used across the voice coil or output transformer for observing maximum response.

I-f and Wave-Trap Alignment

The two i-f transformers are located in cans on the top of the chassis. The first i-f is in the right hand rear corner and the second i-f is behind the speaker. The four trimmers, two for each transformer, are located at the tops of the cans.

Rotate the variable condenser to minimum and set the wave-band switch to medium-wave (central position). Feed 456 kc to the grid of the 6A7 tube and align the four i-f trimmers for maximum response. Feed 456 kc through the antenna and adjust the 456 kc wave-trap for *minimum response*. The wave-trap trimmer is mounted on the wave trap located on top of the chassis behind the speaker.

Location of Coils

The antenna coils for the three bands are wound on one form and mounted on top of the chassis in the front right-hand corner. The three trimmers for these coils are mounted on a bakelite strip to the side of the coil form. The lowest trimmer is for the long-wave antenna coil. The central trimmer is for the medium-wave antenna coil and the top trimmer for the short-wave antenna coil.

The oscillator coils for the three bands are wound on one form and mounted on the inside of the right-hand chassis wall with the trimmers facing out. The trimmer screws are available through three holes in the chassis wall. The trimmer closest to front is for the long-wave oscillator coil, the central trimmer is for the medium-wave oscillator coil and the trimmer furthest from the front is for the short-wave oscillator coil.

The adjusting screws for the dual padder are also available at the right-hand chassis wall. The screw closer to the front is for the long-wave band and the other is for the medium-wave band. The short-wave band has no padder.

Long-Wave Alignment

Rotate the wave-band switch (clockwise) to the long-wave position and set dial to 150. Feed 150 kc through antenna and adjust the long-wave series padder (closest to front on lower row, right wall), for maximum response. Move dial pointer to 345, feed 345 kc and adjust the long-wave oscillator trimmer (closest to front on top row, right wall) and then the long-wave antenna trimmer (lower trimmer on upright coil). Return to 150 kc and readjust the series padder, rocking the variable condenser for maximum response. Return to 345 kc and check.

Medium-Wave Alignment

Rotate switch to medium-wave position (central). With dial at 600 feed 600 kc through the antenna and adjust the medium-wave band series padder (furthest from front on lower row, right wall), for maximum response. Move dial pointer to 1600, feed 1600 kc and adjust the medium-wave oscillator trimmer (on right wall, top row, center) for maximum response and then the medium-wave antenna trimmer (on top of chassis, central trimmer). Return to 600 kc and readjust the medium-wave series padder for maximum response. Return to 1600 kc and check.

Short-Wave Alignment

Rotate switch to the short-wave position (counter-clockwise) and set dial pointer to 15 megacycles. Feed 15 megacycles and adjust the short-wave oscillator trimmer (furthest from front on right wall) for maximum response, *choosing the minimum capacity peak*, and then the short-wave antenna trimmer (top trimmer on upright coil) *choosing the maximum capacity peak.* (See General Instructions below.)

Check all three bands for dead spots or incorrect image responses.

General Instructions

The set's oscillator is higher in frequency than the signal on *all three bands*, so images should be observed on the low frequency side of the signals.

Always choose the minimum capacity peak on oscillator trimmers and maximum capacity peaks on antenna trimmers. The last motion in adjusting trimmers should always be a tightening one, not a loosening one.

Never leave a trimmer with the outside plate so loose that there is no tension on the screw. Either bend the plate up or remove the screw entirely. Loose screws are a sure source of noise, drifting, and microphonism.

In aligning antenna trimmers on the high-frequency signals there is always a tendency for the oscillator to drift, due to interlocking. To compensate for this always keep tuning the variable condenser as the trimmers are being adjusted.

VOLTAGE ANALYSIS

Readings should be taken with a 1000 ohms-per-volt meter. Voltages listed below are from point indicated to the cathode of the 48 tube (B minus). Line voltage for these readings was 117.5 volts, 60 cycles, a.c.

Tube	*Plate*	*Screen*	*Cathode*	*Osc. Plate*	*Fil.*
6A7	99	43	1.1	80	6.3
6K7	99	80	1.8	—	6.3
6H6	—	—	0	—	6.3
6F5	50	—	0	—	6.3
48	87	99	0	—	24

Voltage across speaker field (black and yellow leads)—120

Voltage across filter choke—9.5

The 250 ohm bias resistor, R16 and R17 on schematic diagram, is located underneath the chassis deck near the volume control.

Voltage across the two outside terminals of this resistor—11.5

Voltage from cathode of 48 tube to central terminal of resistor—1.0 volt.

GENERAL NOTES

1. To take the chassis out of the Model 107 cabinet first remove the knobs (knobs are of push-on type) and then the cabinet bottom. Remove the two wood screws and four nuts holding the chassis to the cabinet. With the receiver bottom side up, slide the chassis towards the back and lift out of cabinet.
2. If replacements are made or the wiring disturbed in the r-f section of the circuit, the receiver should be carefully realigned.
3. The filament dropping resistor, part number 2LR-212, is of the cylindrical plug-in type and is located on top of the chassis between the 6H6 and 25Z5 tubes.
4. The output transformer, part number 2LT-221 (T9 on schematic diagram), and the filter choke, part number 2CT-207A (L2 on schematic diagram), are located in the square can on top of the chassis to the left of the speaker.

VOLTAGE ANALYSIS

Readings should be taken with a 1000 ohms-per-volt meter. Voltages listed below are from point indicated to ground (chassis). Line voltage for these readings was 117.5 volts, 60 cycles, a.c.

Tube	Plate	Screen	Cathode	Osc. Plate	Fil.
6A7	105	85	1.6	105	6
6D6	105	105	3.0	—	6
75	45	—	0	—	6
43	100	105	0	—	24

Voltage across speaker field (25Z5 cathode to line switch)—125 volts.

Voltage across choke (chassis to line switch)—20 volts.

Location of Coils and Trimmer Adjustments:

The first i-f transformer, our part 2JT-217, is located on the top of the chassis. The two trimmers for this transformer may be adjusted through two holes in the top of the can. The second i-f transformer is mounted on the inside of the right-hand wall of the chassis, and has one trimmer accessible through a hole in the chassis.

The antenna trimmer is on the front section (antenna) of the variable condenser. The oscillator trimmer is on the rear section (oscillator) of the variable condenser. The dual padding condenser unit mounted on the metal strap at the rear of the chassis has two series padders, one for the long-wave band and one for the medium-wave band. The long-wave series padder is the one closest to the wave-band switch. The one farthest from the switch is the medium-wave series padder.

Alignment Procedure:

1. Rotate wave-band switch (at rear of chassis) to the medium-wave position, clockwise.
2. Rotate the variable condenser to the minimum capacity position and feed 132 kc to the grid cap of the 6A7 tube.
3. Adjust the three i-f trimmers (two on first i-f and one on the second i-f) for maximum response.
4. Rotate the wave-band switch to the long-wave position, counter-clockwise, and set dial pointer to 172.5.
5. Feed 172.5 kc to antenna lead and adjust the long-wave series padder (on dual unit, nearest to switch) for maximum response.
6. Rotate the wave-band switch to the medium-wave position, clockwise, and set the dial pointer at 600.
7. Feed 600 kc to antenna and adjust the medium-wave series padder (one on dual unit, furthest from switch) for maximum response.
8. Set dial pointer to 1425, feed 1425 kc to antenna and adjust the oscillator trimmer, on the rear section of the variable condenser, for maximum response and then adjust the antenna trimmer, on the front section of the variable condenser, for maximum response.
9. Return pointer to 600 kc, feed 600 kc and readjust the medium-wave series padder while rocking the variable condenser (rotate variable condenser shaft back and forth through a small arc) for maximum response.
10. Return pointer to 1425, feed 1425 kc and check the medium-wave adjustments.
11. Rotate wave-band switch to the long-wave position, counter-clockwise. Set pointer at 172.5, feed 172.5 kc and re-adjust the long-wave series padder while rocking the variable condenser for maximum response.

The color coding of the i-f transformer leads is as follows:

Grid—green
Grid return—black
Plate—blue
B plus—red.

Voltage across speaker field—115

Voltage across choke—10.5

Location of I-f's and Trimmers:

The first i-f transformer, part No. KKT-136, is in an oblong coil can, located on top of the chassis directly behind the speaker. The two trimmers for this i-f are accessible through holes in the top of the coil can.

The second i-f transformer, part No. KKT-137B, is in a round coil can located on top of the chassis to the left of the speaker. The single trimmer for this i-f is accessible through a hole in the top of the coil can.

The oscillator and antenna trimmers are located on the top of the variable condenser. The oscillator trimmer is on the rear section and the antenna trimmer is on the front section.

The color coding of the i-f transformer leads is as follows:

FIRST I-F TRANSFORMER
(Part No. KKT-136)
Plate—blue
B plus—red
Grid return—black
Tertiary—black, red tracer
Grid—green

SECOND I-F TRANSFORMER
(Part No. KKT-137B)
Plate—blue
B plus—red
Grid return—black
Grid—green

When replacing the oscillator coil, part number KKT-135, be sure to mount it in the correct position. The locating hole in the square fibre terminal strip should be nearest the rear of the chassis.

GENERAL NOTES

1. The receiver should never be turned on with either the speaker plug or the 43 tube out of its respective socket, since the rapid rise in rectifier voltage will damage the electrolytic condenser.
2. The color coding of the leads of the composite first i-f transformer and oscillator coil, part no. TTT-173, is as follows:
   - B plus—red
   - Plate—blue
   - I-f grid return—white. (See following line.)
   - Oscillator grid return—black
   - Suppressor grid—green with white tracer
   - I-f grid—green

   In some receivers the i-f grid return and the oscillator grid return were brought out in one common black lead.
3. The color coding of the leads of the second i-f transformer, part no. TTT-176A, is as follows:
   - Grid—green
   - Grid return—black
   - Plate—blue
   - B plus—red
4. The color coding of the leads on the power transformer is as follows:
   - Primary—two green leads.
   - High voltage secondary—two black leads.
   - High voltage secondary center-tap—yellow lead.
   - 6.3 volt secondary—two heavy blue leads.
   - 5 volt secondary—two heavy red leads.
5. With a few exceptions, the color coding of the general wiring is as follows:
   - Plate—blue
   - B plus—red
   - Screen—brown
   - Cathode—white or yellow
   - Grid—green
   - Filament and ground—black.
6. When replacing the chassis in the cabinet take precautions to keep any part of the dial and condenser assembly from touching the cabinet, otherwise microphonism will result.
7. It is not necessary to remove the chassis from the cabinet to replace the pilot light. Simply slip the push-on bracket off the dial and unscrew the bulb.

ADJUSTMENTS

An oscillator with frequencies of 456, 1425 and 2500 kc is required.
An output meter should be used across the voice coil or output transformer for observing maximum response.

Location of Coils and Trimmer Adjustments

The two i-f transformers are located on top of the chassis deck. The second i-f is the one directly behind the variable condenser. Part no. TTT-173 is a composite broadcast oscillator coil and first i-f transformer.

The broadcast antenna coil is mounted underneath the chassis deck, directly below the variable condenser. The short-wave oscillator coil is mounted on the right-hand wall of the chassis. The short-wave antenna coil is located underneath the chassis deck near the oscillator coil. The trimmer for this short-wave antenna coil is mounted on the coil tubing.

I-f Alignment

Rotate the wave-band switch to the broadcast position, clockwise, and swing the variable condenser to the maximum capacity position. Feed 456 kc to the stator of the front (antenna) section of the variable condenser. Adjust the four i-f trimmers (at tops of i-f cans) for maximum response.

Broadcast Alignment (Use a .0002 mf condenser as a dummy antenna.)

With the wave-band switch in the broadcast position, set the dial pointer at 1425. Feed 1425 kc to the antenna and adjust first the oscillator trimmer (rear) and then the antenna trimmer (front) on the variable condenser for maximum response.

Short-wave Alignment

Rotate the wave-band switch to the short-wave position, counter-clockwise. Feed 2500 kc through the antenna and rotate the variable condenser in the vicinity of the 2500 mark until this signal is picked up. Adjust the short-wave antenna trimmer (at the top of the small coil beneath the chassis deck) for maximum response on this signal.

PRODUCTION CHANGES

Receivers bearing serial numbers from 119,051 to 122,050—

The two resistors R11 and R12, shown by dotted lines on the schematic diagram were used in the circuit.

Receivers bearing serial numbers from 126,051 to 127,050—

a. R3 and R4, wire-wound tapped resistor, changed from part no. TTR-178 to part no. 2TR-221. In this new resistor R3 is 20,500 ohms, ½ watt, and R4 is 12,500 ohms, 1.5 watts.
b. The volume control was changed from part no. TTR-159A to TTR-159B. The latter control has 250 ohm bias stop.
c. R11 was omitted.
d. R12 was omitted.
e. The speaker was changed from part no. TTS-110 to part no. 2TS-162.

NOTE: Changes a, b, c and d were made simultaneously.

Receivers bearing serial numbers above 127,401—

a. R3 and R4, wire-wound tapped resistor, replaced by carbon resistors.
R3 is part no. DDR-122, 20,000 ohm ½ watt carbon resistor.
R4 is part no. 2TR-225, 12,000 ohm 2 watt carbon resistor.

Receivers bearing serial numbers above 726,018—

a. R14, 50,000 ohm 2 watt carbon resistor, was added. (Part no. 2TR-238.)
b. R13, 25,000 ohm ¼ watt carbon resistor, was added. (Part no. OR-73.)
c. C18, a 0.5 mf 400 volt tubular condenser, was added. (Part no. IC-46.)
d. C6 and R5 were omitted and the grid return of the second i-f transformer was grounded to chassis.

Receivers bearing serial numbers above 750,450—

a. The wave-band switch (S1) was changed from part no. TTS-111E to part no. TTS-111H.
b. The tone-control switch (S3) was changed from part no. 2TS-145B to part no. 2TS-145D.
c. The volume control (R10, S2) was changed from part no. TTR-159B to part no. TTR-159C.
d. The airplane dial was changed from part no. 2TD-80A to part no. 2TD-80B.
NOTE: Above four revisions involve only changes in shaft lengths.

WHEN ORDERING REPLACEMENT PARTS SPECIFY PART NUMBERS

EMERSON PRODUCTION CHANGES AS OF 4/29/36
NOT ALREADY NOTED IN SERVICE NOTES

Chassis Model G-5; Cabinet Models 116 and 121

Receivers bearing serial numbers higher than 753,600:
The bias stop on the volume control, R-10, made 200 ohms instead of 250 and the part number was changed from TTR-159C to TTR-159D

R-3, 20,000 ohm resistor changed from ½ watt to 1 watt and part number changed from DDR-122 to GR-31.

C-10, .006 output condenser, put across 43 plate and screen, instead of plate to ground.

Receivers bearing serial numbers higher than 753,800:
R-6, 150,000 ohm resistor in 76 cathode circuit changed to 50,000 ohms, ¼ watt; part number changed from LLR-152 to KR-53.
Recommended to cure microphonic 76's.

Alignment, Parts

EMERSON RADIO & PHONO. CORP.

An oscillator with frequencies of 456, 1425 and 2500 kc is required.

I-f Alignment

An output meter should be used across the voice coil or output transformer for observing maximum response.

Rotate the wave-band switch to the broadcast position, clockwise, and swing the variable condenser to the maximum capacity position. Feed 456 kc to the stator of the front (antenna) section of the variable condenser. Adjust the four i-f trimmers (at tops of i-f cans) for maximum response.

Short-wave Alignment

Rotate the wave-band switch to the short-wave position, counter-clockwise. Feed 2500 kc through the antenna and rotate the variable condenser in the vicinity of the 2500 mark until this signal is picked up. Adjust the short-wave antenna trimmer (at the top of the small coil beneath the chassis deck) for maximum response on this signal.

Broadcast Alignment (Use a .0002 mf condenser as a dummy antenna.)

With the wave-band switch in the broadcast position, set the dial pointer at 1425. Feed 1425 kc to the antenna and adjust first the oscillator trimmer (rear) and then the antenna trimmer (front) on the variable condenser for maximum response.

Location of Coils and Trimmer Adjustments

The two i-f transformers are located on top of the chassis deck. The second i-f is the one directly behind the variable condenser. Part no. TTT-173 is a composite broadcast oscillator coil and first i-f transformer.

The broadcast antenna coil is mounted underneath the chassis deck, directly below the variable condenser. The short-wave oscillator coil is mounted on the right-hand wall of the chassis. The short-wave antenna coil is located underneath the chassis deck near the oscillator coil. The trimmer for this short-wave antenna coil is mounted on the coil tubing.

The color coding of the leads of the composite first i-f transformer and oscillator coil, part no. **TTT-173, is as follows:**

B plus—red
Plate—blue
I-f and oscillator grid return—black
Suppressor grid—green with white tracer
I-f grid—green

The color coding of the leads of the second i-f transformer, part no. TTT-176A, is as follows:

Grid—green
Grid return—black
Plate—blue
B plus—red

The color coding of the leads on the power transformer is as follows:

Primary—two green leads.
High voltage secondary—two black leads.
High voltage secondary center-tap—yellow lead.
6.3 volt secondary—two heavy blue leads.
5 volt secondary—two heavy red leads.

With a few exceptions, the color coding of the general wiring is as follows:

Plate—blue
B plus—red
Screen—brown
Cathode—white or yellow
Grid—green
Filament and ground—black.

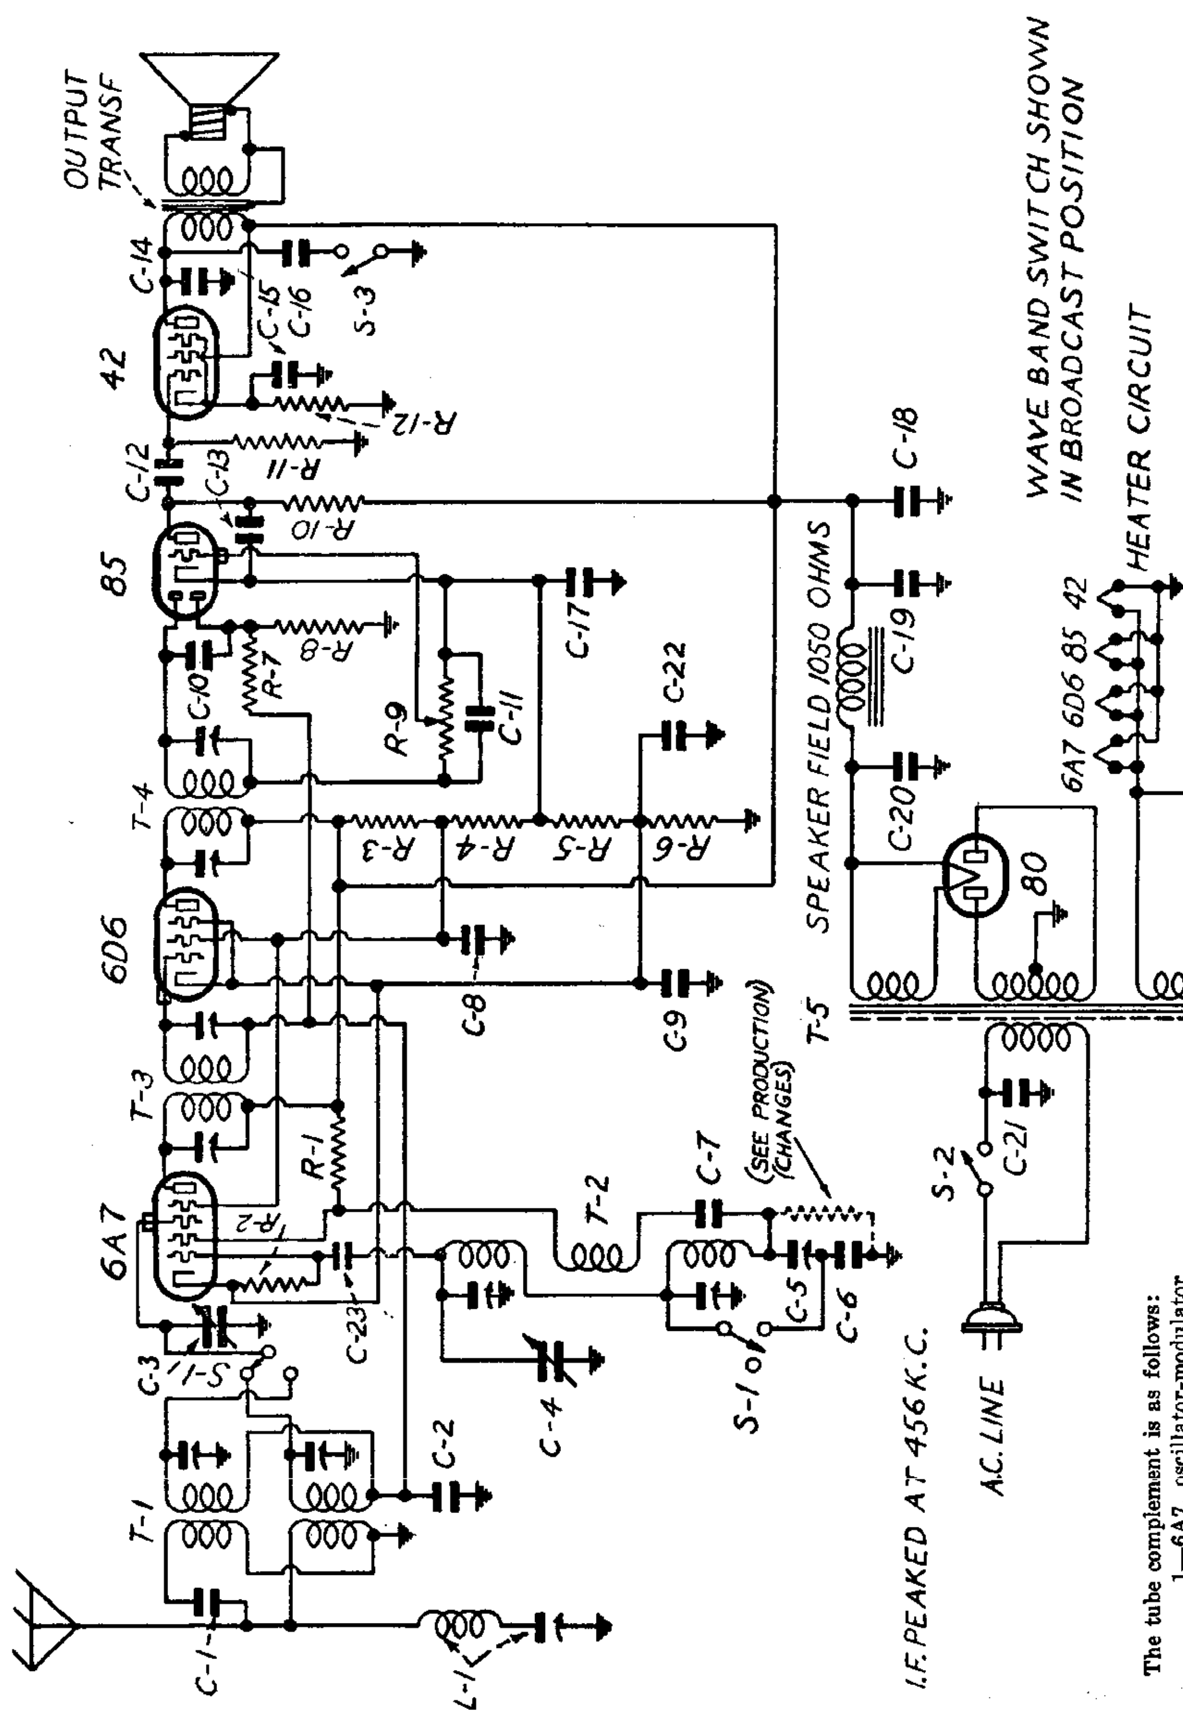
MODEL 117
Chassis C5
Schematic

EMERSON RADIO & PHONO. CORP.



Voltage rating . . . . 110-120 volts, a.c.
Current drain . . . . . 0.5 amps.
Frequency range . . 540 to 1750 kc, 2200 to 7500 kc.

The tube complement is as follows:
1—6A7, oscillator-modulator
1—6D6, i-f amplifier
1—85, diode detector, a.v.c., a-f amplifier
1—42, power output pentode
1—80, full-wave rectifier.

MODEL 117
Chassis C5
Alignment, Voltage
Changes, Notes, Parts

EMERSON RADIO & PHONO. CORP.

GENERAL NOTES

1. The receiver should never be turned on with either the speaker plug or the 42 tube out of its respective socket, since the rapid rise in rectifier voltage will damage the electrolytic condenser.
2. When replacing the chassis in the cabinet take precautions to keep any part of the dial and condenser assembly from touching the cabinet, otherwise microphonism will result.
3. The color coding of the i-f transformers is as follows:

   Grid—green | Grid return—black
   B plus—red | Plate—blue
4. The color coding of the power transformer is as follows:

   Primary—two black leads
   High-voltage secondary—two red leads
   High-voltage secondary center tap—red and yellow lead
   6.3 volt secondary—two green leads
   5 volt secondary—two yellow leads.
5. The adjustable padding condenser for the broadcast band is mounted underneath the chassis (in the corner near the wave-band switch) with the screw adjustment accessible through a hole in the top of the chassis. The short-wave band has a fixed padder which is a 1350 mmf molded mica condenser. (Note that this condenser is coded 1300 mmf.) When replacing this fixed padder be careful to use a condenser which has a capacity within 2% of 1350 mmf, otherwise the short-wave coils may not track.
6. With a few exceptions, the color coding of the general wiring is as follows:

   Plate—blue | Cathode—white or yellow
   B plus—red | Grid—green
   Screen—brown | Fil. and ground—black.

ADJUSTMENTS

An oscillator with frequencies of 456, 600, 1600 and 6000 kc should be used.
An output meter should be used across the voice coil or output transformer for observing maximum response.

Location of Coils and Trimmer Adjustments.

The two i-f transformers are located on top of the chassis deck. The second i-f is the one directly behind the variable condenser. The four trimmers, two for each transformer, are accessible through holes in the tops of the cans.

The 456 kc wave trap is located on top of the chassis deck between the 6A7 tube and the first i-f transformer.

The adjustable padding condenser for the broadcast band is mounted underneath the chassis (in the corner near the 6A7 tube) with the screw adjustment accessible through a hole in the top of the chassis.

The antenna coils for the broadcast and short-wave bands are wound on one form and mounted underneath the chassis deck directly behind the adjustable padding condenser. The trimmers for these coils are also accessible through holes in the top of the chassis. The trimmer nearest the front of the chassis is the short-wave antenna trimmer. The trimmer farthest from the front of the chassis is the broadcast antenna trimmer.

The oscillator coils for the broadcast and short-wave bands are wound on one form and mounted underneath the chassis deck near the variable condenser. The trimmers for these coils are accessible through holes in the top of the chassis. The trimmer nearest the front of the chassis is for the short-wave oscillator coil and the trimmer farthest from the front is for the broadcast oscillator coil.

I-f and Wave-trap Alignment

Rotate the wave-band switch to the broadcast position, clockwise. Set the variable condenser at the minimum capacity position and feed 456 kc to the grid cap of the 6A7 tube. Adjust the four i-f trimmers for maximum response. Feed 456 kc to the antenna lead and adjust the wave-trap trimmer (mounted on wave-trap) for *minimum response.*

Short-wave Alignment

Use a 400 ohm dummy antenna (a 400 ohm resistor in series with the test oscillator antenna lead) in aligning the short-wave coils. Rotate the wave-band switch to the short-wave position (counter-clockwise) and set the dial pointer exactly at 6 megacycles. Feed 6000 kc and adjust the short-wave oscillator trimmer (closest to front beside the variable condenser) for maximum response and then adjust the antenna trimmer (left side of top of chassis, closest to front). Be very careful to choose the minimum capacity peak on the oscillator trimmer. (See General Instructions below.)

Broadcast Alignment

Use a standard dummy antenna in aligning the broadcast coils. (A .0002 condenser may be used as a substitute.) Rotate the wave-band switch to the broadcast position, clockwise. Set the dial pointer at 600 and feed 600 kc. Adjust the broadcast series padder (in corner near 6A7 tube) for maximum response. Move the dial pointer to 1600 and feed 1600 kc. Adjust the broadcast oscillator trimmer (farthest from front beside the variable condenser) for maximum response and then adjust the broadcast antenna trimmer (farthest from front at left side of chassis). Return pointer to 600, feed 600 kc and readjust the broadcast series padder, rocking the variable condenser (rotate the variable condenser shaft back and forth through a small arc) for maximum response.

GENERAL INSTRUCTIONS

The set's oscillator is higher in frequency than the signal, so images should be observed on the low frequency side of the signals.

Always choose the minimum capacity peak on oscillator trimmers and maximum capacity peaks on antenna trimmers. The last motion in adjusting trimmers should always be a tightening one, not a loosening one.

Never leave a trimmer with the outside plate so loose that there is no tension on the screw. Either bend the plate up or remove the screw entirely.

Always use as weak a test signal as possible during alignment.

VOLTAGE ANALYSIS

Readings should be taken with a 1000 ohms-per-volt meter. Voltages listed below are from point indicated to ground (chassis). Line voltage for these readings was 117.5 volts, 60 cycles, a.c.

Tube	Plate	Screen	Cathode	Osc. Plate	Fil.
6A7	255	90	3.5	170	6.3 a.c.
6D6	255	90	3.5	—	6.3 a.c.
85	87	—	5.5	—	6.3 a.c.
42	240	255	16.0	—	6.3 a.c.

B plus at filament of 80 tube—325 volts
Voltage across speaker field—70 volts.

	2TM-211	Escutcheon reflector ring	.10

PRODUCTION CHANGES

In early production:

a. Airplane dial was part number 2ND-34 and had a grey dial face. Later dial, part number 2ND-34B, has a black dial face.

b. C19 and C20 were each 12 mf, 450 volt electrolytics.

c. R2 was originally in position indicated by dotted lines. It was later placed across the oscillator grid and cathode of the 6A7 tube (as now shown in the schematic) and at the same time C23 was added and C22 omitted.

Notes, Voltage, Parts
Alignment

Chassis Models K5 and LLW
(Chassis model number is printed on the license plate)

Voltage rating ....105-125 volts a.c. (unless otherwise specified)
Current drain ....0.5 amps.
Frequency range ....540 to 1750 kc., 150 to 375 kc.

NOTE: The two frequency ranges are referred to as broadcast and long-wave which, in Europe, are commonly known as medium-wave and long-wave broadcast, respectively.

GENERAL NOTES

1. The receiver should never be turned on with either the speaker plug or the output tube out of its respective socket, since the rapid rise in rectifier voltage will damage the electrolytic condenser.
2. When replacing the chassis in the cabinet take precautions to keep any part of the dial and condenser assembly from touching the cabinet, otherwise microphonism will result.
3. The color coding of the i-f transformers is as follows:
   Grid—green
   B plus—red
   Grid return—black
   Plate—blue
4. The color coding of the power transformer is as follows:
   Primary—two black leads
   High-voltage secondary—two red leads
   High-voltage secondary center tap—red and yellow lead
   6.3 volt secondary—two green leads
   5 volt secondary—two yellow leads
5. The dual adjustable padding condenser is mounted on the left side of the front chassis wall. The hexagon nut is the adjustment for the long-wave band and the screw in the center of this nut is the adjustment for the broadcast band.
6. With few exceptions, the color coding of the general wiring is as follows:
   Plate—blue
   B plus—red
   Screen—brown
   Cathode—white or yellow
   Grid—green
   Fil. and ground—black

Tube Data

The tube complement is as follows:
- 1-6A7, oscillator-modulator
- 1-6D6, i-f amplifier
- 1-85, diode detector, a.v.c., a-f amplifier
- 1-42 or 41, power output pentode.
  (In chassis model LLW the output tube is a 41. The 42 tube was used only in the K5 chassis)
- 1-80, full-wave rectifier.

VOLTAGE ANALYSIS

Reading should be taken with a 1000 ohms-per-volt meter. Voltages listed below are from point indicated to ground with volume control turned on full and no signal. Line voltage for these readings was 117.5 volts, 60 cycles, a.c.

Tube	*Plate*	*Screen*	*Cathode*	*Osc. Plate*	*Fil.*
6A7	250	90	3.3	145	6.3 a.c.
6D6	250	90	3.3	—	6.3 a.c.
85	85	—	4.1	—	6.3 a.c.
42 or 41	240	250	15.0	—	6.3 a.c.

B plus at filament of 80 tube—325 volts.
Voltage across speaker field—75 volts.

ADJUSTMENTS

An oscillator with frequencies of 172.5, 345, 456, 600 and 1600 kc should be used.
An output meter should be used across the voice coil or output transformer for observing maximum response.
Use a standard dummy antenna when aligning either band. A .0002 mf condenser may be used as a substitute.

Location of Coils and Trimmer Adjustments

The two i-f transformers are located on top of the chassis deck. The second i-f is the one directly behind the variable condenser. The four trimmers, two for each transformer, are accessible through holes in the tops of the cans.

The dual adjustable padding condenser is mounted on the left side of the front chassis wall. (See General Notes).

The antenna coils for the broadcast and long-wave bands are wound on one form and mounted underneath the chassis deck directly behind the adjustable padding condenser. The trimmers for these coils are accessible through holes in the top of the chassis. The trimmer nearest the front of the chassis is the broadcast antenna trimmer. The trimmer farthest from the front of the chassis is the long-wave antenna trimmer.

The oscillator coils for the broadcast and long-wave bands are wound on one form and mounted underneath the chassis deck near the variable condenser. The trimmers for these coils are also accessible through holes in the top of the chassis. The trimmer nearest the front of the chassis is for the broadcast oscillator coil and the trimmer farthest from the front is for the long-wave oscillator coil.

I-f Alignment

Rotate the wave-band switch to the broadcast position, clockwise. Swing the variable condenser to the minimum capacity position and feed 456 kc to the grid cap of the 6A7 tube. Adjust the four i-f trimmers for maximum response.

Broadcast Alignment

With the switch in the broadcast position set the dial pointer to 60 and feed 600 kc through the dummy antenna. Adjust the broadcast series padding condenser (slotted screw on dual unit at left hand side of front chassis wall) for maximum response. Move the pointer to 160 and feed 1600 kc. Adjust the broadcast oscillator trimmer (closest to front beside variable condenser) for maximum response and then adjust the broadcast antenna trimmer (closest to front at left side of chassis) for maximum response. Return pointer to 60, feed 600 kc and readjust the padding condenser while rocking the variable condenser (rotate back and forth through small arc) for maximum response.

Long-Wave Alignment

Rotate the wave-band switch to the long-wave position, counter-clockwise, and set the dial pointer at 345. Feed 345 kc through the dummy antenna and adjust the long-wave oscillator trimmer (farthest from front beside variable condenser) for maximum response and then adjust the long-wave antenna trimmer (farthest from front at left side of chassis). Move the pointer to 172.5 kc and feed 172.5 kc. Adjust the long-wave series padder (hexagon nut on dual unit) for maximum response. Return the pointer to 345 kc and adjust the long-wave oscillator and antenna trimmers and then return to 172.5 kc and readjust the long-wave padding condenser. If appreciable shift is noticed align again at 345 kc and then at 172.5 kc repeating this procedure until no further change occurs.

GENERAL INSTRUCTIONS

Always choose the minimum capacity peak on oscillator trimmers and maximum capacity peaks on antenna trimmers. The last motion in adjusting trimmers should always be a tightening one, not a loosening one.

Always use as weak a test signal as possible during alignment.

Never leave a trimmer with its outside plate so loose that there is no tension on the screw. Either bend the plate up or remove the screw entirely.

ADJUSTMENTS

An oscillator with frequencies of 150, 350, 456, 600, 1500 and 15,000 kc should be used.

An output meter should be used across the voice coil or output transformer for observing maximum response.

Use a standard dummy antenna when aligning either the long-wave or medium-wave bands. A .0002 mf condenser may be used as a substitute. When aligning the short-wave band use a 400 ohm dummy antenna (a 400 ohm resistor in series with antenna lead).

Location of Coils and Trimmers

The two i-f transformers are located on top of the chassis deck. The second i-f transformer is the one directly behind the variable condenser. The four trimmers, two for each transformer, are accessible through holes in the tops of the cans.

The dual adjustable padding condenser is mounted on the left side of the front chassis wall.

The antenna coils for the three bands are wound on one form and mounted underneath the chassis deck directly behind the adjustable padding condenser. The trimmers for these coils are accessible through holes in the top of the chassis. The trimmer nearest the front of the chassis is the medium-wave antenna trimmer. The central trimmer is the short-wave antenna trimmer. The trimmer farthest from the front of the chassis is the long-wave antenna trimmer.

The oscillator coils for the three bands are wound on one form and mounted underneath the chassis deck near the variable condenser. The trimmers for these coils are also accessible through holes in the top of the chassis. The trimmer nearest the front of the chassis is the medium-wave oscillator trimmer. The central trimmer is the short-wave oscillator trimmer. The trimmer farthest from the front of the chassis is the long-wave oscillator trimmer.

I-f Alignment

Rotate the wave-band switch to the medium-wave (central) position and set the variable condenser to minimum. Feed 456 kc to the grid cap of the 6A7 tube. Adjust the four i-f trimmers for maximum response.

Long-Wave Alignment

With the wave-band switch at long-wave (clockwise) position set the dial pointer at 15 and feed 150 kc to antenna. Adjust the long-wave series padder (hex nut on dual padder) for maximum response. Move pointer to 35 and feed 350 kc to antenna. Adjust the long-wave oscillator trimmer then the long-wave antenna trimmer for maximum response. Reset pointer to 15, feed 150 kc and rock (rotate back and forth through a small arc) the variable condenser while adjusting long-wave series padder for maximum response. Reset pointer to 35, feed 350 kc and check alignment. If readjustment is necessary return to 150 kc and repeat entire procedure.

Medium-Wave Alignment

Set switch at medium-wave (central) position and dial pointer at 60. Feed 600 kc to antenna and adjust medium-wave series padder (slotted screw on dual padder) for maximum response. Move pointer to 150, feed 1500 kc and adjust medium-wave oscillator trimmer and then the medium-wave antenna trimmer for maximum response. Reset pointer to 60, feed 600 kc and rock variable condenser while readjusting medium-wave series padder for maximum response. Reset pointer to 150, feed 1500 kc and check alignment. If readjustment is necessary return to 600 and repeat entire procedure.

Short-Wave Alignment

Set wave-band switch at short-wave (counter-clockwise) position. Set pointer at 15, feed 15 megacycles to antenna and adjust short-wave oscillator trimmer and then short-wave antenna trimmer for maximum response.

GENERAL INSTRUCTIONS

Always choose the minimum capacity peak on oscillator trimmers and maximum capacity peaks on antenna trimmers. The last motion in adjusting trimmers should always be a tightening one, not a loosening one.

Always use as weak a test signal as possible during alignment.

Never leave a trimmer with its outside plate so loose that there is no tension on the screw. Either bend the plate up or remove the screw entirely.

GENERAL NOTES

1. Only the Models F117 and F135 are available for 210-250 volt operation. The standard 105-125 volt Model F117 and F135 receivers may be easily converted for 210-250 volt operation by replacing the ballast resistor. Resistor part no. 8ER-248 is for 105 to 125 volt operation. Resistor part no. 8ER-249 is for 210 to 250 volt operation. Due to the greater amount of heat radiated from the higher voltage resistor, part no. 8ER-249, this conversion can be made only on Models F117 and F135. For Models F122, F133 and F141 it is imperative that an *external* line ballast resistor be used for voltages above 125.
2. If replacements are made or the wiring disturbed in the r-f section of the circuit, the receiver should be carefully re-aligned.
3. One side of the power line is directly grounded to the chassis base. Under no circumstances, therefore, should a ground wire be permitted to come in contact with any metal part of the receiver.
4. When operating the receiver on d.c., it may be necessary to reverse the line plug for correct polarity.
5. When replacing the chassis in the cabinet take precautions to keep any part of the dial and condenser assembly from touching the cabinet, otherwise microphonism will result.
6. The color coding of the i-f transformers is as follows:

   B plus—red Grid return—black
   Grid—green Plate—blue
7. An electrical phonograph pick-up may be connected to this receiver for playing records. Connections to this receiver may be made at the "phono" jack which is located on the rear wall of the receiver chassis. A separate volume control of the potentiometer type is necessary in addition to the phonograph pick-up. The two pick-up lead wires should be connected to the two outside terminals of this volume control. A lead from the center terminal should be plugged into the right-hand hole in the phono jack. A lead from one of the outside terminals of the volume control should be plugged into the other hole in the phono jack. The leads to be plugged in the jack should be fitted with tips. The volume control in the receiver should be turned down to the zero volume position when operating the phonograph. The required over-all resistance of the separate volume control will, of course, depend on the type of phonograph pick-up to be used. A matching input transformer must be used if the pick-up is of the low impedance type. In this case the volume control is connected to the secondary of the transformer. It is important that the phonograph leads be removed from the jack when it is desired to operate the receiver for ordinary radio reception.
8. An efficient antenna system (often called aerial) is necessary to enable a full realization of the merits of the receiver. The Emerson All-Wave Antenna is especially designed for high efficiency and reduction of noise on all three frequency ranges. Complete instructions for the installation of this antenna are supplied with each kit.

VOLTAGE ANALYSIS

Readings should be taken with a 1000 ohms-per-volt meter. Voltages listed below are from point indicated to ground (chassis) with the volume control turned on full and no signal. Line voltage for these readings was 117.5 volts, 60 cycles, a.c.

Tube	*Plate*	*Screen*	*Cathode*	*Osc. Plate*	*Fil.*
6A7	100	45	*1.1	80	6.3
6D6	100	90	2	—	6.3
75	45	—	0	—	6.3
43	88	100	0	—	24

Voltage across speaker field—125

Voltage across filter choke—10

The 250 ohm bias resistor, R14 and R15 on schematic diagram, is located underneath the chassis near the volume control. Voltage across the two outside terminals of this resistor—12. Voltage from chassis to central terminal of resistor—1.

The voltage drop across the ballast resistor part no. 8ER-248 (R18—see schematic diagram) is 49 volts measured between pins 3 and 6. This resistor is for 105 to 125 volt operation.

The voltage drop across the ballast resistor part no. 8ER-249 is 166 volts measured between pins 3 and 7. This resistor is for 210 to 250 volt operation.

**On receivers bearing serial numbers below 847,450 this voltage is 2 volts.*

PRODUCTION CHANGES

a. In receivers bearing serial numbers between 861,950 and 862,950 C21 was .006 mf, 600 volt tubular condenser.

b. In receivers bearing serial numbers below 861,950 r-f choke L5 was not in the circuit.

c. In receivers bearing serial numbers below 847,350 the 6A7 and 6D6 cathodes were connected together. R5 was 150 ohm, 1/2 watt wire-wound resistor and C11 was .25 mf, 200 volt tubular condenser. R8 and C14 were not in the circuit. The screen of 6D6 was connected to B plus through a separate 5000 ohm 1/4 watt carbon resistor and by-passed with a .1 mf, 200 volt tubular condenser. R11 and R13 were 250,000 1/4 watt carbon resistors. R1 was a 500,000 ohm 1/4 watt carbon resistor and was connected directly across the long-wave antenna coil secondary.

Chassis Model L

GENERAL NOTES

1. The receiver should never be turned on with either the speaker plug or the 41 tube out of its respective socket, since the rapid rise in rectifier voltage will damage the electrolytic condenser.
2. When replacing the chassis in the cabinet take precautions to keep any part of the dial and condenser assembly from touching the cabinet, otherwise microphonism will result.
3. The color coding of the i-f transformers is as follows:
   Grid—green; Grid return—black
   B plus—red; Plate—blue
4. The color coding of the power transformer is as follows:
   Primary—two black leads
   High-voltage secondary—two red leads
   High-voltage secondary center tap—red and yellow lead
   6.3 volt secondary—two green leads
   5 volt secondary—two yellow leads.
5. The adjustable padding condenser for the broadcast band is mounted underneath the chassis (in the corner near the wave-band switch) with the screw adjustment accessible through a hole in the top of the chassis. The short-wave band has a fixed padder which is a 1350 mmf molded mica condenser. (Note that this condenser is coded 1300 mmf.) When replacing this fixed padder be careful to use a condenser which has a capacity within 2% of 1350 mmf, otherwise the short-wave coils may not track.
6. With a few exceptions, the color coding of the general wiring is as follows:
   Plate—blue; Cathode—white or yellow
   B plus—red; Grid—green
   Screen—brown; Fil. and ground—black.

ADJUSTMENTS

An oscillator with frequencies of 456, 600, 1600 and 6000 kc should be used.
An output meter should be used across the voice coil or output transformer for observing maximum response.
If the circuit is at all disturbed, both the broadcast and short-wave bands must be realigned.

Location of Coils and Trimmer Adjustments

The two i-f transformers are located on top of the chassis deck. The second i-f is the one directly behind the variable condenser. The four trimmers, two for each transformer, are accessible through holes in the tops of the cans.

The 456 kc wave trap is located on top of the chassis deck between the 6A7 tube and the first i-f transformer.

The adjustable padding condenser for the broadcast band is mounted underneath the chassis (in the corner near the 6A7 tube) with the screw adjustment accessible through a hole in the top of the chassis.

The antenna coils for the broadcast and short-wave bands are wound on one form and mounted underneath the chassis deck directly behind the adjustable padding condenser. The trimmers for these coils are also accessible through holes in the top of the chassis. The trimmer nearest the front of the chassis is the short-wave antenna trimmer. The trimmer farthest from the front of the chassis is the broadcast antenna trimmer.

The oscillator coils for the broadcast and short-wave bands are wound on one form and mounted underneath the chassis deck near the variable condenser. The trimmers for these coils are accessible through holes in the top of the chassis. The trimmer nearest the front of the chassis is for the short-wave oscillator coil and the trimmer farthest from the front is for the broadcast oscillator coil.

I-f and Wave-trap Alignment

Rotate the wave-band switch to the broadcast position, clockwise. Set the variable condenser at the minimum capacity position and feed 456 kc to the grid cap of the 6A7 tube. Adjust the four i-f trimmers for maximum response. Feed 456 kc to the antenna lead and adjust the wave-trap trimmer (mounted on wave-trap) for *minimum response.*

Short-wave Alignment (Alignment of the short-wave band should precede broadcast alignment)

Use a 400 ohm dummy antenna (a 400 ohm resistor in series with the test oscillator antenna lead) in aligning the short-wave coils. Rotate the wave-band switch to the short-wave position (counter-clockwise) and set the dial pointer exactly at 6 megacycles. Feed 6000 kc and adjust the short-wave oscillator trimmer (closest to front beside the variable condenser) for maximum response and then adjust the antenna trimmer (left side of top of chassis, closest to front). Be very careful to choose the minimum capacity peak on the oscillator trimmer. (See General Instructions below.)

Broadcast Alignment

Use a standard dummy antenna in aligning the broadcast coils. (A .0002 condenser may be used as a substitute.) Rotate the wave-band switch to the broadcast position, clockwise. Set the dial pointer at 600 and feed 600 kc. Adjust the broadcast series padder (in corner near 6A7 tube) for maximum response. Move the dial pointer to 1600 and feed 1600 kc. Adjust the broadcast oscillator trimmer (farthest from front beside the variable condenser) for maximum response and then adjust the broadcast antenna trimmer (farthest from front at left side of chassis). Return pointer to 600, feed 600 kc and readjust the broadcast series padder, rocking the variable condenser (rotate the variable condenser shaft back and forth through a small arc) for maximum response.

VOLTAGE ANALYSIS

Readings should be taken with a 1000 ohms-per-volt meter. Voltages listed below are from point indicated to ground (chassis). Line voltage for these readings was 117.5 volts, 60 cycles, a.c.

Tube	*Plate*	*Screen*	*Cathode*	*Osc. Plate*	*Fil.*
6A7	255	90	3.5	170	6.3 a.c.
6D6	255	90	3.5	—	6.3 a.c.
85	37	—	5.5	—	6.3 a.c.
41	240	255	15.0	—	6.3 a.c.

B plus at filament of 80 tube—325 volts
Voltage across speaker field—70 volts.

GENERAL INSTRUCTIONS

The set's oscillator is higher in frequency than the signal, so images should be observed on the low frequency side of the signals.

Always choose the minimum capacity peak on oscillator trimmers and maximum capacity peaks on antenna trimmers. The last motion in adjusting trimmers should always be a tightening one, not a loosening one.

Never leave a trimmer with the outside plate so loose that there is no tension on the screw. Either bend the plate up or remove the screw entirely.

Always use as weak a test signal as possible during alignment.

EMERSON RADIO & PHONO. CORP.

MODEL 119 (Revised)
Chassis U6A
Schematic, Voltage
Alignment

ADJUSTMENTS

An oscillator with frequencies of 456, 600, 1600, 1700, 4500 and 15,000 kc should be used. In addition, an output meter should be used across the voice coil or output transformer for observing maximum response.

I-f Alignment

The i-f transformers ZZT-194 and ZZT-195 are located on the top of the chassis. The four trimmers, two for each i-f transformer, are located at the tops of the cans. Set the wave-band switch to broadcast (extreme clockwise position) and rotate variable condenser to minimum. Feed 456 kc to grid of the 6A8 tube and adjust the four i-f trimmers for maximum response. Then feed 456 kc through the antenna and adjust the wave-trap trimmer for *minimum response*. The trimmer is on the wave-trap, which is located on top of the chassis behind the speaker.

Location of Coils

The antenna coils for the three bands are wound on one form and mounted on top of the chassis. The three trimmers for these coils are mounted on a bakelite strip above the tubing. The trimmer furthest from the end of chassis is for the short-wave antenna coil. The central trimmer is for the police antenna coil and the trimmer nearest the end of chassis is for the broadcast antenna coil.

The oscillator coils for the three bands are wound on one form and mounted underneath the chassis deck on the right-hand-wall with the trimmers facing out. The trimmer screws are available through three holes in the chassis wall. The trimmer closest to front is for the broadcast oscillator coil, the central trimmer is for the police oscillator coil and the trimmer furthest from front is for the short-wave oscillator coil.

The adjusting screws for the dual padder are also available at the right-hand chassis wall. The screw closer to the front is for the broadcast band and the other is for the police band. The short-wave band has no adjustable padder.

Broadcast Alignment

Set the wave-band switch to broadcast position (extreme clockwise) and dial pointer to 600. Feed 600 kc through antenna lead and adjust broadcast padder (lower row on right wall, closest to front) for maximum response. Set pointer to 1600, feed 1600 kc and adjust the broadcast oscillator trimmer (top row on right wall, closest to front) for maximum response, and then the broadcast antenna trimmer (on antenna coil, nearest the end of chassis). Return pointer to 600 and rock the variable condenser (rotate condenser back and forth through small arc) while adjusting the broadcast padder for maximum response. If a readjustment is necessary return to 1600 and realign the antenna and oscillator trimmers.

Police Alignment

Set the wave-band switch to police (central position), pointer to 1700 and feed 1700 kc through antenna lead. Adjust police band padder (furthest from front on right wall, lower row) for maximum response. Set pointer to 4500 and feed 4500 kc. Adjust police band oscillator trimmer (central trimmer on right wall, upper row) for maximum response. If two peaks are heard, select the one of minimum capacity (see General Instructions below), then adjust police band antenna trimmer (central one on top) for maximum response, selecting the peak of maximum capacity. Again feed 1700 kc, with pointer at 1700, rock variable condenser and adjust police band padder for maximum response. Realign at 4500 if necessary.

Short-Wave Alignment

Set wave-band switch to counter-clockwise (short-wave) position and pointer at 15 megacycles. Feed 15,000 kc through antenna. Adjust short-wave oscillator trimmer (furthest from front on right wall, top row) for maximum response. If two peaks are obtained, select the one of minimum capacity.

Check all three bands for dead spots or incorrect image responses.

General Instructions

The set's oscillator is higher in frequency than the signal on all three bands. Images, therefore, should be observed on the low-frequency side of the signals.

Always choose the minimum capacity peak on oscillator trimmers and maximum capacity peaks on the antenna trimmers. The last motion in adjusting trimmers should always be a tightening one.

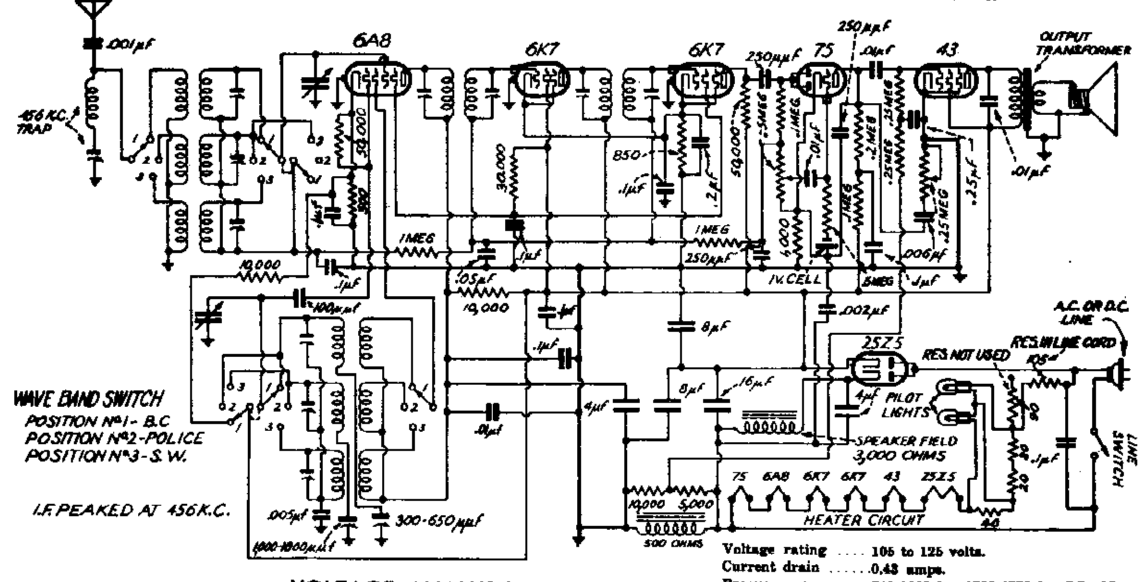
Never leave a trimmer with the outside plate so loose that there is no tension on the screw. Either bend the plate up or remove the screw entirely. Loose screws are a source of noise, frequency drift and microphonism.

In aligning antenna trimmers on the high-frequency signals there is usually a tendency for the oscillator to drift, due to interlocking. To compensate for this, always keep re-tuning the variable condenser.

1. If replacements are made or the wiring disturbed in the r-f section of the circuit, the receiver should be carefully re-aligned.

2. Bias for the grid of the audio section of the 75 tube is obtained by means of a very small one-volt battery (bias cell). The cell assembly is mounted on a bakelite strip in the front corner of the chassis near the volume control. Do not put a voltmeter across this bias cell. If the set distorts, check it by temporarily replacing with a new cell, or some other one-volt source, and noting results. To remove the bias cell, simply pull up on the spring clip and lift the cell from its cup.

4. The filament dropping resistor, (105 -see schematic), is a resistance wire in the special line cord. The cord will, therefore, become warm under normal operating conditions. To insure good heat radiation stretch out the line cord to its full length. Do not attempt to shorten it by cutting.



Voltage rating ..... 105 to 125 volts.
Current drain .... 0.43 amps.
Frequency ranges .. 540-1660 kc, 1580-4750 kc, 5.5—16 mc.

VOLTAGE ANALYSIS

Readings should be taken with a 1000 ohms-per-volt meter. Voltages listed below are from point indicated to B minus (cathode of 43 tube). Line voltage for these readings was 117.5 volts, a.c., 60 cycles.

Tube	*Plate*	*Screen*	*Cathode*	*Osc. Plate*	*Fil.*
6A8	78	50	*7	78	6
6K7 1st i-f	107	107	4.7	—	6
6K7 2nd i-f	70	50	5	—	6
75	45	—	0.2	—	6
43	95	107	0	—	24

The tube complement is as follows:

1—6A8 (metal) Pentagrid oscillator-modulator.
1—6K7 (metal) 1st i-f amplifier.
1—6K7 (metal) 2nd i-f amplifier (adjacent to 75).
1—75 (glass) 2nd detector—a-f amplifier—a.v.c.
1—43 (glass) Power output pentode.
1—25Z5 (glass) Half-wave rectifier.

Voltage across speaker field (25Z5 cathode to line switch) — 107 volts.

Voltage across choke (43 cathode to line switch) — 22 volts.

*Voltage indicated is with wave-band switch in broadcast position. On the police and short-wave bands this voltage is 2.3 volts.

MODEL 119 (Revised) Chassis U6A Schematic, Voltage Alignment

EMERSON RADIO & PHONO. CORP.

ADJUSTMENTS

An oscillator with frequencies of 456, 600, 1600, 1700, 4500 and 15,000 kc should be used. In addition, an output meter should be used across the voice coil or output transformer for observing maximum response.

I-f Alignment

The i-f transformers ZZT-194 and ZZT-195 are located on the top of the chassis. The four trimmers, two for each i-f transformer, are located at the tops of the cans. Set the wave-band switch to broadcast (extreme clockwise position) and rotate variable condenser to minimum. Feed 456 kc to grid of the 6A8 tube and adjust the four i-f trimmers for maximum response. Then feed 456 kc through the antenna and adjust the wave-trap trimmer for *minimum response*. The trimmer is on the wave-trap, which is located on top of the chassis behind the speaker.

Location of Coils

The antenna coils for the three bands are wound on one form and mounted on top of the chassis. The three trimmers for these coils are mounted on a bakelite strip above the tubing. The trimmer furthest from the end of chassis is for the short-wave antenna coil. The central trimmer is for the police antenna coil and the trimmer nearest the end of chassis is for the broadcast antenna coil.

The oscillator coils for the three bands are wound on one form and mounted underneath the chassis deck on the right-hand-wall with the trimmers facing out. The trimmer screws are available through three holes in the chassis wall. The trimmer closest to front is for the broadcast oscillator coil, the central trimmer is for the police oscillator coil and the trimmer furthest from front is for the short-wave oscillator coil.

The adjusting screws for the dual padder are also available at the right-hand chassis wall. The screw closer to the front is for the broadcast band and the other is for the police band. The short-wave band has no adjustable padder.

Broadcast Alignment

Set the wave-band switch to broadcast position (extreme clockwise) and dial pointer to 600. Feed 600 kc through antenna lead and adjust broadcast padder (lower row on right wall, closest to front) for maximum response. Set pointer to 1600, feed 1600 kc and adjust the broadcast oscillator trimmer (top row on right wall, closest to front) for maximum response, and then the broadcast antenna trimmer (on antenna coil, nearest the end of chassis). Return pointer to 600 and rock the variable condenser (rotate condenser back and forth through small arc) while adjusting the broadcast padder for maximum response. If a readjustment is necessary return to 1600 and realign the antenna and oscillator trimmers.

Police Alignment

Set the wave-band switch to police (central position), pointer to 1700 and feed 1700 kc through antenna lead. Adjust police band padder (furthest from front on right wall, lower row) for maximum response. Set pointer to 4500 and feed 4500 kc. Adjust police band oscillator trimmer (central trimmer on right wall, upper row) for maximum response. If two peaks are heard, select the one of minimum capacity (see General Instructions below), then adjust police band antenna trimmer (central one on top) for maximum response, selecting the peak of maximum capacity. Again feed 1700 kc, with pointer at 1700, rock variable condenser and adjust police band padder for maximum response. Realign at 4500 if necessary.

Short-Wave Alignment

Set wave-band switch to counter-clockwise (short-wave) position and pointer at 15 megacycles. Feed 15,000 kc through antenna. Adjust short-wave oscillator trimmer (furthest from front on right wall, top row) for maximum response. If two peaks are obtained, select the one of minimum capacity.

Check all three bands for dead spots or incorrect image responses.

General Instructions

The set's oscillator is higher in frequency than the signal on all three bands. Images, therefore, should be observed on the low-frequency side of the signals.

Always choose the minimum capacity peak on oscillator trimmers and maximum capacity peaks on the antenna trimmers. The last motion in adjusting trimmers should always be a tightening one.

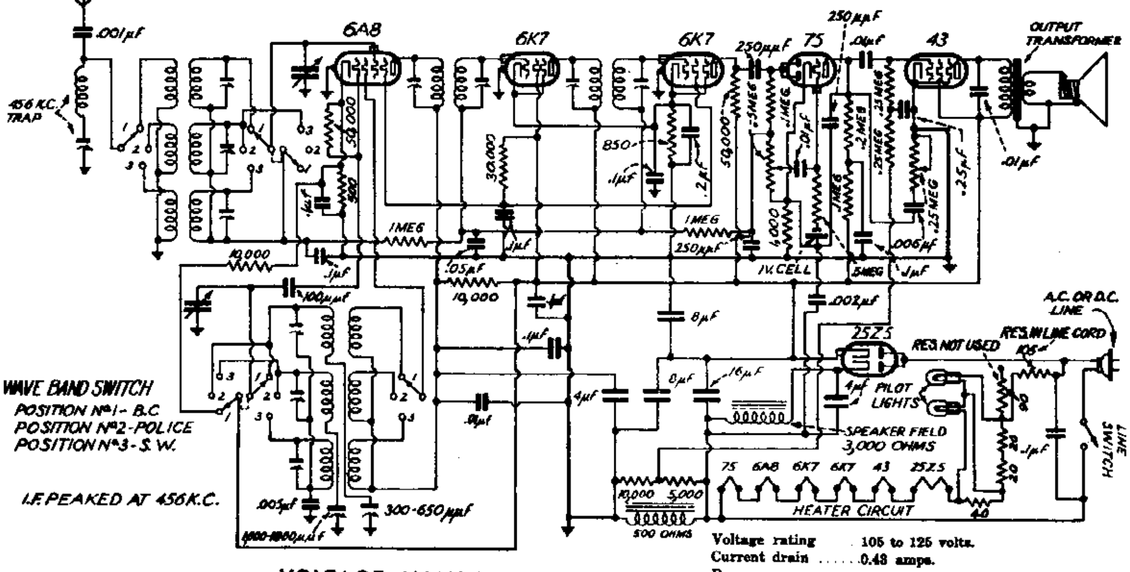
Never leave a trimmer with the outside plate so loose that there is no tension on the screw. Either bend the plate up or remove the screw entirely. Loose screws are a source of noise, frequency drift and microphonism.

In aligning antenna trimmers on the high-frequency signals there is usually a tendency for the oscillator to drift, due to interlocking. To compensate for this, always keep re-tuning the variable condenser.

1. If replacements are made or the wiring disturbed in the r-f section of the circuit, the receiver should be carefully re-aligned.

2. Bias for the grid of the audio section of the 75 tube is obtained by means of a very small one-volt battery (bias cell). The cell assembly is mounted on a bakelite strip in the front corner of the chassis near the volume control. Do not put a voltmeter across this bias cell. If the set distorts, check it by temporarily replacing with a new cell, or some other one-volt source, and noting results. To remove the bias cell, simply pull up on the spring clip and lift the cell from its cup.

4. The filament dropping resistor, (105 -see schematic), is a resistance wire in the special line cord. The cord will, therefore, become warm under normal operating conditions. To insure good heat radiation stretch out the line cord to its full length. Do not attempt to shorten it by cutting.



Voltage rating .... 105 to 125 volts.
Current drain .... 0.48 amps.
Frequency ranges ... 540-1660 kc, 1580-4750 kc, 5.5—16 mc.

VOLTAGE ANALYSIS

Readings should be taken with a 1000 ohms-per-volt meter. Voltages listed below are from point indicated to B minus (cathode of 43 tube). Line voltage for these readings was 117.5 volts, a.c., 60 cycles.

Tube	Plate	Screen	Cathode	Osc. Plate	Fil.
6A8	78	50	*7	78	6
6K7 1st i-f	107	107	4.7	—	6
6K7 2nd i-f	70	50	5	—	6
75	45	—	0.2	—	6
43	95	107	0	—	24

The tube complement is as follows:

1—6A8 (metal) Pentagrid oscillator-modulator.
1—6K7 (metal) 1st i-f amplifier.
1—6K7 (metal) 2nd i-f amplifier (adjacent to 75).
1—75 (glass) 2nd detector—a-f amplifier—a.v.c.
1—43 (glass) Power output pentode.
1—25Z5 (glass) Half-wave rectifier.

Voltage across speaker field (25Z5 cathode to line switch) — 107 volts.

Voltage across choke (43 cathode to line switch) — 22 volts.

*Voltage indicated is with wave-band switch in broadcast position. On the police and short-wave bands this voltage is 2.3 volts.

EMERSON RADIO & PHONO. CORP.

GENERAL NOTES

1. If replacements are made or the wiring disturbed in the r-f section of the circuit, the receiver should be carefully re-aligned.
2. One side of the power line is directly grounded to the chassis base. Under no circumstances, therefore, should a ground wire be permitted to come in contact with any metal part of the receiver.
3. The filament dropping resistor (R10—see schematic) is in a special metal tube at back of the chassis. This tube will, therefore, become quite hot under normal operating conditions. For voltage drop see below.
4. When operating the receiver on d.c. it may be necessary to reverse the line plug for correct polarity.
5. The first i-f transformer (one directly behind variable condenser) is of the plug-in type. To remove, unsolder all leads under the chassis, pinch together the prongs of the plug-in fastener and lift out.
6. The color coding of the i-f transformer leads is as follows:

Grid—green	Plate—blue
Grid return—black	B plus—red

Tube Data

The tube complement, for sets bearing serial numbers above 799801, is as follows:

1—6A7 pentagrid oscillator-modulator.
1—6D6 first i-f amplifier.
1—75 diode detector, audio amplifier, automatic volume control.
1—43 pentode power output.
1—25Z5 dual half-wave rectifier.

On sets bearing serial numbers below 799301, the 75 tube is replaced with a 76 tube, which functions only as a second detector.

VOLTAGE ANALYSIS

Readings should be taken with a 1000 ohms-per-volt meter. Voltages listed below are from point indicated to ground (chassis) with the volume control turned on full and no signal. Line voltage for these readings was 117.5 volts, 60 cycles, a.c.

The voltage analysis on sets bearing serial numbers above 799,301 is as follows:

Tube	*Plate*	*Screen*	*Osc. Plate*	*Cathode*	*Fil.*
6A7	112	50	112	1.5	6 a.c.
6D6	112	112	—	4.6	6 a.c.
75	40	—	—	0.5	6 a.c.
43	100	112	—	15.0	25 a.c.

The voltage analysis on sets bearing serial numbers below 799,301 is as follows:

Tube	*Plate*	*Screen*	*Osc. Plate*	*Cathode*	*Fil.*
6A7	112	50	112	2.5	6 a.c.
6D6	112	112	—	5.5	6 a.c.
76	50	—	—	6.0	6 a.c.
43	100	112	—	15.0	25 a.c.

Voltage across speaker field, (25Z5 cathode to ground)—125 volts.
Voltage across filter choke, (25Z5 cathode to B plus)—12 volts.
Voltage drop across ballast tube, (See R10, schematic)—45 volts, a.c.
Voltage drop across the pilot light section of ballast tube—4 volts, a.c.

ADJUSTMENTS

An oscillator with frequencies of 456 kc and 1500 kc should be used.

An output meter should be used across the voice coil or output transformer for observing maximum response.

Location of I-f Transformers and Trimmers

The first i-f transformer, part number 3CT-274, is in an oblong coil can located on the top of the chassis directly behind the variable condenser. The two trimmers for this i-f are accessible through holes in the top of the coil can.

The second i-f transformer, part number UUT-181 is in a round coil can located on top of the chassis to the right of the speaker. The single trimmer for this i-f is accessible through a hole in the top of the coil can.

The oscillator and antenna trimmers are located on the top of the variable condenser. The oscillator trimmer is on the rear section of the variable condenser and the antenna trimmer is on the front section of the variable condenser.

Alignment Procedure

1. Rotate the variable condenser to the minimum capacity position.
2. Feed 456 kc to the grid cap of the 6A7 tube.
3. Adjust the three i-f trimmers, repeating for maximum response.
4. Set the dial pointer to 1500 and feed 1500 kc to the antenna lead through a standard broadcast dummy antenna. (A .0002 mf mica condenser may be used as a substitute).
5. Adjust the oscillator trimmer (on rear section of variable condenser) for maximum response.
6. Adjust the antenna trimmer (on front section of variable condenser) for maximum response.

Range

The receiver is designed to operate over a frequency range from 540 to 1700 kilocycles. This range covers all of the standard broadcast stations and includes police calls above 1600 kilocycles.

Voltage rating	105-125 volts, a.c. or d.c.
Current drain	0.4 amp.
Frequency range	540 to 1700 kc.

EMERSON RADIO & PHONO. CORP.

A.C.-D.C. Dual-Wave Superheterodyne

SIX TUBES, INCLUDING BALLAST TUBE

ADJUSTMENTS

An oscillator with frequencies of 456, 600, 1425 and 15,000 kc should be used.

In addition an output meter should be used across the voice coil or output transformer for observing maximum response.

Location of Coils and Trimmer Adjustments

The broadcast antenna coil, the short-wave antenna coil and the 456 kc wave trap are one assembly mounted underneath the chassis deck to the right of the variable condenser. The trimmers for these coils are accessible through three holes in the top of the chassis. The trimmer closest to the front of the chassis is for the short-wave antenna coil. The central trimmer is for the broadcast antenna coil and the trimmer farthest from the chassis front is for the 456 kc wave trap.

The broadcast oscillator and short-wave oscillator coils are wound on one tubing and mounted on the inside of the rear chassis wall. The trimmers for these coils are accessible through two holes in the rear chassis wall. The left-hand trimmer (looking at the rear wall) is for the short-wave oscillator coil and the right-hand trimmer is for the broadcast oscillator coil.

The two i-f transformers are in oblong coil cans located on the top of the chassis. The first i-f transformer is the one behind the variable condenser. The trimmers for these transformers are accessible through holes in the tops of the cans.

The broadcast series padding condenser is located on the rear wall of the chassis below the 6A7 tube.

I-f Transformer and Wave-Trap Alignment

Turn the switch clockwise to the broadcast position and rotate the variable condenser to the minimum capacity position. Feed 456 kc to the grid cap of the 6A7 tube and adjust the four i-f trimmers for maximum response. Feed 456 kc to the antenna and adjust the wave-trap trimmer (rear screw beside variable condenser) for minimum response.

Short-Wave Alignment

Use a dummy antenna (400 ohm resistor) when aligning the short-wave coils.

Rotate the wave-band switch counter-clockwise to the short-wave position and set the dial pointer to 15 megacycles. Feed 15 megacycles through the dummy antenna and adjust the short-wave oscillator trimmer (left-hand screw on rear chassis wall) for maximum response and then adjust the short-wave antenna trimmer (front screw beside variable condenser) for maximum response. The variable condenser should be rocked while adjusting the antenna trimmer. (Rotate variable condenser rotor shaft back and forth through a small arc).

Broadcast Alignment

Rotate the wave-band switch to the broadcast position, clockwise, and set the dial pointer at 60. Feed 600 kc through a standard dummy antenna (a .0002 mf condenser may be used as a substitute).

Adjust the broadcast series padding condenser (on rear chassis wall, below 6A7 tube) for maximum response. Move pointer to 142.5, feed 1425 kc and adjust the broadcast oscillator trimmer (right-hand screw on rear chassis wall) for maximum response and then adjust the broadcast antenna trimmer (central screw beside variable condenser) for maximum response. Return pointer to 60, feed 600 kc and readjust the series padding condenser rocking the variable condenser for maximum response.

GENERAL INSTRUCTIONS

The set's oscillator is higher in frequency than the signal, so images should be observed on the low frequency side of the signals.

Always choose the minimum capacity peak on oscillator trimmers and maximum capacity peaks on antenna trimmers. The last motion in adjusting trimmers should always be a tightening one, not a loosening one.

Always use as weak a test signal as possible during alignment.

Never leave a trimmer with the outside plate so loose that there is no tension on the screw. Either bend the plate up or remove the screw entirely.

GENERAL NOTES

1. If replacements are made or the wiring disturbed in the r-f portion of the circuit, the receiver should be carefully re-aligned.
2. One side of the power line is directly grounded to the chassis base. Under no circumstances, therefore, should a ground wire be permitted to come in contact with any metal part of the receiver.
3. The filament dropping resistor (R16 on schematic) is in a special metal tube at the rear of the chassis. This tube will become quite hot under normal operating conditions. For voltage drop specifications, see below.
4. When operating the receiver on d.c. it may be necessary to reverse the line plug to obtain the correct polarity.
5. The two i-f transformers are held to the chassis by snap-on fasteners. To remove an i-f, unsolder all the leads under the chassis, pinch together the prongs of the snap-on fastener and lift the i-f can from the chassis.
6. The color coding of the i-f transformer leads is as follows:
   Grid—green; Plate—blue
   Grid return—black; B plus—red

VOLTAGE ANALYSIS

Readings should be taken with a 1000 ohms-per-volt meter. Voltages listed below are from point indicated to ground (chassis) with the volume control turned on full and no signal. Line voltage for these readings was 117.5 volts, 60 cycles, a.c.

Tube	Plate	Screen	Cathode	Osc. Plate	Fil.
6A7	100.0	42	2.0	90	6.3 a.c.
6D6	100.0	100	2.0	—	6.3 a.c.
75	29.5	0	0	—	6.3 a.c.
43	87.0	100	0	—	25 a.c.

Voltage at 25Z5 cathode—110 volts.
Voltage drop across ballast tube (including pilot-light section) —49 volts.
Voltage drop across each pilot light section—4 volts.

Alignment, Voltage Notes, Parts

VOLTAGE ANALYSIS

Readings should be taken with a 1000 ohms-per-volt meter. Voltages listed below are from point indicated to ground, with no signal. Line voltage for these readings was 117.5 volts, 60 cycles.

Tube	Plate	Screen	Cathode	Osc. Plate	Fil.
6K7 (r-f)	250	100	3.8	—	6.3 a.c.
6A8	250	100	3.8	180	6.3 a.c.
6K7 (i-f)	250	100	3.6	—	6.3 a.c.
6R7	90	—	0	—	6.3 a.c.
6C5	150	—	0	—	6.3 a.c.
6F6	240	250	0	—	6.3 a.c.
6G5	10 (blue lead)	250 (red lead)	0	—	6.3 a.c.

Voltage across speaker field—100 volts.
B plus at 5W4 filament to B minus (center tap of secondary)—350 volts.

ADJUSTMENTS

An oscillator with frequencies of 456, 600, 1600, 1800, 6000 and 16000 kc should be used.

An output meter should be used across the voice coil or speaker output transformer for observing maximum response.

Use a standard dummy antenna for aligning any of the three bands. A .0002 mf condenser may be used for the broadcast band dummy antenna, a .0001 mf condenser for police-band antenna and a 400 ohm resistor for the short-wave antenna.

The i-f transformers are located on the extreme left side of the chassis. The transformer nearest the front of the chassis is the first i-f transformer. The four trimmers for the i-f adjustment are available through holes in the tops of the cans.

The broadcast, police and short-wave coils are all located on the tuner unit. The tuner unit is the separate chassis section floated on rubber and mounted in center of chassis. The location of the trimmers for the coils is shown in the illustration at the right. The three coils for the broadcast band are in separate cans on top of the tuner unit.

Tube Data

The tube complement is as follows:

1—6K7—R-f amplifier (on r-f unit)
1—6A8—Pentagrid modulator-oscillator (on r-f unit)
1—6K7—I-f amplifier
1—6R7—Second detector, a.v.c., and a-f amplifier
1—6C5—A-f amplifier
1—6F6—Pentode output
1—6G5—Electron ray tuning indicator
1—5W4—Full-wave rectifier

I-f Alignment

Set the wave-band switch at the broadcast (clockwise) position and the variable condenser at the minimum capacity position. Feed 456 kc to the grid cap of the 6A8 tube. Adjust the four i-f trimmers carefully for maximum response. Feed 456 kc through a dummy antenna into the antenna terminal and adjust 456 wave-trap for *minimum response.*

Broadcast Alignment

Both pointers on the dial should coincide vertically at 690 kc. The gold pointer may be slipped around its shaft. With the wave-band switch at the broadcast (clockwise) position, set the pointer at 60, feed 600 kc through the antenna (using a standard dummy antenna), and adjust the broadcast series padder for maximum response. Move pointer to 160, feed 1600 kc to the antenna and adjust the oscillator trimmer for maximum response, then adjust detector and antenna trimmers. Reset the pointer to 60, feed 600 kc to antenna and rock the variable condenser (rotate the condenser back and forth through a small arc) while resetting the oscillator padder for maximum response. Return to 1600 and check alignment. If readjustment is necessary, return to 600 and repeat entire procedure.

Police Alignment

Set the switch at police (central) position and the pointer at 1.8. Feed 1800 kc to antenna (using a 0.0001 mf condenser for a dummy antenna), and adjust the police band series padder for maximum response. Move the pointer to 6.0, feed 6000 kc to the antenna and adjust the police-band oscillator for maximum response. If two peaks are obtained select the minimum capacity peak. (See General Instructions below.) Then adjust the antenna and detector trimmers for maximum response. If two peaks are obtained select the maximum capacity peak. Return the pointer to 1.8, feed 1800 kc to the antenna and rock the variable condenser while adjusting the police-band series padder for maximum response. Return to 6000 and check alignment. If readjustment is necessary return to 1800 and repeat entire procedure.

Short-Wave Alignment

Set the wave-band switch at the short-wave (counter-clockwise) position. Move pointer to 16, feed 16000 kc to antenna (using a 400 ohm dummy antenna) and adjust the short-wave oscillator for maximum response. If two peaks are obtained choose minimum capacity peak. Then adjust the detector and antenna trimmers for maximum response. If two peaks are obtained choose the maximum capacity peak.

GENERAL INSTRUCTIONS

The set's oscillator is higher in frequency than the signal on all three bands. Images, therefore, should be observed on the low-frequency side of the signals.

Always choose the minimum capacity peak on oscillator trimmer and maximum capacity peaks on antenna and r-f trimmers. The last motion in adjusting trimmers should always be a tightening one.

Never leave a trimmer with the outside plate so loose that there is no tension on the screw. Either bend the plate up or remove the screw entirely. Loose screws are a source of noise, frequency drift and microphonism.

In aligning antenna trimmers on the high-frequency signals there is usually a tendency for the oscillator to drift, due to interlocking. To compensate for this always keep re-tuning the variable condenser as you align.

GENERAL NOTES

1. A jack is provided at the rear of the chassis for a phonograph attachment. The pickup to be used should be of the high impedance type. A separate potentiometer type volume control is required, the overall resistance to be determined by the type of pickup chosen. The pickup leads should be connected to the two outside terminals of the volume control with the ground lead of the pickup on the right-hand terminal (looking at front with terminals at top) of the control. A lead from this terminal should be plugged into the hole in the phono jack nearest the end of the chassis. A lead from the center terminal of the volume control should be plugged into the other hole in the jack (grid side of jack). Ends of leads to be plugged in jack should be fitted with tips. The volume control in the receiver should be turned to the extreme counter-clockwise (low) position when operating phonograph. Since the phono jack is of the shorting type signals cannot be received by the set when the leads are plugged into the jack. The leads should be removed before attempting to receive broadcast stations.
2. The receiver should never be turned on with either the speaker plug or the 6F6 tube out of their sockets, since the rapid rise in rectifier voltage would damage the electrolytic condenser.
3. Pilot lights may be replaced by slipping the push-on sockets off the dial and unscrewing the bulbs. It is not necessary to remove either the dial or chassis from cabinet.
4. In replacing chassis in cabinet do not tighten mounting screws so much that chassis will not float freely, and do not allow any part of the dial assembly to touch the cabinet. Do not push control knobs on so far that they touch the cabinet front panel. If these precautions are not observed the receiver may become microphonic.
5. The color coding of the power transformer leads is as follows:
   - Primary—two black leads
   - High voltage sec.—two red leads
   - High voltage center tap—red and yellow lead
   - 6.3V sec.—two heavy green leads
   - 5V sec.—two heavy yellow leads
6. The tuning indicator (6G5 tube) is mounted in the cabinet above the dial on all the console type receivers, and in the speaker compartment on the table type receivers. On the table-type receivers it is necessary to remove the speaker from the baffle, in order to remove the tuning indicator tube assembly. The color coding of the tuning indicator tube cable is as follows:
   - Shield—cathode
   - Blue—plate
   - Red—target
   - Filament—Black
   - Green—grid
7. An efficient antenna system (often called aerial) is necessary to enable a full realization of the merits of the receiver. The Emerson All-Wave Antenna is especially designed for high efficiency and reduction of noise on all three frequency ranges. Complete instructions for the installation of this antenna are supplied with each kit.

Alignment, Voltage Socket, Trimmers, Notes

PRODUCTION CHANGES

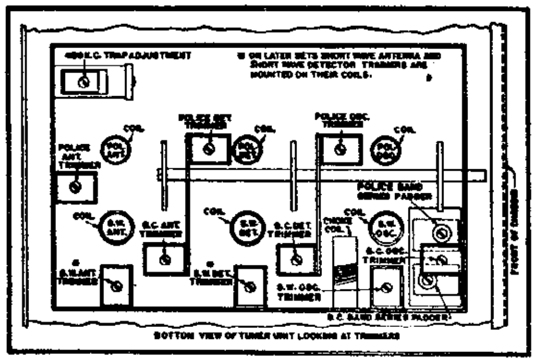
On early receivers C4, C5, C6, C7, C8, C9, C10, C11 and C12 were air trimmers part No. 3AC-252. On these trimmers a clockwise rotation of the trimmer screw decreases the capacity. C21 was a .05 mf 200 volt tubular condenser.

ADJUSTMENTS

Use a standard dummy antenna for aligning any of the three bands. A .0002 mf condenser may be used for the broadcast band dummy antenna, a .0001 mf condenser for police-band dummy antenna and a 400 ohm resistor for the short-wave dummy antenna.

The i-f transformers are located on the extreme left side of the chassis. The transformer nearest the front of the chassis is the first i-f transformer. The four trimmers for the i-f adjustment are available through holes in the tops of the cans.

The broadcast, police and short-wave coils are all located on the tuner unit. The tuner unit is the separate chassis section floated on rubber and mounted in center of chassis. The location of the trimmers for the coils is shown in the illustration at the right. The three coils for the broadcast band are in separate cans on top of the tuner unit.



Checking High-Fidelity Operation

On the oscillograph screen the peak of the selectivity curve (i-f response curve with fidelity-selectivity switch in selective position, clockwise) should appear in a position midway between the two peaks of the high-fidelity curve (i-f response curve with fidelity-selectivity switch in fidelity position, counter clockwise). In other words the central vertical axis of the selectivity curve should be coincident on the screen with the central vertical axis of the high-fidelity curve.

An approximate check of the high-fidelity operation can be made with the use of the oscillator and output meter. First, the i-f's should be very carefully peaked at 456 kc *with the fidelity-selectivity switch in the selective position.* **Turn the switch to the fidelity position, counter-clockwise, and vary the frequency of the oscillator. Two peaks should be observed on the output meter, approximately 7 kc on each side of the selectivity peak.**

I-f Alignment

Set the wave-band switch at the broadcast (clockwise) position and the variable condenser at the minimum capacity position. Feed 456 kc to the grid cap of the 6A8 tube. Adjust the four i-f trimmers carefully for maximum response. Feed 456 kc through a dummy antenna into the antenna terminal and adjust the 456 kc wave-trap for ***minimum response.***

Broadcast Alignment

Both pointers on the dial should coincide vertically at 890 kc. (For adjustment, the gold pointer may be slipped around its shaft.) With the wave-band switch at the broadcast (clockwise) position, set the pointer at 60, feed 600 kc through the antenna (using a standard dummy antenna), and adjust the broadcast series padder for maximum response. Move pointer to 160, feed 1600 kc to the antenna and adjust the oscillator trimmer for maximum response, then adjust detector and antenna trimmers. Reset the pointer to 60, feed 600 kc to antenna and rock the variable condenser (rotate the condenser back and forth through a small arc) while resetting the oscillator padder for maximum response. Return to 1600 and check alignment. If readjustment is necessary, return to 600 and repeat entire procedure.

Police Alignment

Set the switch at police (central) position and the pointer at 1.8. Feed 1800 kc to antenna (using a 0.0001 mf condenser for a dummy antenna), and adjust the police band series padder for maximum response. Move the pointer to 6.0, feed 6000 kc to the antenna and adjust the police-band oscillator for maximum response. If two peaks are obtained select the minimum capacity peak. (See General Instructions below.) Then adjust the antenna and detector trimmers for maximum response. If two peaks are obtained select the maximum capacity peak. Return the pointer to 1.8, feed 1800 kc to the antenna and rock the variable condenser while adjusting the police-band series padder for maximum response. Return to 6000 and check alignment. If readjustment is necessary return to 1800 and repeat entire procedure.

Short-Wave Alignment

Set the wave-band switch at the short-wave (counter-clockwise) position. Move pointer to 16, feed 16000 kc to antenna (using a 400 ohm dummy antenna) and adjust the short-wave oscillator for maximum response. If two peaks are obtained choose minimum capacity peak. Then adjust the detector and antenna trimmers for maximum response. If two peaks are obtained choose the maximum capacity peak.

GENERAL INSTRUCTIONS

The set's oscillator is higher in frequency than the signal on all three bands. Images, therefore, should be observed on the low-frequency side of the signals.

Always choose the minimum capacity peak on oscillator trimmers and maximum capacity peaks on antenna and r-f trimmers. The last motion in adjusting trimmers should always be a tightening one.

Never leave a trimmer with the outside plate so loose that there is no tension on the screw. Either bend the plate up or remove the screw entirely. Loose screws are a source of noise, frequency drift and microphonism.

In aligning antenna trimmers on the high-frequency signals there is usually a tendency for the oscillator to drift, due to interlocking. To compensate for this always keep re-tuning the variable condenser as you align.

Always use as weak a test signal as possible during alignment.

Readings should be taken with a 1000 ohms-per-volt meter. Voltages listed below are from point indicated to ground, with no signal. Line voltage for these readings was 117.5 volts, 60 cycles.

Tube	*Plate*	*Screen*	*Cathode*	*Osc. Plate*	*Fil.*
6A8 osc.-mod.	210	100	3.2	150	6.3 a.c.

VOLTAGE ANALYSIS

Readings should be taken with a 1,000 ohms-per-volt meter. The voltages listed below are from point indicated to A minus with volume control turned on full and no signal. The battery voltages for these readings "A" battery 3 volts, "B" battery 135 volts, "C" battery 4.5 volts.

Tube	Plate	Osc. Plate	Screen	Fil.
1A4	135	—	67.5	2.0
1A6	135	135	67.5	2.0
1A4	135	—	67.5	2.0
1B5/25S	85	—	—	2.0
1F4	125	—	135	2.0

If it is definitely known that a 2 volt storage battery will always be used it is permissable and advisable to short-circuit the two heavy prongs on the 1B1 tube by connecting them with a short piece of bare wire. *Be sure that the two small prongs on the tube are free of this bare wire.*

Location of I-f Transformers and Trimmers

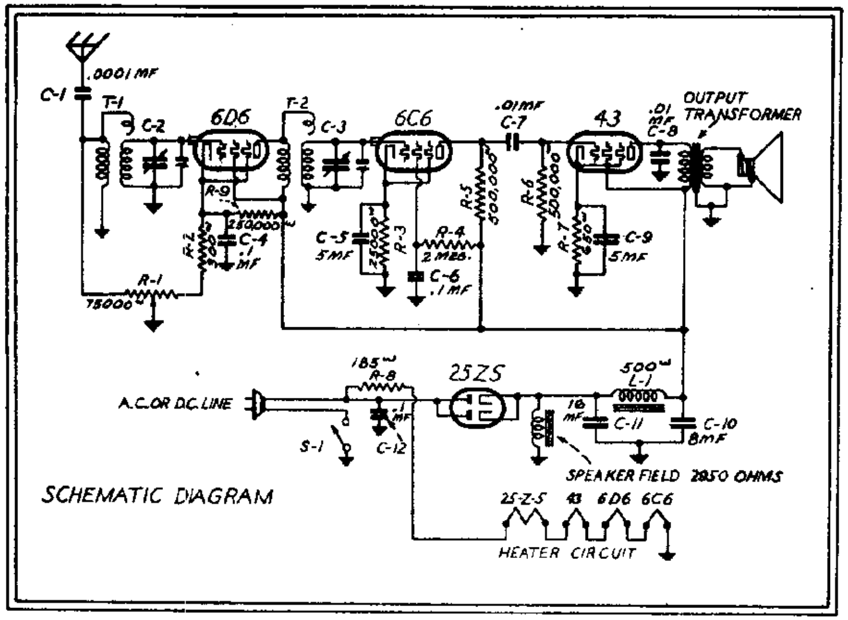
The first i-f transformer, part number 3HT-287 is in an oblong coil can located on the top of the chassis to the right of the speaker. The two trimmers for this i-f are accessible through holes in the top of the coil can.

The second i-f transformer, part number 3HT-288 is in an oblong coil can located directly behind the second i-f tube. The two trimmers for this i-f are accessible through holes in the top of the coil can.

The oscillator, antenna, and r-f trimmers are located on the top of the variable condenser. The oscillator trimmer is on the center section of the variable condenser, the antenna trimmer is on the front section of the variable condenser

MODELS 409, 410, 411
Chassis U4C
Schematic, Voltage
Alignment, Parts

EMERSON RADIO & PHONO. CORP.



SCHEMATIC DIAGRAM

Chassis Model U4C

Voltage rating .... 105 to 130 volts a-c. or d-c.
Current drain .... 0.38 amps.
Frequency range .... 540 to 1650 kc.

TUBE COMPLEMENT

The tubes used are as follows:

- 1 - 6D6, r-f. amplifier.
- 1 - 6C6, biased detector.
- 1 - 43, power output pentode.
- 1 - 25Z5, dual half-wave rectifier.

VOLTAGE ANALYSIS

Readings should be taken with a 1000 ohms-per-volt meter. Voltages listed below are from point indicated to ground (chassis) with volume control turned on full and no signal. The line voltage for these readings was 117.5 volts, 60 cycles, a-c.

Tube	Plate	Screen	Cathode	Fil.
6D6	100	102	3	6.3
6C6	30	21	2	6.3
43	95	101	13	25.0

Voltage across speaker field (25Z5 cathode to chassis) - 118 volts.
Voltage across choke (25Z5 cathode to 43 screen) - 16.5 volts.

ALIGNMENT PROCEDURE

An oscillator with a frequency of 1425 kc. is required.

Rotate the variable condenser shaft 25 degrees from the minimum capacity position. (This may be done by affixing a protractor, or a similarly calibrated scale, to the condenser shaft.) With the condenser in this position, feed 1425 kc. to the antenna and adjust both trimmers on the variable condenser for maximum response. Use as weak a test signal as possible.

Range: The receiver is designed to operate over the broadcast range from 540 to 1650 kilocycles. This range covers all of the standard American broadcast stations and some of the low-frequency police transmitters.

Power Supply: The power supply for this receiver should be either a. c. 50 to 60 cycles, or d. c., of any voltage between 105 and 130 volts. With special external line cord ballast resistors this receiver may be operated on higher voltages.

THE RECEIVER WAS DESIGNED TO OPERATE WITHOUT A GROUND. UNDER NO CIRCUMSTANCES SHOULD A GROUND WIRE BE PERMITTED TO COME IN CONTACT WITH ANY METAL PART OF THE RECEIVER.

PRODUCTION CHANGES

In early production receivers—
a. R9 was omitted.
b. R4 was a 500,000 ohm ¼ watt carbon resistor.

REPLACEMENT PARTS

ALIGNING INSTRUCTIONS FOR

MODEL 260 SERIES

In order to adjust accurately the various trimmer condensers of the receiver in accordance with the following instructions, it is essential to use a shielded signal generator capable of giving a modulated carrier which can be attenuated at 456 KC and 1500 KC.

This receiver is equipped with an automatic overload control which necessitates setting the manual volume control of the receiver to the maximum position, to assure accuracy in alignment. To control the signal output of the receiver it will be necessary to use the attenuator control of the signal generator.

NOTE: Do not remove knobs, screws or chassis from the cabinet before removing the line cord plug from the power line socket. If the above precaution is not followed a severe electric shock, or damage to the receiver, may result.

ADJUSTMENT OF I.F. CONDENSERS

The three (3) intermediate frequency (I.F.) condensers are located as shown in the sketch.

1st - Turn the rotor plates of the ganged variable condenser to a position where no broadcast station carrier is heard. If this is not possible, connect a .1 mfd. tubular condenser from the oscillator stator section (see sketch) of the ganged variable condenser to chassis.

2nd - Disconnect the control grid lead from the 6A7 oscillator-modulator tube.

3rd - Connect the high potential lead of the signal generator to the control grid of the 6A7 oscillator-modulator tube, and the low potential lead to the receiver chassis.

4th - Place an output meter (copper oxide type) across the speaker voice coil terminals so that variations in signal output can be noted.

5th - Place the signal generator in operation and adjust the carrier frequency to 456 KC. Regulate the attenuator control of the signal generator so that the output signal is low enough to insure accuracy in adjusting the I.F. condensers.

6th - With the aid of a bakelite type screw driver, adjust the three (3) I.F. condensers to resonance as indicated by the greatest swing of the needle on the output meter.

ADJUSTMENT OF THE GANGED VARIABLE CONDENSER

The compensators are located at the top of their respective tuning condenser section and can be adjusted with the aid of a screw drive

1st - Remove signal generator connection from control grid of 6A7 oscillator-modulator tube and replace control grid lead.

2nd - Connect the antenna wire of the receiver to the high potentio lead of the signal generator through a 250 mmfd. condenser.

3rd - Adjust the carrier frequency of the signal generator to 1500 KC.

4th - Set the dial pointer directly at "E" in the word "POLICE" with the ganged variable condenser rotor plates open.

5th - Rotate the receiver dial to read 1500 KC.

6th - Starting with the compensator nearest the front of the receiver, adjust each compensator (as indicated on sketch) for maximum signal output. Do not disturb the setting of the gang condenser during these operations.

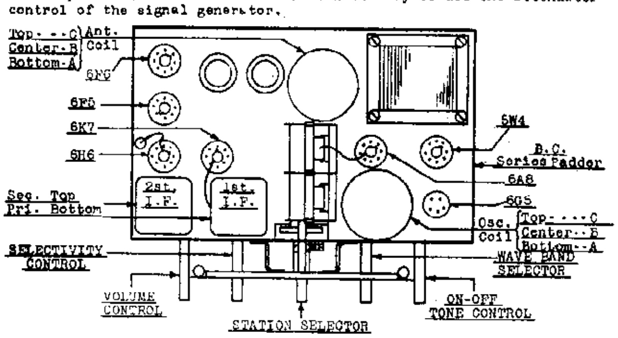
Alignment, Voltage Socket, Trimmers

FADA RADIO & ELECTRIC CORP.

ALIGNING INSTRUCTIONS FOR MODEL 270 SERIES

In order to adjust accurately the various trimmer condensers of the receiver in accordance with the following instructions, it is essential to use a shielded signal generator capable of giving a modulated carrier which can be attenuated at 456 KC, 600 KC, 1500 KC, 2 MC, 5 MC, 6 MC and 15 MC.

This receiver is equipped with an automatic volume control which necessitates setting the manual volume control of the receiver to its maximum position to insure accuracy in alignment. To control the signal output of the receiver it will be necessary to use the attenuator control of the signal generator.



ADJUSTMENT OF I.F. CONDENSERS

The four (4) intermediate frequency (I.F.) condensers are located as shown in the sketch.

IMPORTANT: All adjustments must be made with the selectivity control in the "S" position.

1st - Disconnect the outside antenna system from the receiver.

2nd - Disconnect the control grid lead from the 6A8 tube.

3rd - Connect the high potential lead of the signal generator to the control grid of the 6A8 tube, and the low potential side to the receiver "ground" lead.

4th - Place an output meter (copper oxide type) across the speaker voice coil so that variations in signal output can be noted.

5th - Place the signal generator in operation and adjust the carrier frequency to 456 KC. Regulate the attenuator control of the signal generator so that the output signal is low enough to insure accuracy in adjusting the I.F. condensers.

6th - With the aid of a bakelite type screw driver, adjust the four (4) I.F. condensers to resonance; adjusting first the I.F. condenser across the secondary winding of the 2nd I.F. transformer and then each in turn, ending with the adjustment of the condenser across the primary winding of the 1st I.F. transformer.

ADJUSTMENT OF BAND "A" SHUNT COMPENSATORS

The compensators are located as indicated on the sketch.

1st - Remove the signal generator connection from the control grid of the 6A8 tube and replace the control grid lead.

2nd - Connect the antenna wire of the receiver chassis through a 400 ohm carbon resistor to the high potential side of the signal generator. The ground wire should remain connected to the signal generator.

3rd - Adjust the carrier frequency output of the signal generator to 15 MC.

4th - Turn the wave band selector switch to band "A" and set the calibrated dial of the receiver to read 15 MC.

5th - Adjust the "A" band oscillator shunt compensator for maximum signal output. If two peaks are noted on this adjustment, the proper one is that with the compensator farthest "in". To determine that this compensator has not been adjusted to the image frequency, turn the receiver dial to approximately 15.9 MC. If no signal can be heard at this setting even with a greater signal generator output, the compensator has been improperly adjusted and it will be necessary to re-adjust to the proper peak. After re-adjusting check to see that the image frequency comes in at 15.9 MC. It is well to bear in mind throughout these adjustments that with the same signal input to the receiver, the image response point should be weaker than the original signal frequency output reading.

6th - Having determined the correct peak, and maximum setting, for the "A" band shunt compensator, adjust the antenna band "A" shunt compensator for maximum output.

7th - Adjust the carrier frequency output of the signal generator to 6 MC. Rotate the station selector to pick up this 6 MC signal and check for calibration and sensitivity.

ADJUSTMENT OF BAND "B" SHUNT COMPENSATOR

The compensators are located as indicated in the sketch.

1st - Turn the wave band selector switch to band "B".

2nd - Adjust the carrier frequency output of the signal generator to 5 MC.

3rd - Turn the receiver dial to read 5 MC.

4th - Adjust the band "B" oscillator shunt compensator for maximum signal output. If two peaks are noted on this adjustment, the proper one is that with the compensator farthest "out". To determine that this compensator has not been adjusted to the image frequency, turn the receiver dial to approximately 4 MC. If no signal is heard at this setting, even with a greater signal generator output, the compensator has been improperly adjusted and it will be necessary to re-adjust to the proper peak. After re-adjusting check to see that the image frequency comes in at 4 MC.

5th - Having determined the correct peak and maximum setting for the band "B" oscillator shunt compensator, adjust the antenna shunt compensator for maximum output.

6th - Adjust the carrier frequency output of the signal generator to 2 MC. Rotate the station selector to pick up this 2 MC signal and check for calibration and sensitivity.

ADJUSTMENT OF BAND "C" SHUNT COMPENSATOR

The compensators are located as indicated in the sketch.

1st - Remove the 400 ohm resistor from the high potential side of the signal generator and insert a 250 mmfd. mica condenser in its place.

2nd - Turn the wave band selector switch to band "C".

3rd - Adjust the carrier frequency to 1500 KC.

4th - Set the calibrated dial of the receiver to read 1500 KC.

5th - Adjust the band "C" oscillator shunt compensator for maximum signal output.

6th - Adjust band "C" antenna shunt compensator for maximum signal output.

ADJUSTMENT OF BAND "C" OSCILLATOR SERIES TRIMMER

1st - Adjust the carrier frequency output of the signal generator to 600 KC.

2nd - Turn the calibrated dial of the receiver to pick up this 600 KC signal.

3rd - With the aid of a bakelite type screw driver, adjust band "C" oscillator series trimmer (see sketch) until a maximum signal is indicated on the output meter. To insure perfect alignment it is necessary to "rock" the ganged variable condenser in order to follow the maximum signal output.

4th - Having determined the maximum peak of band "C" oscillator series trimmer, re-adjust the carrier frequency of the signal generator to 1500 KC. Turn the calibrated dial to 1500 KC and re-adjust band "C" oscillator shunt compensator, and then, antenna shunt compensator for maximum signal output as outlined in the foregoing instructions.

FAIRBANKS-MORSE HOME APP., INC.

MODEL 40

INTERMEDIATE FREQUENCY ALIGNMENT

1 - Turn the gang condenser to approximately one half maximum capacity (half meshed).

2 - Supply a 456 kilocycle signal from the signal generator to the antenna lead of the receiver through a .1 Mfd. condenser connected in series with the signal generator lead.

3 - Back the regeneration control trimmer (see Figure 1) out (counter-clockwise) to a point just below the point of oscillation.

4 - Adjust the two trimmers of the intermediate frequency transformer (see Figure 1) for maximum output with minimum input from the service oscillator.

RADIO FREQUENCY ALIGNMENT

The parallel or high frequency trimmer condensers are on the gang condenser. These trimmers are used for aligning the high frequency end of the broadcast band. The location of the trimmers is shown in Figure 1.

1 - Tune the receiver to 1500 kilocycles.

2 - Supply a 1500 kilocycle signal from the signal generator to the antenna lead of the receiver through a standard dummy antenna or a 200 Mmfd.(.0002 Mfd.)condenser, connected in series with the signal generator lead.

3 - Adjust the trimmer condenser on the front section of the gang condenser (Figure 1) to bring in the signal.

4 - Adjust the rear (R.F.) trimmer on the gang condenser for maximum output with minimum input from the service oscillator.

5 - Adjust the regeneration control by turning the adjusting screw clockwise until oscillation starts. Then back the adjusting screw out approximately one quarter turn. Check the sensitivity and, if the receiver is weak, bring up the sensitivity by readjusting the regeneration control.

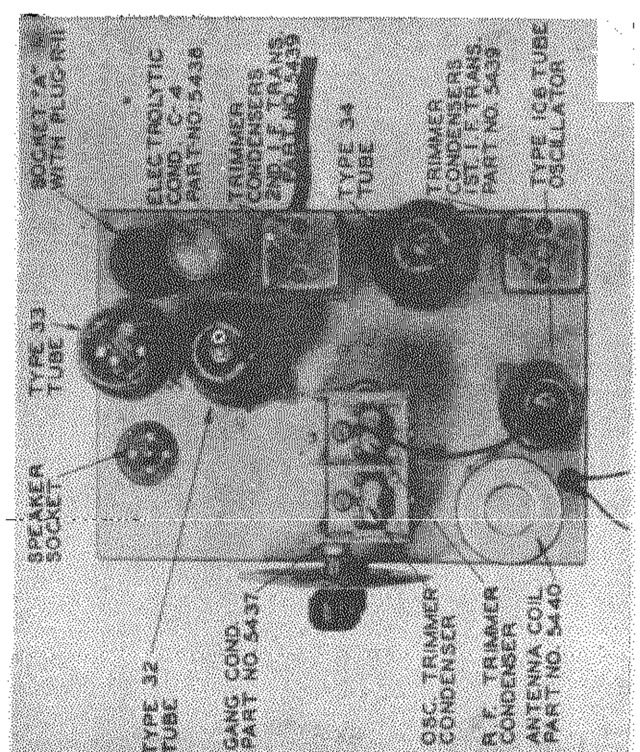
FAIRBANKS MORSE HOME APPLIANCES, INC.

MODEL 41

I-F. ALIGNMENT:
Set dial at 530 kc. with gang condenser fully meshed and tighten set screw. Connect 456-kc. signal to grid of 1C6 and adjust i-f. trimmers.
R-F. ALIGNMENT:
Set dial to 1500 kc. Connect 1500-kc. signal to antenna lead (blue) through dummy or .0002-mf. condenser. Adjust oscillator and r-f. trimmers in this order.
BATTERY DATA:
If set is operated on Air Cell "A" battery, the resistance link plug must be in Socket "A".
If set is operated on 2-volt storage battery, the jumper link must be substituted for the plug.
If a 3-volt battery is used, a special ballast tube is plugged in the "A" socket. Tube part #5674



MODEL 54
MODEL 66
Alignment, Notes
Transformer Data

MODELS 54 AND 66

INTERMEDIATE FREQUENCY ALIGNMENT

1 - Turn the gang condenser to maximum capacity (fully meshed).

2 - Set band selector switch on "Broadcast" position.

3 - Supply a 456 kilocycle signal from the signal generator to the grid of the first detector tube (6A7 or 6A8) through a .1 Mfd. condenser connected in series with the signal generator lead.

4 - Adjust the four trimmers of the two intermediate frequency transformers (see Figure 3) for maximum output with minimum input from the service oscillator.

RADIO FREQUENCY ALIGNMENT The parallel or high frequency trimmer condensers for each coil are housed in the same shield can with the coil. These trimmers are used for aligning the high frequency end of each band. The location of the various trimmers is shown in Figure 3.

The oscillator, adjustable, series padding condenser is used for tracking the oscillator at the low frequency end of the broadcast band. The padding condenser may be adjusted from the top of the chassis through the holes indicated in Figure 3. Since a fixed mica padding condenser is employed on the short wave band, no adjustment is necessary. While making padding condenser adjustments, the gang condenser should be rotated back and forth across the signal to insure adjustment to the peak of greatest intensity.

DIAL ADJUSTMENT Before making any radio frequency alignment adjustments, close the variable tuning condenser (maximum capacity), loosen the screw that secures the dial pointer, place the pointer in a horizontal position (gang condenser still closed) and then tighten the screw.

BROADCAST BAND

1 - Turn the band selector switch to the broadcast (counter-clockwise) position.

2 - Tune the receiver to 1715 kilocycles.

3 - Supply a 1715 kilocycle signal from the signal generator to the antenna lead of the receiver through a standard dummy antenna or a 200 Mmfd.(.0002 Mfd.)condenser, connected in series with the signal generator lead.

4 - Adjust the broadcast band oscillator trimmer condenser (Figure 3)for maximum output with minimum input from the signal generator.

5 - Tune the receiver to 1500 kilocycles.

6 - Supply a 1500 kilocycle signal from the signal generator to the antenna lead of the receiver, through the same connections used in the previous adjustment.

7 - Adjust the broadcast band radio frequency and preselector trimmers (see Figure 3) for maximum output with minimum input from the signal generator.

8 - Tune the receiver to 600 kilocycles.

9 - Supply a 600 kilocycle signal to the antenna of the receiver through the same connections as previously used.

10 - Adjust the broadcast band oscillator padding condenser (top of chassis, see Figure 3)for maximum output with minimum input from the signal generator, at the same time rocking the tuning condenser back and forth across the signal to insure the peak of greatest intensity.

11 - Check at 1715 kilocycles and then at 600 kilocycles. Make any adjustments that are necessary to obtain satisfactory calibration.

POLICE BAND

1 - Turn the band selector switch to the police band (center) position.

2 - Tune the receiver to a 2.4 megacycles.

3 - Supply a 2.4 megacycle signal from the signal generator to the antenna lead of the receiver through a 400 ohm carbon resistor (dummy antenna), connected in series with the signal generator lead.

4 - The 2.4 megacycle signal should be received near the calibrated section of the dial. If this is not the case, check the oscillator tube, switch connections and coils. No adjustment is necessary on this band.

SHORT WAVE BAND

1 - Turn the band selector switch to the short wave (clockwise) position.

2 - Tune the receiver to 18 megacycles.

3 - Supply an 18 megacycle signal from the signal generator to the antenna lead of the receiver through a 400 ohm carbon resistor (dummy antenna), connected in series with the signal generator lead.

4 - Turn the short wave oscillator trimmer(see Figure 3)all the way in and back it out until the 18 megacycle signal from the signal generator is received. The first signal, found at about 17 megacycles, should be the image; the second should be the 18 megacycle signal.

5 - Adjust the short wave radio frequency trimmer (see Figure 3) for maximum output with minimum input from the signal generator.

6 - Check and, if necessary, readjust all trimmers for maximum output with minimum input from the signal generator.

WARNING The image signal should be received at approximately 17 megacycles on the dial. If not, the oscillator has been aligned to the image frequency and the oscillator trimmer condenser must be backed out until the correct signal is received at 18 megacycles and the image at approximately 17 megacycles. If readjustment is found necessary, the antenna and radio frequency stage trimmers should also be checked again.

THE MODEL 54 CHASSIS The Model 54 chassis employs a type 6A7 pentagrid converter. The incoming signal is supplied to this tube through a preselector coil arrangement. This tube serves the dual function of first detector and oscillator. A type 6D6 tube is employed as the intermediate frequency amplifier. This tube and the two intermediate frequency transformers are responsible for the selectivity and gain obtained from the intermediate frequency amplifier.

A type 75 tube performs the triple function of diode detector, automatic volume control and first audio amplifier tube. The output of the triode section of the type 75 tube is resistance coupled to a type 42 tube, connected as a pentode in the power output stage. A type 80 rectifier tube is employed in a conventional power supply circuit.

THE MODEL 66 CHASSIS The Model 66 chassis employs a type 6A8 tube as the pentagrid converter. A type 6K7 is used in the intermediate frequency amplifier. A type 6H6 diode, connected as a half wave rectifier, performs the dual function of second detector and automatic volume control tube. A type 6F5 tube is employed as the first audio amplifier and the output of this stage is resistance coupled to the type 6F6 tube, connected as a pentode in the power output stage. A single type 5Z4 full wave rectifier tube is employed in a conventional power supply circuit.

AUTOMATIC VOLUME CONTROL

MODEL 66 CHASSIS A type 6H6 tube is employed as the second detector in a half wave rectifier circuit, the diode plates being connected together. Current flows from the diode plates to the cathode and to ground. Here it is picked up at the point where resistor R-10 is grounded and flows through resistors R-10 and R-11, through the secondary of the second intermediate frequency transformer, back to the plates, thus forming the complete circuit.

The D. C. component of this current produces a voltage drop across resistor R-10 in proportion to the strength of the incoming signal. The grid returns of the 6A8 pentagrid converter and the 6K7 intermediate frequency amplifier are connected through the isolating resistors R-3 and R-8 to the point of juncture between resistors R-10 and R-11, thus adding the voltage drop obtained across resistor R-10 to the fixed bias on the two controlled tubes. The fixed bias is obtained from the individual bias resistors, R-2 and R-9, located in the cathode circuits of the tubes. Resistor R-10 is also the manual volume control. The audio component of voltage drop across the resistor is taken off on the sliding arm of the control through condenser C-8 and is applied to grid of the type 6F5, first audio amplifier tube.

MODEL 54 CHASSIS The A. V. C. circuit and its operation in the Model 54 chassis is identical to that in the Model 66. The only differences are in the tubes. A type 75 tube performs the dual function of diode rectifier and first audio amplifier in place of the type 6H6 tube and the type 6F5 tube in the Model 66 chassis. A type 6D6 tube is found in place of the type 6K7 tube in the intermediate frequency stage. A type 6A7 pentagrid converter replaces the type 6A8 found in the Model 66 chassis.

THE ANTENNA

A good outside antenna is recommended for best results. An inside antenna will usually give satisfactory results on local broadcast stations, but it cannot be relied upon for distant and short wave reception.

The most suitable antenna for use in large cities or congested radio districts, where interference is a serious problem, is the doublet. In small centers of population, where interference is not serious, a single wire antenna having a total length of from 75 to 100 feet, erected as high as possible, with a good insulator at each end, will prove satisfactory. The lead-in should go to the receiver by the most direct route and should be kept away, as far as possible, from obstructions. Such an antenna will have less directional properties and less tendency to pick up power line interference than a low antenna with a long horizontal lead.

THE FAIRBANKS-MORSE ANTENNA For those installations where a doublet type antenna is most suitable, the Fairbanks-Morse engineers offer the FAIRBANKS-MORSE MODEL 20 NOISE REDUCING ANTENNA SYSTEM. This antenna is especially designed for these receivers and requires no switching arrangement, since it automatically balances itself to the receiver on all bands.

The BLUE wire on the receiver is to be connected to the antenna. The BLACK wire on the receiver is to be connected to the ground. When a FAIRBANKS-MORSE ANTENNA is used, the BLUE wire from the receiver is to be connected to the red wire on the antenna set coupler, and the BLACK wire from the receiver is to be connected to the black wire on the antenna set coupler and to a good ground.

MODEL 56

ALIGNMENT PROCEDURE

To insure obtaining the performance the model 56 receiver is capable of delivering, it is essential that it be aligned perfectly. For this reason, it is urged that the following instructions be studied carefully before any alignment adjustments are attempted.

Proper adjustment of the various tuned circuits will be possible only through the use of an accurate and reliable signal generator employed in conjunction with an output meter, which may be connected across the voice coil leads of the loud speaker.

NOTE - All adjustments should be made with the volume control "full on". Any desired variation in signal strength should be obtained by adjusting the output of the signal generator.

INTERMEDIATE FREQUENCY ALIGNMENT

1 - Turn the gang condenser to maximum capacity (fully meshed).

2 - Set the band selector switch on the "Broadcast" position.

3 - Supply a 456 kilocycle signal from the signal generator to the antenna lead of the receiver through a .1 Mfd. condenser connected in series with the signal generator lead.

4 - Adjust the four trimmers of the two intermediate frequency transformers (see Figure 1) for maximum output with minimum input from the service oscillator.

5 - Adjust the wave trap trimmer "A" (see Figure 1) for minimum output.

RADIO FREQUENCY ALIGNMENT The parallel or high frequency trimmer condensers for the broadcast band are on the gang condenser. These trimmers are used for aligning the high frequency end of the broadcast band. The location of the trimmers is shown in Figure 1.

The oscillator adjustable series padding condenser is used for tracking the oscillator at the low frequency end of the broadcast band. The padding condenser may be adjusted from the top of the chassis through the hole indicated in Figure 1. While making padding condenser adjustments, the gang condenser should be rotated back and forth across the signal to insure adjustment to the peak of greatest intensity.

DIAL ADJUSTMENT Before making any alignment adjustments, close the variable tuning condenser (maximum capacity), place the dial pointer in a horizontal position (gang condenser still closed) and then proceed with the following adjustments.

BROADCAST BAND

1 - Turn the band selector switch to the broadcast (counter-clockwise) position.

2 - Tune the receiver to 1500 kilocycles.

3 - Supply a 1500 kilocycle signal from the signal generator to the antenna lead of the receiver through a standard dummy antenna or a 200 Mmfd. (.0002 Mfd.) condenser, connected in series with the signal generator lead.

4 - Adjust the trimmer condensers on the gang condenser (Figure 1) for maximum output with minimum input from the signal generator.

5 - Tune the receiver to 600 kilocycles.

6 - Supply a 600 kilocycle signal to the antenna of the receiver through the same connections as previously used.

7 - Adjust the broadcast band oscillator padding condenser "B" (top of chassis, see Figure 1) for maximum output with minimum input from the signal generator, at the same time rocking the tuning condenser back and forth across the signal to insure the peak of greatest intensity.

8 - Check at 1500 kilocycles and then at 600 kilocycles. Make any adjustments that are necessary to obtain satisfactory calibration.

ANTENNA AND GROUND CONNECTIONS

The BLUE wire on the receiver is to be connected to the antenna. The BLACK wire on the receiver is to be connected to the ground. When a FAIRBANKS-MORSE ANTENNA is used, the BLUE wire from the receiver is to be connected to the red wire on the antenna set coupler and the BLACK wire from the receiver is to be connected to the black wire on the antenna set coupler and to a good ground.

ALIGNMENT PROCEDURE MODEL 63 MODEL 71

Proper adjustment of the various tuned circuits will only be possible through the use of an accurate and reliable signal generator employed in conjunction with an output meter, which may be connected across the voice coil leads of the loud speaker.

NOTE - All adjustments should be made with the volume control "full on". Any desired variation in signal strength should be obtained by adjusting the output of the signal generator.

INTERMEDIATE FREQUENCY ALIGNMENT

1 - Turn the gang condenser to maximum capacity (fully meshed).

2 - Supply a 456 kilocycle signal from the signal generator to the grid of the first detector tube (6A7 or 6A8) through a .1 Mfd. condenser connected in series with the signal generator lead.

3 - Adjust the four trimmers of the two intermediate frequency transformers (see Figure 1) for maximum output with minimum input from the service oscillator.

RADIO FREQUENCY ALIGNMENT The parallel or high frequency trimmer condensers for each coil are housed in the same shield can with the coil. These trimmers are used for aligning the high frequency end of each band. The location of the various trimmers is shown in Figure 1.

The oscillator, adjustable, series padding condensers are used for tracking the oscillator at the low frequency end of each band. The padding condenser may be adjusted from the rear of the chassis through the holes indicated in Figure 1. Since a fixed mica padding condenser is employed on the short wave band, no adjustment is necessary. While making padding condenser adjustments, the gang condenser should be rotated back and forth across the signal to insure adjustment to the peak of greatest intensity.

DIAL ADJUSTMENT Before making any radio frequency alignment adjustments, close the variable tuning condenser (maximum capacity), loosen the screw that secures the dial pointer, place the pointer in a horizontal position (gang condenser still closed) and then tighten the screw.

BROADCAST BAND

1 - Turn the band selector switch to the broadcast (counter-clockwise) position.

2 - Tune the receiver to 1500 kilocycles.

3 - Supply a 1500 kilocycle signal from the signal generator to the antenna lead of the receiver through a standard dummy antenna or a 200 Mmfd. (.0002 Mfd.) condenser, connected in series with the signal generator lead.

4 - Adjust the broadcast band oscillator trimmer condenser (Figure 1) for maximum output with minimum input from the signal generator. Then adjust the broadcast band radio frequency and antenna stage trimmers for maximum output.

5 - Tune the receiver to 600 kilocycles.

6 - Supply a 600 kilocycle signal to the antenna of the receiver through the same connections as previously used.

7 - Adjust the broadcast band oscillator padding condenser (rear of chassis, see Figure 1) for maximum output with minimum input from the signal generator, at the same time rocking the tuning condenser back and forth across the signal to insure the peak of greatest intensity.

8 - Check at 1500 kilocycles and then at 600 kilocycles. Make any adjustments that are necessary to obtain satisfactory calibration.

POLICE BAND

1 - Turn the band selector switch to the police band (center) position.

2 - Tune the receiver to 5.4 megacycles.

3 - Supply a 5.4 megacycle signal from the signal generator to the antenna lead of the receiver through a 400 ohm carbon resistor (dummy antenna), connected in series with the signal generator lead.

4 - Adjust the police band oscillator trimmer condenser (Figure 1) for maximum output with minimum input from the signal generator, then adjust the police band radio frequency and antenna stage trimmers for maximum output.

5 - Tune the receiver to 1.8 megacycles.

6 - Supply a 1.8 megacycle signal to the receiver through the same connections used on the previous adjustment.

7 - Adjust the police band oscillator padding condenser (rear of chassis, see Figure 1) for maximum output with minimum input from the signal generator, at the same time rocking the tuning condenser back and forth across the signal to insure the peak of greatest intensity.

8 - Check at 5.4 megacycles and then at 1.8 megacycles and make any adjustments that are necessary to obtain satisfactory calibration.

SHORT WAVE BAND

1 - Turn the band selector switch to the short wave (clockwise) position.

2 - Tune the receiver to 18 megacycles.

3 - Supply an 18 megacycle signal from the signal generator to the antenna lead of the receiver through a 400 ohm carbon resistor (dummy antenna), connected in series with the signal generator lead.

4 - Turn the short wave antenna stage trimmer (see Figure 1) all the way in and then back it out one turn.

5 - Turn the short wave radio frequency stage trimmer (see Figure 1) all the way in and back it out one-half turn.

6 - Turn the short wave oscillator trimmer (see Figure 1) all the way in and back it out until the 18 megacycles signal from the signal generator is received. The first signal, found at about 17 megacycles, should be the image; the second, should be the 18 megacycle signal.

7 - Check and, if necessary, readjust all three stages for maximum output with minimum input from the signal generator.

WARNING - The image signal should be received at approximately 17 megacycles on the dial. If not, the oscillator has been aligned to the image frequency and the oscillator trimmer condenser must be backed out until the correct signal is received at 18 megacycles and the image at approximately 17 megacycles. If readjustment is found necessary, the antenna and radio frequency stage trimmers should also be checked again.

AUTOMATIC VOLUME CONTROL

MODEL 71 CHASSIS A type 6H6 tube is employed as the second detector in a half wave rectifier circuit, the diode plates being connected together. Current flows from the diode plates to the cathode and to ground. Here it is picked up at the point where resistor R-12 is grounded and flows through resistor R-12 and R-13, through the secondary of the second intermediate frequency transformer, back to the plates, thus forming the complete circuit.

The D.C. component of this current produces a voltage drop across resistor R-12 in proportion to the strength of the incoming signal. The grid returns of the 6K7 radio frequency amplifier, the 6A8 pentagrid converter and the 6K7 intermediate frequency amplifier, are connected through the isolating resistors R-5, R-6 and R-21 to the point of juncture between resistors R-12 and R-13, thus adding the voltage drop obtained across resistor R-12 to the fixed bias on the three controlled tubes. Resistor R-12 is also the manual volume control. The audio component of voltage drop across the resistor is taken off on the sliding arm of the control through condenser C-16 and is applied to grid of the type 6F5, first audio amplifier tube.

MODEL 63 CHASSIS The A.V.C. circuit and its operation in the model 63 chassis is identical to that in the model 71. The only differences are in the tubes. A type 75 tube performs the triple function of diode rectifier, automatic volume control and first audio amplifier in place of the type 6H6 tube and the type 6F5 tube in the model 71 chassis. Type 6D6 tubes are found in place of the type 6K7 tubes in the radio frequency and intermediate frequency stages. A type 6A7 pentagrid converter replaces the type 6A8 found in the model 71 chassis.

THE ANTENNA

The most suitable antenna for use in large cities or congested radio districts, where interference is a serious problem, is the doublet. In small centers of population, where interference is not serious, a single wire antenna having a total length of from 75 to 100 feet, erected as high as possible, with a good insulator at each end, will prove satisfactory. The lead-in should go to the receiver by the most direct route and should be kept away, as far as possible, from obstructions. Such an antenna will have less directional properties and less tendency to pick up power line interference than a low antenna with a long horizontal lead.

THE FAIRBANKS-MORSE ANTENNA For those installations where a doublet type antenna is most suitable, FAIRBANKS-MORSE engineers offer the FAIRBANKS-MORSE MODEL 20 NOISE REDUCING ANTENNA SYSTEM. This antenna is especially designed for these receivers and requires no switching arrangement, since it automatically balances itself to the receiver on all bands.

The BLUE wire on the receiver is to be connected to the antenna. The BLACK wire on the receiver is to be connected to the ground. When a FAIRBANKS-MORSE ANTENNA is used, the BLUE wire from the receiver is to be connected to the red wire on the antenna set coupler and the BLACK wire from the receiver is to be connected to the black wire on the antenna set coupler and to a good ground.

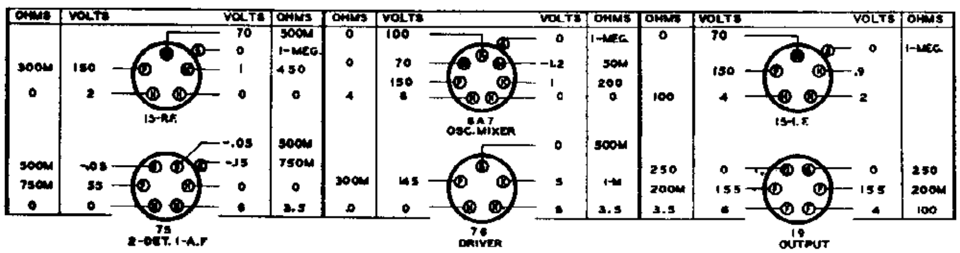
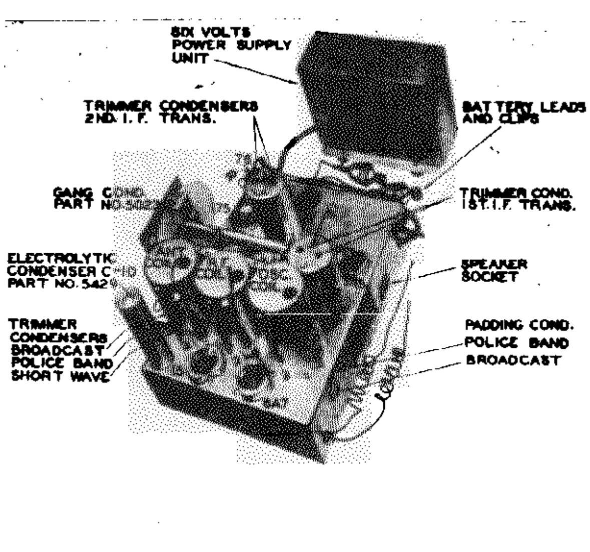
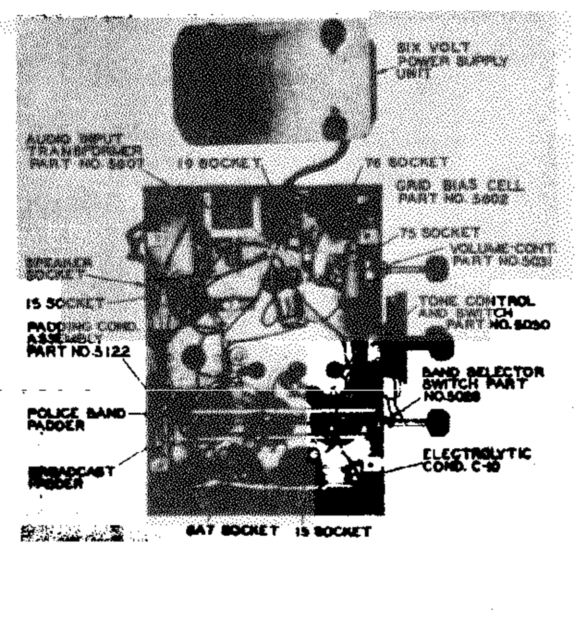
MODEL 67 (6 VOLT BATTERY) RADIO RECEIVER

NAME	No.
WIRING DIAGRAM FOR MODEL # 67	7522

FAIRBANKS MORSE HOME APPLIANCES, INC.







FAIRBANKS-MORSE HOME APP., INC.

MODEL 67

TUBES AND CIRCUIT

The information in this service manual covers the model 67, a 6 volt battery operated radio receiver chassis, with a self-contained "B" power supply unit. Many familiar design features that have proven their value over a period of years are combined in this chassis with the latest worthwhile developments of the radio industry and several new developments of the FAIRBANKS-MORSE laboratories.

The model 67 chassis employs a type 15 tube in the radio frequency amplifier stage. The incoming signal is fed to this tube through the antenna coil on each of the three bands. Through the use of this stage, high image and signal to noise ratios are maintained on all bands. Amplification and some selectivity are also realized from this stage.

A type 6A7 pentagrid converter is employed. This tube serves the dual function of first detector and oscillator. A type 15 tube is employed as the intermediate frequency amplifier. This tube and the two special intermediate frequency transformers are responsible for the exceptional selectivity and high gain obtained from the intermediate frequency amplifier.

A type 75 tube performs the triple function of diode detector, automatic volume control and first audio amplifier tube. The output of the triode section of the type 75 tube is resistance coupled to a type 76 tube, which drives a type 19 tube in a class "B" power output stage.

A full-wave synchronous type vibrator is employed in the power supply. This vibrator accomplishes the dual functions of interrupting the primary current and rectifying the secondary current. The power supply unit is housed in an individual container that is separate from the chassis and is connected to the chassis by means of a power supply cable.

AUTOMATIC VOLUME CONTROL

A type 75 tube is employed as the second detector in a half wave rectifier circuit, the diode plates being connected together. Current flows from the diode plates to the cathode and through resistors R-10 and R-11, through the secondary of the second intermediate frequency transformer, back to the plates, thus forming the complete circuit.

The D.C. component of this current produces a voltage drop across resistor R-10 in proportion to the strength of the incoming signal. The grid returns of the type 15 radio frequency amplifier, the type 6A7 pentagrid converter and the type 15 intermediate frequency amplifier are connected through the isolating resistors R-3, R-4 and R-9 to the point of juncture between resistors R-10 and R-11, thus adding the voltage drop obtained across resistor R-12 to the fixed bias on the three controlled tubes. The fixed bias is obtained from the individual bias resistors, R-1, R-17 and R-8, located in the cathode circuits of the tubes. Resistor R-10 is also the manual volume control. The audio component of voltage drop across this resistor is taken off on the sliding arm of the control through condenser C-24 and is applied to the grid of the triode section of the tube which serves as the first audio amplifier.

ALIGNMENT PROCEDURE

To insure obtaining the performance the model 67 is capable of delivering, it is essential that it be aligned perfectly. For this reason, it is urged that the following instructions be studied carefully before any alignment adjustments are attempted.

Proper adjustment of the various tuned circuits will only be possible through the use of an accurate and reliable signal generator employed in conjunction with an output meter, which may be connected, through a blocking condenser, from plate to ground on the output tube.

NOTE - All adjustments should be made with the volume control "full on". Any desired variation in signal strength should be obtained by adjusting the output of the signal generator.

INTERMEDIATE FREQUENCY ALIGNMENT

1 - Turn the gang condenser to maximum capacity (fully meshed).

2 - Supply a 456 kilocycle signal from the signal generator to the grid of the type 6A7 first detector tube through a .1 Mfd. condenser connected in series with the signal generator lead.

3 - Adjust the four trimmers of the two intermediate frequency transformers (see Figure 1) for maximum output with minimum input from the service oscillator.

RADIO FREQUENCY ALIGNMENT The parallel or high frequency trimmer condensers for each coil are housed in the same shield can with the coil. These trimmers are used for aligning the high frequency end of each band. The location of the various trimmers is shown in Figure 1.

The oscillator, adjustable, series padding condensers are used for tracking the oscillator at the low frequency end of each band. The padding condenser may be adjusted from the rear of the chassis through the holes indicated in Figure 1. Since a fixed mica padding condenser is employed on the short wave band, no adjustment is necessary. While making padding condenser adjustments, the gang condenser should be rotated back and forth across the signal to insure adjustments to the peak of greatest intensity.

BATTERY AND POWER SUPPLY

BATTERY A storage battery having a capacity of at least 135 ampere hours should be used with the receiver. The storage battery should be located as far from the chassis of the receiver as the battery cables will permit. Attach the long, red lead from the receiver to the positive (+) side of the storage battery. Attach the long, black lead from the receiver to the negative (-) side of the battery.

FUSE In case of difficulty, the fuse located in a metal cartridge near the end of the positive (red) battery lead should be checked. A 15 ampere fuse, FAIRBANKS-MORSE part number 5605, should be used for replacement purposes.

POWER SUPPLY UNIT The power supply unit contains all of the parts of the power supply circuit, including the vibrator. The power supply unit should be located as far from the receiver chassis as the length of the cable will permit. The power supply cable (the cable with a plug on its end) should be plugged into the socket on the side of the power supply unit.

The corrugated fibre container in which the power supply unit is packed is designed to reduce mechanical vibration and noise. For this reason, it should not be removed.

THE WINCHARGER The "Wincharger" is designed to eliminate battery charging difficulties by charging the battery continuously as long as a breeze of sufficient velocity is blowing. Service information concerning this unit must be obtained from the manufacturer, The Wincharger Corporation, 2700 Hawkeye Drive, Sioux City, Iowa.

5 - Tune the receiver to 1.8 megacycles.

6 - Supply a 1.8 megacycle signal to the receiver through the same connections used on the previous adjustment.

7 - Adjust the police band oscillator padding condenser (rear of chassis, see Figure 1) for maximum output with minimum input from the signal generator, at the same time rocking the tuning condenser back and forth across the signal to insure the peak of greatest intensity.

8 - Check at 5.4 megacycles and then at 1.8 megacycles and make any adjustments that are necessary to obtain satisfactory calibration.

SHORT WAVE BAND

1 - Turn the band selector switch to the short wave (clockwise) position.

2 - Tune the receiver to 18 megacycles.

3 - Supply an 18 megacycle signal from the signal generator to the antenna lead of the receiver through a 400 ohm carbon resistor (dummy antenna), connected in series with the signal generator lead.

4 - Turn the short wave antenna stage trimmer (see Figure 1) all the way in and then back it out one turn.

5 - Turn the short wave radio frequency stage trimmer (see Figure 1) all the way in and back it out one-half turn.

6 - Turn the short wave oscillator trimmer (see Figure 1) all the way in and back it out until the 18 megacycle signal from the signal generator is received. The first signal, found at about 17 megacycles, should be the image; the second, should be the 18 megacycle signal.

7 - Check and, if necessary, readjust all three stages for maximum output with minimum input from the signal generator.

WARNING - The image signal should be received at approximately 17 megacycles on the dial. If not, the oscillator has been aligned to the image frequency and the oscillator trimmer condenser must be backed out until the correct signal is received at 18 megacycles and the image at approximately 17 megacycles. If readjustment is found necessary, the antenna and radio frequency stage trimmers should also be checked again.

DIAL ADJUSTMENT Before making any alignment adjustments, close the variable tuning condenser (maximum capacity), loosen the screw that secures the dial pointer, place the pointer in a horizontal position (gang condenser still closed) and tighten the screw.

BROADCAST BAND

1 - Turn the band selector switch to the broadcast (counter-clockwise) position.

2 - Tune the receiver to 1500 kilocycles.

3 - Supply a 1500 kilocycle signal from the signal generator to the antenna lead of the receiver through a standard dummy antenna or a 200 Mmfd. (.0002 Mfd.) condenser, connected in series with the signal generator lead.

4 - Adjust the broadcast band oscillator trimmer condenser (Figure 1) for maximum output with minimum input from the signal generator. Then adjust the broadcast band radio frequency and antenna stage trimmers for maximum output.

5 - Tune the receiver to 600 kilocycles.

6 - Supply a 600 kilocycle signal to the antenna of the receiver through the same connections as previously used.

7 - Adjust the broadcast band oscillator padding condenser (rear of chassis, see Figure 2) for maximum output with minimum input from the signal generator, at the same time rocking the tuning condenser back and forth across the signal to insure the peak of greatest intensity.

8 - Check at 1500 kilocycles and then at 600 kilocycles. Make any adjustments that are necessary to obtain satisfactory calibration.

POLICE BAND

1 - Turn the band selector switch to the police band (center) position.

2 - Tune the receiver to 5.4 megacycles.

3 - Supply a 5.4 megacycle signal from the signal generator to the antenna lead of the receiver through a 400 ohm carbon resistor (dummy antenna), connected in series with the signal generator lead.

4 - Adjust the police band oscillator trimmer condenser (Figure 1) for maximum ouput with minimum input from the signal generator, then adjust the police band radio frequency and antenna stage trimmers for maximum output.

ANTENNA AND GROUND CONNECTIONS

The BLUE wire on the receiver is to be connected to the antenna. The BLACK wire on the receiver is to be connected to the ground. When a FAIRBANKS-MORSE ANTENNA is used, the BLUE wire from the receiver is to be connected to the red wire on the antenna set coupler and the BLACK wire from the receiver is to be connected to the black wire on the antenna set coupler and to a good ground.

NOTE - The antenna lead-in should be placed so as to avoid running close to the battery, power supply unit or the cables to avoid pickup from the power supply unit.

MODEL 82

MODEL 82
MODEL 90
Alignment,
Oscillograph Notes

FAIRBANKS-MORSE HOME APP., INC.

MODEL 82 AND 90

ALIGNMENT PROCEDURE

To insure obtaining the performance the models 82 and 90 are capable of delivering, it is essential that they be aligned perfectly. For this reason, it is urged that the following instructions be studied carefully before any aligment adjustments are attempted.

Proper adjustment of the various tuned circuits will only be possible through the use of an accurate and reliable signal generator employed in conjunction with an output meter connected across the voice coil leads of the speaker. In the adjustment of the third intermediate frequency transformer, it is recommended that a cathode ray oscillograph be used for most accurate results.

With the receiver operating on the "Sharp" position, the intermediate frequency amplifier resonance curve will appear on the screen. When the receiver is switched to the "3RD DIMENSION" position, symetrical double humps, approaching a wide flat top resonance curve, should appear in place of the "Sharp" resonance curve (see Figure 10). Each side of the curve should be of equal amplitude. If this is not the case, the trimmers of the third intermediate frequency transformer should be adjusted until the proper curve is obtained. The adjustment of one trimmer, in addition to effecting its own side of the curve, will reflect in the other side and, for this reason, great care must be exercised in making these adjustments.

R.F. ALIGNMENT The parallel or high frequency trimmer condensers for each coil are housed in the same can with the coil. These trimmers are used for aligning the high frequency end of each band. The location of the various coils and their respective trimmers is shown on Figure 8. It is essential that the bands be aligned in the order they appear in the following instructions. In other words, the police band alignment must be completed before the broadcast band alignment is started because of the interlocking effect of the padding condensers on these bands.

Adjustable series padding condensers are used for tracking the oscillator at the low frequency end of each band. The padding condensers may be adjusted from the top of the chassis, through the holes indicated in Figure 8. Since a fixed mica padding condenser is employed on the short wave band, no adjustment is necessary. While making padding condenser adjustments, the gang condenser should be rotated back and forth across the signal to insure adjustment to the peak of greatest intensity.

NOTE: All adjustments, unless otherwise noted, should be made with the volume control "Full on". Any desired variation in signal strength should be obtained by adjusting the output of the signal generator.

INTERMEDIATE FREQUENCY ALIGNMENT With the range switch on the broadcast position, the fidelity switch on "Sharp" (clockwise) and the gang condenser closed (maximum capacity), supply a 455 kilocycle signal, stage by stage, to the intermediate frequency amplifier, beginning with the grid of the second intermediate frequency tube. To accomplish this, a .1 Mfd. condenser should be connected between the signal generator supply lead and the second intermediate frequency tube.

The trimmers of the third intermediate frequency transformer (Figure 8) should be adjusted for maximum output with minimum input from the signal generator. Then the signal generator lead should be moved to the first intermediate frequency tube and the trimmers of the second intermediate transformer should be adjusted. The next step is to supply the signal to the grid of the first detector tube and adjust the trimmers of the first intermediate frequency transformer. This method of procedure is essential because of the extreme selectivity of the receiver. After each stage has been aligned, it is well to go back over all adjustments to make sure they are accurate.

The next step in the intermediate frequency alignment is to supply a very strong (about 1000 microvolt) signal to the grid of the first detector tube through the .1 Mfd. condenser. CAUTION: Before the signal is applied to the receiver, the volume control should be retarded to zero. After the signal is applied to the receiver, the volume control should be advanced slowly and carefully until a suitable indication appears on the output meter.

The fidelity switch should be turned to the high fidelity or Third Dimension position. Symetrical double humps should appear, one on each side of where the sharp resonance point appeared on the "Sharp" position (see Figure 10), when the signal generator is tuned approximately 8 kilocycles on each side of the resonance point. The two humps must be of equal amplitude. If this is not the case, the trimmers of the third intermediate frequency transformer must be adjusted until a condition of equal amplitude is obtained. This may be found to be a very difficult adjustment unless an oscillograph is used.

USE OF THE OSCILLOGRAPH A signal generator with a sweep circuit must be employed in making this check. The output of the signal generator should be fed to the grid of the first detector tube in the receiver. The grid clip must be removed from the tube, but, since the first detector is one of the A.V.C. controlled tubes, it is necessary to complete the grid circuit. To accomplish this, connect a large resistor (about 50,000 or 100,000 ohms) between the grid clip and the grid cap of the tube. The low side of the signal generator should be connected to the chassis ground.

The "vertical" binding posts of the oscillograph should be connected to the audio output of the second detector. In the model 82, a type 85 tube serves as a diode rectifier and, in the model 90, a type 6H6 tube is employed. In both of these circuits, R-21 is the manual volume control resistor. The high side connection from the "vertical" plates should be made to the point of juncture between resistors R-21 and R-13. The low side connection may be made to ground. Thus, the audio voltage is applied to the "vertical" plates of the oscillograph.

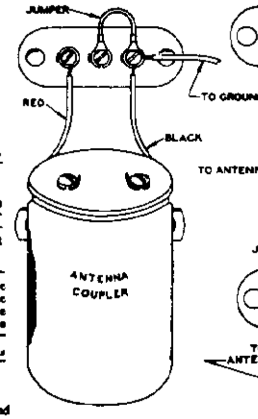

FIGURE 4

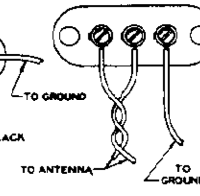

FIGURE 5

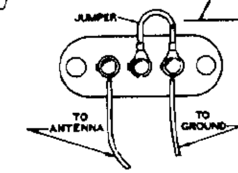

FIGURE 6

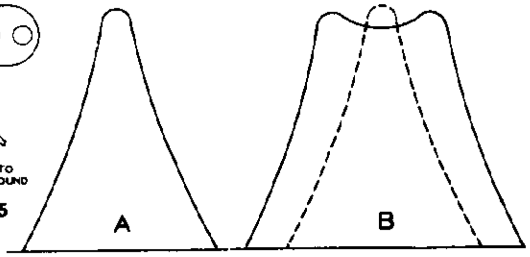

FIGURE 10

ALIGNMENT PROCEDURE (CONTINUED)

POLICE BAND (1.7 to 5.5 Megacycles) With the band selector switch in the police or "P" position and the fidelity switch on the "Sharp" position, supply a 5 megacycle signal from the signal generator to the antenna of the receiver, using a 400 ohm carbon resistor in series with the signal generator lead. Tune the receiver to 5 megacycles and then adjust the oscillator, radio frequency and antenna stage police band trimmers for maximum output with minimum input from the signal generator. WARNING: Care must be exercised to avoid aligning the receiver to the image frequency as outlined under "short wave band".

Supply a 1.8 megacycle signal to the receiver and tune the receiver to 1.8 megacycles. Adjust the police band oscillator padding condenser (located on the chassis at the rear, (see Figure 8) for the signal of greatest intensity, rocking the gang condenser back and forth across the signal while making the adjustment. Check at 5 megacycles and then at 1.8 megacycles to correct for any frequency change.

BROADCAST BAND (540 to 1740 kilocycles) With the band selector switch on the broadcast or "B" position, supply a 1500 kilocycle signal from the signal generator to the receiver, using a standard dummy antenna or a 200 Mmfd. condenser in series between the signal generator and the antenna post of the receiver to serve as the dummy antenna. Make certain that the fidelity switch is on the "Sharp" position.

Tune the receiver to 1500 kilocycles and adjust the radio frequency, antenna and oscillator stage broadcast band trimmers for maximum output with minimum input from the signal generator.

Supply a 600 kilocycle signal to the receiver through the same connections. Tune the receiver to 600 kilocycles. Adjust the broadcast band oscillator padding condenser (located on the chassis at the rear, (see Figure 8) for the peak of greatest intensity while rocking the tuning condenser back and forth across the signal. Recheck at 1500 kilocycles and then at 600 kilocycles and make any frequency corrections that appear necessary.

LONG WAVE BAND (140 to 360 kilocycles) With the band selector switch on the long wave or "L" position, supply a 350 kilocycle signal from the signal generator to the antenna of the receiver, using a standard dummy antenna or a 200 Mmfd. condenser in series with the lead. Make sure the fidelity switch is on the "Sharp" position. Tune the receiver to 350 kilocycles and adjust the oscillator, radio frequency and antenna stage trimmer condensers for maximum output with minimum input from the signal generator.

Supply a 175 kilocycle signal to the receiver through the same connections used in the previous adjustment. Tune the receiver to 175 kilocycles. Adjust the long wave oscillator padding condenser for the peak of greatest intensity while rocking the tuning condenser back and forth across the signal. Readjust at 350 kilocycles and then at 175 kilocycles as many times as may be necessary to obtain satisfactory tracking.

SHORT WAVE BAND (5.5 to 18.4 Megacycles) Turn the band selector switch to the short wave or "S" position. Supply an 18 megacycle signal from the signal generator through a 400 ohm carbon resistor (dummy antenna) to the antenna post of the receiver. Tune the receiver to 18 megacycles on the dial. Turn the short wave R.F. trimmer in all the way and then back it out one-half turn. Turn the short wave oscillator trimmer in all the way and then back it out until the 18 megacycle signal (the first signal found at about 17 megacycles should be the image; the second, should be the 18 megacycle signal) from the signal generator is received. Readjust all three short wave trimmers for maximum output with minimum input from the signal generator.

WARNING: The image signal should be received at approximately 17 megacycles after the above adjustments have been made. If it cannot be located, the oscillator has probably been aligned to the image frequency and the oscillator trimmer must be backed out until the proper signal comes in at 18 megacycles and the somewhat weaker image is received at approximately 17 megacycles. If this readjustment is necessary, it will also be necessary to again align all three trimmers for maximum output.

GANG CONDENSER PLATES The adjustment of the various plates of the gang condenser is very critical, since it must be accurate on all bands. These adjustments are made in the factory with precision equipment and under no condition should it be necessary to change them by bending plates.

FAIRBANKS-MORSE HOME APP., INC.

MODEL 82 AND 90 RADIO RECEIVER

ANTENNA AND GROUND CONNECTIONS

FAIRBANKS-MORSE ANTENNA A set coupling transformer or coil is supplied with the FAIRBANKS-MORSE antenna kit. This coupler is to be attached to the radio cabinet directly to the rear of the antenna terminals on the chassis. The red lead from the coupler is to be connected to the antenna terminals on the rear of the receiver chassis. The black lead from the coupler is to be attached to the ground terminal on the rear of the receiver chassis. (When the chassis is viewed from the rear, the left hand terminal is Antenna and the right hand terminal is Ground). The connector link or jumper must remain between the center terminal and the ground terminal of the terminal strip (see Figure 4).

ORDINARY DOUBLET ANTENNA When a doublet type of antenna that does not employ coupling transformers is to be used on the receiver, the connector link or jumper should be removed from between the ground terminal and the center terminal on the rear of the chassis. The transmission lines or lead-in wires from the antenna should be connected to the left hand terminal and the center terminal of the terminal strip. The right hand terminal should be used for the ground connection (see Figure 5).

ORDINARY ANTENNA When an ordinary single wire antenna is to be used on the receiver, the antenna lead-in wire should be connected to the left hand terminal on the terminal strip on the rear of the chassis. The connector link or jumper must remain between the center terminal and the ground terminal of the terminal strip (see Figure 6). As a rule, it is a good policy to erect the antenna as high as possible and run the lead-in to the receiver by as direct a route as possible. The most satisfactory antenna for any installation will vary, depending largely upon local structural details and sources of interference. It should be kept as far as possible from buildings, trees and other obstructions. The antenna should not run parallel to nearby power lines and should not run near a tin roof or any metallic structure.

In general, the longer the antenna, the better the results will be on distant stations, especially if the flat portion of the antenna is erected as high as possible. When conditions permit, we recommend an antenna between 75 and 100 feet in length, including the lead-in, and at least 30 feet high.

GROUND CONNECTIONS The ground lead is to be connected to the right hand terminal on the terminal strip located on the rear of the chassis (see Figure 4 and 5).

Since the ground is an essential part of the installation, care must be exercised to see that a good ground is obtained with any type of antenna. In many installations, a satisfactory ground can be made by connecting to a nearby cold water pipe by means of an approved ground clamp. The pipe to which the connection is made should be cleaned thoroughly and scraped or filed bright at the point where the connection is to be made. If no other suitable ground is available, a length of galvanized iron pipe or a ground rod may be driven into moist earth. This usually proves to be a very satisfactory ground.

INTERFERENCE AND THE ANTENNA

The results obtainable from these radio receivers can be no better than the antennae. In order to enjoy the full advantage of 3RD DIMENSION TONE, the background noises ordinarily heard in a radio receiver must be reduced to a minimum. A high order of sensitivity has been incorporated in these radio receivers so that weak, distant stations may be readily tuned in. This also makes the receiver sensitive to such local interference as is given off by vacuum cleaners, door bells, oil burners, elevators and all sorts of small appliances.

It has been found that most of this man-made static travels close to the ground and is picked up on the lead-in of the average antenna. It follows then that, if an antenna could be developed with a special lead-in arrangement that would reject this interference, it would give far better and more noise-free reception than has been possible before.

THE FAIRBANKS-MORSE ANTENNA FAIRBANKS-MORSE engineers offer you just such an antenna as is described in the previous paragraph and, in addition, the FAIRBANKS-MORSE MODEL 20 NOISE REDUCING ANTENNA SYSTEM is especially designed to match the sensitive antenna circuit in these receivers. This assures maximum performance on all wave bands and without the necessity of switching the antenna from band to band, since, through ingenious design, this antenna system automatically balances itself to the receiver on any band. In addition to these features, the antenna is designed to eliminate dead spots and is of the proper length to give maximum results on all wave bands.

THIRD DIMENSION TONE

THIRD DIMENSION TONE is FAIRBANKS-MORSE'S improved high fidelity reproduction. THIRD DIMENSION TONE is designed to bring in a program just as it is rendered before the microphone in the broadcasting station studio. High notes that are not heard on a conventional radio come in with marvelous clearness, giving depth to music.

THIRD DIMENSION TONE is natural, unadulterated quality. It puts nothing into a program that does not exist in the original broadcast. If overtones have been lost in making a radio transcription, in transmission over a broadcast chain, or if the studio or transmitter do not broadcast them, THIRD DIMENSION TONE will not restore the missing musical elements. When listening to programs in which certain notes are missing, little difference will be noted when the switch is turned to the Third Dimension position. However, when the studio program and transmitter are of high quality and when the receiver is located reasonably close to them, the Third Dimension switch will open up a new world of radio realism.

FEATURES The special construction of the audio input transformer and the audio frequency equalizer circuit, both special THIRD DIMENSION TONE features, have been discussed in other paragraphs, but there is still one more outstanding feature that contributes much to make THIRD DIMENSION TONE outstanding over ordinary high fidelity.

In high fidelity transmission, a much wider band is required than has been the case with conventional transmitters in the past. In some cases, a band 30 kilocycles wide is employed, as compared to 10 kilocycles for ordinary transmission. It becomes evident then, that in order to enjoy the advantages of high fidelity transmission, the receiver must accept a band as wide as that being used by the transmitter. However, because only few stations operate high fidelity transmitters as yet and because the number of high quality regular stations is limited, it is necessary to employ an arrangement whereby the receiver may be switched from high fidelity to regular reception or, in other words, from a broad to a selective Intermediate Frequency channel at the will of the operator.

I.F. COUPLING CIRCUIT There are numerous ways in which the coupling in the intermediate frequency transformers can be varied to change from a selective to a broad circuit. However, to do this without detuning the receiver is a difficult engineering problem. FAIRBANKS-MORSE engineers have developed special first and second intermediate frequency transformers in which the primaries and secondaries are made up of multiple windings and connected in conjunction with a switch so the selectivity may be changed from sharp to broad at will without detuning the receiver.

The secondary of each intermediate frequency transformer is composed of three sections, the upper, center and lower (see Figures 1 and 2). The primary is composed of two sections, the upper and lower. The upper sections of the primary and secondary are loosely coupled to each other and constitute the major portion of the primary and secondary inductance respectively. The lower section of the primary and the center section of the secondary are tightly coupled. The coupling between the lower section of the secondary and the primary is loose. When the switch is on the Third Dimension position, the lower section of the secondary is out of the circuit and the secondary winding is made up of the other two windings, connected in series. Because the coupling between the lower section of the primary and the center section of the secondary is tight, a broad response will result.

When the switch is on the "Sharp" position, the center section of the secondary is cut out of the circuit and the loosely coupled lower section is substituted, thus the selectivity is increased the desired amount. Since the inductance of the center section and the lower section of the secondary are identical, the tuning is not altered when switching from the "Sharp" to the Third Dimension position. Because of this very practical and unique design, it is possible to arrange the tuning indicator circuit in such a manner that it is only engaged on the "Sharp" position of the switch. This serves to remind the operator that all tuning should be done on the "Sharp" setting to insure perfect resonance and most faithful reproduction.

Alignment Procedure

Models C-6, 64 and 74

General - When making alignment adjustments, the chassis should be placed in a metal case, similar to the regular set case, having suitable holes to make the various trimmers accessible. All adjustments should be made with the volume control advanced to maximum. An output meter and an accurate service oscillator should be used in making all adjustments.

I-F. Alignment - Supply a 177.5 kc. signal from a reliable service oscillator to the grid of the type 6A7 tube through a 200 mmfd. condenser. Set the gang condenser to 1000 kc. Align the four intermediate frequency trimmer condensers for maximum output with minimum input from the service oscillator. The two intermediate frequency transformers are housed in the square cans at the rear and on top of the chassis. The trimmer condensers are accessible through the two round holes in the top of each of these cans. After these adjustments have been made, the trimmers should all be checked again to make sure that the correct peaks have been obtained.

R-F., Oscillator and Antenna Alignment - Set the gang condenser at 1400 kc. Supply a 1400 kc. signal from a reliable service oscillator to the front antenna connector at the left side of the chassis, through a 200 mmfd. condenser. This connection should be made through the standard length of shielded antenna lead-in as supplied with the receiver.

The oscillator high frequency trimmer condenser should be adjusted for maximum output with minimum input from the service oscillator. The oscillator trimmer condenser is located on the rear section of the gang condenser. The r-f. trimmer condenser should next be adjusted in the same manner. This trimmer is located on the center section of the gang condenser. The antenna trimmer is located on the front section of the gang condenser and should be adjusted in the same manner.

Oscillator Padding Condenser Adjustment - Set the gang condenser to 600 kc. Supply a 600 kc. signal to the antenna of the set in the same manner as described in the previous paragraph. Adjust the low frequency padding condenser for maximum output with minimum input from the service oscillator, at the same time rocking the gang condenser back and forth across the signal to make sure the peak of greatest intensity is obtained. The low frequency padding condenser is located at the rear of the left side of the chassis.

Note - After these adjustments have been made, the set should be checked at 1400 kc. to make sure the correct alignment still exists. If not, the oscillator, r-f. and antenna adjustments, as well as the padding condenser adjustments, must be repeated.

MODEL 90
Circuit and AVC Data

FAIRBANKS-MORSE HOME APP., INC.

Tuning Indicator Transformer Notes

TUBES AND CIRCUIT

MODEL 82 CHASSIS The model 82 chassis employs a type 6D6 tube in the radio frequency amplifier stage. The incoming signal is fed to this tube through the antenna coil on each of the four bands. Through the use of this stage, high image and signal to noise ratios are maintained on all bands. Amplification and some selectivity are also realized in this stage.

A type 6A7 pentagrid converter is employed. This tube serves the dual function of first detector and oscillator. The oscillator section of the tube, on all but the long wave band, is connected to a MacNabb constant voltage oscillator circuit. Through the use of both inductive and capacitive coupling, the output of the oscillator remains at a uniform level over the entire frequency range of the band in use. On the long wave band, the oscillator tube works easily and with fairly constant intensity on all frequencies and, for this reason, only capacitive coupling is employed.

Two type 6D6 tubes serve as intermediate frequency amplifiers. These tubes, together with the three intermediate frequency transformers, comprise the I.F. amplifier. Here most of the gain and selectivity of the receiver is realized.

A type 85 tube, connected as a diode, performs the triple function of second detector, automatic volume control and first audio amplifier tube. The output of this tube is coupled to two type 42 tubes, connected as pentodes, in a class "A" output stage. The input transformer is of special design, being wound for low leakage inductance, which makes for high efficiency, high fidelity reproduction. Condenser C-23 and resistor R-22 comprise an audio frequency equaliser circuit connected across the primary of the output transformer. A type 80 full wave rectifier tube is employed in a conventional power supply circuit.

MODEL 90 CHASSIS The model 90 chassis employs a type 6K7 tube in the radio frequency amplifier stage. The pentagrid converter in this chassis is a type 6A8 tube. Two type 6K7 tubes are used in the intermediate frequency amplifier. A type 6H6 diode performs the dual function of second detector and automatic volume control tube. No gain is obtained from this stage and, as a results, a type 6C5 tube is employed as the first audio amplifier, driving two type 6F6 tubes, connected as pentodes, in a class "A" power output stage. In the power supply section, a type 5Z4 tube is connected as a full wave rectifier in a conventional power supply circuit.

AUTOMATIC VOLUME CONTROL

MODEL 90 CHASSIS A type 6H6 tube is employed to perform the dual function of second detector and delayed automatic volume control. In the diode section of this tube, one plate is used for the audio signal, while the other plate is used for A.V.C. The R.F., first detector and first I.F. tubes have a fixed minimum bias applied to their grids, which is obtained from the separate bias resistors (R-1, R-2 and R-9) located in the cathode circuits of the respective tubes. An R.F. voltage is applied to the A.V.C. diode plate from the secondary of the third I.F. transformer, through condenser C-16, is rectified and, in so doing, current flows from the plate to the cathode and to ground, where it is picked up at the point where R-11 is grounded, flows through R-11 and back to the plate, thus forming the complete circuit. This current flow creates a voltage drop across resistor R-11 that is in proportion to the strength of the incoming signal. This voltage is applied to the grids of the controlled tubes, through isolating resistors R-3, R-4 and R-10, and is added to the fixed bias on the tubes, thus producing automatic volume control.

Two resistors (R-16 and R-17) are located between the cathode of the 6H6 tube and ground. The cathode of the 6C5 first audio amplifier is also connected to ground through these resistors, thus the plate current of the 6C5 flows through resistors R-16 and R-17, producing a voltage drop. Half of this drop is applied to the grid of the 6C5, through resistor R-20 and serves as a grid bias. The total drop is applied to the A.V.C. diode plate, thereby biasing it negatively about 10 volts and producing A.V.C. delay.

An R.F. voltage is also applied to the second diode plate from the secondary of the third I.F. transformer. Current flows from the plate to cathode, through resistors R-21 and R-13, through the secondary of the I.F. transformer, back to the plate. This current produces an audio voltage across resistor R-21, the manual volume control. This voltage is taken off through condenser C-19 and is applied to the grid of the first audio amplifier tube. Resistor R-13 and condenser C-17 and C-18 comprise a "tweet" filter circuit.

MODEL 82 CHASSIS The A.V.C. circuit and its operation in the model 82 chassis is identical to that in the model 90. The only differences are in the tubes. In the model 82 chassis, a type 85 tube performs the triple function of diode detector, automatic volume control and first audio amplifier. The connections to the triode section of this tube are the same as those of the type 6C5 tube in the case of the model 90.

TUNING INDICATORS

THE SHADOW LINE TUNING INDICATOR On all model 82 and on some model 90 chassis, the tuning indicator is of the magnetic type, operating a vane in such a manner as to cast a shadow of variable width on the upper portion of the dial. When the shadow is contracted to its narrowest possible dimension, the receiver is properly tuned. This indicator is connected into the circuit as indicated on the schematic diagrams, Figures 1 and 2. It will be noted that the tuning indicator is only in the circuit when the 3rd Dimension switch is on the "Sharp" position. This is intended to encourage tuning only on the "Sharp" position.

The 6E5 is a high vacuum, heater cathode type of cathode ray tube, designed to indicate visually the effect of change in the controlling voltage. The tube, therefore, is a voltage indicator. The visible effect is observed on a flourescent target located in the dome of the bulb. For different controlling voltages, the pattern of the target varies through a shaded angle from 90 degrees to approximately 0 degrees. Exact tuning is indicated by the narrowest shaded angle obtainable.

In the type 6E5, the cathode provides a source of electrons. These are attracted to the prositively-charged target (T), (see Figure 3). Electrons impinging on the coated target cause it to glow. The extent of flourescent area is controlled by means of the "ray-control electrode", which is an extension of the triode plate (P). The voltage on the ray-control electrode is determined by the voltage applied to the grid (G) of the triode. This voltage is obtained by tapping the A.V.C. circuit between resistors R-10 and R-11 by means of a voltage divider network consisting of two 1 megohm resistors, R-24 and R-25, connected in series to ground. Through this arrangement, the grid of the 6E5 tube has half of the control voltage applied to it. The target is connected to the high voltage supply at the same point where the first intermediate frequency tube "B" supply lead is connected.

A series resistor R-26 is connected between the triode plate and the high voltage supply. The effect of the series resistor is to reduce the voltage applied to the triode plate and, consequently, to the ray-control electrode, under conditions of decreased triode grid bias (increased triode plate current). Under these conditions, the flourescent area on the target will become wider. For conditions of increasing triode grid bias (decreasing triode-plate current), the triode plate voltage increases and approaches the value of the supply voltage. Under these conditions, the flourescent area on the target will beden narrower, indicating that the receiver is approaching the resonance point.

The 6E5 is so connected that it operates only when the receiver is switched to "Sharp". When the receiver is switched to "3rd DIMENSION", the grid circuit is grounded, thus rendering the tube inoperative. A condenser C-31 is connected as a filter from the point of juncture between resistors R-24 and R-25 to ground, thus preventing audio voltage from entering the tube.

THE CATHODE RAY TUNING INDICATOR On some model 90 chassis, an electron ray or cathode ray tube tuning indicator, known as the 6E5, is employed. The connections for this tube are shown in Figure 3.

Tuning Indicator Notes

MODEL 100 and 110

TUBES AND CIRCUIT

MODEL 100 CHASSIS The model 100 chassis employs a type 6D6 tube in the radio frequency amplifier stage. The incoming signal is fed to this tube through the antenna coil on each of the four bands. Through the use of this stage, high image and signal to noise ratios are maintained on all bands. Amplification and some selectivity are also realized in this stage.

A type 6A7 pentagrid converter is employed. This tube serves the dual function of first detector and oscillator. The oscillator section of the tube, on all but the long wave band, is connected to a MacNabb constant voltage oscillator circuit. Through the use of both inductive and capacitive coupling, the output of the oscillator remains at a uniform level over the entire frequency range of the band in use. On the long wave band, the oscillator tube works easily and with fairly constant intensity on all frequencies and, for this reason, only capacitive coupling is employed.

Two type 6D6 tubes serve as intermediate frequency amplifiers. These tubes, together with the three intermediate frequency transformers, comprise the I.F. amplifier. Here most of the gain and selectivity of the receiver is realized.

A type 76 tube, connected as a diode, performs the dual function of second detector and automatic volume control tube. Since no gain is obtained from this stage, the output is resistance coupled to another type 76 tube that serves as an audio amplifier. The output of this tube is, in turn, resistance coupled to a type 42 tube, connected as a triode, driving two type 2A3 tubes in a class "A" output stage.

The input transformer is of special design, being wound for low leakage inductance, which makes for high efficiency high fidelity reproduction. Condenser C-22 and Resistor R-25 comprise an audio frequency equalizer circuit connected across the secondary of the input transformer. A type 5Z3 full wave rectifier tube is employed in a conventional power supply circuit.

MODEL 110 CHASSIS The model 110 chassis employs a type 6K7 tube in the radio frequency amplifier stage. The pentagrid converter in this chassis is a type 6A8 tube. Two type 6K7 tubes are used in the intermediate frequency amplifier. A type 6H6 diode, connected as a half wave rectifier, performs the dual function of second detector and automatic volume control tube. As in the case of the type 76 tube in the model 100 chassis, no gain is obtained from this stage and, as a result, a type 6C5 tube is employed as the first audio amplifier. A type 6F6 tube, connected as a triode, is the second audio frequency amplifier, driving two type 2A3 tubes in a class "A" power output stage.

In the power supply section, two type 5Z4 tubes, each connected as a half wave rectifier, are employed in a full wave rectifier circuit. By connecting the rectifier tubes in this manner, the drain on each tube is reduced, thus lessening the possibility of difficulty and assuring better regulation than if only one rectifier were used to supply the entire current requirements of the receiver.

TUNING INDICATORS

THE SHADOW LINE TUNING INDICATOR On all model 100 and on some model 110 chassis, the tuning indicator is of the magnetic type, operating a vane in such a manner as to cast a shadow of variable width on the upper portion of the dial. When the shadow is contracted to its narrowest possible dimension, the receiver is properly tuned. This indicator is connected into the circuit as indicated on the schematic diagrams, Figures 1 and 2. It will be noted that the tuning indicator is only in the circuit when the 3rd Dimension switch is on the "Sharp" position. This is intended to encourage tuning only on the "Sharp" position.

THE CATHODE RAY TUNING INDICATOR On some model 110 chassis, an electron ray or cathode ray tube tuning indicator, known as the 6E5, is employed. The connections for this tube are shown in Figure 3.

The 6E5 is a high vacuum, heater cathode type of cathode ray tube, designed to indicate visually the effect of change in the controlling voltage. The tube, therefore, is a voltage indicator. The visible effect is observed on a flourescent target located in the dome of the bulb. For different controlling voltages, the pattern of the target varies through a shaded angle from 90 degrees to approximately 0 degrees. Exact tuning is indicated by the narrowest shaded angle obtainable.

In the type 6E5, the cathode provides a source of electrons. These are attracted to the positively-charged target (T), (see Figure 3). Electrons impinging on the coated target cause it to glow. The extent of flourescent area is controlled by means of the "ray-control electrode", which is an extension of the triode plate (P). The voltage on the ray-control electrode is determined by the voltage applied to the grid (G) of the triode. This voltage is obtained by tapping the A.V.C. circuit between resistors R-16 and R-17 by means of a voltage divider network consisting of two 1 megohm resistors (R-26 and R-27) connected in series to ground. Through this arrangement, the grid of the 6E5 tube has half of the control voltage applied to it. The target is connected to the high voltage supply at the same point where the first intermediate frequency tube "B" supply lead is connected.

A series resistor R-28 is connected between the triode plate and the high voltage supply. The effect of the series resistor is to reduce the voltage applied to the triode plate and, consequently, to the ray-control electrode, under conditions of decreased triode grid bias (increased triode plate current). Under these conditions, the flourescent area on the target will become wider. For conditions of increasing triode grid bias (decreasing triode-plate current), the triode plate voltage increases and approaches the value of the supply voltage. Under these conditions, the flourescent area on the target will become narrower, indicating that the receiver is approaching the resonance point.

The 6E5 is so connected that it operates only when the receiver is switched to "Sharp". When the receiver is switched to "3rd DIMENSION", the grid circuit is grounded, thus rendering the tube inoperative. A condenser C-31 is connected as a filter from the point of juncture between resistors R-26 and R-27 to ground, thus preventing audio voltage from entering the tube.

LONG WAVE BAND (140 to 360 Kilocycles) With the band selector switch on the long wave or "L" position, supply a 350 kilocycle signal from the signal generator to the antenna of the receiver, using a standard dummy antenna, or a 200 Mmfd. condenser in series with the lead. Make sure the fidelity switch is on the "Sharp" position. Tune the receiver to 350 kilocycles and adjust the oscillator, radio frequency and antenna stage trimmer condensers for maximum output with minimum input from the signal generator.

Supply a 175 kilocycle signal to the receiver through the same connections used in the previous adjustment. Tune the receiver to 175 kilocycles. Adjust the long wave oscillator padding condenser for the peak of greatest intensity while rocking the tuning condenser back and forth across the signal. Readjust at 350 kilocycles and then at 175 kilocycles as many times as may be necessary to obtain satisfactory tracking.

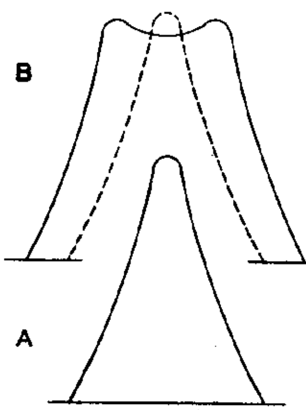
SHORT WAVE BAND (5.5 to 18.4 Megacycles) Turn the band selector switch to the short wave or "S" position. Supply an 18 megacycle signal from the signal generator through a 400 ohm carbon resistor (dummy antenna) to the antenna post of the receiver. Tune the receiver to 18 megacycles on the dial. Turn the short wave R.F. trimmer in all the way and then back it out one-half turn. Turn the short wave oscillator trimmer in all the way and then back it out until the 18 megacycle signal (the first signal found at about 17 megacycles should be the image; the second, should be the 18 megacycle signal) from the signal generator is received. Readjust all three short wave trimmers for maximum output with minimum input from the signal generator.

WARNING: The image signal should be received at approximately 17 megacycles after the above adjustments have been made. If it cannot be located, the oscillator has probably been aligned to the image frequency and the oscillator trimmer must be backed out until the proper signal comes in at 18 megacycles and the somewhat weaker image is received at approximately 17 megacycles. If this readjustment is necessary, it will also be necessary to again align all three trimmers for maximum output.

GANG CONDENSER PLATES The adjustment of the various plates of the gang condenser is very critical, since it must be accurate on all bands. These adjustments are made in the factory with precision equipment and under no condition should it be necessary to change them by bending plates.

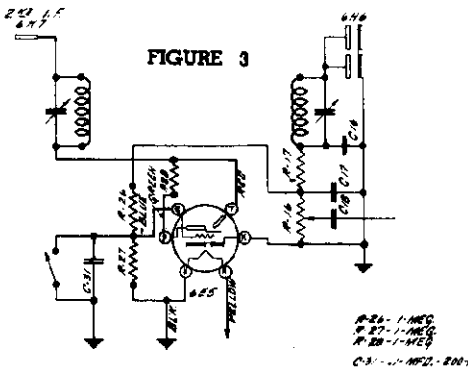
B

A



SELECTIVITY CURVES
FIGURE 13

FIGURE 3



CATHODE RAY TUNING INDICATOR USED ON MODEL 110

AUTOMATIC VOLUME CONTROL

MODEL 110 CHASSIS A type 6H6 tube is employed as the second detector in a half wave rectifier circuit, the diode plates being connected together. Current flows from the diode plates to the cathode and to ground. Here it is picked up at the point where resistor R-16 is grounded and flows through resistors R-16 and R-17, through the secondary of the third intermediate frequency transformer back to the plates, thus forming the complete circuit.

The DC component of this current produces a voltage drop across resistor R-16 in proportion to the strength of the incoming signal. The grid returns of the 6K7 radio frequency amplifier, the 6A8 pentagrid converter and the 6K7 first intermediate frequency amplifier are connected, through the isolating resistors R-6, R-7 and R-15, to the point of juncture between resistors R-16 and R-17, thus adding the voltage drop obtained across resistor R-16 to the fixed bias on the three controlled tubes. The fixed bias is obtained from the individual bias resistors R-2, R-4 and R-11, located in the cathode circuits of the tubes. Resistor R-16 is also the manual volume control. The audio component of the voltage drop across this resistor is taken off on the sliding arm of the control through condenser C-18 and is applied to the grid of the 6C5 audio amplifier tube.

MODEL 100 CHASSIS The A.V.C. circuit and its operation in the model 100 chassis is identical to that in the model 110. The only differences are in the tubes. A type 76 tube is employed as the diode rectifier in place of the 6H6. A type 76 tube is also used as the first audio amplifier in place of the 6C5 metal tube. Type 6D6 tubes will be found in place of type 6K7 tubes in the radio frequency and intermediate frequency amplifier stages. A 6A7 pentagrid converter replaces the 6A8 found in the model 110.

MODEL 100
MODEL 110
Alignment, Trap, Transformer Data

FAIRBANKS-MORSE HOME APP., INC.

ALIGNMENT PROCEDURE

To insure obtaining the performance the models 100 and 110 are capable of delivering, it is essential that they be aligned perfectly. For this reason, it is urged that the following instructions be studied carefully before any alignment adjustments are attempted.

Proper adjustment of the various tuned circuits will only be possible through the use of an accurate and reliable signal generator employed in conjunction with an output meter connected across the voice coil leads of the speaker. In the adjustment of the third intermediate frequency transformer, it is recommended that a cathode ray oscillograph be used for most accurate results.

NOTE: All adjustments, unless otherwise noted, should be made with the volume control "full on". Any desired variation in signal strength should be obtained by adjusting the output of the signal generator.

INTERMEDIATE FREQUENCY ALIGNMENT With the range switch on the broadcast position, the fidelity switch on "Sharp" (clockwise) and the gang condenser closed (maximum capacity), supply a 456 kilocycle signal, stage by stage, to the intermediate frequency amplifier, beginning with the grid of the second intermediate frequency tube. To accomplish this, a .1 Mfd. condenser should be connected between the signal generator supply lead and the second intermediate frequency tube.

The trimmers of the third intermediate frequency transformer (Figure 6) should be adjusted for maximum output with minimum input from the signal generator. Then the signal generator lead should be moved to the first intermediate frequency tube and the trimmers of the second intermediate transformer should be adjusted. The next step is to supply the signal to the grid of the first detector tube and adjust the trimmers of the first intermediate frequency transformer. This method of procedure is essential because of the extreme selectivity of the receiver. After each stage has been aligned, it is well to go back over all adjustments to make sure they are accurate.

The next step in the intermediate frequency alignment is to supply a very strong (about 1000 microvolt) signal to the grid of the first detector tube through the .1 Mfd. condenser. CAUTION: Before the signal is applied to the receiver, the volume control should be retarded to zero. After the signal is applied to the receiver, the volume control should be advanced slowly and carefully until a suitable indication appears on the output meter.

The fidelity switch should be turned to the high fidelity or Third Dimension position. Symetrical double humps should appear, one on each side of where the sharp resonance point appeared on the "Sharp" position (see Figure 13), when the signal generator is tuned approximately 8 kilocycles on each side of the resonance point. The two humps must be of equal amplitude. If this is not the case, the trimmers of the third intermediate frequency transformer must be adjusted until a condition of equal amplitude is obtained. This may be found to be a very difficult adjustment unless an oscillograph is used.

USE OF THE OSCILLOGRAPH A signal generator with a sweep circuit must be employed in making this check. The output of the signal generator should be fed to the grid of the first detector tube in the receiver. The grid clip must be removed from the tube, but, since the first detector is one of the A.V.C. controlled tubes, it is necessary to complete the grid circuit. To accomplish this, connect a large resistor (about 50,000 or 100,000 ohms) between the grid clip and the grid cap of the tube. The low side of the signal generator should be connected to the chassis ground.

The "vertical" binding posts of the oscillograph should be connected to the audio output of the second detector. In the model 100, a type 76 tube serves as a diode rectifier and in the model 110, a type 6H6 tube is employed. In both of these circuits, R-16 serves the dual purpose of manual and automatic volume control resistor. The high side connection from the "vertical" plates should be made to the point of juncture between resistors R-15, R-16 and R-17. The low side connection may be made to ground. Thus, the audio voltage is applied to the "vertical" plates of the oscillograph.

With the receiver operating on the "Sharp" position, the intermediate frequency amplifier resonance curve will appear on the screen. When the receiver is switched to the "3RD DIMENSION" position, symetrical double humps, approaching a wide flat top resonance curve, should appear in place of the "Sharp" resonance curve (see Figure 13). Each side of the curve should be of equal amplitude. If this is not the case, the trimmers of the third intermediate frequency transformer should be adjusted until the proper curve is obtained. The adjustment of one trimmer, in addition to effecting its own side of the curve, will reflect in the other side and, for this reason, great care must be exercised in making these adjustments.

R.F. ALIGNMENT The parallel or high frequency trimmer condensers for each coil are housed in the same can with the coil. These trimmers are used for aligning the high frequency end of each band. The location of the various coils and their respective trimmers is shown on Figure 6. It is essential that the bands be aligned in the order they appear in the following instructions. In other words, the police band alignment must be completed before the broadcast band alignment is started because of the interlocking effect of the padding condensers on these bands.

Adjustable series padding condensers are used for tracking the oscillator at the low frequency end of each band. The padding condensers may be adjusted from the top of the chassis, through the holes indicated in Figure 6. Since a fixed mica padding condenser is employed on the short wave band, no adjustment is necessary. While making padding condenser adjustments, the gang condenser should be rotated back and forth across the signal to insure adjustment to the peak of greatest intensity.

DIAL ADJUSTMENT Before making any radio frequency alignment adjustments, close the variable tuning condenser (maximum capacity) and adjust the black dial pointer to a horizontal position (gang condenser still closed).

POLICE BAND (1.7 to 5.5 Megacycles) With the band selector switch in the police or "P" position and the fidelity switch on the "Sharp" position, supply a 5 megacycle signal from the signal generator to the antenna of the receiver, using a 400 ohm carbon resistor in series with the signal generator lead. Tune the receiver to 5 megacycles and then adjust the oscillator, radio frequency and antenna stage police band trimmers for maximum output with minimum input from the signal generator. WARNING: Care must be exercised to avoid aligning the receiver to the image frequency as outlined under "short wave band".

Supply a 1.8 megacycle signal to the receiver and tune the receiver to 1.8 megacycles. Adjust the police band oscillator padding condenser (located on the chassis at the rear, see Figure 6) for the signal of greatest intensity, rocking the gang condenser back and forth across the signal while making the adjustment. Check at 5 megacycles and then at 1.8 megacycles to correct for any frequency change.

BROADCAST BAND (540 to 1740 Kilocycles) With the band selector switch on the broadcast or "B" position, supply a 1500 kilocycle signal from the signal generator to the receiver, using a standard dummy antenna or a 200 Mmfd. condenser in series between the signal generator and the antenna post of the receiver to serve as the dummy antenna. Make certain that the fidelity switch is on the "Sharp" position.

Tune the receiver to 1500 kilocycles and adjust the radio frequency, antenna and oscillator stage broadcast band trimmers for maximum output with minimum input from the signal generator.

Supply a 600 kilocycle signal to the receiver through the same connections. Tune the receiver to 600 kilocycles. Adjust the broadcast band oscillator padding condenser (located on the chassis at the rear, see Figure 6) for the peak of greatest intensity while rocking the tuning condenser back and forth across the signal. Recheck at 1500 kilocycles and then at 600 kilocycles and make any frequency corrections that appear necessary.

10 KILOCYCLE AUDIO TRAP

Because of the band width necessary to obtain high fidelity reproduction, if a station is operating on a channel adjacent to the station channel being listened to, a 10 kilocycle beat (high pitched whistle) may be heard in the background. To reduce the possibility of this interference, Fairbanks-Morse engineers have developed a 10 kilocycle wave trap, found in the models 100 and 110 chassis. This trap circuit consists of a large, air core choke coil (see Figure 4), and a variable condenser, connected in series. This trap is connected from the plate of the first audio amplifier tube to ground.

ADJUSTMENT It should not be necessary to adjust the trap circuit unless either the choke coil or condenser has been replaced. To adjust the trap, tune in on two adjacent channels on which two distant stations are operating. Turn the selectivity switch to the 3RD DIMENSION POSITION. Tune the interfering whistle to its loudest point by tuning between the two stations. Adjust the 10 kilocycle trap trimmer, located on the front of the chassis (see Figure 4), until the whistle is reduced to a minimum.

Yellow	High Voltage	154.5 ohms
* Black & Yellow	Center Tap (Hi-Volt.)	
White	110 Primary	2.45 ohms

The secondary of each intermediate frequency transformer is composed of three sections, the upper, center and lower (see Figures 1 and 2). The primary is composed of two sections, the upper and lower. The upper sections of the primary and secondary are loosely coupled to each other and constitute the major portion of the primary and secondary inductance respectively. The lower section of the primary and the center section of the secondary are tightly coupled. The coupling between the lower section of the secondary and the primary is loose. When the switch is on the Third Dimension position, the lower section of the secondary is out of the circuit and the secondary winding is made up of the other two windings, connected in series. Because the coupling between the lower section of the primary and the center section of the secondary is tight, a broad response will result.

When the switch is on the "Sharp" position, the center section of the secondary is cut out of the circuit and the loosely coupled lower section is substituted, thus the selectivity is increased the desired amount. Since the inductance of the center section and the lower section of the secondary are identical, the tuning is not altered when switching from the "Sharp" to the Third Dimension position. Because of this very practical and unique design, it is possible to arrange the tuning indicator circuit in such a manner that it is only engaged on the "Sharp" position of the switch. This serves to remind the operator that all tuning should be done on the "Sharp" setting to insure perfect resonance and most faithful reproduction.

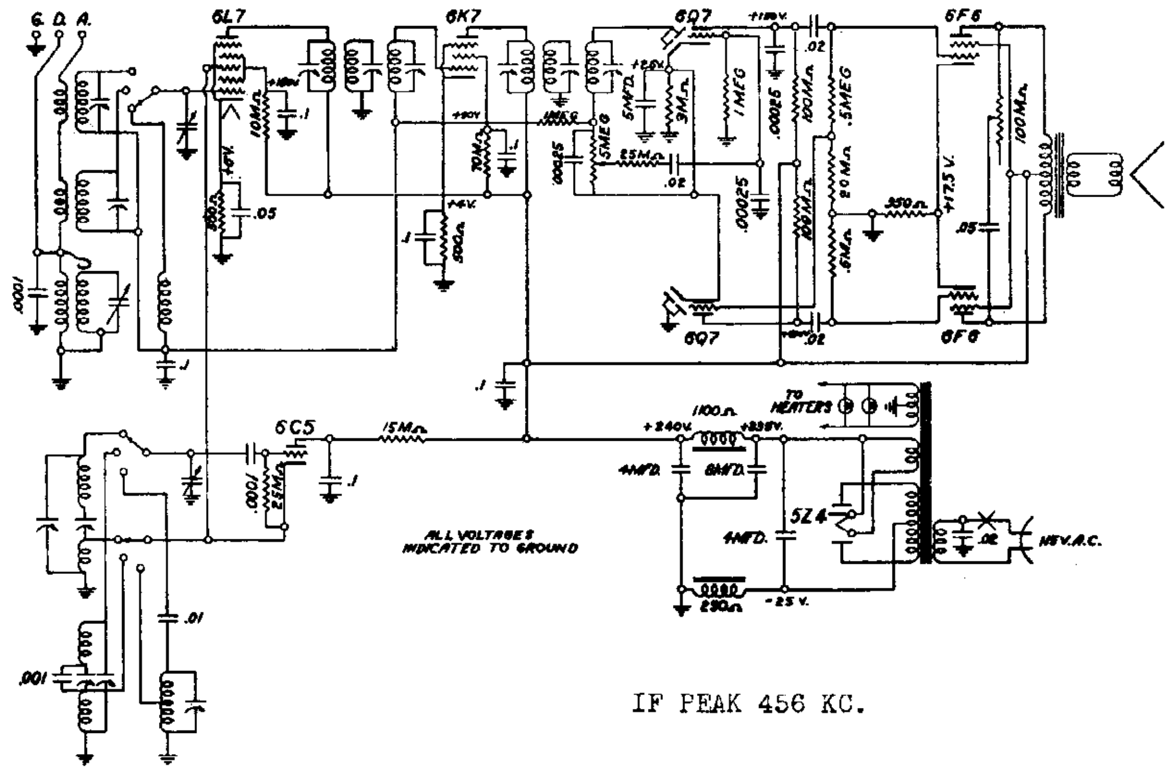
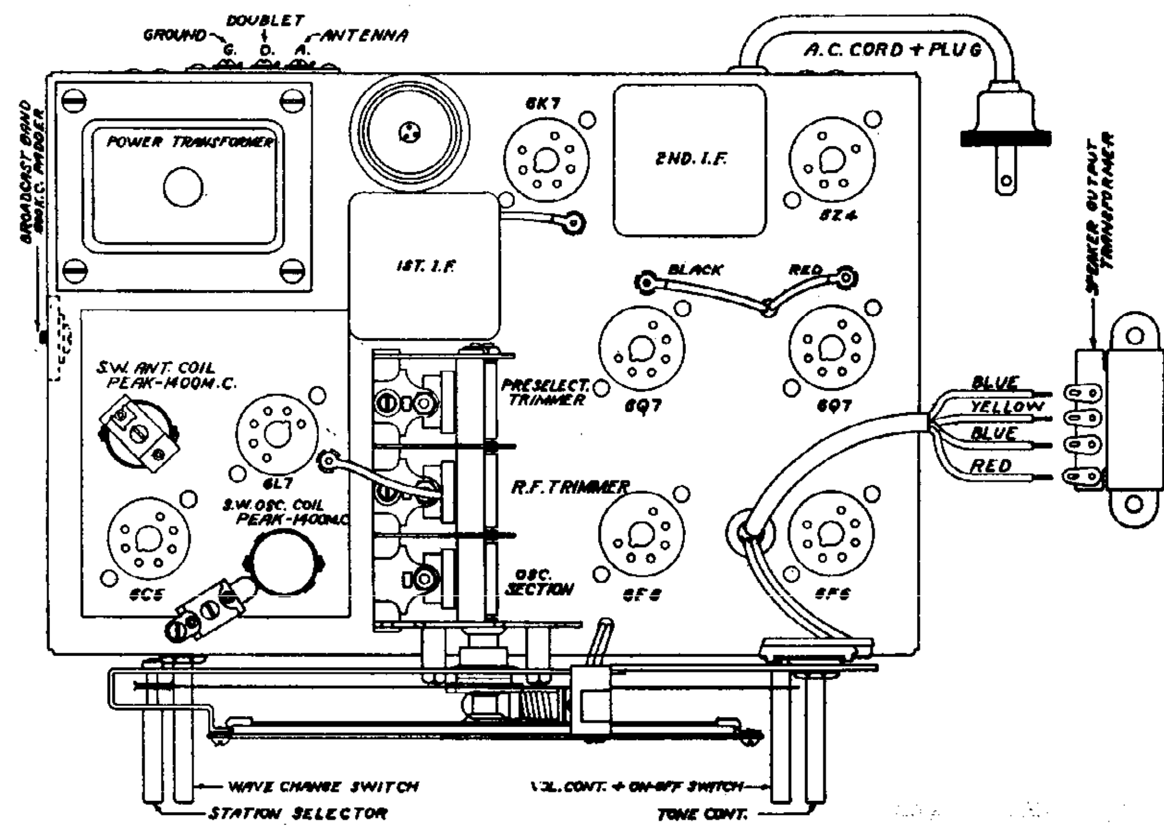
1 - Rebalance I.F. Transformers, applying a 175 K.C. note at 6A7 control grid.
2 - Open variable condenser all the way (minimum capacity) apply a 1720 K.C. note from oscillator at the antenna of receiver.
3 - Check oscillator section of variable to 1720 K.C. then adjust interstage and antenna to maximum peak.
4 - Adjust low frequency padder by applying a 600 K C oscillator note into antenna and while rocking variable condenser across signal adjust padder until maximum output is obtained.

FEDERATED PURCHASER

Eight Tube A.C. Superheterodyne



IF PEAK 456 KC.



FEDERATED PURCHASER

Eight Tube A.C. Wave Superheterodyne

This receiver is designed to operate from a power supply main of 110-120 volts, 60 cycle alternating current (AC). **Never plug into a DC outlet.**

ALIGNMENT DATA

GENERAL DATA The alignment of this receiver requires the use of a test oscillator that will cover the frequencies of 456, 600, 1400, 1800, 4000, 6000, and 14,000 KC and an output meter to be connected across the primary or secondary of the output transformers. If possible, all alignment should be made with the volume control on maximum and the test oscillator output as low as possible, to prevent the AVC from operating and giving false readings.

CORRECT ALIGNMENT PROCEDURE The intermediate frequency (I.F.) stage should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the Broadcast Band should always be the next procedure; after which, either or both of the Short Wave Bands may be aligned.

I.F. ALIGNMENT Adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tubes (6L7) through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the chassis ground. Align all six I.F. trimmers to peak or maximum reading on the output meter.

BROADCAST BAND ALIGNMENT Adjust the oscillator to 1400 KC and connect the output to the antenna post marked "A" through a .0001 mfd. mica condenser to give the equivalent of an antenna about 60 feet. Set the receiver pointer to 1400 KC and adjust the oscillator trimmer to peak. This trimmer is mounted on the oscillator coil and is located directly under the 6C5 socket. (This adjustment must be made from the bottom of the chassis.) After this has been carefully done, the next step is to adjust the center and rear trimmers of the gang condenser to peak. The center gang section tunes the R.F. or grid coil of the 6L7 tube and the rear condenser section tunes the pre-selector stage circuit.

Next, re-set the dial pointer on the receiver and the test oscillator to 600 KC. Slowly increase or decrease the oscillator padding condenser and at the same time continuously tune back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment seems a little complicated but is the easiest way to adjust the oscillator to the pre-selector or R.F. section. The padding condenser is located in the left end of the chassis. Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 600 KC.

If it is found that in returning to 1400 KC the pointer is accurately on scale, the only readjustments that should be made (in this recheck) are the center and rear trimmers of the gang condenser. If the pointer is found off scale, it may be corrected and put on scale by realignment of the oscillator trimmer. Alignment of the pointer can **only** be corrected by adjustment of the oscillator trimmer.

This completes the correct sequence of operations in properly aligning the receiver for the Broadcast Band, and **must always be done before** attempting to align the Short Wave Bands.

FOREIGN BAND The Foreign Band of 19 to 49 meters can be adjusted by the two trimmers located on the top of the chassis. The R.F. trimmer is located directly on top of the R.F. or Antenna coil and the oscillator trimmer is mounted on the chassis near the front of the oscillator coil. Set the test oscillator to 14,000 KC. In preparing the test oscillator for alignment of this band, connect a 400 ohm carbon resistor in series with the .0001 mfd. condenser on the output lead of the test oscillator. This resistor is used with the test oscillator only on the Short Wave Bands and should not be used for Broadcast Band alignment. The next operation is to adjust the R.F. and oscillator trimmers for peak at 14,000 KC and as the inherent design of the circuit has been expressly engineered for simplicity in servicing, no other adjustments are necessary for aligning this band.

Note: In order to prevent alignment on the image frequency, it is suggested that alignment be started with the antenna coil trimmer screwed down tightly. To check this adjustment, readjust the pointer to 13100 KC where the image frequency should be found. If properly aligned, the image frequency will be found to be weaker. If, however, the signal at 13100 KC is found to be stronger than the signal at 14000 KC, it signifies that alignment was incorrectly made on the image frequency.

Important: Do not attempt any adjustment of the gang condenser trimmers in aligning the Foreign Band as this will throw the Broadcast Band out of alignment.

POLICE BAND In preparing the test oscillator for alignment of this band, connect a 400 ohm carbon resistor in series with a .0001 mfd. condenser on the output lead of the test oscillator. This resistor is used with the test oscillator only on the Short Wave Bands and should not be used for Broadcast Band alignment.

Set the receiver pointer to 4000 KC (also test oscillator) and adjust the oscillator circuit trimmer to peak. The oscillator trimmer is mounted on the oscillator coil, which is located underneath the chassis. The oscillator coil is wound with enamel wire and is mounted to the front edge of the chassis. After this has been carefully done, the next step is to adjust the antenna trimmer to peak. The antenna trimmer is attached to the antenna coil; also mounted underneath the chassis and wound with enamel wire. The antenna coil is located nearest the power transformer. Now reset the dial pointer and the test oscillator to 1800 KC in preparation for adjusting the police band padding condenser. This padding condenser is mounted on the underside of the chassis, directly underneath the gang condenser. Slowly increase or decrease the oscillator padding condenser and at the same time continuously tune back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment seems a little complicated, but is the easiest way to correctly adjust the oscillator to the R.F. or antenna section.

Return to 4000 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made 1800 KC.

If it is found that in returning to 4000 KC the pointer is accurately on scale, the only readjustment that should be made (in this recheck) is the trimmer on the enamel wire antenna coil located underneath the chassis near the power transformer. If the pointer is found off scale, it may be corrected and put on scale by readjustment of the oscillator trimmer. Alignment of the pointer can only be corrected by adjustment of the oscillator trimmer.

Important: There are only three trimmer adjustments necessary for the Police Band. Do not attempt any adjustment of the gang condenser trimmers in aligning the Police Band; otherwise, the Broadcast Band will be thrown out of alignment.

SERVICE DATA FOR ALL BANDS

If it is suspected that the oscillator has stopped but is doubtful due to the presence of the usual amount of noise level, it is suggested that the oscillator plate voltage be checked. An approximate normal minimum oscillating voltage for the plate of the 6C5 (oscillator tube) at 115 volt line potential is as follows:

Broadcast Band	600 KC	125 Volts
	1400 KC	100 Volts
Foreign Band	6000 KC	135 Volts
	14000 KC	140 Volts
Police Band	1700 KC	135 Volts
	4000 KC	110 Volts

Another way of ascertaining whether the tube is oscillating is to ground the grid of the 6C5. If oscillating properly, grounding the grid will cause an appreciable drop in oscillator voltage.

FEDERATED PURCHASER

Seven Tube 6 Volt Battery All Wave Superheterodyne

ALIGNMENT DATA

The alignment of this receiver requires the use of a test oscillator which will cover the frequencies of 456, 600, 1400, 1800, 4000, 6000, and 14,000 KC and an output meter which is to be connected across the primary or secondary of the output transformer. If possible, all alignments should be made with the volume control on maximum and the test oscillator output as low as possible, to prevent the AVC. from operating and giving false readings.

CORRECT ALIGNMENT PROCEDURE

The intermediate frequency (I.F.) stages should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the Broadcast Band should always be the next procedure; after which, either or both of the Short Wave Bands may be aligned.

I.F. ALIGNMENT

Adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tube (1C6) through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the chassis ground. Align all five I.F. trimmers to peak or maximum reading on the output meter. As there are two stages of I.F. in this receiver, there will be consequently three I.F. transformers to align. The I.F. transformer nearest the type (30) diode detector has only one trimmer, (single tuned) and should be the first adjustment. Next adjust the center I.F. transformer, which has two trimmers (double tuned) for maximum output; then adjust the two trimmers on the input I.F. transformer (double tuned) for peak.

BROADCAST BAND ALIGNMENT

Adjust the oscillator to 1400 KC and connect the output to the antenna post marked "A" through a .0001 mfd. mica condenser to give the equivalent of an antenna about 60 feet. Set the receiver pointer to 1400 KC and adjust the front gang condenser trimmer (oscillator circuit) to peak. After this has been carefully done, the next step is to adjust the center trimmer of the gang condenser to peak. The center condenser section tunes the RF or grid circuit of the 1C6 tube. Next, re-set the dial pointer on the receiver and the test oscillator to 600 KC. Slowly increase or decrease the oscillator padding condenser and at the same time continuously tune back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment may seem a little complicated but is the easiest way to adjust the oscillator to the R.F. section. The padding condenser is located on the left hand side of the chassis, near the extreme front left corner.

Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 600 KC.

This completes the correct sequence of operations in properly aligning the receiver for the Broadcast Band, and **must always be done before** attempting to align the Short Wave Bands.

FOREIGN BAND ALIGNMENT

The Foreign Band of 19 to 49 meters can be adjusted by the two trimmers on the short wave coils located on the top of the chassis. In preparing the test oscillator for alignment of this band, connect a 400 ohm carbon resistor in series with the .0001 mfd. condenser on the output lead of the test oscillator. Set the receiver pointer to 14,000 KC (also test oscillator). The oscillator coil is located alongside the oscillator section of the tuning condenser (front section of gang), and the antenna or R.F. is the other coil remaining on top of the chassis. These two trimmers should be adjusted for peak at 14,000 KC (adjust oscillator trimmer first) and as the inherent design of the circuit has been expressly developed for simplicity in servicing, no other adjustments are necessary for aligning this band.

Note: Always start this procedure by having the oscillator coil trimmer loose (out all the way), and the antenna coil trimmer fairly tight (in all the way); otherwise it is possible to make a false alignment on the image frequency. In order to prevent alignment on the image frequency, it is suggested that the following check be made: Readjust the pointer to 13,100 KC where the image frequency should be found. If properly aligned, the image frequency will be found to be weaker. If, however, the signal at 13,100 KC is found to be stronger than the signal at 14,000 KC, it signifies that alignment was incorrectly made on the image frequency.

IMPORTANT: Do not attempt any adjustment of the gang condenser trimmers in aligning the Foreign Band as this will throw the Broadcast Band out of alignment.

POLICE BAND

In preparing the test oscillator for alignment of this band, connect a 400 ohm carbon resistor in series with a .0001 mfd. condenser on the output lead of the test oscillator. This resistor is used with the test oscillator only on the Short Wave Bands and should not be used for Broadcast Band alignment.

Set the receiver pointer to 4000 KC (also test oscillator) and adjust the oscillator circuit trimmer to peak. The oscillator trimmer is mounted on the oscillator coil, which is located underneath the chassis. The oscillator coil is wound with enamel wire and is mounted to the front edge of the chassis. This coil can be identified by the use of a layer of yellow cambric (Empire Cloth) separating the two windings. After this has been carefully done, the next step is to adjust the antenna trimmer to peak. The antenna trimmer is attached to the antenna coil; also mounted underneath the chassis and wound with enamel wire. The antenna coil is mounted at right angles to the oscillator coil and is nearest to the rear of the chassis.

Now reset the dial pointer and the test oscillator to 1800 KC in preparation for adjusting the police band padding condenser. This padding condenser is mounted on the underside of the chassis, directly underneath the gang condenser. Slowly increase or decrease the oscillator padding condenser and at the same time continuously tune back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment may seem a little complicated, but is the easiest way to correctly adjust the oscillator to the R.F. or antenna section.

Return to 4000 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made 1800 KC.

If it is found that in returning to 4000 KC the pointer is accurately on scale, the only readjustment that should be made (in this recheck) is the trimmer on the enamel wire antenna coil located underneath the chassis near the power transformer. If the pointer is found off scale, it may be corrected and put on scale by readjustment of the oscillator trimmer. Alignment of the pointer can only be corrected by adjustment of the oscillator trimmer.

Important: There are only three trimmer adjustments necessary for the Police Band. Do not attempt any adjustment of the gang condenser trimmers in aligning the Police Band; otherwise, the Broadcast Band will be thrown out of alignment.

SERVICE DATA FOR ALL BANDS

If it is suspected that the oscillator has stopped but is doubtful due to the presence of the usual amount of noise level, it is suggested that the oscillator plate voltage be checked. To ascertain whether the tube is oscillating, ground the oscillator grid of the 1C6 (short stator and rotor plates of oscillator section on gang condenser). If oscillating properly, grounding the grid will cause an appreciable drop in oscillator voltage.

FIRESTONE

CIRCUIT DESCRIPTION

The Air Chief chassis Model 165 includes a speaker that is mounted directly on the chassis.

This receiver uses a superheterodyne circuit which employs five tubes. The intermediate frequency is 456 KC. The tuning range of this chassis includes, in addition to the standard broadcast band, the two police radio bands.

The signal picked up by the antenna is impressed on the primary of the antenna transformer, which has connected across it a wave trap for the purpose of eliminating 456 KC. interference. The signal is then tuned and impressed on the control grid of the 6D6 oscillator and first detector. The suppressor, or No. 3 grid of the 6D6, is used as the oscillator grid. The 456 KC. output of the first detector is amplified in the I. F. stage, using a 6D6 tube.

The second detector is of the grid leak-grid condenser type, and uses a 6C6 tube. The 6D6 is resistance coupled to the 41 pentode power amplifier. Bias for the output tube is obtained by grid return connection to the negative end of a resistor connected between the center tap of the power transformer high-voltage winding and ground. The bias potential so obtained is filtered by a resistance-capacity filter.

The volume control is double acting. It simultaneously changes the antenna signal input and the I. F. stage bias. Because of the sensitivity of this receiver, and due to the fact that it does not have A.V.C., it requires an antenna that is shorter than usual. The short antenna is particularly necessary where intereference from powerful local stations is encountered, and where difficulty is experienced in properly controlling the volume.

When tuning on the short wave band, local broadcast stations can be heard in the background at their regular positions on the dial. This is a normal condition, and is due to the tapped coil method of tuning the antenna coil secondary to the short wave band. No aligning adjustments are required on the short wave band.

ALIGNING EQUIPMENT

For proper alignment of this receiver, an output meter and a high grade modulated service oscillator are essential. The oscillator should be capable of generating the frequencies of 456 KC., 600 KC. and 1400 KC. The test oscillator calibration should be checked, using broadcast station signals as standards. For trimmer adjustment, it is advisable to use an all bakelite screwdriver, although one with a small metal tip may be used.

ALIGNING PROCEDURE

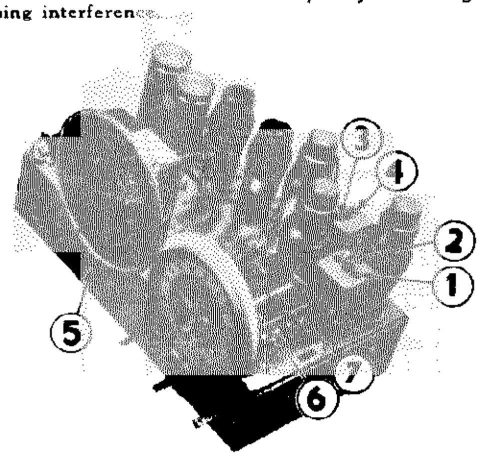
The step by step routine given below should be carefully followed. The trimmer numbers referred to are shown in the illustration.

ALIGNING THE I.F. CIRCUIT

1. Connect the output meter in series with a .25 mfd. condenser between the plate of the 41 tube and ground, or across the voice coil, depending on the type of meter.
2. Turn the volume control to the maximum volume position. (Note: The volume control should be kept in this position throughout the entire alignment procedure.) Ground the antenna lead to the chassis.
3. Turn the range switch to the right (clockwise) to the broadcast position.
4. Adjust the test oscillator to exactly 456 KC. and connect its output in series with a .1 mfd. condenser to the control grid of the 6D6 first detector tube and the chassis.
5. Align I. F. trimmers No. 1, 2, 3 and 4 for maximum output as indicated on the output meter. No inward or sideward pressure should be applied to the alignment tool, or the condenser may spring back to a different setting as soon as the tool is removed.
6. Repeat all I. F. trimmer adjustments since the changing of each trimmer will affect the others to a certain extent.

456 KC. WAVE TRAP ADJUSTMENT

1. Disconnect the antenna lead from ground.
2. Connect the test oscillator output in series with a .00025 mfd. condenser to the antenna lead, and connect the test oscillator ground lead to the receiver chassis. Ground the chassis.
3. Without changing the test oscillator from the frequency setting used in aligning the I. F. stage, adjust trimmer No. 5 for **MINIMUM** output. Increase the test oscillator output as a minimum is reached, in order to obtain a clearly defined setting of the trimmer. **NOTE:** If code interference transmitted on a frequency in the neighborhood of 456 KC. is troublesome, the wave trap should be adjusted for **MINIMUM** output with the test oscillator set to the same frequency as the signal that is causing interference.



DIAL CALIBRATION

If the receiver should require calibration, proceed as follows:

1. Turn the gang condenser to full mesh and check to see that the dial pointer indicates 530 KC. If it does not, remove the dial glass and turn the pointer to 530 KC. when the gang condenser is in full mesh. Replace the dial glass.
2. Adjust the test oscillator to 1400 KC.
3. Turn the condenser gang until the dial pointer indicates 1400 KC.
4. Adjust trimmer No. 6 (oscillator shunt trimmer) for maximum output without changing the setting of the gang condenser.

R. F. ALIGNMENT

1. Set the test oscillator to 1400 KC. and apply the signal to the receiver antenna lead through a .00025 mfd. condenser.
2. Tune the receiver to the signal for maximum output.
3. Adjust trimmer No. 7 (detector shunt trimmer) for maximum output.

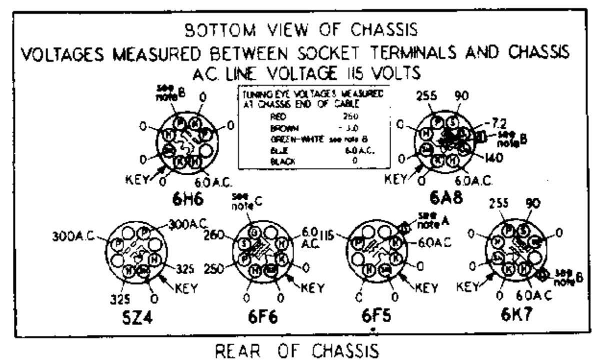
NOTE D: In receivers having serial numbers below 453,400 resistors 59, 60, and 61 are omitted and the screen grids of the 6K7 and 6A8 receive their current through a 26,000 ohm 1/4 watt resistor which is connected to the screen grid of the 6F6. The anode grid of the 6A8 is connected in series with a 21,000 ohm 1/4 watt resistor to the screen grid of the 6F6. Condenser 62 (4 mfd. 250 V.) is also omitted.

SOCKET VOLTAGES

VOLUME CONTROL ON FULL — ANTENNA GROUNDED
RANGE SWITCH SET ON BROADCAST POSITION — DIAL TUNED TO 530 KC.



IMPORTANT: Use a high resistance voltmeter of 1000 ohms per volt.
NOTE A: The grid bias for the 6F5 is −1.3 volts measured across resistor 29.
NOTE B: The grid bias for the 6A8, 6K7, and the anode voltage of the A.V.C. section of the 6H6 is −3.0 volts measured across resistors 29 and 54.
NOTE C: The grid bias for the 6F6 output tube is −17.0 volts measured across resistors 29, 54 and 27.

MODEL R-166 PARTS LIST

Diagram Number	Part Number	DESCRIPTION	List Price

Alignment, Socket
Trimmers, Parts

FIRESTONE

CALIBRATION AND ALIGNMENT

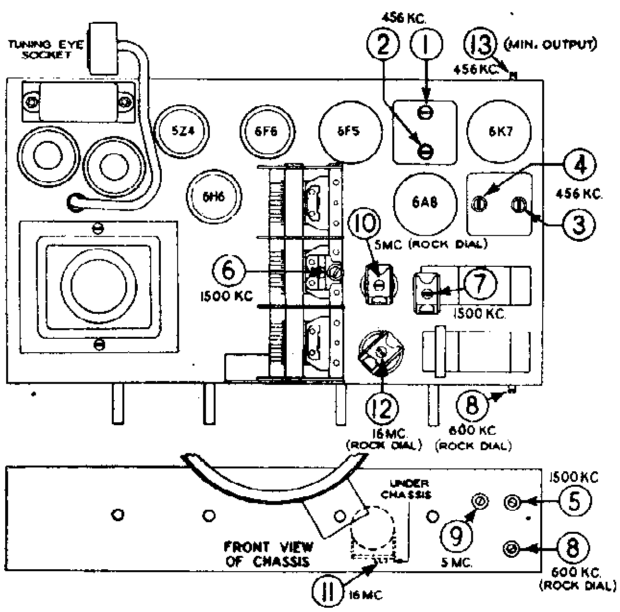
ALIGNING EQUIPMENT: For proper alignment, an output meter and an accurately calibrated oscillator with a tuning range from 456 KC. to 16 MC. are required.

Connect the output meter from the plate of the output tube to chassis. A convenient point to make the plate connection is to the yellow wire on the speaker socket.

ALIGNING THE I. F. AMPLIFIER: Turn the volume control to maximum volume position and keep it in this position throughout the entire alignment procedure. Turn the range switch to the broadcast position (fully clockwise).

Connect the test oscillator output leads to the 6A8 control grid and chassis with a **.1 mfd. condenser in series with the oscillator output.** Set the oscillator to exactly 456 KC. Set the receiver dial at any point where it has no tuning effect on the oscillator signal.

Adjust the four I.F. trimmers, Nos. 1, 2, 3 and 4, for maximum output meter deflection, then repeat the trimmer adjustment.



TRIMMER LOCATIONS

Trimmer Number		Alignment Frequency
1.	2nd I.F. transformer trimmer	456 KC.
2.	2nd I.F. transformer trimmer	456 KC.
3.	1st I.F. transformer trimmer	456 KC.
4.	1st I.F. transformer trimmer	456 KC.
5.	Broadcast oscillator shunt trimmer	1500 KC.
6.	Broadcast antenna shunt trimmer	1500 KC.
7.	Broadcast detector shunt trimmer	1500 KC.
8.	Broadcast oscillator series padder	600 KC.
9.	Police oscillator shunt trimmer	5 MC.
10.	Police antenna shunt trimmer	5 MC.
11.	Short wave oscillator shunt trimmer	16 MC.
12.	Short wave antenna shunt trimmer	16 MC.
13.	Wave-trap trimmer	456 KC.

BROADCAST BAND CALIBRATION AND ALIGNMENT: With the gang condenser in full mesh, the dial pointer should be on the white horizontal line below 530 KC. on the dial scale.

Turn the range switch to the extreme clockwise position and connect the test oscillator output to the A and G terminals of the receiver with a 400 ohm carbon resistor in series with the A terminal and the oscillator output.

Adjust the test oscillator to exactly 1500 KC. and turn the receiver dial pointer to 1500 KC. on the tuning dial. To calibrate the dial, adjust trimmer No. 5 for maximum output.

Carefully tune the receiver to the signal and adjust trimmers Nos. 6 and 7 for maximum output.

Adjust the test oscillator to 600 KC. and tune the receiver to the signal. Adjust trimmer No. 8 for maximum output. Then try to increase the output meter reading by detuning No. 8 slightly and retuning the receiver dial. If the output goes down, detune the trimmer in the opposite direction. Continue detuning the trimmer and retuning the receiver dial until maximum output meter deflection is secured. This operation is commonly known as "rocking" and when performed as described will give maximum selectivity and sensitivity even though the dial may be slightly off calibration at 600 KC.

WAVE-TRAP ADJUSTMENT: The wave-trap adjusting trimmer, No. 13, is located on the back of the chassis. Leave the test oscillator connected to the A and G terminals through a 400 ohm resistor and set the oscillator at 456 KC. Then adjust the wave-trap trimmer No. 13 for **minimum output.** If some particular station with a frequency near 456 KC. causes code interference, it may be desirable to adjust the wave-trap on the actual frequency of the interfering station.

Check the adjustment of trimmers 5, 6, and 7 at 1500 KC.

BAND NO. 2 CALIBRATION AND ALIGNMENT: Turn the range switch to the center position.

Adjust the test oscillator to exactly 5.0 MC. and turn the receiver dial pointer to exactly 5.0 MC. on the tuning dial.

To calibrate the dial, adjust trimmer No. 9 for maximum output. If two peaks are found, the proper one is that with the trimmer screw farthest out.

Carefully tune the receiver to the signal and adjust trimmer No. 10 for maximum output. Then try to increase the output by detuning No. 10 slightly and retuning the receiver dial. Continue detuning No. 10 and retuning the dial until the output meter deflection is a maximum.

BAND NO. 3 CALIBRATION AND ALIGNMENT: Turn the range switch to the extreme counter-clockwise position. Be sure the D and G terminals on the antenna terminal strip are connected together.

Set the test oscillator to 16 MC. and turn the receiver dial pointer to exactly 16 MC. on the tuning dial.

To calibrate the dial, adjust trimmer No. 11 for maximum output. Check to see that it has been adjusted to the proper peak by tuning the receiver to approximately 15.1 MC. A repeat signal should be heard at this point. If none is present, even with greatly increased oscillator output, retune the receiver to 16 MC. and adjust trimmer No. 11 to the proper peak with the trimmer screw farther out.

Carefully tune the receiver to the signal and adjust trimmer No. 12 to a peak. Then try to increase the output by detuning the trimmer slightly and retuning the dial until a maximum output meter deflection is secured. Check the adjustment by tuning the receiver to the image at about 15.1 MC. The image should be much weaker than the 16 MC. signal. If the signal at 15.1 MC. dial setting is equal to or stronger than the 16 MC. signal, trimmer No. 12 is not set to the proper peak. Turn the trimmer in a turn or so, then readjust as above.

A DISCUSSION OF THE FUNCTION AND APPLICATION OF THE MAGIC ELIMINODE

The Magic Eliminode unit contains elements to perform the function of elimination of ignition interference introduced through supply leads and the antenna system. The interference introduced through the speaker leads and dial light lead is filtered by conventional low-pass filter chokes No. 3 and No. 4, condensers No. 17 and No. 18. Since the "A" lead No. 8 supplies the energy for balancing, this function is performed first, then the energy prevented from passing on to the receiver by another low-pass filter choke No. 1, condensers No. 16 and No. 19.

The "A" lead balancer consists of a pair of mutually coupled inductance coils No. 9 and No. 14, with an interposed electrostatic shield No. 10, and means for varying the coupling between these coils. This coupling variation is provided by varying the size of the aperture between these coils by a movable shutter No. 12, driven by screw No. 13. This provides a smoothly adjustable and constant coupling, permitting the coils to remain fixed and preventing the possibility of phase distortion by keeping their position constant and parallel. A filter circuit, chokes No. 5 and No. 6 and condenser No. 7, is used in conjunction with the balancer to provide means for removing odd phase components of ignition interference and sometimes completely removing interference of low intensity.

Since the balancer derives its energy from the "A" system, it follows that the "A" lead supplies w[illegible] CANNOT be by-passed at the point of its connection to the automobile wiring system. If that is done, [illegible] balancing energy will be available in the balancing unit. It is of utmost importance that the receiver be [illegible] tracking condition and the antenna stage trimmed at 600 K.C. after being connected to the car antenna. If [illegible] done, the balance which is obtained at one point in the broadcast band will not hold at another point in [illegible].

INSTALLATION OF MODELS CONTAINING THE MAGIC ELIMINODE

In the 1936 Motorolas the necessity for proper grounding between the receiver housing, jiffy bracket [illegible] the car body is just as important as it was in any previous Motorola model and its installation. The antenna [illegible] of such construction that free radiation from the car system will not penetrate its shield. However, if the [illegible] end of the shield is not connected to the body in the proper manner, the standing wave on the shield, due to [illegible] connection will be introduced into the antenna lead and seriously disturb the balancing condition, that is, [illegible] of balance and its consistency across the band. There are several supply leads and control cables entering the [illegible] of the receiver. The connection between these control cables and the housing MUST be good. The filter[illegible] supply leads entering the sets is taken care of in the eliminode unit. Since the "A" lead, however, carries [illegible] pares of "A" current modulated by the auto ignition system, this lead has a very high intensity of ign[illegible] around it. Consequently, if it is placed close to the antenna trimmers or lengyres in the housing, the energ[illegible] by it can be intercepted by the grid of the first tube or its associated receiver circuits. In view of this fact [illegible] desirable to dress the "A" lead in back of or along the top rear edge of the receiver, but above all, away [illegible] antenna trimmer openings.

There are several points on the car wiring circuit to which the "A" lead of the set can be connected. [illegible] are depending upon the "A" circuit for balancing energy, the "A" lead must be connected to some poi[illegible] system having a relatively high ignition potential. This point is usually at or near the ammeter or igniti[illegible] Connecting it to the starter cable, which is practically the battery itself, will usually result in insufficient [illegible] energy.

ELIMINATION OF IGNITION INTERFERENCE WITH THE MAGIC ELIMINODE

There are several sources of interference encountered in auto radio receivers, such as interference created by the generator, gasoline gauge, oil pressure gauge, and such devices. This is ordinarily removed by a by-pass condenser. The ignition system itself radiates to the antenna from various wiring elements or metallic members. These can be divided into four general classifications.

(1) Radiation from the ignition secondary system, that is, spark plugs and leads thereto.
(2) Radiation from the ignition primary system including all of the leads connected to it.
(3) Radiation from metallic members or leads connected to distributor breaking points.
(4) Radiation from free metal members.

The first source of interference, is encountered in earlier makes of cars, where the effective shielding of the hood, bulkhead and other metal surrounding the spark plug leads is poorly connected to the car frame, permitted radiation from these leads to reach the antenna itself.

In the later type of car construction where welding of component parts is employed and a good connection between hood and body is provided either by the car manufacturer or the installer, this type of interference is very low or negligible.

The second source of interference, namely that radiated from the "A" system either to the roof antenna or to the under-car plate is still a very serious and stumble interference. This interference is regular in character; in other words, of constant intensity for any given motor speed and readily balanceable by the balancer unit, provided that in the case of the under-car installation the antenna plate is on the correct side of the car. This can be determined by observing whether upon opening the shutter, No. 12, from an entirely closed position, the interference decreases or increases. If the interference continues to increase as the shutter is opened the antenna plate must be mounted under the opposite running board. If this additive condition occurs on a roof antenna, the balancer itself must be reversed.

The third type of interference usually encountered on cars having a relatively high resistance path between the ground side of the ignition primary and the breaker points is of an intermittent, irregular character and emanates from breaker point disturbances. This breaker point disturbance may be either a poor condition of the points themselves, or a poor adjustment of same, or the wrong time constant of the secondary circuit. This time constant is sometimes disrupted to such an extent by a distributor suppressor that serious flashing at the points occurs, resulting in breaker point disturbance.

Ordinarily, this interference is not of the same phase or wave shape as the major intensity to be balanced out. Therefore, a breaker point filter should be employed, unless some other effective means can be used, such as improving the point condenser itself, without disturbing the "A" system from the balancing standpoint. With this type of interference removed by a filter, the major intensity can be balanced out in the regular manner.

Any metal member standing free from the body of the car for an appreciable distance adjacent to or in a position to radiate to the antenna system, will sometimes contribute great intensity. Such members are exhaust pipes, torque tubes, gear shift levers, poorly grounded instrument panels, or other metal members of the car in poor connection with the frame. If the connection between one of these radiating members is of high but constant resistance and can be balanced, then no matter how high the intensity, the balance will remain constant. If, however, the resistance of the connection is variable with the motion of the car or weather conditions, and since any change in its connection will change the condition of the balance, this connection must be made permanent. In the case of the freely floating exhaust pipe where the intensity received is exceedingly high, this member should be bonded to the frame through a good, low resistance and non-inductive connection. This will reduce the intensity to a reasonable degree and once balance is obtained, it will remain throughout the life of the installation.

The point in the band at which the eliminode is balanced should be ordinarily at the point of greatest interference, since at this point any error in balancing will be very apparent. A great number of roof installations require the use of a dome-light filter.

The improved Motorola dome-light filter will absolutely eliminate transmission of interference via the dome-light wire to the antenna. If, after balance has been obtained, it is observed that when tuning to any, the low frequency end of the band, a small amount of interference still remains, observe whether turning on or off the dome-light affects this interference. If so, the installation of the dome-light filter is incorrect in that a poor ground has been made or its location in the dome-light circuit is incorrect.

If this condition occurs relocate the filter to secure a better ground connection to the car body.

ALIGNMENT PROCEDURE

Remove the receiver from its housing and connect the speaker and hot "A" lead into the receptacle at the rear of the chassis, as shown in Fig. (1). Connect an 1100 mmf. dummy antenna across the two antenna receptacles (a) (b) Fig. 1 to replace the antenna pads located in the "MAGIC ELIMINODE UNIT."

Use an accurate, well shielded signal generator, such as Monarch Model 12 Generator, with a 200 mmf. condenser in series with the generator feeder at all times, and a good quality sensitive output meter.

I. F. ALIGNMENT AT 262 K.C. — ALL MODELS

Connect the output of the generator to the grid of the 1st I.F. tube. Turn the volume control of the receiver [illegible]

[illegible]

[illegible]

[illegible]

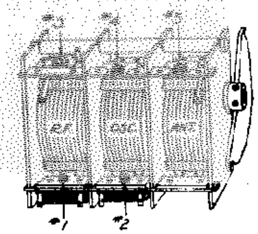

Fig. 2

[illegible] section of tuning condenser) for maximum output.

Set the generator to 1600 K.C. and adjust the oscillator trimmer on the top of the center section of the variable condenser (No. 4 Fig. 2) for maximum output.

Next set the generator to 600 K.C. and rotate the variable condensers until the signal is heard. Now adjust the 600 K.C. pad located at bottom of center section of tuning condenser (No. 2 Fig. 2) for maximum output.

While adjusting rock the variable condensers back and forth to properly synchronize the R.F. and oscillator tuning condensers at this frequency.

Next set the generator frequency to 1400 K.C. and adjust trimmer (No. 3 Fig. 2) on the end section of tuning condenser for maximum reading of output meter. At this time it is well to check several points between 1400 K.C. and 600 K.C. and if necessary bend the end plates of the oscillator section of the tuning condenser slightly to secure perfect tracking across the frequency range.

Next couple the 1400 K.C. generator signal through the 1100 mmf. dummy antenna plugged into the antenna receptacle (a, b Fig. 1) and adjust the antenna trimmer condenser (No. 5, Fig. 2) for maximum reading of output meter.

This completes the alignment and no changes are necessary after placing chassis in housing.

Below is a table showing the input signal in microvolts required for each stage to secure 1 watt output at the voice coil of the receiver.

This will provide an easy method of checking the gain of each successive stage while aligning, and will quickly isolate any stage that falls below the normal average gain.

These readings are correct when using a 200 mmf. condenser as a dummy antenna in series with the signal generator feeder. The antenna stage reading will vary considerably with different values of dummy antenna; therefore, when using more than 200 mmf. the microvolt input required will be less and when using less than 200 mmf. the microvolt input required will be more.

GOLDEN VOICE

Average Microvolt Input	Generator Feeder Connected to Grid of	Generator Set at	Output Meter Across Voice Coil
50,000 to 80,000	6-K-7	262KC	Note—Voice coil resistance is 2 ohms—2.82 volts AC equals 1 watt output.
800 to 1,200	6-A-8	262KC	
900 to 1,600	6-A-8*	600KC	
35 to 50	6-K-7	600KC	
1 to 2	Ant.	600KC	

MODEL 60

50,000 to 80,000	6-K-7	262KC	Voice coil resistance is 2 ohms—1.78 volts equals 1 watt output.
1,500 to 2,000	6-A-8	262KC	
1,300 to 2,000	6-A-8*	600KC	
30 to 60	6-K-7	600KC	
1 to 3	Ant.	600KC	

ADDITIONAL SERVICE NOTES

ADJUSTING PANEL TYPE CONTROL

The M-33 panel type control head may be adjusted by rotating the dial scale to the frequency desired for setting, for example 70 (700 K.C.), then insert a small screw driver through the hole at the bottom of the control head and push upward. This throws the film drum out of mesh with the idler gear. While holding the film drum in this position turn in the station desired, for example (WLW 700 K.C.), then allow the film drum to re-mesh with the idler gear.

BALANCING SETS TO HIGH CAPACITY AERIALS

The antenna systems in all models are adjusted to an antenna capacity range from 50 MMF to 375 MMF. However, should you desire to increase this range for extremely large aerials up to 700 MMF it may be done on all models, except No. 50, by removing the chassis from the housing and turning to the left, the flat head brass screw located in the lower center of the front face of the Eliminode casting. About two turns will be sufficient. Replace chassis and readjust antenna trimmer screws. If the antenna capacity is greater than 700 MMF it will be necessary to use the antenna series condenser, Part No. M94.

REVERSING PHASE IN BALANCING SYSTEM OF MAGIC ELIMINODE

In rare cases in cars having roof aerials it may be found that when operating the balancer the interference is additive and balance cannot be obtained. When this occurs it may be corrected by removing the cover from the Magic Eliminode and locating coil No. 9, Page 1. Pull this coil upward and revolve it 180° around the two bars as an axis and so that the two contacts face the Electrostatic shield. Be sure to replace ALL screws in Eliminode cover.

CHASSIS PICKUP

When installing Models No. 60, No. 80 and Golden Voice in the motor compartment of the car, a preliminary test for chassis pickup should be made before attempting to balance out the antenna interference.

When making this test it is necessary to use a well shielded dummy antenna plugged into the set in place of the regular antenna lead-in. The dummy antenna can be made by using a standard Motorola antenna series condenser, Part No. M-94, and short circuiting the inside connection to the shell.

Balance the antenna trimmer very carefully to this dummy so that the set is at maximum sensitivity, and then run the car motor. Should chassis pickup occur it can be isolated to the end of the set from which the flexible shafts and connections protrude.

Clean the paint around the flexible shaft bushings so that they ground perfectly to the set housing.

Keep the "A" lead away from the antenna trimmer screw openings.

Clean the cover wipers on the set housing, and if necessary, replace the small snap-in plug in the left-end of the set with an 8/32 self-tapping screw so as to secure a better ground of the cover to the rear half of the set housing.

Proceed with the Eliminode balancing only after all trace of chassis pickup is eliminated.

1100 MMF DUMMY ANTENNA

This may be made from Motorola Part No. 1439 pad condenser connected across a two-way plug Motorola Part No. 2036, and adjusted to 1100 MMF. Use the M-24 antenna capacity bridge to adjust to the correct capacity.

(NOTE):—Do not confuse this with the 1100MMF Pivot Condenser (No. 1 Fig. 2).

POWER SUPPLY OF GOLDEN VOICE

Reference to the Golden Voice circuit diagram will show that a separate bias rectifier is used. This is a new departure in auto radio construction and accounts for the high efficiency of this receiver; however, when replacing the OZ-4 rectifier be sure to use one requiring only 12 to 15 milliamperes ionization current. Otherwise the power output of the receiver will drop when the set is in operation and the switch is turned off and immediately turned on again.

BIAS CELLS

In Models No. 50 and No. 60 the bias is supplied to the grid of the 75 tube by a 1.2 volt bias cell. This cell has an average life of two to three years; therefore, replacement is seldom necessary. Check it by replacement only, as a true voltage reading cannot be secured with an ordinary voltmeter.

VIBRATOR REPLACEMENTS

When replacing the vibrator in Models 80 and Golden Voice use only Mallory No. 94 or Radiart No. 5310. When replacing the vibrator in Models No. 50 and No. 60 use Radiart No. 5300 or Utah No. 18914.

SERVICE CABLES

Service extension cables for bench servicing of Models No. 60, No. 80 and Golden Voice may be secured from your Motorola Distributor at $1.00 net.

MODEL 80

20,000 to 40,000	78	262KC	Voice coil resistance is 3 ohms—1.73 volts equals 1 watt output.
800 to 1,400	6-A-7	262KC	
800 to 1,400	6-A-7*	600KC	
50 to 80	78	600KC	
1 to 3	Ant.	600KC	

MODEL 50

25,000 to 30,000	78	262KC	Voice coil resistance is 3.5 ohms—1.87 volts equals 1 watt output.
1,000 to 4,000	6-A-7	262KC	
1,000 to 4,000	6-A-7*	600KC	
60 to 100	78	600KC	
2 to 6	Ant.	600KC	

*Microvolt input required may be 10-20% more at 600KC than at 262KC. This is due to normal conversion loss in the translator tube. If greater, replace translator tube.

MODELS 50,60,80, Golden Voice Changes,Chassis

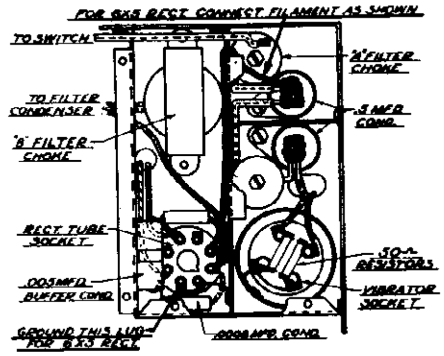
GALVIN MFG. CO.

We have been advised by the manufacturer that intermittent operation of their Motorola Golden Voice models, is due to low battery voltage delivered to the set from the car's battery. Check all connections between the car battery and the radio set to avoid undue voltage drop in the car wiring, as the OZ-4 rectifier tube will fail to start and fail to operate on a battery voltage of less than 5½ volts.

The OZ-4 tube requires 15 milliamperes or more of drain to produce ionization and proper rectification in this tube, and on battery voltages of less than 5½ volts the plate current drain of the receiver is insufficient to provide the 15 milliamperes starting current. Should the car wiring and the condition of the car battery indicate that at times the voltage may fall below 5½ volts, replace the OZ-4 rectifier tube with a 6X5 metal filament type rectifier.

With the exception of a few Golden Voice sets the filament contacts of the rectifier socket have been wired at the factory and the 6X5 rectifier may be plugged in the socket in place of the OZ-4. This will completely eliminate the difficulty due to low battery voltage.

On those Golden Voice sets not having the filament contacts of the rectifier socket wired, this wiring can be inserted by inverting the chassis and removing the cover from the hash compartment and connecting the filament contacts of the rectifier socket, as shown in the accompanying sketch. One contact to ground as indicated by the heavy arrow at the bottom of the socket and the other contact to the .5 mfd. condenser as indicated by heavy arrow at the top of the sketch. When replacing cover be sure that all screws are tight.



Connections when using a 6X5 in Motorola Golden Voice set

PRICES ARE SUBJECT TO CHANGE WITHOUT NOTICE

Control Heads

Part No.	Description	List Price
M-33-A	Film type control head with shafts	$7.00
M-68	Cadillac-LaSalle control head and shafts, plate and knobs	8.00
M-66	Oldsmobile control head and shafts with knobs	8.00
M-99	Airplane type control head and shafts	7.00
M-100	Small airplane type control head and shafts	7.00
M-95	Running board antenna plate	2.95

Medallion Plates and Knobs

Part No.	Description	List Price
M-14	1934 DeSoto Medallion plate and knobs	$1.00
M-15	1934 Ford Medallion plate and knobs	1.00
M-16	1934 Walnut Medallion plate and knobs	1.00
M-17	1934 Plymouth Medallion plate and knobs	1.00
M-20	1934 Packard Medallion plate and knobs	1.00
M-21	Clamp mounting complete with knobs	1.00
M-29	1935 Ford Stand. Medallion plate and knobs	1.00
M-30	1935 Ford DeLuxe Medallion plate and knobs	1.00
M-31	1935 Plymouth (early), Dodge Medallion plate and knobs	1.00
M-31A	1935 Plymouth (late) Medallion plate and knobs	1.00
M-31B	1935 DeSoto Airstream Medallion plate and knobs	1.00
M-32	1935 Chrysler Airstream Medallion plate and knobs	1.00
M-34	1935 Chevrolet Medallion plate and knobs	1.00
M-35	1935 Pontiac Medallion plate and knobs	1.00
M-36	1935 Oldsmobile Medallion plate and knobs	1.00
M-38	1935 Studebaker Dictator Medallion plate and knobs	1.00
M-38A	1935 Studebaker President Medallion plate and knobs	1.00
M-39	1935 DeSoto Airflow Medallion plate and knobs	1.00

M-78E	1936 Chrysler Airstream "8" Medallion plate and knobs	1.00
M-78S	1936 Chrysler Airstream "6" Medallion plate and knobs	1.00
M-82	1936 DeSoto Airflow and Custom Medallion plate and knobs	1.00
M-83	1936 DeSoto DeLuxe Medallion plate and knobs	1.00
M-84	1936 Nash "400" Medallion plate and knobs	1.00
M-85	1936 Lafayette Medallion plate and knobs	1.00
M-86	1936 Studebaker President Medallion plate and knobs	1.00
M-89	Under-rim dash mounting and knobs (film type)	1.00
M-90	Steering post control assembly and knobs	1.00

Standard Speakers

Part No.	Description	List Price
2322	5 in. speaker only	$3.25
M-96	6 in. under-cowl speaker complete	6.50
2156	6 in. speaker only	4.25
M-97	8 in. under-cowl speaker complete	9.50
2158	8 in. speaker only	6.00
M-98	10 in. under-cowl speaker complete	12.50
2329	10 in. speaker only	7.50

Overhead Speakers

Part No.	Description	List Price
1844A	1935 Ford ear-level speaker cpt.	$6.50
M-75	1936 General Motors type ear-level speaker complete	6.50
M-80	1936 Ford type ear-level speaker cpt.	6.50
M-87	1936 Nash-Lafayette type ear-level speaker complete	6.50
M-88	1936 Graham, 1935-'36 Studebaker, Reo (all models) ear-level speaker cpt.	6.50

Dual Speaker Combinations

Part No.	Description	List Price
M-92	6 in. under-cowl speaker with General Motors type ear-level speaker—or—back-seat speaker	$13.00
M-93	8 in. under-cowl speaker with General Motors type ear-level speaker—or—back-seat speaker	16.00

Miscellaneous Items

Part No.	Description	List Price
M-1	Generator condensers	$0.40
	In lots of 100	.35
M-2	Screw-in type distributor suppressors	.30
	In lots of 100	.25
M-3	Plug-in type distributor suppressors	.30
	In lots of 100	.25
M-4	Spark plug suppressors	.30
	In lots of 100	.25
M-5	Dome light filters	.60
	In lots of 100	.50
M-6	Wheel Static Eliminators	.10
M-7	Service Tuning Shafts	.22
M-8	Extension service cables (specify model No.)	(Net) 1.00
M-24	Antenna capacity bridge	(Net) 4.95
M-26	Ammeter condenser	.30
M-27	Floor board screen	.30
M-28	Elastic stop nuts	.05
MF-37	1935 Ford engine compartment mounting	.85
M-42	Special shielded Ford ignition coil cond.	.50
M-44	Low loss lead-in for 1935 under-car aerial	1.25
M-52	Touch-up paint kit	.50
M-53	Wire brush	1.50
M-91	Antenna junction box (corner post)	.15
M-94	1936 Dodge series antenna condenser	.30
M-101	1936 Ford engine compartment mounting	1.00
M-102	1936 Ford under cowl mounting	.40
1938	1936 Ford hood bonding strip	.10
2423	Fuse insulator ("A" lead) per doz.	.25

Model Golden Voice

Chassis

Part No.	Description	List Price
	Chassis only—less tubes	$45.00
2002	Volume control bracket	.10
2003	Volume control shaft support bracket	.10
2050	3-gang variable condenser	3.50
2051	Variable condenser mounting bracket	.15
2400	Shoulder screw (68TS)	.05
2401	Variable condenser drive gear (K-61A)	.25
2053	Variable condenser adjustment cam	.05
2168	Volume control	1.00
2023	Volume control funnel	.05
2071	Antenna coil (complete in can)	1.60
2073	R. F. coil with plate choke (cpt. in can)	1.00
2075	Oscillator coil (complete in can)	1.00
2077-B	I. F. coil (complete in can)	1.25
2080	Diode coil (complete in can)	1.75
2407	Standard metal tube sockets (state type)	.15
2408	6N6 socket (special 8-7 prong)	.15
2034	2-way receptacle	.15
2035	5-way receptacle	.25
2038	Eliminode and chassis wiper	.20
1942	D/L mounting strip	.10
2409	Grid caps for metal tubes (per doz.)	.25
2410	.00005 mfd. type "O" condenser	.15
1039	.0001 mfd. type M. T. condenser	.15
2418	.0002 mfd. type M. T. condenser	.20
1042	.0005 mfd. 1000 V. condenser	.20
1400	.01 mfd. 100 V. T. T. condenser	.12
1403	.03 mfd. 120 V. condenser	.12
2251	.01 mfd. 300 V. condenser	.15
2252	.05 mfd. 400 V. condenser	.20
2254	.05 mfd. 25 V. condenser	.15
2256	.1 mfd. 200 V. condenser	.15
2264	.25 mfd. 200 V. condenser	.30
2261	.025 mfd. 300 V. condenser	.15
2275	.01 mfd. 100 V condenser with 1 meg. resistor	.20
2276	.02 mfd. 600 V. condenser	.20
2277	.05 mfd. 120 V. condenser	.20
1777	Resistors (state value)	.15
2095	Input choke	1.25
2382	Output transformer	1.50
2167-A	Tone control	.50
2505	Sensitivity control	.50
2170	Tone control knob	.10

"B" Power

Part No.	Description	List Price
2020	Transformer can	$0.35
2021	Transformer can base	.10
2325	Power transformer	3.00
2030	Vibrator clamp	.10
2098	Filter choke (55 mills)	.70
2115	3 layer bank choke	.30
2116	3 layer bank choke	.30
1588	Power choke complete in shield	.35
2404	Vibrator	4.50
2326	Electrolytic condenser	2.50
2259	.5 mfd. 120 V. condenser	.40
2260	.005 mfd. 1600 V. condenser	.50
2411	.0008 mfd. 1000 V. M. W. condenser	.15
2033	Vibrator socket (4 prong)	.10
	O. Z. 4 Tube (Raytheon)	1.75

Outer Housing

Part No.	Description	List Price
2300	Medallion plate	$1.00
2308	Front cover	2.00
2309	Back cover	1.75
2419	Gold plug buttons (large)	.03
2420	Gold plug buttons (medium)	.03
1900	Small gold plug buttons (small)	.03
2018	Jiffy mounting bracket	.60
2019	Set mounting contact wiper	.10
2017	Set mounting studs	.05
2172	5/16-¾ hex. head P. K. screws	.05
2171	5/16-18 hex. steel nuts (self locking)	.05
1995	Steel washers	.05

Speaker

Speaker only—see page 1.

Part No.	Description	List Price
2330	Housing only	$2.50
2331	Chrome bezel only	1.00
2332	Grill screen	.20
2333	Grill cloth	.25
2175	7 prong cable	.35
1500	Small pin prongs	.08
1501	Large pin prongs	.08
2155	Short speaker mounting stud	.20
1118	Long speaker mounting stud	.30
1797	2½ in. steel washers	.03
	⅜ in.—16 hex. head steel nuts (per doz.)	.25
2154	Spacer block (for mounting)	.10
2421	Cone and voice coil assembly	3.25
2422	Field coil	2.00
	Speaker replacement	5.00

NOTE: Due to the fact that speaker cones cannot be replaced by the service man in the field, it will be necessary to return all speakers to us for service. A charge will be made for parts and service according to the above rate (1799-1800).

Motorola Model 5T71

Part No.	Description	List Price
101	Control Head less shaft and cable	$6.00
102	BX-Flexible Shaft Complete	2.25
103	Walnut or Black Knobs	.10
104	Keys (No. 2178)—Each	.30
105	Dial Lights (No. 50)	.15
106	Lock Switch (No. 2174)	.75
107	Steering Post Clamps	.20
108	Volume Control (41-055)	1.00
109	Celluloid Dial	.25
110	Variable Condensers	3.50
111	Audio Choke (A-2016 or C-1013)	1.75
112	R. F. Coil	1.70
113	Antenna Coil	1.70
115	.01 Mfd. Tubular Condenser	.15
116	.05 Mfd. Tubular Condenser	.15
117	.003 Bakelite Condenser	.25
118	.00025 Mfd. Bakelite Condenser	.15
119	"A" Battery Cable	1.25
120	Speaker Cable	.75
121	"B" Battery Cable	.90
122	Antenna Cable	.75
123	Control Cable	1.10
124	Complete Cable Assembly	5.25
125	Resistors — State Value	.15
126	Speaker Housing	2.00
127	5X—.1 Mfd. Condenser (No. 7063)	1.00
128	Condenser Gear (K8-0)	.50
129	8 Mfd. Electrolytic Condenser	.50
130	6 Way Receptacle or Plug	.25
131	Tube Sockets	.15
132	Pinion Housing (K-5-3)	.30
133	4 Ohm Flexible Wire Wound Resistor	.20
134	Antenna Plug or Receptacle	.10

5T71 Speakers—Output Transformers—Speaker Cones

Part No.	Description	List Price
135	00990-D-16 Jensen Speaker	$6.50
135-A	Z-1158 Output Transformer for above	1.65
136	1675-D-15 Jensen Speaker	6.60

7T47A Speakers—Output Transformers—Speaker Cones

Part No.	Description	List Price
440	483-D 15 Jensen Speaker	$6.60
440-A	Z-1156 Output Transformer for above	2.10
441	2324-D-15 Stud Mounting Jensen Speaker	6.50
441-A	M-2324-1 Output Transformer for Above	2.10
442	Cone and Voice Coil Assembly for Jensen Speaker 483-A	2.25
443	Cone and Voice Coil Assembly for Jensen Speaker 2324-D-15	2.25
	Speaker Replacement Price List	3.25

Motorola Models S-10 and Home Sets—1933

Part No.	Description	List Price
1150	3 Gang Variable Condenser (R-175-A)	3.00
1151	10 Mfd. 20 Volt Electrolytic Condenser	.50
1152	J-8 Volume Control 50M Ohm (R-2083)	1.10
1153	S-10 Volume Control 500M Ohm (R-1009)	1.00
1154	S-10 Sensitivity Control (R-1008)	.80
1155	S-10 and J-8 Tone Control (13029)	.60
1156	20 Ft. Remote Control Cable (R-107)	2.50
1157	Spec. Lgth. Remote Control Cable (Per Ft.)	.15
1158	R. F. Plate Choke (RC-115)	.75
1159	S-10 and J-8 Antenna Coil Complete (AD-109-10)	.75
1160	J-8 R. F. Coil Complete (AD-111)	.60
1161	S-10 R. F. Coil Complete (RR-111)	.60
1173	S-10 Electrolytic Condenser (R-8800)	2.00
1174	25 Mfd S-10 Electrolytic Condenser (R-2520)	.75
1175	Fuse Block (F-2-B)	.15
1176	Bakelite Cap for Same (710)	.15
1177	1 Amp. Fuse (7AG)	.10
1178	Audio Transformer (0392-K)	2.50
1179	Power Transformer (2401)	4.50
1180	Filter Choke (1067-U)	2.10
1181	Filament Transformer (2399)	2.50
1182	12 Mfd. Electrolytic Cond. (No. 61130)	1.25
1183	Choke Coil for J-8 (No. 1725)	1.50
1184	Magnavox Speaker (R-2AGD)	9.00

1169	Remote Control Cabinets J-8 or S-10	1.50
1170	Tunalites (R-1054)	2.50
1171	6/8 Volt Dial Lights (No. 40)	.12
1172	J-8 Electrolytic Condenser (R-31632)	3.00
1185	Spec. R-2ADC Magnavox Output Trans.	1.75
1186	Magnavox Cone and Voice Coil Assembly	2.00
1187	Rola K-7 Speaker (RK-720)	12.00
1188	Spec. T-9452 Rola Output Transformer	1.45
1189	Rola Cone and Voice Coil Assembly	3.25
1190	AC Cord and Plug	.50
1191	J-8 Amplifier Cabinet	15.00
1192	S-10 Amplifier Cabinet	10.00

NOTE: Escutcheon Plates, Dials and Drives No Longer Available.

M-33

Part No.	Description	List Price
	1935 Film Type Control Head	
1681	Model 57 horizontal dial scale	$0.25
1682	Model 75 horizontal dial scale	.25
1622	Model 100 horizontal dial scale	.25
M-48	Model 57 vertical dial scale	.25
M-49	Model 75 vertical dial scale	.25
M-50	Model 100 vertical dial scale	.25
1624	Celluloid indicator film shield	.25
1608	Dial drive roller	.50
1606	Helical cut gear	.35
1604	Tuning shaft and drive worm gear	.50
M-44	Low loss lead-in	1.25
1654	Dual generator condenser	.40
1807	Dial light assembly complete less bulb	.30
1007	No. 50 dial light	.15

M-33A

Part No.	Description	List Price
	1936 Panel Type Control Head	
2211	Roller sprocket	$0.15
2212	Volume control shaft	.10
2213	Tuning shaft	.20
2214	Idler gear	.20
2215	Idler gear bushing	.10
2221	Celluloid crystal	.15
2222	Dial film strip	.25
2223	Dial light shield (green)	.10
2223-A	Dial light shield (red)	.10
2223-B	Dial light shield (blue)	.10
2227	Film tension spring	.20
2228	Sprocket hold-down spring	.10
2225	Tuning shaft 25 x 13/16 in.	1.00
2226	Volume control shaft 26 7/16 in.	1.00
1007	No. 50 dial light (6/8 volt)	.15
1526	Flexible shaft bushings	.25
1759	K-218 wire clips (per doz.)	.15
1807	Dial light assembly less bulb	.30

Motorola Models No. 34—Dual "6"—Twin "8"

Part No.	Description	List Price
	No. 34—D "6"—T "8" Control Unit	
1001-A	No. 34 Control Head Complete, less Shafts	4.00
1001-B	Dual-6 Control Head Complete less shafts	4.25
1001-C	Twin-8 Control Head Complete less shafts	4.25
1002	Pair Flexible Shafts Complete .... Pr.	2.00
1003	Tone Control Knob	.10
1004	Tuning Knob	.15
1005	Key Knob — Volume	.15
1006	Keys (Per Pair)	.25
1007	Dial Lights (Round Bulb)	.15
1008	Dial Crystal	.15
1010-A	Model 34 Volume Control (K-5468)	1.00
1010-B	Dual 6 and Twin-8 Volume Control (K-68)	1.00
1011-A	No. 34 Dial Plate	.15
1011-B	Dual-6 Dial Plate	.15
1011-C	Twin-8 Dial Plate	.15
1012	Die Cast Gear for Variable Cond. (K-61)	.25
1013	Bezel Ring	.10
1014	Dial Light Assembly Complete	.50
1015	Horse Shoe Washers .... Doz.	.25
1016	Dial Pointers .... Each	.05
	No. 34—D "6"—T "8" Chassis	
1017-A	Model No. 34—3 Gang Variable Cond.	2.50
1017-B	Dual-6—3 Gang Variable Condenser	2.50
1017-C	Twin-8—3 Gang Variable Condenser (State Make of Condenser when ordering.)	2.50
1018-A	Model 34 Antenna Coil Complete in Can	.60
1018-B	Dual-6 & Twin 8 Antenna Coil Cpt. in Can	.60
1019	R. F. Coil	.60
1020	Oscillator Coil	.80
1021	I. F. Coil	1.50
1022	Diode Coil	1.50
1023-A	Plate Choke—Enclosed Type	.20
1023-B	Plate Choke—Open Type	.20
1024	Padder Condenser (1000 MMF) All Models	.50
1025	.2 Mfd. 200 V. Condenser (101)	.20
1025	.2 Mfd. 200 V. Condenser (101)	.20
1026	.02 Mfd. 300 V. Condenser (025)	.15
1027	.25 Mfd. 300 V. Condenser (102)	.20
1028	.01 Mfd. 100 V. Tiny Tot Condenser (100)	.12
1029	.05 Mfd. 200 V. Condenser (103)	.15
1030	.05 Mfd. 400 V. Condenser (104)	.18
1031	.02 Mfd. 200 V. Condenser (105)	.15
1032	.02 Mfd. 400 V. Condenser (106)	.15
1033	.1 Mfd. 300 V. Condenser (107)	.15
1034	.01 Mfd. 400 V. Condenser (108)	.15
1035	.1 Mfd. 200 V. Condenser (114)	.15
1036	.01 Mfd. Padder Condenser (120)	.25
1037	.007 Mfd. 500 V. Tubular Condenser (141) (Replaces K-140)	.20
1038	.001 Mfd. Mica Condenser	.15
1039	.0001 Mfd. Mica Condenser	.15
1040	.0003 Mfd. Mica Condenser	.15
1041	.0005 Mfd. Mica Condenser	.15
1042	.0005 Mfd. White Dot Condenser	.20
1043	Resistors — (State value)	.15
1044	Twin-8 Input Audio Choke (2361-A)	1.00
1045	Twin-8 Output Transformer (2351)	1.25
1046	Twin-8 Input and Output Assemb. (10707) (Replaces No. 1044 and No. 1045)	2.50
1047	Variable Condenser Adjustment Cam	.10
1048	Variable Cond. Adj. Cam Guide Bracket	.10
1049	Variable Condenser Tension Spring	.05
1050	7 Way Chassis Plug	.50
1051	8 Point Solder Lug Strip	.10
1052	7 Point Solder Lug Strip	.10
1053	2 Way Speaker Receptacle — Dual-6 (No. 1802-C)	.10
1054	8 Point Solder Lug Strip with Tone Control Spring M-34	.15
1094	Dual-6 Speaker Plug (No. 2902)	.10
1095	Front Cover Only M-34 (No. 539)	.50
1096	Front Cover Cpt. less Speaker M-34 (539)	1.10
1098	Hash Wiper Springs .... Per Doz.	.25
1099	Dual 6 Term. Strip—3 Term. (No. 1731)	.10
1100	M-34 Term. Strip—2 Terminal (No. 1730)	.10
1101	Twin-8 Housing Terminal Strip (No. 1742)	.15
1102	"A" Battery Cable (Yellow) D-6 and T-8	.20
1103	"A" Bat. Cable (Black) D-6 and No. 34	.15
1104	3 Wire Speaker Cable	.25
1105	3½ Ft. Shielded Ant. Lead, D-6 and T-8	.35
1106-A	Antenna Lead M-34 (Male)	.30
1106-B	Antenna Lead M-34 (Female)	.20
1107	Solder Lug Strip 3 Pt. No. 34—D-6 and T-8	.16
1108	7 Way Chassis Receptacle	.50
1109	1 Way Antenna Receptacle	.10
1111	.004 Mfd. 500 V. Cond. and Choke (111)	.25
1112	.01 Mfd. 300 V. Cond. and Choke (112)	.25
1113	.001 Mfd. Red Dot Condenser	.15
1114	.005 Mfd. Yellow Dot Condenser	.20
	No. 34—D "6"—T "8" "B" Power Unit	
1095	Twin-8 "B" Power Unit Complete	12.00
1096	Dual-6 "B" Power Unit Complete	12.00
1057	Power Transf. (D-6 & T-8) (No. 2552)	2.50
1058	Power Transformer (D-6) (P-2534)	2.00
1059	Power Transformer (T-8) (P-2534MS)	2.25
1060	Power Transformer (M 34 Only) (P-2463)	2.00
1061	Radiart Vibrators M-34 (No. 3460-A)	4.50
1062	Elkonode Dual 6 & Twin-8 (T-33)	4.50
1063	Radiart Vibrator Dual-6 (No. 3399 and 3417)	4.50
1064	Filter Choke (5135-2543) (Interchangeable D-6 and T-8)	.70
1065	Filter Choke M-34 (No. 4430)	.60
1066	Filter Block for Twin-8 (No. 8825)	1.80
1067	Filter Block for Dual-6 (No. 8426)	1.75
1068	Filter Block M-34 (No. 34)	1.20
1069	77-E Lattice Wound "B" Hash Choke Assembly	.25
1070	Dual 77-E Lattice Wound "B" Hash Choke Assembly	.50
1071	Hash Choke (No. 4386)	.30
1072	Hash Choke M-34 (No. 4402)	.30
1073	Hash Choke M-34 (No. 4403)	.30
1074	Twin-8 Hash Chokes—Flat Type	.20
1075	Elkonode Shock Absorber Rubber Ring	.10
1076	4 Way Plug for Power Pack	.20
1077	Radiart Vibrator Socket	.10
1078	Mallory Elkonode Socket	.10
1079	4 Way Floating Type Elk. Recept. (741)	.25
1080	Bakelite Shell for Elkonode Recept. (716)	.20
1081	.5 Mfd. 120 V. Condenser (126)	.25
1082	.01 Mfd. 1600 Volt Condenser (131)	.25
1083	.5 Mfd. 120 V. Tubular Condenser (113)	.22
1084	.5 Mfd. 120 V. Elliptical Condenser (116)	.25
1084	.5 Mfd. 120 V. Electrolytic Cond. (116)	.25
1085	.02 Mfd. 1000 V. Condenser (117)	.20
1086	.5 Mfd. 120 V. Tubular Condenser (127)	.25
1087	.02 Mfd. 1000 V. Buffer Condenser (128)	.25
1088	Dual .5-.01 Mfd. Condenser (109 or 119)	.60
	No. 34—D "6"—T "8" Speakers	
1115	Twin-8 Speaker Housing	.90
1116	Twin-8 Grill	.40
1117	Twin-8 Speaker Short Mtg. Stud	.20
1118	Twin-8 Speaker Lug Mtg. Stud	.30
1119	Model 34 Quam Nichols Speaker (K-346)	3.75
1120	Dual-6 Jensen or Rola Speaker (K655)	4.50
1121	Twin-8 Magnavox or Rola Speaker (K-840)	6.00
1122	T-8 Speaker Cpt. in Housing with Mgt. Bolts	8.30
1123	D-6 Speaker Cpt. Cover with Conn. Plug	5.50
1124	34 Front Cover Cpt. with Speaker and Plug	5.00
1125	Model 34 Output Transformer (T-348)	1.00
1126	Z-1033 Dual-6 Output Transformer	1.25
1127	Output Transf. for T-8 (See 1045 or 1046)	
1128	Cone and Voice Coil Assembly for Mod. 34	1.60
1129	Jensen Cone and Voice Coil Assembly for Dual-6	2.00
1130	Rola Cone and Voice Coil Assembly for Dual-6	2.00
1131	Rola Cone and Voice Coil Assembly for Twin-8	2.25
1132	Magnavox Cone and Voice Coil Assembly for Twin-8	2.25
	Model 34 Speaker Replacement	1.85
	Model D6 Speaker Replacement	2.75
	Model T8 Speaker Replacement	4.10
	No. 34—D "6"—T "8" Outer Housing, Cable and Filters	
1090	Rear Cover for Twin-8	.50
1091	Front Cover for Twin-8	.40
1092	Dual-6 Back Cover	.30
1093	Dual-6 Front Cover	.30

Motorola Models No. 44 and Super "6"

Part No.	Description	List Price
	No. 44 and Super "6"—Control Unit	
901	Control Head Complete	$6.00
902-A	32" Flexible Shaft (Model 44)	3.25
902-B	36" Flexible Shaft (Model S-6)	3.50
903	Spacer Block	.20
603	Clutch Spring	.10
904	Filler Ring	.20
905	Hexagon Nut (Eccentric)	.15
906	Convex Glass Crystal	.25
907	Chrome Plated Band	.25
908	Mounting Strap	.25
909-A	Dial Plate (Model 44)	.15
909-B	Dial Plate (Model S-6)	.15
910	Special Black Knob	.20
911	Condenser Gear, Bakelite (State Coarse or Fine Tooth)	.30
912	Keys (K-01) .... Each	.20
913	Dial Light (No. 50)	.15
914	Drive Pinion	.30
928	.25 Mfd. 300 V. Tubular Cond. (No. 1840)	.20
929	.01 Mfd. 300 V. Tubular Cond. (No. 1741)	.15
930	.05 Mfd. 400 V. Tubular Cond. (No. 1999)	.15
931	.09 Mfd. 300 V. Tubular Cond. (No. 1972)	.15
932	.01 Mfd. 400 Volt Tubular Condenser	.15
933	2M-20M-20M Ohm Candohm Resistor (No. 4220A)	.50
934	2M-20M-20M-370 Ohm Candohm Resistor (No. 4422)	.60
935	Any Resistor (State Ohmage)	.15
936	10 Mfd. Electrolytic Condenser (No. 1020)	.30
937	1 Way Plug	.10
938	4 Way Plug	.20
939	Tube Socket, State Type	.10
	No. 44 and Super "6"—"B" Power Supply	
940-A	44 Power Pack Cpt. in Can with Cover	12.00

Motorola Models No. 44 and Super "6" (Cont.)

Part No.	Description	List Price
915	500,000 Ohm Volume Control (8651-C)	1.00
916	Dial Light Socket	.15
917	Dial Light Assembly Complete	.30
	No. 44 and Super "6"—Chassis	
918	2 Gang Variable Condenser (44SM)	2.00
919-A	Model 44 Antenna Coil Complete in Can	1.00
919-B	Model S-6 Antenna Coil Complete in Can	1.00
920-A	Model 44 Oscillator Coil Complete in Can	.90
920-B	Model S-6 Oscillator Coil Complete in Can	.90
921	1st I. F. Coil Complete in Can	1.25
922	2nd I. F. Coil Complete in Can	1.25
923-A	Model 44 Diode Coil Complete in Can	1.00
923-B	Model S-6 Diode Coil Complete in Can	1.00
924	.0005 Mfd. Midget Mica Condenser	.15
925	Alum. Tube Shield and Base (No. 01090)	.20
926	Audio I. F. Trans. (No. 2311) (S-6 Only)	1.30
927	.1 Mfd. 200 V. Condenser (No. 1649)	.15
	Outer Housing, Cable and Filters	
959	Model 44 Front Cover Cpt. less Speaker	.50
960	Model S-6 Front Cover Cpt. less Speaker	.40
961-A	Model 44 Back Cover	.40
961-B	Model S-6 Back Cover	.40
962	2 Way Receptacle (J-1802)	.15
963	4 Way Receptacle (No. 1804-C)	.20
964	Antenna Plug Shield Assembly	.35
965	Polarizing Receptacle (No. 1825)	.25
966	Cable Terminal Strip (3-T)	.10
967	"A" Battery Cable (Black)	.15
968	Speaker Cable (S-6 Only)	.25
969	Antenna Loom in Running Lengths, per ft.	.10
970	3½ Ft. Antenna Shielded Loom	.35
971	Red Dot Condensers, Mica	.15
972	.25 Mfd. 160 V. Tubular Condenser	.20
973	Dial Lite Filter Choke and Condenser	.25
974	20 Turns No. 12 Wire Eliminode Choke (Used on "A" Battery and Power Supply)	.20
975	26 Turns No. 16 W. Hash Eliminode Choke	.20
976	Volume Control Bracket	.10
977	Clutch Spring for Shaft Cone (No. 20-C)	.05
940-B	S-6 Power Pack Cpt. in Can with Cover	12.00
941	2 Way Plugs	.10
942	T-60 or 70-B Elkonode in Can with Plug	5.50
943	T-35 Elkonode in Cardboard Container with Leads (Model 44)	3.75
944	Vibrator (Utah) (G-536)	5.00
945	Power Transformer (No. 2250) (44 Only)	2.25
946	Power Transformer (No. 2270) (S-6 & 44)	2.25
947	Power Transformer (Utah) (No. 1092)	1.95
948	Filter Choke (No. 2060-F)	1.00
949	Filter Choke Coil (Utah) (No. 4267)	1.00
950	Axley only for T-35 Elkonode	.80
951	8/12 Mfd. 300 V. Electrolytic Cond. (8123)	1.50
952	8/4 Electrolytic Condenser (No. 8420)	1.20
953	4/6 Mfd. Electrolytic (Utah) (No. 46200)	1.00
954	.5 Mfd. 160 V. Tubular Cond. (1706)	.50
955	.01 Mfd. 1600 V. Tubular Cond. (1709)	.40
956	5 Prong Socket with Spacer Pin	.15
957	R. F. Choke Coil Cpt. in can with Condenser and Leads	.70
978	S-6 Speaker Housing (N*)	.75
979	Speaker Grill 4" for S-6 Only	.40
980	Short Speaker Stud	.20
981	Long Speaker Stud	.30
982	Thumb Screw for Stud Assembly	.10
983	Model 44 Speaker on front cover with plug connector complete	3.75
984	S-6 Speaker in Housing with Mtg. Studs and Cable Complete	8.50
985	Utah Model 44 Speaker less O. P. Transf. (No. 2060)	3.00
986	Magnavox Speaker less O. P. Transf. (44)	3.00
987	Utah Speaker for S-6 (Less Transf.) (6510)	6.50
988	Output Transformer for 44 (No. 7121)	1.25
989	Output Transf. for S-6 (No. 7202)	1.50
990	Cone and Voice Coil Assembly for No. 2060 Speaker	1.60
991	Cone and Voice Coil Assembly for Magnavox Speaker	1.60
992	Cone and Voice Coil Assembly for No. 6510 Speaker	2.00
	44 Speaker Replacement	3.25
	56 Speaker Replacement	4.25

Model "50"

Part No.	Description	List Price
	Chassis	
	Chassis only—less tubes	$27.50
2349	Tube shield	.40
2345	Variable condenser mounting bracket	.25
2050	3 gang variable condenser	3.50
2053	Variable condenser adjustment cam	.05
2400	Shoulder screw 68TS	.05
2054	Variable condenser tension spring	.10
2336	Volume control	1.00
2023	Volume control funnel	.05
2339	Antenna coil (complete in can)	1.50
2073	R. F. coil (complete in can)	1.00
2074	Oscillator coil (complete in can)	1.00
2340	I. F. coil (complete in can)	1.25
2337	Diode coil (complete in can)	1.50
2320	Output transformer	1.00
599	Glass-tube sockets (state type)	.10
2402	Grip caps (per doz.)	.25
1815	Bias cell	.20
1777	Resistors (state value)	.15
1039	.0001 mfd. MT condenser	.15
1040	.0003 mfd. MT condenser	.15
1041	.0005 mfd. MT condenser	.15
2269	.007 mfd. 500 V. condenser	.20
2252	.05 mfd. 400 V. coupling condenser	.20
2255	.01 mfd. 1000 V. condenser with 500M ohm resistor and mounting strap	.50
2256	.1 mfd. 200 V. condenser	.15
2258	.25 mfd. 300 V. condenser	.30
1403	.03 mfd. 100 V. condenser	.15
2254	.05 mfd. 25 V condenser	.15
2251	.01 mfd. 300 V. condenser	.15
	"B" Power	
2020	Transformer can	$0.35
2021	Transformer can base	.10
2030	Vibrator hold-down clamp	.10
2316	Filter choke	.60
2315	Power transformer	2.00
1588-C	Power choke (complete in shield)	.35
2404	Vibrator	4.50
2317	Electrolytic condenser	1.40
2116	3 layer hash choke	.30
2272	.01 mfd. buffer condenser	.25
2259	.5 mfd. 120 V. condenser	.40
2093	Vibrator socket (special)	.10
	Outer Housing	
2341	Front cover only	$1.75
2342	Back cover	1.25
1500	Plug button (small)	.03
1792	Plug button (large)	.03
2018	Jiffy mounting bracket	.60
2019	Set mounting contact wiper	.10
2017	Set mounting bolts	.05
2171	5/16 in. hex. head steel nuts	.05
2172	5/16 in. x ⅝ in. H. H. P. K. screws	.05
	Speaker	
	Speaker only—see page 1.	
2555	Speaker plug (3 way) and cap	$0.10
2323	3 Way Socket	.10
2321	Grill screen	.10
2319	Grill cloth	.15
2425	Cone and voice coil	1.75
2426	Field coil	2.00
	Speaker replacement	2.80

NOTE: Due to the fact that speaker cones cannot be replaced by the service man in the field, it will be necessary to return all speakers to us for service. A charge will be made for parts and service according to the above rate (1799-1800).

Part No.	Description	List Price
	Cables and Eliminode System	
2334	Choke coil (resistance wire)	$0.35
2535	Choke coil (enameled wire)	.25
2118-A	Speaker field choke	.20
2119	Speaker voice coil choke	.20
2120	"A" lead filter choke	.35
1403	.03 mfd. 100 V. condenser	.15
2271	.5 mfd. 120 V. condenser	.40
2270	.1 mfd. 25 V. condenser	.15
2313	600 mmfd. padder condenser	.40
2510	Large prong dial light receptacle	.10
2311	Small prong antenna receptacle	.10
2176	Antenna loom complete	.75
2417	"A" cable complete with fuse	.40
2416	30 ampere fuse	.05

Models H-45—G-54—W-58 Home Sets—1934

Part No.	Description	List Price
120	2 Gang Variable (For G-54—W-58) (No. 5-456)	2.00
1202	2 Gang Variable (For H-45) (No. 5-24000)	2.00
1203	Vol. Control (G-54—W-58) (No. 5100)	1.00
1204	Volume Control (H-45) (No. 4338)	1.00

1225	Mallory Bias Cell	.20
1226	Any Resistor (State value)	.10
1227	5000 Ohm Red Devil Resistor 10 Watt	.30
1228	Cordohm and Plug for H-45	1.00
1229	A. C. Cord and Plug (G-54 and W-58)	.50
1230	5" Dynamic Speaker for H-45 (A-437)	5.50
1231	Output Transformer for Same (T-467)	.85
1232	Cone and Voice Coil Assembly (H-45)	1.00
1233	8" Dynamic Speaker for (G-54 and W-58) (A-583)	6.50
1234	Output Transformer for Same (T-610-A)	1.25
1235	Cone and Voice Coil Assembly (G-54—W-58)	2.25
1236	Knobs for H-45 (No. 259-260) .... Pair	.25
1237	Knobs for G-54 and W-58 (No. 157) .... Each	.10
1328	Celluloid Dial for G-54—W-58 (No. 520)	.20

Motorola Model No. 55

Part No.	Description	List Price
601	Control Head	$6.00
602	Flexible Shaft Complete with Pinion	3.50
603	Clutch Spring	.10
604	Shielded Dial Light Wire Cpt. with Dial Light Socket	.50
715	Volume Control	1.00
606	2 Gang Variable Condenser	2.00
607	Antenna Coil Complete in Can with Leads	1.00
608	Oscillator Coil Cpt. in Can with Leads	.80
609	I. F. Transformer Complete in Can	1.25
610	Diode Feeder Complete in Can	1.25
611	Resistors — State Value	.15
612	Tube Socket — State Type	.10
613	.05—160 Volt Condenser	.20
614	.015—200 Volt Condenser	.18
615	.0005 Mica Condenser	.12
616	.05—300 Volt Condenser	.20
617	.01—200 Volt Condenser	.18
618	.25—160 Volt Condenser	.20
619	.01 Mfd. 160 Volt Condenser	.15
	T-31 Elkonode (55A)	3.75
620	.5 Mfd. 160 Volt Condenser	.25
621	.0025 Mfd. Hash Filter Condenser	.20
622	2 Point Terminal Strip	.12
623	Filter Choke (No. 1663-G)	1.00
624	Power Transformer (No. 2149)	2.00
625	No. 34 Elkonode	3.75
626	Power Pack Assembly Complete	12.00
627	Dual 8 Mfd. Electrolytic Condenser	1.50
628	8-30 Mfd. Electrolytic Condenser	1.70
629	Hash Filter Choke	.30
630	.01—1600 V. Buffer Condenser	.30
631	"A" Solenoid Choke	.25
632	.25 Mfd. 300 Volt Condenser	.35
633	Antenna Cable	.40
634	"A" Cable—3 Lead Shield	.80
635	5/16" Oval Head Set Mtg. Bolts	.05
636	Magnavox Dynamic Speaker No. 150-D-55	6.25
637	No. 2150 Output Transformer	1.25
638	Cone & Voice Coil Assembly for Magnavox Speaker No. 150	2.00
	Speaker Replacement Charge	3.25

Motorola Model 57

Part No.	Description	List Price
1770	Model 57 control head cpt. less shafts	$4.00
1761	Pair flexible shafts cpt. (30 in. long)	2.00
1761-A	Pair flexible shafts cpt. (24 in. long)	2.00
1761-B	Pair flexible shafts cpt. (18 in. long)	2.00
1761-C	Pair flexible shafts cpt. (36 in. long)	2.00
1003	Tone control knob (K-30)	.10
1509	Iron core I.F. coil cpt. in can	2.00
1510	Iron core diode coil cpt. in can	2.00
1451	Small tube shield (Fin. type)	.15
1455	Dual tube shield (Fin. type)	.20
1429	750 mfd. padder condenser (Red dot)	.50
1691	250 mmf. padder condenser (Blue dot)	.50

Motorola Model 57 (Cont.)

1473-4	Volume control shaft cpt.	1.00
1473-5	Tuning shaft cpt.	1.00
1004	Tuning knob (Black finish)	.20
1005	Key knob Vol. control (Black finish)	.20
1006	Keys (Per pair)	.25
1007	Dial light (No. 50)	.15
1008	Dial crystal	.15
1557	Model 57 dial plate only	.15
1013-A	Bezel ring and cork gasket	.10
1769	Dial light assembly cpt. less Bulb	.30
1016	Dial pointers (K-9)	.05
1015	Horseshoe washers (per dozen)	.25
1012	Die cast gear for variable cond. (K-41-A)	.25
1449	Model 57 Volume control	1.00
1771	Dial plate and pointer assembly cpt.	.35
1758	Idler gear and shaft assembly	.15
1326	Bushings for end of flexible shafts	.30
1420	Drive shaft pinion fitting	.15
1422	Volume control shaft fitting	.15
1756	Mounting bracket for steering post	.15
1760	Pinion fitting for key	.15
1762	Flexible shafts any length (per ft. each shaft)	.40
1772	Steel gears	.05
1773	Tin sleeves for vol. control shaft	.05
1774	¼ x ⅝ in. fill. head screw for mtg. control	.03

Chassis

1442	2 gang variable condenser	$2.00
1053	2 way chassis receptacle (1802)	.10
1441	2 way speaker receptacle (1 large and 1 small prong)	.10
1109	1 way Antenna receptacle (91-S)	.10
1776	Sockets (state type)	.10
1520	Variable tension spring	.05
1502	Antenna coil cpt. in can	.60
1503	Oscillator coil cpt. in can	.80
1507	I.F. coil cpt. in can	1.90
1508	Diode coil cpt. in can	1.90
1574	New style air core antenna coil cpt. in can	.70
1670	Iron core ant. coil cpt. in can	2.00
1511	New type oscillator coil cpt. in can	.80

Outer Can, Cables and Filters

1457	Outer can only	$1.25
1458	Front cover only	1.25
1459-C	Back cover assembly cpt.	3.00
1458-C	Front cover cpt. with speaker and grill	5.90
1459-M	Back cover cpt. for 62 model	3.75
1842	Black plug buttons	.03
1393	1 way ant. plug (91-P and lug)	.10
1392	2 way elim. plug (1902 and lug)	.10
1443	2 way speaker plug and cap	.10
1341	"A" battery cable and shield (36 ins. long)	.25
1543	"A" battery cable and shield (26 ins. long)	.20
1343-C	Shielded antenna lead in less bushings	.50
1545	3 Ft. antenna lead (replaces above)	.35
1500	Small cover hold down buttons	.05
1113	.001 red dot mica condenser	.15
1408	.5 mfd. 25 V. condenser	.30
1548	.5 mfd 25 V. condenser (replaces above)	.25
1369	Hash choke (Pie wound in fibre container)	.15
1497-A	Hash choke (Round)	.20
1497-B	Hash choke (Round)	.20
1493-C	Hash choke (No. 15 wire)	.30
1826	Set mtg. studs (K-3516)	.05

1815	Bias cell	.20
1803	Bias cell mounting cup and terminal	.10
1520-B	Terminal mtg. strip and cone control spring	.10
1040	.003 mfd mica condenser	.15
1042	.0005 mfd mica condenser (White dot)	.20
1038	.001 mfd mica condenser	.15
1046-A	.00112 mfd mica condenser (Green dot)	.20
1400	.01 mfd 100 V. condenser	.12
1404	.05 mfd 400 V. condenser	.10
1416	.01 mfd 300 V. condenser	.15
1417	.1 mfd 100 V. condenser	.15
1418	.1 mfd 300 V. condenser	.20
1026	.02 mfd 300 V condenser (K-025)	.15
1816	.004 mfd 500 V. condenser (K-152)	.15
1517	.25 mfd 25 V. condenser	.20
1569	.01 mfd 250 V. condenser	.15
1409	.05 mfd 25 V. condenser	.15
1034	.01 mfd 25 V. condenser (K-100)	.15
1027	.25 mfd 300 V. condenser (K-102)	.20
1777	Resistors (state value)	.15

"B" Power Unit

1836	Power transformer (2985-A)	$2.00
1837	Filter choke (C-1492)	.60
1424	(Electrolytic condenser) (4 and 2 mfd at 250 volts)	1.00
1540	(Electrolytic condenser) (5, 5 and 10 mfd. at 200/200 and 25 volt). New	1.30
1453	Transformer can only	.90
1460	Elkonode socket case	.20
1461	Top cover for same	.05
1462	Bottom cover for same	.05
1350	Elkonode contact washer	.05
1784	Mallory Elkonode (53T)	4.50
1785	Radiart Vibrator (5815-B)	4.50
1405	.5 mfd 50 Volt condenser	.35
1413	.01 mfd 1600 Volt condenser	.25
1516	.02 mfd 400 Volt condenser	.20
1825	Hash choke (4506)	.30
1787	Lattice wound hash choke assembly (77-B)	.25
1838	18 T. No. 20 wire choke coil	.10
1493-A	28 T. No. 18 wire choke coil (in tube)	.20
1703	Perforated spun tube shield (G-621-U)	.15
1794	Shakeproof lockwashers (4018-32)	.05
1795	2¼ in. steel washers (K-225)	.03
1796	8 x ½ in. oval hd. self tapping screws (per 100)	1.00
1564	Sponge Rubber (per doz.)	.25

Speaker

1550	5 in. Dynamic speaker only	$3.75
1550-A	Speaker cpt. with 2 way plug	5.90
1521	Wire screen for grill	.10
1551	Grill cloth	.10
1552	Cardboard gasket	.05
1458-C	Speaker cpt. mt'd. on front cover	5.50
1839	Output transformer only	1.00
1840	Cone and voice coil assembly (replaced at factory)	1.75
1841	Speaker field coil (replaced at factory)	2.00
	Speaker Replacement	1.85

NOTE Due to the fact that dust-proofed-type speaker cones cannot be replaced by the service man in the field, it will be necessary to return all speakers to us for service. A charge will be made for parts and service according to the above rate (1799-1800).

Model "60"

Chassis

Part No.	Description	List Price
	Chassis only—less tubes	$50.00
2011	Tube shield (fin type)	.30
2013	Tube shield (formed)	.20
2050	3-Gang variable condenser	3.50
2051	Variable condenser mounting bracket	.15
2400	Shoulder screw (68TS)	.05
2055	Variable condenser adjustment cam	.05
2401	Variable condenser drive gear (K41A)	.25
2054	Variable condenser tension spring	.10
2166	Volume control	1.00
2023	Volume control funnel	.05
2071	Antenna coil (complete in can)	1.60
2073	R. F. coil (complete in can) includes plate choke	1.00
1403	.03 mfd. 100 V. TT condenser	.12
2273	.003 mfd. 100 V. condenser	.12
2251	.01 mfd. 300 V. condenser	.15
2254	.05 mfd. 25 V. condenser	.15
2278	.01 mfd. 100 V. condenser and 500M ohm resistor (with mounting straps)	.30
2256	.1 mfd. 200 V. condenser	.15
2257	.1 mfd. 25 V. condenser and mounting strap	.20
2258	.25 mfd. 300 V. condenser	.30
2263	.03 mfd. 300 V. condenser	.15
2267	.1 mfd. 25 V. condenser	.15
1777	Resistors (state value)	.15
2170	Tone control knob	.10
2146	Tone control terminal strip	.10
2148	Tone control screw	.10
2014-C	Tone control assembly complete	.40

"B" Power

2020	Transformer can	$0.35
2021	Transformer can base	.10
2030	Vibrator hold-down clamp	.10
2099	Power transformer	2.50
2100	Filter choke (70 mills)	.70
2115	3 layer hash chokes	.30
2116	3 layer hash chokes	.30
1588-C	Power choke complete in shield	.35
2404	Elkonode (94) Mallory	4.50
2188	Electrolytic condenser	1.60
2259	.5 mfd. 120 V. condenser	.40
2260	.005 mfd. 1600 V. condenser	.40
2033	Vibrator socket (special)	.10
1776	No. 84 socket	.10

Outer Housing

2015	Front cover (less ornaments)	$1.50
2016	Rear cover	1.25
2196	Medallion plate	.50

Part No.	Description	List Price
2076	Oscillator coil (complete in can)	1.00
2077	I. F. coil (complete in can)	1.25
2078	Diode coil (complete in can)	1.60
2094	Output transformer	1.25
1776	Glass tube sockets (state type)	.10
2034	2-way receptacle	.15
2035	5-way receptacle	.25
2038	Eliminode and chassis wiper	.20
1929	Lug D/L Mounting Strip	.10
2402	Grid caps (per doz.)	.25
1815	Bias cell	.20
2040	D/L Mounting and B. C. cup	.15
1039	.0001 mfd. type M. T. condenser	.15
2403	.00015 mfd. type M. T. condenser	.15

Part No.	Description	List Price
2341	.0001 mfd. trimmer condenser	.15
2243	.0003 mfd. trimmer condenser	.20
2342	Padder condenser	.30
2259	.5 mfd. 120 V. condenser	.40
2416	30 ampere fuse (3-AG)	.05
2176	51 in. antenna loom, complete with plug	.75
2176A	44 in. antenna loom, complete with plug	1.00
2178	Male section "A" cable	.30
2179	"A" cable—battery end—comp. with fuse	.25
2181	Female junction box only	.10
2180	Junction box mounting strap	.05
2041	1 way antenna receptacle	.10
2042	Antenna lead plug and ferrule only	.20
2055	Elim. screw tension washer	.05

Motorola Model 75

Control Unit

Part No.	Description	List Price
1766	Model 75 control hd. cpt. less shafts	$6.25
1761	Pair flexible shafts cpt. (30 in.)	2.00
1473-4	Vol. control shaft cpt.	1.00
1473-5	Tuning control shaft cpt.	1.00
1003	Tone control knob (K-50)	.10
1761	Pair flexible shafts cpt. (30 ins. long)	2.00
1761-A	Pair flexible shafts cpt. (24 ins. long)	2.00
1761-B	Pair flexible shafts cpt. (18 ins. long)	2.00
1761-C	Pair flexible shafts cpt. (36 ins. long)	2.00
1764	Tuning knob (Ivory finish)	.20
1765	Key knob (Vol. control) (Ivory finish)	.20
1006	Keys (Per pair)	.25
1007	Dial lite No. 50	.15
1008	Dial crystal	.15
1736	Mounting bracket	.15
1565	Dial plate only (Model 75)	.15
1013-A	Bezel ring and cork gasket	.10
1763	Dial light assembly cpt. (less bulb)	.30
1016	Dial pointers (K-9)	.05
1015	Horseshoe washers (per dozen)	.25
1012	Die cast gear for var. condenser	.25
1466-A	Volume control (Model 75)	1.00
1767	Tone control assembly cpt.	.25
1768	Dial plate and pointer assembly cpt.	.35
1758	Idler gear and shaft	.15
1759	Clip fasteners for T.C. and D.L. wires (per dozen)	.15
1326	Bushings for end of flexible shafts	.30
1422	Volume control shaft fitting	.15
1420	Drive shaft pinion fitting	.15
1760	Pinion fitting for key	.15
1762	Flexible shafts any length (per ft. each shaft)	.40
1772	Steel Gears	.05
1773	Tin sleeves for vol. control shaft	.05
1774	¼ x ⅝ in. fill. head screw for mtg. control	.05

"B" Power Output

1818	Power transformer (2839-B)	$2.25
1819	Power transformer (3030)	2.25
1820	Filter choke (2543-F)	.70
1821	Filter choke (3050)	.70
	6 and 6 mfd. at 350 volt, 3 lead	1.60
1465	Electrolytic condenser	
1466	Electrolytic condenser 6/4/5 mfd at 200/200/12½ volts. New	1.60
1363	Transformer can	.40
1357	Elkonode socket case	.20
1358	Top cover	.10
1359	Bottom cover	.10
1350	Elkonode contact washer	.05
01457	Aluminum tube shield	.15
01109	Tube shield base	.05
1822	50 ohm ½ watt resistors	.15
1787	Lattice wound hash choke assembly (77-B)	.25
1823	Hash choke (4506)	.30
1872	Hash choke (4402)	.30
1490	13 turns No. 16 wire choke	.20
1493	30 turns No. 18 wire choke	.20
1516	.02 mfd 400 Volt condenser	.20
1405	.5 mfd 50 Volt condenser	.35
1415-B	.01 mfd 1600 Volt condenser	.25
1419-B	.02 mfd 1000 Volt condenser	.25
1548	.5 mfd 25 Volt condenser	.25
1784	Mallory elkonode (53T.)	4.50
1785	Radiart Vibrator (5015-B replaces all models)	4.50
1786	Spec. elkonode for 12 volt operation (G-53T.)	5.50

Outer Housing, Cables and Eliminode

1365-C	(Model 75 outer can cpt. with Eliminode system and cables, less covers)	$9.00
1365-M	Same except for 79 Model	10.00
1367	Back cover	1.00
1366	Front cover only	1.25
1366-C	Front cover cpt. with speaker Grill, and spkr. plug	6.00
1366-M	Same except for 79 Model	6.25
1824	(Eliminode travel section cpt. with choke and bracket, ready to mount)	1.50
1349	Terminal strip	.20
1109	1 way receptacle	.10
1331	4 way socket	.20
1326	Bushing for ant. and M/N cables	.30
1341	"A" battery cable (36 ins. long)	.25
1543	"A" battery cable (26 ins. long)	.20
1343	Antenna lead in and bushing cpt.	.60
1346	Motor noise lead in and bushing cpt.	.60
1344	Shielded loom for ant. junction box	.15

Chassis

Part No.	Description	List Price
1467	3 gang variable condenser	$2.50
1811	1 way antenna plug (91-P)	.10
1434	4 way male plug	.20
1441	2 way speaker receptacle (1 large and 1 small pin)	.10
1776	Sockets (state type)	.10
1520	Variable tension spring	.05
1362	Tube shield with vol. cont. bracket	.25
1361	Dual tube shield (Fin. type)	.25
1439	1000 mmf. padder condenser	.50
1492	Antenna coil cpt. in can	.60
1483-A	R.F. coil cpt. in can (with plate choke)	.90
1812	Oscillator coil cpt. in can	.90
1587	New style diode coil cpt. in can	1.30
1813	I.F. Coil cpt. in can (K-685)	1.30
1814	Diode coil cpt. in can (K-690)	1.30
1666	Iron core antenna coil cpt.	2.00
1815	Bias cell	.20
1801	Mt. cup for bias cell	.15
1817	.0002 mfd. mica condenser	.15
1040	.0003 mfd. mica condenser	.15
1041	.0005 mfd. mica condenser	.15
1038	.001 mfd. mica condenser	.15
1400	.01 mfd. 100 Volt condenser	.12
1400 A	.01 mfd. 100 Volt condenser	.12
1403	.03 mfd. 120 Volt condenser	.15
1027	.25 mfd. 300 Volt condenser (K-102)	.20
1816	.004 mfd. 500 Volt condenser (K-142)	.15
1514	.1 mfd. 200 Volt condenser	.15
1515	.007 mfd. 500 Volt condenser	.20
1518	.01 mfd. 400 Volt condenser	.15
1506	.01 mfd. 400 Volt condenser	.15
1513	.05 mfd. 25 Volt condenser	.35
1575	.05 mfd. 120 Volt condenser	.20
1777	Resistors (state value)	.15
1790	Junction box assembly complete	.50
1545	Antenna lead in (new style)	.40
1545-A	Motor Noise lead in (new style)	.40
1333	Motor noise ant. receptacle (large prong)	.10
1333	Antenna receptacle (small prong)	.10
1300	Small pin cable prong	.08
1301	Large pin cable prong	.08
1374	Small fibre extruded washers (per dozen)	.30
1390	Long condenser plates	.05
1391	Round condenser plates	.05
1348	Insulator for round plates (per dozen)	.30
1476	Insulator for long plate (per dozen)	.30
1592	Extruded insulator for long plate	.03
1440	½ in x ½ in. wood dowel (per dozen)	.30
1480	½ in. x 1½ in. wood dowel (per dozen)	.30
1369	Small hash choke (pie wound)	.15
1469	Medium hash choke (pie wound)	.20
1040	.003 mfd. mica condenser	.15
1041	.0005 mfd. mica condenser	.15
1408	.5 mfd. 25 V. condenser	.30
1548	.5 mfd. 25 V. condenser	.25
1493-C	Hash choke (No. 15 wire)	.30
1407	Tone control choke and bracket	.20
1497-D	Hash choke	.20
1488	Hash choke	.20
1351	Steel gear for elim. adjust.	.15
1337	¼ in. eliminode travel screw	.10
1305	Ground clamp	.10
1825	Green plug button	.05
1794	Shakeproof lockwashers (4018-32)	.05
1795	2¼ in. steel washers (K-225)	.05
1796	8 x ½ in. oval hd. self tapping screws (per 100)	1.00
1826	Set mtg. studs (K-3516)	.05

Speaker

1560	6 in. Dynamic speaker (6551-A-K-6A)	$4.00
1827	Output transformer for same (Z-1195)	1.25
1566	6 in. Dynamic speaker (6732-A-P6-R-7018)	4.00
1828	Output transformer for same (6732-A)	1.25
1829	Speaker cone and voice coil (replaced at factory)	2.25
1830	Speaker field coil (replaced at factory)	2.00
1443	2 way plug and cap	.10
1561	Grill cloth only	.15
1527	Wire screen for grill	.10
1562	Paper gasket	.05
	Speaker replacement	2.75

NOTE: Due to the fact that speaker cones cannot be replaced by the service man in the field, it will be necessary to return all speakers to us for service. A charge will be made for parts and service according to the above rate (1829-1830).

2116	5 layer hash choke	.30
1500	Power choke complete in shield	.35
2404	Elkonode	4.50
2185	Electrolytic condenser	2.00
2259	.5 mfd. 120 V. condenser	.40
2268	.005 mfd. 1600 V. condenser	.30
2411	.0008 mfd. 1000 V. M. W. condenser	.35
2033	Vibrator socket 4 prong spec.	.10
1473	Grill screen	.10
2175	Speaker cable with pin prongs	.35
1500	Small pin prongs	.08
1501	Large pin prongs	.08

Model 80 (Cont.)

Part No.	Description	List Price
2198	Medallion plates (each)	.50
2199	Name plate	.50
1792	Black plug buttons (large)	.05
2412	Black plug buttons (medium)	.03
1500	Black plug buttons (small)	.03
2018	Jiffy mounting bracket	.60
2019	Set mounting contact wiper	.10
2017	Set mounting bolts	.05
2172	5/16 x ⅝ in. H. H. P. K. screws	.05
2171	5/16-18 hex. steel nuts self-locking	.05

Speaker

Part No.	Description	List Price
	Speaker only—see page L	
1375	Speaker housing	$0.90
1376	Speaker bezel	.60
2169	Grill cloth	.15
2155	Short speaker stud	.20
1118	K-305 Long speaker stud	.30
1797	K-250 2½ in. steel washer	.05
	⅜ x 16 hex. steel nuts (per doz.)	.25
1809	⅜ x 16 x ¾ in. thumb screw	.05
	⅜ in. iron washer (per doz.)	.25
	⅜ in. lockwasher (per doz.)	.25
2413	Cone and voice coil	2.75
2414	Field coil	2.00
2096	Output transformer	1.25
	Speaker replacement	4.00

NOTE: Due to the fact that speaker cones cannot be replaced by the service man in the field, it will be necessary to return all speakers to us for service. A charge will be made for parts and service according to the above rate (1799-1800).

M-99

Airplane Type Control Head

Part No.	Description	List Price
2205	Pointer disc assembly	$0.25
2206	Dial plate (background)	.10
2207	Etched glass dial face	.25
2208	Bezel ring	.15
2415	K-13 stop set screws for knobs (per doz.)	.25
1008	Dial crystal	.15
2144	Felt washer for bezel	.05
1807	Dial light assembly less bulb	.30
1007	No. 50 6/8 volt dial light	.15
	3 ft. No. 20—1/64 black wire and plug	.10
2225	Tuning shaft, 25 15/16 in.	1.00
2226	Volume control shaft, 26 7/16 in.	1.00
1326	Flexible shaft bushings	.50
1759	K-218 Wire clips (per doz.)	.15

Motorola Model 100

Control Unit

Part No.	Description	List Price
1750	Model 100—Control head cpt. less shafts	$5.00
1761	Pair flexible shaft cpt. (30 ins. long)	2.00
1761-A	Pair flexible shafts cpt. (24 ins. long)	2.00
1761-B	Pair flexible shafts cpt. (18 ins. long)	2.00
1761-C	Pair flexible shafts cpt. (36 ins. long)	2.00
1473-4	Vol. control shaft cpt.	1.00
1473-5	Tuning shaft cpt.	1.00
1751	Tone control knob (K-37)	.10
1752	Tone control resistance unit (K-36)	.25
1753	Tone control assembly cpt. less resistor	.25
1754	Tuning knob (chrome plated)	.20
1755	Key knob (Vol. control) (chrome plated)	.20
1006	Keys per pair	.25
1007	Dial lite No. 50	.15
1008	Dial crystal	.15
1756	Mounting bracket for steering post	.15
1535	Glass Dial face	.30
1530	Black background plate	.10
1531	Retainer ring for dial face	.05
1532	Pointer disc	.05
1015-A	Bezel ring and cork gasket	.15
1763	Dial light assembly cpt.	.30
1015	Horseshoe washer (per dozen)	.25
1012	Die cast gear for variable	.25
1757	Pointer disc and shaft assembly cpt.	.15
1758	Idler gear and shaft	.15
1399	Volume control	1.00
1759	Clip fasteners for T.C. and D.L. wires (per dozen)	.15
1326	Bushing for end of flexible shafts	.50
1422	Volume control shaft fitting	.15
1420	Drive shaft Pinion fitting	.15
1760	Pinion fitting for key	.15
1762	Flexible shafts any length (per ft. each shaft)	.40
1772	Steel gears	.05
1773	Tin sleeves for vol. control shaft	.05
1774	¼ x ⅜ in. fil. head screw for mtg. control	.05
1410	.01 mfd. 100 volt & 20 M. ohm condenser and padder	.15
1412	.03 mfd. 400 volt and coil condenser tone control	.35
1368	.002 mfd. 100 volt and 25 M. ohm condenser and padder	.20
1777	Resistors (state value)	.15
1435	500 ohm candohm resistors	.25
1436	50-70 ohm candohm resistors	.25
1438	290 ohm and 200 ohm variable resistor	.40

Chassis

Part No.	Description	List Price
1303	3 gang variable condenser	$2.50
1311	Tube shield (finished type)	.50
1520	Variable tension spring	.05
1312	Variable condenser shield	.25
1331	4 way receptacle	.15
1548	1 way ant. receptacle	.10
1776	Sockets (state type)	.10
1439	1000 mmf. padder condenser	.50
1482	Antenna coil cpt. in can (76 tube)	.75
1581	New type antenna coil cpt. in can (37 tube)	.75
1483	R.F. coil cpt. in can and plate choke	.75
1583	New style R.F. coil cpt. in can and plate choke	.75
1485	Oscillator coil cpt. in can	.90
1850	I.F. Coil cpt. in can (K-605)	1.30
1855	Diode coil cpt. in can (K-690)	1.50
1585	New Style I.F. coil cpt. in can	1.30
1587	New style diode coil cpt. in can	1.50
1586	New style plate choke only	.20
1779	Output transformer only	1.25
1780	Input audio choke only	1.25
1690	Iron core antenna coil cpt. in can	2.00
10857	Audio and output transformer assembly (76 tube)	2.50
1554	Audio and output transformer assembly (37 tube)	2.50
1040	.003 mfd. mica condenser	.15
1041	.0005 mfd. mica condenser	.15
1042	.0005 mfd. mica condenser (1000 volt—white dot)	.20
1400	.01 mfd. 100 volt condenser	.12

1402	.25 mfd. 300 volt condenser	.30
1404	.05 mfd. 400 volt condenser	.18
1406	.02 mfd. 400 volt condenser	.15
1407	.01 mfd. 300 volt condenser	.25
1409	.05 mfd. 130 volt condenser	.18
1791	Any length Speaker cable cpt. (state length) (per foot)	.15
1327	Bushing for ant. and M/N.	.30
1412	.03 mfd. 400 V. condenser and coil	.35
1403	.03 mfd. 25 V. condenser	.12
1408	.5 mfd. 25 V. condenser	.30
1043	.0005 mfd. mica condenser	.15
1497	40 T—No. 18 wire hash choke	.20
1494	50 T—No. 18 wire hash choke	.20
1491	6 T—No. 14 wire hash choke	.20
1792	Black plug buttons	.03
1793	Set mounting studs (K-3536)	.05
1794	Shakeproof lockwashers (4018-32)	.05
1795	2¼ in. steel washers (K-225)	.03
1796	8x¼ in. oval hd. self tapping screws (per 100)	1.00

Speaker

Part No.	Description	List Price
1470	8 in. dynamic speaker (Early Model)	$6.00
1570	8 in. dynamic speaker (Late Model)	6.00
1375	Speaker housing only	.90

"B" Power Unit

Part No.	Description	List Price
1781	Power transformer (2988)	$2.50
1782	Filter choke (2543-D)	.70
1388	Electrolytic condenser (8/8/25 mfd. 550/350/25 volt	1.75
1307	Transformer can	.40
1309	Elkonode socket case	.15
1308	Cover for same	.10
1306	Choke and condenser shield can	.25
1350	Blk. contact washer	.05
1783	Perforated tube shield (G-621-U)	.15
1784	Mallory Elkonode (53T)	4.50
1785	Radiart Vibrator (5015-B replaces all models)	4.50
1786	Spec. elkonode for 12 volt operation (G-55 T)	5.50
1405	.5 mfd. 50 v. condenser	.35
1403	.03 mfd. 120 v. condenser	.12
1406	.02 mfd. 400 v. condenser	.20
1413-0	.01 mfd. 1600 v. condenser (oil type)	.50
1567	.01 mfd. 1600 v. condenser (wax type)	.35
1419	.02 mfd. 1000 v. condenser	.25
1572	.02 mfd. 1000 v. condenser	.35
1787	Lattice wound hash choke assembly (77-E)	.25
1588	New style hash choke	.35
1588-C	New style hash choke asmd. in shield	.35
1497-C	Hash choke (paper tube)	.30
1788	Hash choke (3 layer pie wound) (K-6810A)	.35

Outer Housing, Cables and Eliminodes

Part No.	Description	List Price
1315-C	Model 100—outer can cpt. with Eliminode system and cables, less covers	$10.00
1315-M	Same except for 110 Model	11.00
1317	Back Cover only	1.00
1316	Front cover only	1.00
1316-C	Front cover cpt. with name plate	1.25
1789	Eliminode travel section cpt. with choke and bracket, ready to mount	1.50
1314	Terminal strip	.20
1330	4 way male plug	.20
1347	1 way ant. plug	.10
1341	"A" battery cable	.25
1343	Antenna lead in and bushing cpt.	.60
1346	Motor noise lead in bushing cpt.	.60
1345	Antenna lead in (new style)	.40
1345-A	Motor noise lead in (new style)	.40
1344	Shielded loom for ant. junction box	.15
1790	Junction box assembly cpt.	.50
1333	Antenna receptacle (small prong)	.10
1335	Motor noise receptacle (large prong)	.10
1300	Small pin cable prong	.08
1301	Large pin cable prong	.08
1374	Small fibre extruded washers (per dozen)	.50
1390	Long condenser plates	.05
1391	Round condenser plates	.05
1308	Insulator for round cond. plates (per doz.)	.30
1309-A	Insulator for 6 long condenser plates, each	.10
1476	Insulator for single long condenser plate (per dozen)	.30
1437	½x7⁄8 in. wooden dowel (per dozen)	.30
1440	½x⅜ in. wooden dowel (per dozen)	.30
1309	Small hash choke (pie wound)	.15
1351	Steel gear for elim. adjust.	.15
1337	¼ in. eliminode travel screw	.10
1305	Ground clamp	.10
1342	3½ ft. speaker cable cpt. with term. prongs	.35
1302	Motorola name plate	.30
1376	Chrome plated speaker bezel	.60
1472	Wire screen for speaker	.10
1471	Grill cloth for speaker	.05
1117	Short speaker stud (K-302)	.20
1118	Long speaker stud (K-305)	.30
1797	2½ in. steel washers	.05
1798	Speaker cpt. in housing with mtg. studs, etc.	8.60
1799	Speaker cone and voice coil (replaced at the factory)	2.75
1800	Speaker field coil (replaced at the factory)	2.00
1809	⅜-16 x ⅜ Thumb Screw	.05
	Speaker Replacement	4.10

NOTE: Due to the fact that speaker cones cannot be replaced by the service man in the field, it will be necessary to return all speakers to us for service. A charge will be made for parts and service according to the above rate (1799-1800).

Special for Model 110

Part No.	Description	List Price
1690	Iron core antenna coil	$2.00
1315-M	Special outer can complete	11.00
1612-C	Special tone control assembly	.60
1333	1 way antenna receptacle	.10
M-44	Low loss lead-in	1.25
1654	Dual generator condenser	.40
1493-C	No. 15 wire hash choke	.30

Special Accessories for 1935 Ford Models

Part No.	Description	List Price
1542F	8 Ft. Speaker Cable	$1.00
1458-FC	Model F-57 Special Front Cover complete	2.50
1844	Special Ford Ant. Junction Box (All Models)	.40
1646	Overhead Speaker Mounting Bracket only	1.50
1645	Bezel Ring for same	.40
1644	Grill Screen for Ford or Studebaker	.25
M-51	Bezel Ring and screws for Studebaker Not	.35
1643	Grill Cloth for Ford or Studebaker	.15
1640-F	6" Dynamic Speaker for Overhead Mounting (all models)	4.00
1844-A	Ford Overhead Speaker complete with Bracket, Bezel and Cable, ready to mount	6.50
1366-FC	Model F-75 Special Front Cover complete	2.50
1651-F	Terminal Strip for Front Cover	.20

In the first models of this receiver a bypass condenser block (P-82600) containing condensers: C2, C4, C10, C14, C15 and C16 was used. Condenser C16 was removed in the later models and added as a separate tubular condenser (P-81132) while the other condensers remained in the block (P-82600-D).

A second condenser change from the earlier models was in the electrolytic filter block (P-82002). In this block section C24 was changed from an 8 mfd.. 250 volt

MODEL 5-Y
Alignment
Drive Cord Data
Resistance Data

GAMBLE-SKOGMO, INC.

Condenser Alignment

Misalignment or mistracking of condensers generally manifests itself as broad tuning and lack of volume at portions or all of the standard wave band. The receivers are all properly aligned at the factory with precision instruments and realignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment. A signal generator that will provide accurately calibrated signals over the standard wave band and an output meter are required for indicating the effect of adjustments.

First remove the cover of the box. Leave the antenna and battery cables connected to the chassis.

Disconnect the car antenna and connect antenna cable lead to the lead from the signal generator.

Set the signal generator for 1450 K. C. Turn the rotor to the full open position. The antenna lead from the signal generator adjustment is connected to the antenna lead of the receiver. Adjust the trimmer of the oscillator section of the 2 gang condenser until maximum output is obtained. The oscillator section is the one with the cut plate rotor.

Now set the signal generator for 1400 K. C. and turn the rotor until maximum output is obtained. Adjust the other two trimmers on the gang condenser for maximum output.

To calibrate the receiver, tune in a station of known frequency at about the center of the dial. Remove the escutcheon plate and glass. The pointer is held in position by friction. Grasp the pointer at the center and turn it until it points to the frequency of the station being received.

The use of the cut plate type of condenser eliminates the necessity of a 600 K. C. padder and, therefore, no adjustment at this frequency is required.

Adjusting Antenna Trimmer

After the receiver is installed and the car antenna is connected it will be necessary to adjust the antenna trimmer. Tune in a weak signal between 1200 and 1400 K. C. with the volume control about three-fourths on. Drop the chassis from the cover. The location of the antenna trimmer is shown in Fig. 2. Turn the adjusting screw of this condenser up or down until maximum output is obtained. CAUTION—Do not turn any of the other trimmer adjusting screws for this adjustment.

Removing Chassis From Case

First unsolder the black, brown, yellow, and green speaker leads which connect to the terminal strip adjacent to the vibrator unit. Next, notice the small length of braided shielding which is soldered to the solder lug that is secured to the chassis case between the dial scale and the station selector control shaft. Unsolder this shielding at the lug.

Remove the 4 screws which hold the chassis in the case — 2 are in the side and 2 on the speaker panel of the chassis case. (Do not remove the four speaker mounting screws.)

Remove the two control knobs by pulling them off of the shaft.

Next remove the volume control. To do this first loosen the hexagonal nut on the inside of the case with a flat wrench. Then unscrew and remove the round knurled nut from the front.

The chassis may then be taken out.

Replacing Vibrator Unit

The vibrator unit is plugged in in the same manner as a tube. This unit may, in case of failure, be readily replaced. CAUTION—Polarity, as explained in the label on the unit and in the label on the metal box in the chassis, must be observed when plugging in vibrator unit.

In replacing the vibrator unit be sure to replace the corrugated cardboard pad, which prevents the unit from working its way out of the socket.

When servicing this receiver, a new vibrator unit should be tried out in the same manner as a new set of tubes would be tried out.

One or more vibrator units should be kept on hand for replacement purposes.

Replacing Volume Control

To remove the volume control and the switch, first pull the knob from the volume control shaft. Next loosen the hexagonal nut on the inside of the case with a flat end wrench. Then unscrew and remove the round knurled nut from the front.

The old volume control and switch connections may now be unsoldered and the new unit put in its place and the leads resoldered.

Fasten the volume control to the case in the reverse order in which it was removed.

D. C. Resistance of Windings

Following are the D. C. resistances of the various windings in the chassis. The values given below will vary slightly in different sets.

Part No.	Item	Code	D.C. Resistance in Ohms

Replacing Drive Cord

The drive cord in this receiver may be replaced as follows:

Fig. 3—Cord Drive—Top View

First remove the chassis from the case as explained on page 4.

Some of the first models did not have two fibre "end" washers on the drive shaft to protect the drive cord as shown in Fig. 3. If this is the case, these washers should be put on as follows:

Separate and take off the horse-shoe lock washer which holds the drive shaft in position. This may be done with a fine jewel, long nose plier.

Now pull the drive shaft out just far enough to permit the two fibre washers to be slipped over the end of the shaft.

Then slip the shaft back into place and replace the horse-shoe lock washer.

Knot one end of the new drive cord and with the condenser plates in a completely closed position, slip the drive cord through the small hole "A" in the drive drum — see Fig. 4. The knot will then be on the inside of the drum.

Now wrap the cord around the lower half of the drive drum as indicated and bring it up to the drive shaft. Proceed by wrapping it in a clockwise direction (from

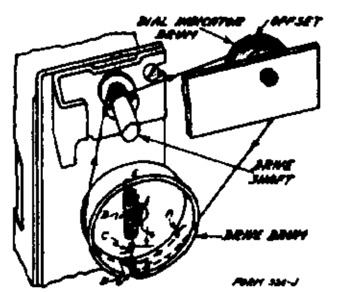

Fig. 4—Cord Drive Replacement

front) around the drive shaft three and one-quarter turns between the two fibre washers, progressing towards the front of the chassis. Be sure that the condenser plates are kept in a closed position and that the cord is held tight.

Set the dial indicator drum so that the offset is at the top or a little to the right of the center — see Fig. 4.

Wrap the cord from the drive shaft once around the offset in the dial indicator drum and then approximately one and one-half turns around the drum itself in a clockwise direction, progressing toward the back.

From the dial indicator drum draw the cord over the lower right hand quarter of drive drum as shown in Fig. 4.

Fig. 5—Drive "Take-up" Spring

Then bring the cord inside of the drum by way of the turned-in portion of the flange at "B".

Tie the drive tension spring "D" to the loose end of the cord at the point "C" just above the top edge of the lip "B" as shown in the illustration. This should be done so that the lower hook of spring "D" at point "C" will be between ⅛" and ¼" from top edge of the turned-in portion of the flange "B" in the flange of the drive drum. After the spring is hooked and the drive turned over several times the tension in the cord will cause this distance to become about ¼".

Now, by applying a tension on the drive spring "D", hook the other end of the spring into the small hole "E" near the top of the drive drum. Hook spring from the inside out.

After the cord has been put on it may be necessary to calibrate the receiver as explained in the article on condenser alignment.

All of the earlier models did not have drive shaft "take-up" springs. This spring will prevent any tendency toward change of setting should the receiver be subjected to vibration. To insert these springs and fibre washers on the drive shaft proceed as follows:

Remove the station selector knob by pulling it off of the shaft.

Slip the small fibre washer over the shaft and clip the "take-up" spring to the drive bracket as shown in Fig. 5.

The chassis may now be replaced into the case in the reverse order of the manner in which it was removed.

Condenser Alignment

Misalignment or mistracking of condensers generally manifests itself is broad tuning and lack of volume at portions or all of the broadcast band. The receivers are all properly aligned at the factory with precision instruments and realignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment. A signal generator that will provide accurately calibrated signals over the broadcast band and an output indicating meter are advisable. The procedure is as follows:

As the I.F. stages are self-tuned, no I.F. aligning at the intermediate frequency of 175 K.C. is required.

First set the signal generator for a signal of exactly 1400 K.C. Connect the antenna lead from the signal generator to the antenna lead of the receiver and the ground lead of the signal generator to the ground of the receiver. Then turn the tuning condenser rotor until the marker is at 1400 K.C. on the dial scale. Adjust the two trimmers on the tuning condenser for maximum output adjusting the oscillator trimmer first.

Next set the signal generator for a signal of 600 K.C. and adjust the oscillator 600 K.C. trimmer. The adjusting screw will be seen at the side of the tuning condenser and is reached from the top of the chassis. A non-metallic screw-driver is necessary for this adjustment. Turn the tuning condenser rotor until maximum output is obtained. Then turn the rotor slowly back and forth over this setting at the same time adjusting the 600 K.C. trimmer screw until the highest output is obtained.

Circuit Data, Changes
Alignment

GAMBLE-SKOGMO, INC.

Dual band coverage is accomplished by means of dual sets of R. F. and oscillator coils and a three section double throw switch. The various circuits made and broken as this switch is thrown are indicated in the schematic circuit diagram Fig. 2.

Referring to the schematic, the standard wave coils are indicated by the letter B, while the short wave coils are indicated by the letter D. The antenna transformer primaries are connected in series. When the switch is in the standard wave position, the B secondary is connected to the grid circuit of the 6D6 R.F. amplifier while the C secondary is open circuited. When the switch is in the short wave position, the C secondary is connected to the grid circuit of this tube while the B secondary is short circuited. The secondary in use is tuned by the antenna section of the three gang condenser.

The output of the R. F. 6D6 tube is fed through another R. F. transformer with tuned secondary into a second 6D6 tube which functions as the first detector. The interstage section of the three gang condenser is used for tuning this circuit. As in the case of the antenna transformer, the R. F. interstage transformer standard wave windings are indicated in the schematic by the letter B, while the short wave windings are indicated by the letter D. The connections to the two coils are made in the same manner as described above for the antenna R. F. transformer.

A separate type 76 tube is employed in the oscillator circuit. Referring to the schematic, B is the standard wave grid coil and D is the short wave grid coil. The winding shown below is the oscillator plate coil. The grid coil in use is tuned by the oscillator section of the three gang condenser. The oscillating circuit is always resonant at 456 KC above the frequency to which the R. F. amplifier is tuned. When the switch is in the standard wave position, connections are completed to the B grid coil and the D grid coil is open circuited. When the switch is in the short wave position, connections are completed to the D grid coil and the B grid coil is short circuited. Padding condensers C22 and C23 are used in conjunction with the standard wave and short wave oscillator circuits respectively.

The oscillator potential is fed into the cathode circuit of the 6D6 first detector tube. This results in the intermediate or beat frequency of 456 K.C. being present in the plate circuit of this tube.

One stage of I. F. amplification is employed using a 6D6 tube. The primaries and secondaries of the first and second I. F. transformers are tuned by small trimmer condensers.

A type 6B7 duo diode pentode tube functions as the second detector and a one stage audio amplifier. The two diode plates are connected together. AVC voltage is applied through isolating resistors to the control grid circuits of the R. F. and I. F. tubes. The audio voltage developed across volume control resistor R9 is applied through the movable arm to the control grid of the 6B7 tube. Resistance coupling is used between the first audio stage and the output stage which employs a type 42 output pentode tube. A type 80 full wave rectifier tube is used in the power unit.

Alignment and Calibration

A signal generator that will provide an accurately calibrated signal at 456, 1730, 1500, 600, 18,300, 15,000 and 6000 KC and an output indicating meter are required. It will be practically impossible to align the receiver if unsatisfactory apparatus is used.

Use a non-metallic screw driver for the adjustments. The complete procedure is as follows:

I. F. Adjustment

Set the signal generator for a signal of 456 KC.

Connect the antenna lead of the signal generator thru a .1 MF condenser to the grid of the 1st detector.

Connect the ground lead of the signal generator to the chassis ground.

Turn the band switch to the standard wave position.

Turn the volume control to the maximum position.

Attenuate the signal from the signal generator to prevent the leveling-off action of the A.V.C.

Then adjust the four I. F. trimmers until maximum output is obtained. The adjusting screws for these condensers are reached from the top of the chassis, and the location is shown in Fig. 6.

1730 KC Adjustment

Set the signal generator for 1730 KC.

Turn the rotor of the tuning condenser to the full open position.

Keep the band switch in the standard wave position.

Connect the antenna lead of the receiver through a 250 mmf. condenser to the output of the signal generator.

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the oscillator standard wave trimmer (C19) until maximum output is obtained. The location of this trimmer is shown in Fig. 4.

1500 KC Adjustment

Set the signal generator for 1500 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Loosen the pointer set screw and set the pointer at the 1500 KC mark on the standard wave band scale. Retighten the set screw.

Adjust the interstage standard wave trimmer (C7) and antenna standard wave trimmer (C2) until maximum output is obtained.

Do not change the setting of the oscillator standard wave trimmer.

600 KC Adjustment

Set the signal generator for 600 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 600 KC trimmer until the peak of greatest intensity is obtained. See Fig. 4 for location of this trimmer.

Be sure to use a non-metallic screw driver for this adjustment.

18,300 KC Adjustment

Set the signal generator for 18,300 KC.

Turn the rotor of the tuning condenser to the full open position.

Turn the band switch to the short wave position.

As mentioned above, keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the oscillator short wave trimmer (C20) until maximum output is obtained. See Fig. 4 for location of this trimmer.

If a maximum output peak cannot be reached, it may be due to the fact that the antenna and interstage short wave trimmers are screwed down too far. Back off these two trimmer screws two or three turns and then adjust the oscillator short wave trimmer for maximum ouptut.

15,000 KC Adjustment

Set the signal generator for 15,000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the interstage short wave trimmer (C8) and antenna short wave trimmer (C3) until maximum output is obtained.

When adjusting the interstage short wave trimmer, it will be necessary at the same time to turn the tuning condenser rotor slowly back and forth until the peak of greatest intensity is obtained.

Then go back and repeat the procedure as given for the 18,300 KC adjustment. If it is found necessary to make any appreciable change in the setting of the oscillator short wave trimmer, the 15,000 KC adjustment must be repeated.

Do not make any further change in the setting of the oscillator short wave trimmer.

6000 KC Adjustment

Set the signal generator for 6000 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 6000 KC trimmer until the peak of greatest intensity is obtained. See Fig. 4 for location of this trimmer.

Use a non-metallic screw driver for this adjustment.

Servicing R. F. Coil Assemblies

The R. F. coil assemblies in this receiver are sold complete with can. This is due to the fact that the trimmers are soldered to the can, and cannot be easily disassembled.

The lead colors and resistances of the various windings in each assembly are shown in Fig. 3.

If it is ever necessary to remove one of coil assemblies from the can, proceed as follows: First remove the nuts from the screws at the top of the can. The outside lug on the trimmer condenser is inserted in a slot in the coil can, and this lug is soldered into position.

Apply a soldering iron to the can at the point of the soldered connection. Then with a screw driver lift up on the outside edge of the trimmer (edge soldered to can) until the trimmer is clear of the can. After the trimmers are all unsoldered, the coil can be taken out.

Twenty-five Cycle Receivers

The twenty-five cycle receiver differs from the sixty cycle receiver only in the fact that a different power transformer is used. The correct power transformer is shown in the parts list.

The twenty-five cycle chassis can be operated satisfactorily from a sixty cycle power supply. However, the reverse is not true, the sixty cycle receiver cannot be operated from a twenty-five cycle power supply.

A 115-230 Volt, 40 to 60 cycle as well as other power transformers with special power ratings are also available for this model.

Phonograph Connections

Phonograph connections can be made as shown in Fig. 7. The parts required are shown in the parts list. Knockouts are provided in the back panel of the chassis for mounting the phono jack and phono switch —see Fig. 8.

For mounting the 12 mfd. 25 volt dry electrolytic condenser, two No. 27 drill holes should be drilled in the side of the chassis base directly below the wet electrolytic condensers. These holes are 1¼" from the bottom, ⅞" and 3¼" from the front of the chassis.

The ground lug which extends out from the side of the chassis should be bent back into the chassis wall.

The connections are made by opening the diode return circuit at the volume control. Unsolder the shielded lead which runs from the I. F. transformer to the volume control at the lug on the volume control. Cut this lead to length and connect it to the switch as shown in Fig. 7. The extra length of shielded lead which is provided, is connected from the volume control R9 to the phono switch as illustrated.

Remove the ground from the cathode terminal of the 6B7 2nd detector tube by bending the chassis ground lug away from this terminal. Be sure to solder back to this ground lug any leads that were connected to it (not including cathode connection of socket).

Connect one side of the 12 mfd. 25 volt electrolytic condenser to ground and the other side of the condenser to the cathode terminal of the 6B7 2nd detector and the phono switch as shown in Fig. 7. To this same terminal on the phono switch connect the 900 ohm .2 watt resistor. The other side of this resistor goes to ground. Complete the other connections as illustrated.

A high impedance pick-up should be used. If a low impedance pick-up is used a step-up transformer will be required for sufficient volume. The volume control and tone control of the set will regulate the phono volume and tone.

Changes in Early Models

In the early models of this receiver the oscillator standard wave trimmer C19 was in the oscillator coil can—see Fig. 4.

In the early models the antenna transformer had two B primary windings as shown in Fig. 5. In later models only one winding was used as shown in Fig. 3.

Replacing Drive Cord

Remove chassis from cabinet.

Take off the pilot light assembly by lifting off the two sockets and spring clips.

Detach the large pointer by removing the screw at the center of the dial.

Loosen the dial assembly by taking out the two screws which secure the bottom of this assembly to the chassis.

Then lay the complete dial assembly face downward in front of the chassis. It is not necessary to remove the volume control and tone control collars which hold the indicator cords of these two controls in position.

Turn the drive drum until the opening in this drum is approximately vertical and with the hole at the top as shown in Fig. 4.

Remove the tension spring and the old drive cord.

See that the eyelet is in the hole in the drive drum as shown in Fig. 4. Insert one end of the drive cord from the outside through the hole in the eyelet in the drive drum.

Tie the end of the cord which has been inserted in the hole to one end of the tension spring.

Wrap the cord in a clockwise direction (facing front of chassis) around the drive drum approximately one-half turn.

Then tilt the chassis up on its back panel and bring the cord mentioned in the previous paragraph down to the drive shaft. Wrap it two and one-half times around the drive shaft as shown in Fig. 4.

Then bring this cord up from the drive shaft and wrap it around the drive drum approximately one and one fifth

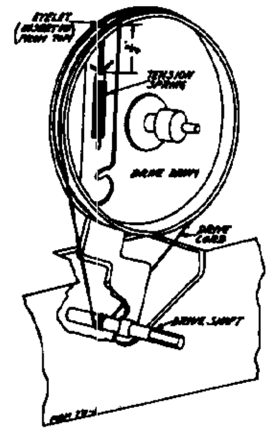

Fig. 4—Drive Cord Replacement

turns in a clockwise direction until it is up to the hole in this drum as illustrated.

Insert the free end of the cord through the hole in the eyelet and tie it to the end of the tension spring. The end of the spring, when hanging free, should be approximately ¾" from the flange of the drum as shown in Fig. 4. Cut off the surplus length of cord after it is knotted.

Then secure the other end of the tension spring over the spur on the drive drum.

Replace the dial assembly and pointer.

Replace the pilot light assembly after which the chassis may be reinstalled in the cabinet.

Phono Connections

Phonograph connections can be made as shown in Fig. 5. A single pole double throw switch and double pin jack are required. These should be mounted on the back panel of the chassis close to the 2nd detector. The connections are made by opening the diode circuit at the point shown in the illustration and completing the connections to the switch and pin jacks as indicated. A high impedance pick-up should be used. If a low impedance pick-up is used a step-up transformer will be required for sufficient volume. The volume control of the set will regulate the phono volume.

Change in Early Models

In the early models of this receiver the side of the trimmer condenser C27 which is shown in Fig. 1 as connected to ground was connected to the B+ side of the 3rd I. F. coil primary.

Condenser Alignment

Correct alignment is extremely important in connection with all wave receivers. The receivers are all properly aligned at the factory with precision instruments and re-alignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment. A signal generator that will provide an accurately calibrated signal of 456 K. C and accurately calibrated signals over the broadcast and short wave bands, 530-1740 K. C. and 5.8-18.3 M. C., is required. An output indicating meter is also necessary. It will be practically impossible to align the receiver if unsatisfactory apparatus is used.

Use a non-metallic screw driver for the adjustments. The complete procedure is as follows:

Intermediate Frequency Adjustment

Set the signal generator for 456 K. C. Connect the antenna lead of the signal generator to the grid of the 1st detector through a .05 mfd. condenser. Turn the tuning condenser rotor until the plates are completely out. The ground lead from the signal generator goes to the ground lead of the receiver. The volume control should be at the maximum position. Reduce the signal so that A. V. C. action is not obtained.

Then adjust the five I. F. trimmer condensers until maximum output is obtained. The adjusting screws for the 1st and 2nd trimmer condensers are reached from the top of the chassis and are in the round I. F. cans - See Fig. 2. The openings to these trimmer condensers are covered over by small cover plates which are held in position by screws. Loosen these screws until the cover plates can be swung around. **CAUTION - Use an insulated screwdriver for adjusting trimmers to prevent short circuiting to ground.** In the 3rd I. F. coil, only the primary has a variable trimmer condenser. This condenser is mounted on the back panel of the chassis as shown in Fig. 2 and the adjustment screw is reached through a hole in the back panel.

Broadcast Band Adjustment

The broadcast short wave switch should be in the broadcast position. Set the signal generator for 1740 K. C. Turn the rotor to the full open position. The antenna lead from the signal generator is in this instance connected to the antenna lead of the receiver. Reduce the signal so that A. V. C. action is not obtained. Adjust the oscillator broadcast trimmer until maximum output is obtained. This trimmer is on the tuning condenser and its location is shown in Fig. 2.

Then set the signal generator for 1500 K. C. Turn the rotor until maximum output is obtained. Loosen the set screw in the pointer hub and set the pointer at the 1500 K. C. mark on the broadcast band scale. Retighten the hub set screw. Then adjust the antenna and 1st detector broadcast trimmers until maximum output is obtained.

Next set the signal generator for 600 K. C. and adjust the 600 K. C. trimmer. The adjusting screw is reached through a hole in the front panel of the chassis as shown in Fig. 2. Turn the tuning condenser rotor until maximum output is obtained. Then turn the rotor slowly back and forth over this setting at the same time adjusting the 600 K. C. trimmer screw until the highest output is obtained.

Short Wave Band Adjustment

CAUTION—After the broadcast band alignment as described above has been made, do not change the adjustment of any of the broadcast band trimmers.

In aligning the short wave band of the receiver, it will be noted that the signal will be heard with the signal generator set at two points 912 K. C. apart. That is, if the receiver is tuned to 15,000 K. C. a signal will be heard when the signal generator is set at 15,000 K. C. and again at approximately 15,912 K. C. This is due to image reception or the fact that a 456 K. C. beat is obtained when the signal is 456 K. C. lower than the receiver oscillator and also when the signal is 456 K. C. higher than the receiver oscillator. Care should be taken to see that the receiver is tracked with the signal generator adjusted to the lower of the two frequencies at which a signal is heard, in order that the oscillator in the receiver will be 456 K.C. higher in frequency than the signal.

Turn the broadcast short wave switch to the short wave position. Turn the rotor to the full open position. As explained above, the volume control should be at the maximum position and the signal should be reduced to prevent A. V. C. action. Set the signal generator for 18,300 K. C. Then adjust the oscillator short wave trimmer for maximum output. This trimmer is reached from under the chassis and its position is shown in Fig. 2. If a maximum output peak cannot be reached, it may be due to the fact that the antenna and 1st detector short wave trimmers are screwed down too far. Back off these two trimmer screws two or three turns and then adjust the oscillator short wave trimmer for maximum output.

Next set the signal generator for 15,000 K. C. Turn the rotor until maximum output is obtained. Then adjust the antenna and 1st detector short wave trimmers for maximum output.

Next set the signal generator for 6000 K. C. and adjust the 6000 K. C. trimmer. This condenser is mounted on the front panel of the chassis as shown in Fig. 2 and is reached through a hole in the front panel. Turn the tuning condenser rotor until maximum output is obtained. Then turn the rotor slowly back and forth over this setting, at the same time adjusting the 6000 K. C. trimmer screw until the highest output is obtained.

Alignment and Calibration

Correct alignment is extremely important in connection with all wave receivers. The receivers are all properly aligned at the factory with precision instruments and realignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment.

A signal generator that will provide an accurately calibrated signal at 456, 1730, 1500, 600, 5800, 5000, 18,300, 15,000 and 6000 KC and an output indicating meter are required. It will be practically impossible to align the receiver if unsatisfactory apparatus is used. If a station is tuned in with the selectivity control in the broad position and this control is then turned to the sharp position, the station may disappear. This is not an indication that the receiver is out of alignment.

Use a non-metallic screwdriver for the adjustments. The complete procedure is as follows:

I. F. Adjustment

Set the signal generator for a signal of 456 KC.

Connect the output of the signal generator to the grid of the 1st detector through a 0.1 MF condenser.

Connect the ground lead of the receiver to the ground post of the signal generator.

Turn the band selector to the Range B position (standard wave band—purple dial color).

Turn the selectivity control to the sharp position and keep it in this position for all adjustments.

Turn the volume control to the maximum position.

Attenuate the signal from the signal generator to prevent the leveling-off action of the A.V.C.

Then adjust the five I.F. trimmers until maximum output is obtained. The adjusting screws for these condensers are reached from the top of the chassis, and the location is shown in Fig. 5.

Range B Alignment

1730 KC Adjustment

Set the signal generator for 1730 KC.

Turn the rotor of the tuning condenser to the full open position.

Keep the band selector in the standard wave position.

Connect the antenna lead of the receiver through a 200 mmf. condenser to the output of the signal generator.

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the oscillator Range B trimmer (C38) until maximum output is obtained. The location of this trimmer is shown in Fig. 3.

1500 KC Adjustment

Set the signal generator for 1500 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Loosen the pointer set screw and set the large pointer at the 1500 KC mark on the standard wave band scale. Retighten the set screw.

Adjust the 1st and 2nd interstage Range B trimmers (C8 and C13) and antenna Range B trimmer (C2) to maximum.

Do not change the setting of the oscillator Range B trimmer.

600 KC Adjustment

Set the signal generator for 600 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 600 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

Be sure to use a non-metallic screwdriver for this adjustment.

Range C Alignment

5800 KC Adjustment

Set the signal generator for 5800 KC.

Connect the antenna lead of the receiver through a 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band selector to the Range C position (1st short wave band—green dial color).

As mentioned above, keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the oscillator Range C trimmer (C40) until maximum output is obtained. See Fig. 3 for location of this trimmer.

5000 KC Adjustment

Set the signal generator for 5000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the 1st and 2nd interstage Range C trimmers (C9 and C12) and antenna Range C trimmer (C3) to maximum.

Do not change the setting of the oscillator Range C trimmer.

Range D Alignment

18,300 KC Adjustment

Set the signal generator for 18,300 KC.

Keep the antenna lead of the receiver connected through the 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band selector to the Range D position (2nd short wave band—red dial color).

As mentioned above, keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the oscillator Range D trimmer (C41) until maximum output is obtained. See Fig. 3 for location of this trimmer.

15,000 KC Adjustment

Set the signal generator for 15,000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the 1st and 2nd interstage Range D trimmers (C10 and C11) and antenna Range D trimmer (C4) to maximum.

When adjusting the 2nd interstage Range D trimmer, it will be necessary at the same time to turn the tuning condenser rotor slowly back and forth until the peak of greatest intensity is obtained.

Then go back and repeat the procedure as given for the 18,300 KC adjustment. If it is found necessary to make any appreciable change in the setting of the oscillator Range D trimmer, the 15,000 KC adjustment must be repeated.

Do not make any further change in the setting of the oscillator Range D trimmer.

6000 KC Adjustment

Set the signal generator for 6000 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 6000 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

Use a non-metallic screwdriver for this adjustment.

Twenty-five Cycle Receivers

The twenty-five cycle receiver differs from the sixty cycle receiver only in the fact that a different power transformer is used. The correct power transformer is shown in the parts list.

The twenty-five cycle receiver can be operated satisfactorily from a sixty cycle power supply. However, the reverse is not true, the sixty cycle receiver cannot be operated from a twenty-five cycle power supply.

A 115-230 Volt, 40 to 60 cycle as well as other power transformers with special power ratings are also available for this model.

Servicing R. F. Coil Assemblies

The R. F. transformers and oscillator coil assemblies in this receiver are sold complete with can. This is due to the fact that the trimmers are soldered to the can, and cannot be easily disassembled.

The lead colors and resistances of the various winding in each assembly are shown in Fig. 4.

If it is ever necessary to remove one of these coil assemblies from the can, proceed as follows: First remove the nuts from the screws at the top of the can. The outside lug on the trimmer condenser is inserted in a slot in the coil can, and this lug is soldered into position.

Apply a soldering iron to the can at the point of the soldered connection. Then with a screw driver lift up on the outside edge of the trimmer (edge soldered to can) until the trimmer is clear of the can. After the trimmers are all unsoldered, the coil can be taken out.

Phonograph Connections

Phonograph connections can be made as shown in Fig. 7. The parts required to make this installation are shown in the parts list.

To mount the phono switch and phono jack, knockouts are provided in the back panel of the chassis as shown in Fig. 8.

The connections are made by opening the diode circuit at the volume control. Unsolder the condenser C24 from the lug on the volume control and reconnect this condenser to the new terminal strip provided (see parts list). This terminal strip should be secured to the inside of the front panel of the chassis base at a point near the volume control and should be soldered in position. From the terminal lug on the above strip, and from the volume control lug from which the condenser C24 was removed, connect leads to the phono switch on the rear panel of the chassis as shown in Fig. 7. Before connecting these two leads permanently to the switch, twist them together and enclose them in the shielded sleeving provided, being sure to ground the shielding at the extreme ends to the chassis base. At the point where the shielding passes the electrolytic condenser cover the cable with insulating tape. Complete the connections as shown in Fig. 7.

A high impedance phonograph pickup of good quality should be used. If a low impedance pickup is used, a step-up transformer will be required for sufficient volume. The volume control and tone control of the set will regulate the phono volume and tone.

BATTERY SET

GENERAL Always eliminate all possible sources of trouble external to the receiver itself such as: Defective aerial, ground, or lightning arrestor, tubes, batteries, loud speakers.

TUBE FUNCTIONS "1-C-6" First detector—oscillator, "34" first I F amplifier, "34" second I F amplifier, "30" diode second detector, "32" first audio, "30" audio driver. "19" class B power tube.

CHECKING PARTS The resistance of coils and resistors is shown on the circuit diagram together with condenser capacities. Any defective part—either shorted or open—will result in either weak or distorted reception or none at all.

ALIGNMENT If all parts check OK and sensitivity is still low it is probably due to the set being out of alignment. It is necessary to use a reliable test oscillator or signal generator having accurate calibration and positive attenuation.

I F ALIGNMENT 456 K. C. Open tuning condenser (High Frequency dial setting). Connect signal generator to grid cap of 1-C-6 tube leaving present cap in place. Use a small condenser .002-.01 in series with signal generator lead wire. Adjust all five trimmers—two in top of each square I F transformer and the one in the top of the round (output) I F transformer. Go over these adjustments several times—it is best to use an output meter to indicate "peak". Reduce the output of the signal generator for final adjustments.

WAVE TRAP With the signal generator still on 456 K. C.—connect to antenna wire of set and adjust wave trap condenser to *minimum signal*.

The above will usually bring the set back to normal, check operation on stations and if satisfactory do not make any further adjustments.

BROADCAST BAND With the tuning condenser open and the signal generator set on 1735 K. C.—adjust B. C. Oscillator trimmer. Next—close tuning condenser and set signal generator to 540 K. C. adjust variable padding condenser for maximum signal. Adjust B. C. Antenna coil trimmer for maximum at 1400 K. C.

SHORT WAVE This is the most difficult for the service man and unless it is certain that the set does not compare favorably with a similar model under the same conditions of operation—the alignment should be left unchanged. If the service man feels that the short wave operation could be improved—proceed as follows: Connect signal generator to antenna and ground leads using a 300 ohm resistor in series with the antenna lead as a "dummy antenna". Set signal generator at 15,500 K. C. and tune in on the set (wave change switch in Short Wave position—left). Adjust S. W. oscillator trimmer—see diagram—using a fiber screw driver, move the point of response to the highest frequency setting possible on the dial or near the end of the 19 M. band. Then without moving the tuning dial turn the trimmer screw tighter and you should be able to find a second point of response (the image). Move trimmer back to "loose" position. If the image response cannot be found move the dial and readjust trimmer until it can be heard. Be sure to return to the "loose" or fundamental setting. Next adjust the S. W. antenna coil trimmer for best response retuning the dial at the same time. The low frequency end of the short wave band is fixed by the .004 mica padding condenser and will not change unless this condenser becomes defective.

ADDITIONAL NOTE The power output can be increased with only a slight increase in "B" current by increasing the 90 Volt connection to 112½ Volts. This increases the plate voltage on the driver tube.

	Power Transformer Pilot Lamp Sec.	T6	.3
P-2153	Vibrator Unit Magnetizing Coil		1025
	Vibrator Unit Filter Chokes		3.0

Condenser Alignment

Misalignment or mistracking of condensers generally manifests itself as broad tuning and lack of volume at portions or all of the broadcast band. The receivers are all properly aligned at the factory with precision instruments and realignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment. A signal generator that will provide accurately calibrated signals over the broadcast band and at the intermediate frequency, and an output meter are required for indicating the effect of adjustments.

First set the signal generator for 1730 K. C. Turn the rotor to the full open position. The antenna lead from the signal generator adjustment is connected to the antenna lead of the receiver. Adjust the trimmer of the oscillator section of the 3 gang condenser until maximum output is obtained. The oscillator section is the one with the cut plate rotor.

Now set the signal generator for 1400 K. C. and turn the rotor until maximum output is obtained. Adjust the other two trimmers on the gang condenser for maximum output.

To obtain dial scale calibration tune in an 800 K. C. signal and set the dial pointer at that mark on the dial scale. When calibrated in this manner, the setting will be approximately correct at both ends of the scale.

The use of the cut plate type of condenser eliminates the necessity of a 600 K. C. padder and no adjustment at this frequency, therefore, is required.

Servicing Power Unit

Vibrator Unit

The vibrator is mounted inside the "B" power unit. Normally the vibrator will last upward of 1000 hours. However, in the same manner as a tube it may become defective in less time and require replacement.

If the tubes light and by touching the power unit case, no vibration is felt, then the vibrator unit is probably not operating. If the pilot lamp is not lighted this will be a further indication of the same fact.

To replace the vibrator unit in the power supply remove the end of the case on which the label is placed by taking out the four screws which hold the vibrator shield can to the framework. The old vibrator may then be withdrawn and a new unit inserted in the same manner as a tube.

One or more of the vibrator units should be kept on hand for replacement purposes. It is advisable when servicing the receiver, to try one out in the same manner as a new set of tubes would be tried.

Changes in Early Models

In the early models condenser C65, shown in the R.F. Schematic Fig. 2, was not used. A 20 mmf. condenser, also designated as C65, was connected in parallel with condenser C14.

Condenser C10 from B+ to ground was not used in early models. Another condenser in the early models, also designated as C10 and 250 mmf. in value, was connected from the A.V.C. amplifier plate to ground.

Resistor R38 was not used in early models.

On the A.F. chassis the speaker sockets were wired with ground to the opposite side of voice coil.

MODEL 26-FM-552 Circuit Data Alignment, Phono-Data

GAMBLE-SKOGMO, INC.

Circuit

This model is a four band receiver with a tuning range in each band as shown in the specifications above. Four band coverage is accomplished by means of four sets of antenna, interstage and oscillator coils and a six section four position switch.

Among the many features incorporated in this receiver are Improved Automatic Volume Control, Adjustable Selectivity Control, Dual Volume and Sensitivity Control, Bass Compensator and a 30 Watt High Fidelity Audio Amplifier. These are discussed in the following circuit description.

Referring to the R.F. Schematic Fig. 2, the following are the code numbers of the R.F. and Oscillator Assemblies:

- T1 —Antenna R.F. Transformer
- T2 —E Range Antenna R.F. Transformer
- T3 —1st Interstage R.F. Transformer
- T4 —E Range Interstage R.F. Transformer
- T5 —2nd Interstage R.F. Transformer
- T9 —Oscillator Inductors
- T10—E Range Oscillator Inductors

The standard wave, 1st, 2nd and 3rd short wave coils in each assembly are indicated by the letters B, C, D and E, respectively. The six sections of the band switch are designated in the R.F. schematic Fig. 2 and in Fig. 5 as the antenna section, interstage primary section 2, interstage primary section 1, interstage secondary section, oscillator section 2 and oscillator section 1.

The band switch completes connections to the coils in use. It also short circuits the antenna R.F. transformer secondaries, the interstage transformer primaries and secondaries and the oscillator coils of lower frequency, not in use.

The antenna transformer with tuned secondary feeds into a type 6K7 R.F. amplifier tube. The output of this tube is fed into a double tuned R.F. stage. The output of the latter actuates the control grid of a 6K7 tube which functions as the 1st detector.

A separate type 76 tube is employed in the oscillator circuit. The oscillating circuit is always resonant at a frequency which is 456 KC above the frequency to which the R.F. amplifier is tuned.

The oscillator potential is fed into the cathode circuit of the 6K7 first detector tube. As a result of the beating of the two frequencies, the intermediate or beat frequency of 456 KC is present in the plate circuit of this tube.

Two stages of I.F. amplification are employed using 6K7 tubes. The primaries and secondaries of the first and second I.F. transformers and the primary of the 3rd I.F. transformer are tuned by small trimmer condensers.

Referring to the 1st and 2nd I.F. transformers T6 and T7 in Fig. 2, it will be noted that there are coupling windings below the primaries.

When the selectivity control is in the sharp position, the coupling winding is open circuited and the loose coupling which exists between the primary and secondary of this transformer results in high selectivity. When the selectivity control is in the broad position, the coupling winding which is wound under the primary is connected in series with the secondary. This provides overcoupling which results in a greatly widened resonance curve. Passage of a wide range of audio frequencies is thus obtained.

A dual manual volume control is employed. In one section the audio voltage applied to the 1st audio tube is varied (R8). In the other section the R.F. and 1st I.F. bias is varied (R2). The purpose of the latter section is to reduce the sensitivity of the receiver at low volume settings in order to cut down noise pick-up between stations. The variable section R2 is shorted out by the band selector switch when it is in the Range D and E positions.

The 3rd I.F. transformer has 2 secondary windings. One of these windings works into the diode section of the 6B7 signal diode. The other winding works into the 76 A.V.C. diode.

The audio voltage developed by the signal diode across volume control resistor R8 is transmitted through the movable arm to the control grid of the pentode section of the 6B7 tube, which acts as a one stage audio amplifier. The pentode plate of this tube is connected through the "B" power cable to one side of the primary of the push-pull input transformer in the power stage.

The audio voltage developed across volume control resistor R8 is also applied through the movable arm to the control grid of the triode section of the 6F7 bass amplifier. A resistance capacity filter composed of condensers C36 and C37 and resistor R14 in the triode plate circuit of this tube bypasses the higher audio frequencies. The lower audio frequencies which pass through this filter develop a voltage across resistors R38, R17 and R18.

R17 is the bass note control and is connected mechanically to the manual volume control. The movable arm is connected to and applies the bass audio voltage to the control grid of the pentode section of the 6F7 bass amplifier. At high volume settings the movable arm is at the low potential end of R17 (near R18). At low volume settings it is at the other end of this resistor in order to increase the bass note response. The reason for the increase in low note response is that the characteristics of the ear are such that the low notes are not heard as well as the middle register notes at lower volume levels.

The plate of the pentode section of the 6F7 tube is connected through the "B" power cable to the other side of the primary of the push-pull input transformer.

The A.V.C. system used in this receiver is one which has a flat characteristic over an extremely wide input range. As mentioned above, it will be seen in Fig. 2 that one of the 3rd I.F. transformer secondary windings works into the 76 A.V.C. diode tube. A signal passing through this transformer will result in a voltage across diode resistor R19. This voltage is applied to the control grid of the 76 A.V.C. amplifier.

Referring now to Figs. 2 and 3, there is a diode circuit consisting of the A.V.C. amplifier voltage winding of power transformer T11 (sixth winding from top) the plate and cathode elements of the 45 bias rectifier tube and resistors R22, R23 and R24. The diode current flowing in this circuit establishes a drop across these resistors. This voltage is below ground and furnishes operating voltages for the 76 A.V.C. amplifier tube which functions as a DC amplifier. Under no signal conditions, the plate of this tube is at ground potential. The grid is at the voltage of the maximum negative voltage end of resistor R23 while the cathode is at the minimum negative voltage end of this resistor. The resulting bias voltage brings this tube below the cut-off point and no plate current flows.

When a signal of a predetermined value or greater flows in the 3rd I.F. transformer, the voltage established across diode resistor R19 reduces the bias voltage of the A.V.C. amplifier to the point at which plate current flows in this tube. The plate current establishes a drop in resistor R25, lowering the plate voltage by the amount of this drop. The plate of the A.V.C. amplifier tube is connected to the control grid circuits of the R.F. and 1st I.F. tubes, resulting in A.V.C. action.

The ouput stage employs four type 2A3 tubes arranged in push-pull parallel. Fixed bias voltage for these tubes is obtained from a diode circuit in which are the output bias winding of power transformer T11 (fifth winding from top) and the grid and cathode elements of the type 45 bias rectifier tube. 30 watts of undistorted output may be obtained. Two 12" auditorium type dynamic speakers are used. Each speaker is provided with deflecting vanes for the purpose of spreading the directional higher audio notes through the entire room.

Two type 5Z3 tubes connected in parallel are used as "B" power rectifiers in the power unit. There are 2 power transformer assemblies, T11 and T12. In assembly T11 the top 4 windings illustrated in Fig. 3 supply the tube heater and filament voltages and the pilot lamp voltages. As mentioned, the fifth winding supplies the output stage bias voltage and the sixth winding supplies the A.V.C. amplifier tube voltages. Assembly T12 supplies the "B" voltage.

To reduce hum, DC is used in the heater circuits of the 6F7 and 6B7 tubes. The 2 heaters are connected in series in the negative "B" line.

The 45 bias rectifier tube, mention of which has already been made, has two functions. The cathode and grid elements act as a diode supplying bias voltage for the output tubes. The cathode and plate elements act as a diode supplying operating voltages for the A.V.C. amplifier. The two associated transformer windings must be in phase and wired as per the color code in the A.F. Schematic, Fig. 3.

The phono short circuiting plug, which is in the phono socket completes the signal diode circuit connections. Phonograph circuit connections are explained in the article under that name in this manual.

Metal Tubes

One type of the new metal tubes is used in this receiver, namely the 6K7. This replaces the type 6D6 glass tube. This metal tube operates at the same voltages and is nearly identical in characteristics to the corresponding glass tube which it replaces. In Fig. 7 are shown the metal tube pin positions from a bottom socket view.

The shells of metal tubes get quite hot and users should be cautioned against touching them.

Phonograph Connections

A phonograph socket is provided on the R.F. chassis by means of which phonograph connections can be made without electrical changes in the chassis. The receiver is shipped from the factory with a plug in this socket. If no phonograph is used this plug must be inserted as it completes the signal diode circuit for radio reception.

Two sets of accessories are supplied for phonograph connections for this model. One set is used when the phonograph is contained in a separate cabinet, and the other set is used when the phonograph and radio are in a combination cabinet. The electrical connections are the same in both cases and are illustrated in Fig. 13 (A). Parts required in either case are shown in the parts list in this manual.

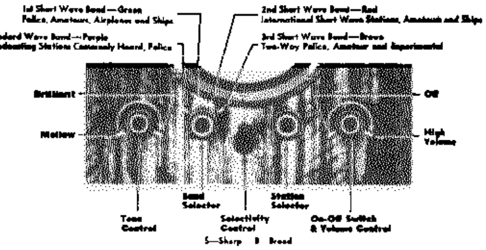

Fig. 1—Location and Function of Controls

Phonograph in Separate Cabinet

For this assembly, a 5 conductor cable and a small metal panel assembly are supplied. This assembly has the radio-phono switch, tip jacks for pick-up leads and terminal plate for phono cable.

The phono panel is mounted at the most convenient place in the cabinet at which connections can be completed. The switch is secured to the motor board as illustrated in Fig. 14.

The socket at the end of the cable is secured to the terminal plate on the panel and the plug at the other end of the cable is inserted into the phono socket on the R.F. chassis.

When the switch is thrown to the radio side, the phono pick-up is excluded from the signal diode circuit. When it is thrown to the phono side, the signal diode circuit is opened and the phonograph connections completed to this circuit. Resistor R13 is short circuited. This brings the grid and cathode of the 76 A.V.C. amplifier to the same potential and causes a plate current in this tube of sufficient intensity to bring the R.F. and 1st I.F. tubes to the point of cut off (See article on circuit for further information regarding operation of A.V.C. system).

Phonograph and Radio in Combination Cabinet

For this assembly, a number of separate items as shown in the parts list are supplied. The phono short circuiting plug supplied with the receiver is used after certain changes have been made.

First take off the shell of this plug by twisting the shell in either direction. The shell is then drilled and equipped with a rubber grommet as shown in Fig. 13 (B). Next unsolder and remove the jumper wire from the plug as shown in Fig. 13 (A). Extend the leads through the hole in the shell and solder the leads to the prongs on the plug as illustrated. Complete the connections to the switch and tip jacks as shown. The switch is mounted on the motor board and the tip jacks at the nearest convenient place.

The description of the connections as given for the separate phonograph cabinet also applies to the combination.

Alignment and Calibration

Correct alignment is extremely important in connection with all-wave receivers. The receivers are all properly aligned at the factory with precision instruments and realignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment.

A signal generator that will provide an accurately calibrated signal at 456, 1730, 1500, 600, 5800, 5000, 18,300, 15,000, 6000, 48,000 and 40,000 KC and an output indicating meter are required. It will be practically impossible to align the receiver if unsatisfactory apparatus is used. If a station is tuned in with the selectivity control in the broad position and this control is then turned to the sharp position, the station may disappear. This is not an indication that the receiver is out of alignment.

Use a non-metallic screwdriver for the adjustments. The complete procedure is as follows:

I. F. Adjustment

Set the signal generator for a signal of 456 KC.

Connect the output of the signal generator to the grid of the 1st detector through a 0.1 mf. condenser.

Connect the ground lead of the receiver to the ground post of the signal generator.

Turn the band selector to the Range B position (standard wave band—purple dial color).

Turn the selectivity control to the sharp position and keep it in this position for all adjustments.

Turn the volume control to the maximum position.

Attenuate the signal from the signal generator to prevent the levelling-off action of the A.V.C.

Then adjust the five I.F. trimmers until maximum output is obtained. The adjusting screws for these condensers are reached from the top of the chassis, and the location is shown in Fig. 4.

Range B Alignment

1730 KC Adjustment

Set the signal generator for 1730 KC.

Turn the rotor of the tuning condenser to the full open position.

Keep the band selector in the standard wave position.

Connect the antenna lead of the receiver through a 200 mmf. condenser to the output of the signal generator.

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the oscillator Range B trimmer (C74) until maximum output is obtained. The location of this trimmer is shown in Fig. 6.

1500 KC Adjustment

Set the signal generator for 1500 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Loosen the pointer set screw and set the large pointer at the 1500 KC mark on the standard wave band scale. Re-tighten the set screw.

Adjust the 1st and 2nd interstage Range B trimmers (C17 and C18) and antenna Range B trimmer (C3) to maximum.

Do not change the setting of the oscillator Range B trimmer.

600 KC Adjustment

Set the signal generator for 600 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 600 KC trimmer until the peak of greatest intensity is obtained. See Fig. 6 for location of this trimmer.

Be sure to use a non-metallic screwdriver for this adjustment.

Range C Alignment

5800 KC Adjustment

Set the signal generator for 5800 KC.

Connect the antenna lead of the receiver through a 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band selector to the Range C position (1st short wave band—green dial color).

As mentioned above, keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the oscillator Range C trimmer (C56) until maximum output is obtained. See Fig. 6 for location of this trimmer.

5000 KC Adjustment

Set the signal generator for 5000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the 1st and 2nd interstage Range C trimmers (C16 and C19) and antenna Range C trimmer (C4) to maximum.

Do not change the setting of the oscillator Range C trimmer.

Range D Alignment

18,300 KC Adjustment

Set the signal generator for 18,300 KC.

Keep the antenna lead of the receiver connected through the 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band selector to the Range D position (2nd short wave band—red dial color).

As mentioned above, keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the oscillator Range D trimmer (C57) until maximum output is obtained. See Fig. 6 for location of this trimmer.

15,000 KC Adjustment

Set the signal generator for 15,000 KC. Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the 1st and 2nd interstage Range D trimmers (C15 and C20) and antenna Range D trimmer (C5) to maximum.

When adjusting the 2nd interstage Range D trimmer, it will be necessary at the same time to turn the tuning condenser rotor slowly back and forth until the peak of greatest intensity is obtained.

Then go back and repeat the procedure as given for the 18,300 KC adjustment. If it is found necessary to make any appreciable change in the setting of the oscillator Range D trimmer, the 15,000 KC adjustment must be repeated.

Do not make any further change in the setting of the oscillator Range D trimmer.

6000 KC Adjustment

Set the signal generator for 6000 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 6000 KC trimmer until the peak of greatest intensity is obtained. See Fig. 6 for location of this trimmer.

Use a non-metallic screwdriver for this adjustment.

Range E Alignment

48,000 KC Adjustment

Set the signal generator for 48,000 KC.

Keep the antenna lead of the receiver connected through the 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band selector to the Range E position (3rd short wave band—brown dial color).

Adjust the oscillator Range E trimmer (C30) until maximum output is obtained. See Fig. 6 for location of this trimmer.

40,000 KC Adjustment

Set the signal generator for 40,000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the interstage Range E trimmer (C14) and antenna Range E trimmer (C6) to maximum.

Do not change the setting of the oscillator Range E trimmer

Switch Contact Location Numbering

A standard arrangement for switch contact location numbering has been adopted. This numbering is illustrated in Fig. 9. In contact locations not used, the number applying to that particular location is not employed.

Twenty-five Cycle Receivers

The twenty-five cycle receiver differs from the sixty cycle receiver in the fact that special twenty five cycle filament and "B" power transformers must be used. It also has two additional condensers in the power unit—C67 and C68 as illustrated in Fig. 3. The twenty-five cycle transformers and the condensers are shown in the parts list.

The twenty-five cycle receiver can be operated satisfactorily from a sixty cycle power supply if the two condensers C67 and C68 are removed. However, the reverse is not true, that is, a sixty cycle receiver cannot be operated from a twenty-five cycle power supply.

115-230 Volt, 40 to 60 cycle filament and "B" power transformers are also available for this model.

MODEL 26-FM-552
Parts List

GAMBLE-SKOGMO, INC.

Replacement Parts

NOTICE—A change has been made in our parts numbering system. Old parts which are used in new receivers will have a new number assigned to them. For your convenience we are listing below the new part number and the corresponding old part number, should there be one. **Order by new part number only.**

There is a large letter stamped on the bottom side of the chassis base which identifies the set as to major part changes. When ordering parts please be sure to mention the series number and this large letter.

MISCELLANEOUS

(IN R. F. CHASSIS)

New Part No.	Old Part No.	Description	List Price
P-3A120	1944	Type 6B7 Tube Socket (7 Prong)	$ .15
P-3A121	1948	Type 6F7 Tube Socket (7 Prong)	.15
P-3A126	2022	Type 76 Tube Socket (5 Prong)	.10
P-3A211		Type 6K7 Tube Socket (7 Prong) Metal Tube	.15
P-3A213		Phone Socket (6 Prong) in R.F. Chassis	.10
P-6A206		Phono Plug and Cap Assembly	.40

P-9A391	L3	High Frequency Oscillator Tracking Coil	.25
*P-52X35	L4	Filter Reactor	2.45
*	L5	10 KC Reactor (Part of P-40X201)	.85
*P-52X36	L6	Filter Reactor	3.55
*P-40X201	B1	Block Condenser (C59 & C60) and 10 KC Reactor—(L5) Assembly	2.35

*These items are part of the A.F. Chassis. All others are on R.F. Chassis.

DIAL AND DRIVE ASSEMBLY

New Part No.	Old Part No.	Description	List Price
		Dial Assembly Complete Less Large Pointers, less Pilot Lamp Sockets and Bulbs	$5.75
P-28X35		Gear Spreader Springs Only	.10
P-28X49		Tension Pulley Spring Only	.10
P-8X36		Drive Belt	.20
P-28X46		Pointer Slide Take-up Spring	.10
P-10X9		4 Inch Indicator Cords . . . doz.	.10
P-29X51		Brass Collars and Set Screws only for securing above Drive Cords to Shaft	.20
		Dial Strip Only (Specify Series No. and Name of Receiver)	.65
P-30X43		Dial Clamp to secure Dial Strip to Frame (with 6-32 x 3/16" Mounting Screw)	.10
		Double End Pointer (Specify Series No. and Name of Receiver)	.10
P-15X26		Micrometer Pointer	.10
P-7A26	2012	Pilot Lamp Bulb (6 - 8V)	.15
P-7A34		Pilot Lamp Sockets and Spring Clip	.15

PHONO ATTACHMENT PARTS

(The following parts are recommended for use when Radio and Phonograph are in separate cabinets)

The first two items only are required

New Part No.	Old Part No.	Description	List Price
P-13X228		Phono Cable (20 feet long)	$5.25
P-13A7		Phono Panel and Switch Assembly Complete	4.15
		The following items are part of the phono panel and switch assembly (P-13A7) listed above and may be purchased separately:	
P-25X261		Phono Attachment Panel Only	2.00
P-2A50		Phono Switch	.60
P-3A12	1193	Phono Jack	.10
P-6A205		6 Prong Phono Cable Pin Plate	.10
P-19X6	20251	Flat Washers	.10
P-10A36	2122	Switch Knob	.20

(The following parts are recommended for use when Radio and Phonograph are in the same cabinet)

The first item only is required

New Part No.	Old Part No.	Description	List Price
P-13A8		Complete Phono Kit (includes all following parts)	1.20
P-6X2	10153	Rubber Grommet	.10
P-2A50		Phono Switch	.60
P-3A12	1193	Phone Jack	.10
P-10A36	2122	Switch Knob	.20
5 Ft.		Shielded Hook-up Wire	.20

Prices Subject to Change Without Notice.

D. C. Resistance of Windings

Refer to Figs. 12, 2 & 3.

Part No.	Winding	Code	D. C. Resistance in Ohms
P-9A428	Antenna R.F. Transformer	T1	
	Range B Primary Winding		22.5
	Range C Primary Winding		0.35
	Range D Primary Winding		0.2

Condenser Alignment

Misalignment or mistracking of condensers generally manifests itself as broad tuning and lack of volume at portions or all of the standard wave band. The receivers are all properly aligned at the factory with precision instruments and realignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment. A signal generator that will provide accurately calibrated signals over the standard wave band and at the intermediate frequency, and an output meter are required for indicating the effect of adjustments.

First set the signal generator to a frequency of 175 KC. Connect the antenna lead of the lead generator to the grid of the 1st detector thru a .05 mfd. condenser. The ground lead from the signal generator goes to the ground lead of the receiver. Adjust trimmer condenser C9 on the back panel of the chassis until maximum output is obtained. A non-metallic screw driver should be used in making this adjustment as the I. F. trimmer is at B+ potential.

Next set the signal generator for 1730 KC. Turn the rotor to the full open position. The antenna lead from the signal generator is in this instance connected to the antenna lead of the receiver. Adjust the trimmer of the oscillator section of the 3 gang condenser until maximum output is obtained. The oscillator section is the one with the cut plate rotor.

Then set the signal generator for 1400 KC and turn the rotor until maximum output is obtained. Adjust the other two trimmers on the gang condenser for maximum output.

To obtain dial scale calibration tune in an 800 KC signal and set the dial pointer at that mark on the dial scale. When calibrated in this manner, the setting will be approximately correct at both ends of the scale.

The use of the cut plate type of condenser eliminates the necessity of a 600 KC padder and no adjustment at this frequency, therefore, is required.

Replacing Drive Cord

Remove chassis from cabinet.

Take off the pilot light assembly by lifting off the two sockets and spring clips.

Detach the large pointer by removing the screw at the center of the dial.

Loosen the dial assembly by taking out the two screws which secure the bottom of this assembly to the chassis.

Then lay the complete dial assembly face downward in front of the chassis. It is not necessary to remove the volume control and Off-On switch collars which hold the indicator cords of these two controls in position.

Turn the drive drum until the opening in this drum is approximately vertical and with the hole at the top as shown in Fig. 4.

Remove the tension spring and the old drive cord.

See that the eyelet is in the hole in the drive drum as shown in Fig. 4. Insert one end of the drive cord from the outside through the hole in the eyelet in the drive drum.

Tie the end of the cord which has been inserted in the hole to one end of the tension spring.

Wrap the cord in a clockwise direction (facing front of chassis) around the drive drum approximately one-half turn.

Then tilt the chassis up on its back panel and bring the cord mentioned in the previous paragraph down to the drive shaft. Wrap it two and one-half times around the drive shaft as shown in Fig. 4.

Then bring this cord up from the drive shaft and wrap it around the drive drum approximately one and one fifth turns in a clockwise direction until it is up to the hole in this drum as illustrated.

Insert the free end of the cord through the hole in the eyelet and tie it to the end of the tension spring. The end of the spring, when hanging free, should be approximately ⅜" from the flange of the drum as shown in Fig. 4. Cut off the surplus length of cord after it is knotted.

Then secure the other end of the tension spring over the spur on the drive drum.

Replace the dial assembly and pointer.

Replace the pilot light assembly after which the chassis may be reinstalled in the cabinet.

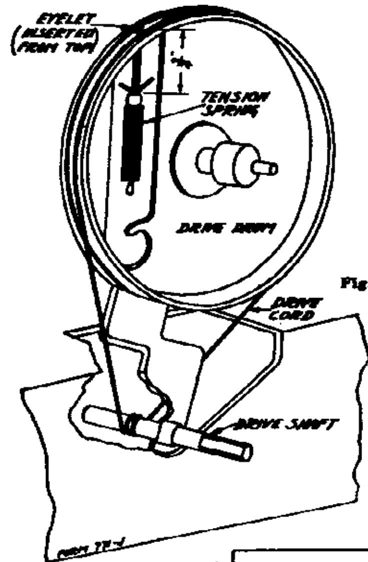

Fig. 4 Drive Cord Replacement.

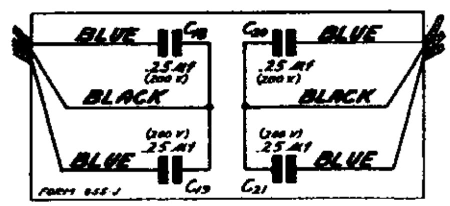

Fig. 3. Four Section Condenser in Power Unit Box

D. C. Resistance of Windings

Following are the D. C. resistances of the various windings in the chassis. The values given below will vary slightly in different sets.

Service Notes For The Six Volt Battery Operated Six Tube Superheterodyne Receiver

ALIGNMENT PROCEDURE: Realignment of this receiver should never be necessary unless one of the oscillator, antenna, or I.F. coils has been replaced. Lack of sensitivity, and poor tone quality may be due to any one or a combination of causes, such as weak or defective tubes, battery or speaker, inadequate or excessively long antenna, open or grounded bias resistor, bypass condenser, etc. Under no circumstances should realignment be attempted until all other possible sources have been first thoroughly investigated and have been definitely proven not to be the cause.

If an I.F. tube is replaced it is advisable to realign the I.F. amplifer, particularly if the replacement tube is one of a different manufacture than the one in the receiver. It is important when aligning to carefully follow the procedure in the order given, otherwise the receiver will lack sensitivity and the dial calibration will be incorrect.

IT IS IMPERATIVE THAT AN ACCURATELY CALIBRATED OSCILLATOR BE USED WITH SOME TYPE OF OUTPUT MEASURING DEVICE.

INTERMEDIATE ALIGNMENT:

1. Connect the high side of the test oscillator output to the control grid of the 1C6 modulator tube through a .02 Mfd. condenser. Leave the grid cap connected to the grid terminal of the tube, and connect the ground side of the test oscillator to the receiver ground.
2. Set the test oscillator frequency to 465 kilocycles (this must be accurate).
3. Align the second intermediate transformer by turning one of the trimmer screws accessible through holes in the top of the transformer shields up and down (increasing and decreasing capacity) until maximum reading is obtained on the output meter, after which adjust the other trimmer screws of the same transformer for maximum sensitivity.
4. Adjust the first intermediate transformer in the same manner as the second I.F. transformer.

TO ALIGN THE VARIABLE CONDENSER: It is important when aligning the gang condenser, padding and trimmer to follow the procedure carefully, otherwise the receiver will be insensitive and the dial calibration will be incorrect. The padding and trimmer condensers located underneath the chassis will be referred to by their function as indicated on the circuit diagram.

1. Connect the high output side of the test oscillator through a 400 ohm resistor to the receiver antenna lead and the low side to the set ground.
2. Place the band selector switch for operation on the 5.8 to 18 megacycle band, tune the receiver dial, and set the test oscillator frequency to EXACTLY 18 MEGACYCLES.

Rotate gang condenser so that plates are completely out of mesh and then tune in the 18 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING THE 18 MEGACYCLE OSCILLATOR TRIMMER. When adjusting this trimmer two peaks, the fundamental and the image peak will be noticed. CARE MUST BE TAKEN THAT THE FUNDAMENTAL PEAK AND NOT THE IMAGE PEAK IS USED FOR ALIGNING THE RECEIVER AT 18 MEGACYCLES. Always back off the trimmer to minimum capacity, then screw down the trimmer (add capacity) until the first peak which is the fundamental and the proper one to use is tuned in. If the trimmer is screwed down beyond the point where the first peak is received, the incorrect image peak will be tuned in. After completing adjustment of the oscillator trimmer at 18 megacycles always check to see if the proper peak has been used. To do this leave the test oscillator frequency at 18 megacycles, increase the output of the test oscillator and tune the receiver dial to approximately 17 megacycles. Then vary the receiver dial slightly to the right and left of 17 megacycles, and if the fundamental peak was used in aligning at 18 megacycles the test oscillator signal will be heard at approximately 17 megacycles on the receiver dial. If it is not possible to receive the signal, then the fundamental peak was not used and the 18 megacycle oscillator trimmer must be properly readjusted.

3. With band selector switch set for operation on 5.8 to 18 megacycle band tune the receiver dial and set test oscillator frequency to EXACTLY 16 MEGACYCLES and adjust 16 MEGACYCLE ANTENNA TRIMMER FOR MAXIMUM 16 MEGACYCLE SIGNAL SENSITIVITY.
4. Place band selector switch for operation on 1.8 to 5.8 megacycle band, tune the receiver dial, and set test oscillator frequency to EXACTLY 5.8 MEGACYCLES.

Rotate gang condenser so that plates are completely out of mesh and BRING IN 5.8 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING THE 5. MEGACYCLE OSCILLATOR TRIMMER.

5. Leave the band selector switch for operation on the 1.8 to 5.8 megacycle band and tune the receiver dial and set the test oscillator frequency to approximately 2 megacycles. While rocking the gang condenser slightly to the right and left, adjust the 2 megacycle oscillator padder condenser for maximum sensitivity.
6. Replace the 400 ohm resistor in series with test oscillator lead with a 200 mmfd. condenser, place the band selector switch for operation on the 535 to 1720 kilocycle band and set test oscillator frequency to EXACTLY 1720 KILOCYCLES.

Rotate gang condenser so that plates are completely out of mesh and BRING IN THE 1720 KILOCYCLE SIGNAL TO MAXIMUM OUTPUT by adjusting 1720 kilocycle oscillator trimmer.

7. With band selector switch placed for operation on the 535 to 1720 kilocycle band set test oscillator frequency and receiver dial to EXACTLY 1400 KILOCYCLES. Adjust 1400 kilocycle preselector and antenna trimmers for maximum 1400 kilocycle signal sensitivity.
8. Leave band selector switch for operation on 535 to 1720 kilocycle band, tune receiver dial and set test oscillator frequency to approximately 600 kilocycles. While rocking gang condenser slightly to right and left adjust 600 kilocycle oscillator padder for maximum sensitivity.

SERVICE NOTES
FOR THE
TWO BAND
SIX VOLT BATTERY OPERATED
FOUR TUBE SUPERHETERODYNE RECEIVER

ALIGNMENT PROCEDURE: REALIGNMENT OF THIS RECEIVER SHOULD NEVER BE NECESSARY UNLESS ONE OF THE OSCILLATOR, ANTENNA, OR I. F. COILS HAS BEEN REPLACED. LACK OF SENSITIVITY, SELECTIVITY, AND POOR TONE QUALITY MAY BE DUE TO ANY ONE OR A COMBINATION OF CAUSES, SUCH AS WEAK OR DEFECTIVE TUBES, BATTERY, OR SPEAKER, INADEQUATE OR EXCESSIVELY LONG ANTENNA, OPEN OR GROUNDED RESISTOR, BYPASS CONDENSER, ETC. UNDER NO CIRCUMSTANCES SHOULD REALIGNMENT BE ATTEMPTED UNTIL ALL OTHER POSSIBLE SOURCES HAVE BEEN FIRST THOROUGHLY INVESTIGATED AND HAVE BEEN DEFINITELY PROVEN NOT TO BE THE CAUSE. IF AN I. F. TUBE IS REPLACED IT IS ADVISABLE TO REALIGN THE I. F. AMPLIFIER, PARTICULARLY IF THE REPLACEMENT TUBE IS ONE OF A DIFFERENT MANUFACTURE THAN THE ONE IN THE RECEIVER. IT IS IMPORTANT WHEN ALIGNING TO CAREFULLY FOLLOW THE PROCEDURE IN THE ORDER GIVEN, OTHERWISE THE RECEIVER WILL LACK SENSITIVITY AND THE DIAL CALIBRATION WILL BE INCORRECT. IT IS IMPERATIVE THAT AN ACCURATELY CALIBRATED OSCILLATOR BE USED WITH SOME TYPE OF OUTPUT MEASURING DEVICE.

INTERMEDIATE ALIGNMENT:

1. CONNECT THE HIGH SIDE OF THE TEST OSCILLATOR OUTPUT TO THE CONTROL GRID OF THE 1C6 MODULATOR TUBE THROUGH A .02 MFD. CONDENSER. LEAVE THE GRID CAP CONNECTED TO THE GRID TERMINAL OF THE TUBE, AND CONNECT THE GROUND SIDE OF THE TEST OSCILLATOR TO THE RECEIVER GROUND.

2. SET THE TEST OSCILLATOR FREQUENCY TO 465 KILOCYCLES (THIS MUST BE ACCURATE).

3. ALIGN THE SECOND INTERMEDIATE TRANSFORMER BY TURNING ONE OF THE TRIMMER SCREWS ACCESSIBLE THROUGH HOLES IN THE TOP OF THE TRANSFORMER SHIELDS UP AND DOWN (INCREASING AND DECREASING CAPACITY) UNTIL MAXIMUM READING IS OBTAINED ON THE OUTPUT METER, AFTER WHICH ADJUST THE OTHER TRIMMER SCREW OF THE SAME TRANSFORMER FOR MAXIMUM SENSITIVITY.

4. ADJUST THE FIRST INTERMEDIATE TRANSFORMER IN THE SAME MANNER AS THE SECOND I. F. TRANSFORMER.

TO ALIGN THE VARIABLE CONDENSER: IT IS IMPORTANT WHEN ALIGNING THE GANG CONDENSER, PADDING CONDENSER, AND WAVE TRAP TO FOLLOW THE PROCEDURE CAREFULLY, OTHERWISE THE RECEIVER WILL BE INSENSITIVE AND THE DIAL CALIBRATION WILL BE INCORRECT. THE TRIMMER AND PADDING CONDENSER WILL BE REFERRED TO BY THEIR FUNCTION AS INDICATED ON THE CIRCUIT DIAGRAM.

1. CONNECT THE HIGH OUTPUT SIDE OF THE TEST OSCILLATOR THROUGH A .00025 MFD. CONDENSER TO THE RECEIVER ANTENNA LEAD AND THE LOW SIDE TO THE SET GROUND.

2. SOME CODE AND AIRCRAFT SIGNALS ARE BROADCAST ON A FREQUENCY THE SAME OR NEAR THE INTERMEDIATE FREQUENCY OF THE RECEIVER. TO ELIMINATE INTERFERENCE FROM THESE SIGNALS A 465 KILOCYCLE ANTENNA FILTER IS INCORPORATED IN THE RECEIVER. TO ADJUST, TUNE RECEIVER DIAL TO APPROXIMATELY 1000 KILOCYCLES AND SET TEST OSCILLATOR FREQUENCY TO EXACTLY 465 KILOCYCLES. THEN ADJUST THE 465 KILOCYCLE WAVE TRAP TRIMMER CONDENSER FOR MINIMUM 465 KILOCYCLE SIGNAL RESPONSE.

3. PLACE BAND SELECTOR SWITCH FOR OPERATION ON THE 1720-540 KILOCYCLE BAND, ROTATE GANG CONDENSER SO THAT PLATES ARE COMPLETELY OUT OF MESH, SET TEST OSCILLATOR FREQUENCY TO EXACTLY 1720 KILOCYCLES, AND ADJUST 1720 KILOCYCLE OSCILLATOR TRIMMER FOR MAXIMUM 1720 KILOCYCLE SIGNAL OUTPUT.

4. WITH BAND SELECTOR SWITCH SET FOR OPERATION ON THE 1720-540 KILOCYCLE BAND, SET THE TEST OSCILLATOR FREQUENCY AND RECEIVER TUNING DIAL TO EXACTLY 1400 KILOCYCLES. THEN ADJUST 1400 KILOCYCLE ANTENNA TRIMMER FOR MAXIMUM 1400 KILOCYCLE RESPONSE.

5. TUNE RECEIVER DIAL AND SET TEST OSCILLATOR FREQUENCY TO APPROXIMATELY 600 KILOCYCLES. WHILE ROCKING GANG CONDENSER SLIGHTLY TO RIGHT AND LEFT ADJUST 600 KILOCYCLE OSCILLATOR PADDER FOR MAXIMUM SENSITIVITY.

6. PLACE BAND SELECTOR SWITCH FOR OPERATION ON THE 2.3-6.2 MEGACYCLE BAND, ROTATE GANG CONDENSER SO PLATES ARE COMPLETELY OUT OF MESH, AND SET TEST OSCILLATOR FREQUENCY TO EXACTLY 6.3 MEGACYCLES. BRING IN 6.3 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT WITH 6.3 MEGACYCLE OSCILLATOR TRIMMER.

7. WITH BAND SELECTOR SWITCH ON 2.3-6.3 MEGACYCLE BAND SET RECEIVER DIAL AND TEST OSCILLATOR FREQUENCY TO EXACTLY 5.8 MEGACYCLES. ADJUST 5.8 MEGACYCLE ANTENNA TRIMMER FOR MAXIMUM 5.8 MEGACYCLE SIGNAL RESPONSE.

8. LEAVE BAND SELECTOR SWITCH FOR OPERATION ON THE 2.3-6.3 MEGACYCLE BAND, TUNE RECEIVER DIAL AND SET TEST OSCILLATOR FREQUENCY TO APPROXIMATELY 2.5 MEGACYCLES. THEN WHILE ROCKING GANG CONDENSER SLIGHTLY TO RIGHT AND LEFT ADJUST 2.5 MEGACYCLE PADDING CONDENSER FOR MAXIMUM SENSITIVITY.

Service Notes For The Two Band Thirty-Two Volt Six Tube Superheterodyne Receiver

ALIGNMENT PROCEDURE: Realignment of this receiver should never be necessary unless one of the oscillator, antenna or I. F. coils has been replaced. Lack of sensitivity, selectivity, and poor tone quality may be due to any one or a combination of causes, such as weak or defective tubes, battery, or speaker, inadequate or excessively long antenna, open or grounded resistor, bypass condenser, etc. Under no circumstances should realignment be attempted until all other possible sources have been first thoroughly investigated and have been definitely proven not to be the cause. If an I. F. tube is replaced it is advisable to realign the I. F. amplifier, particularly if the replacement tube is one of a different manufacture than the one in the receiver. It is important when aligning to carefully follow the procedure in the order given, otherwise the receiver will lack sensitivity and the dial calibration will be incorrect.

It is imperative that an accurately calibrated oscillator be used with some type of output measuring device.

INTERMEDIATE ALIGNMENT:

1. Connect the high side of the test oscillator output to the control grid of the 6A7 oscillator modulator tube through a .02 mfd. condenser. Leave the grid cap connected to the grid terminal of the tube, and connect the ground side of the test oscillator to the receiver ground.

2. Set the test oscillator frequency to 465 kilocycles (this must be accurate).

3. Align the second intermediate transformer by turning one of the trimmer screws accessible through holes in the top of the transformer shields up and down (increasing and decreasing capacity) until maximum reading is obtained on the output meter, after which adjust the other trimmer screw of the same transformer for maximum sensitivity.

4. Adjust the first intermediate transformer in the same manner as the second I. F. transformer.

TO ALIGN THE VARIABLE CONDENSER: It is important when aligning the gang condenser, padding condenser, and wave trap to follow the procedure carefully, otherwise the receiver will be insensitive and the dial calibration will be incorrect. The trimmer and padding condenser will be referred to by their function as indicated on the circuit diagram.

1. Connect the high output side of the test oscillator through a .00025 mfd. condenser to the receiver antenna lead and the low side to the set ground.

2. Some code and aircraft signals are broadcast on a frequency the same or near the intermediate frequency of the receiver. To eliminate interference from these signals a 465 kilocycle antenna filter is incorporated in the receiver. To adjust, tune receiver dial to approximately 1000 kilocycles and set test oscillator frequency to exactly 465 kilocycles. Then adjust the 465 kilocycle wave trap trimmer condenser for minimum 465 kilocycle signal response.

3. Place band selector switch for operation on the 1720-540 kilocycle band, rotate gang condenser so that plates are completely out of mesh, set test oscillator frequency to exactly 1720 kilocycles, and adjust 1720 kilocycle oscillator trimmer for maximum 1720 kilocycle signal output.

4. With band selector switch set for operation on the 1720-540 kilocycle band, set the test oscillator frequency and receiver tuning dial to EXACTLY 1400 KILOCYCLES, then adjust 1400 kilocycle antenna trimmer for maximum 1400 kilocycle signal response.

5. With band selector switch set for operation on the 1720-540 kilocycle band, tune receiver dial and set test oscillator frequency to approximately 600 kilocycles. While rocking gang condenser slightly to right and left adjust 600 kilocycle oscillator padder for maximum sensitivity.

6. Place band selector switch for operation on the 2.35-6.2 megacycle band, rotate gang condenser so plates are completely out of mesh, and set test oscillator frequency to exactly 6.2 megacycles. Bring in 6.2 megacycle signal to maximum output with 6.2 megacycle oscillator trimmer.

7. With band selector switch on 2.35-6.2 megacycle band set receiver dial and test oscillator frequency to exactly 5.8 megacycles. Adjust 5.8 megacycle antenna trimmer for maximum 5.8 megacycle signal response.

6 Tube
Automobile Radio

June 1936

This model is a 6 tube automobile radio covering the standard wave band. It has a tuning range as shown in the specifications above. The signal is fed through an antenna transformer with tuned secondary into a 6D6 tube which functions as an R.F. amplifier. A tapped connection is provided in the primary of the antenna transformer for installations in cars in which a high capacity antenna is used.

The output of the R.F. tube is fed through another R. F. transformer with tuned secondary into a 6C6 tube which functions as the first detector and oscillator. The oscillating circuit is tuned by the oscillator section of the gang condenser and is always resonant at a frequency 175 KC above the frequency to which the R.F. circuits are tuned.

One stage of I.F. amplification is employed using a 6D6 tube. The primary and secondary of the first I.F. transformer and the primary of the second I.F. transformer are tuned by small trimmer condensers.

A 75 dual diode-triode tube functions as a diode 2nd detector, AVC tube and a one stage audio amplifier. AVC voltage is applied to the control grid circuits of the 6D6 R.F. and I.F. tubes. The manual volume control varies the audio voltage applied to the grid of the 75 tube.

In the output stage a 41 tube is employed. A dynamic reproducer is used. Provision is made for a single roof speaker and dual speaker (chassis and roof) connections. The electrical connections for the different speaker installations are shown in the schematic. For the single 8 inch or dual 5¼ inch speakers, the tapped connection of the output transformer secondary is used.

The vibrator in the power unit interrupts the current through the primary of the power transformer. The use of a vibrating interrupter in the primary circuit and a high ratio transformer results in the application of high voltage AC to the rectifier tube plates. The 84 full wave rectifier tube, filter choke and filter condensers convert this high voltage AC into high voltage DC for the plate and screen circuits.

Alignment and Calibration

Misalignment of condensers generally manifests itself as broad tuning and lack of volume at portions or all of the standard wave band. The receivers are all properly aligned at the factory with precision instruments and realignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment.

A signal generator that will provide accurately calibrated signals over the standard wave band and at the intermediate frequency, and an output meter are required for indicating the effect of adjustments.

Use a non-metallic screwdriver for the adjustments. The complete procedure is as follows:

I. F. Adjustment

Set the signal generator for a signal of 175 KC.

Connect the output of the signal generator through a .05 mf. condenser to the stator of the R. F. interstage section of the tuning condenser. (See Fig. 2 for location of this section.)

Connect the ground lead of the signal generator to the chassis ground.

Set the volume control at the maximum position.

Attenuate the signal from the signal generator to prevent the levelling-off action of the AVC.

Then adjust the three I.F. trimmers until maximum output is obtained. The location of these trimmers is shown in Fig. 2.

1575 KC Adjustment

Set the signal generator for 1575 KC.

Turn the rotor of the tuning condenser to the full open position.

If a low capacity antenna is used, connect the shielded antenna lead from the chassis through a 150 mmf. condenser to the antenna post of the signal generator. (If high capacity, use 1500 mmf.)

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent AVC action.

Adjust the trimmer of the oscillator section of the three gang condenser until maximum output is obtained—see Fig. 2 for location of this trimmer.

1400 KC Adjustment

Set the signal generator for 1400 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the R.F. interstage and antenna 1400 KC trimmers for maximum output.

Do not change the setting of the oscillator trimmer.

600 KC Adjustment

Set the signal generator for 600 KC.

Connect the output of the signal generator through a .05 mf. condenser to the control grid of the 6D6 R.F. tube.

Turn the tuning condenser rotor until maximum output is obtained. Then turn the tuning condenser rotor back and forth, at the same time adjusting the 600 KC padder (see Fig. 2) until the peak of greatest intensity is obtained.

Re-connect the output of the signal generator to the shielded antenna lead.

Adjust the 600 KC antenna trimmer to maximum. This trimmer is reached from the outside of the case —see Fig. 3.

Adjusting Antenna 600 KC Trimmer

After the receiver is installed and the car antenna is connected, it will be necessary to adjust the antenna trimmer. Tune in a weak signal at approximately 600 KC with the volume control about three-fourths on. Turn the adjusting screw of the antenna 600 KC trimmer up or down until maximum output is obtained. See Fig. 3 for location of this trimmer.

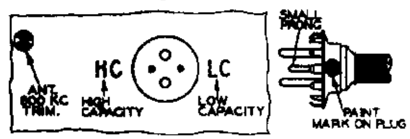

Fig. 3—Antenna Plug Insertion

Calibrating the Receiver

To calibrate the receiver, tune in a station of known frequency. At the back of the control head is the calibration screw. Remove the pilot lamp assembly. Insert a fine blade screwdriver and turn this screw until the pointer on the dial scale is at the frequency of the station being received. The knob must be held during this adjustment.

If the control head is inaccessible it may be calibrated by setting the pointer from the front. Remove the crystal by inserting a knife blade under the lower edge. Loosen the pointer screw, set the pointer and retighten.

Roof Speaker

The Ford and General Motors 1936 automobiles have provision for mounting a speaker in the car roof (Ford 5¼ inch speaker, General Motors 5¼ or 8 inch speaker). This model is so designed that roof speaker installations in those cars can readily be made.

There are three general types of speaker installation. In the first type of installation the single 5¼ inch speaker attached to the chassis cover is used.

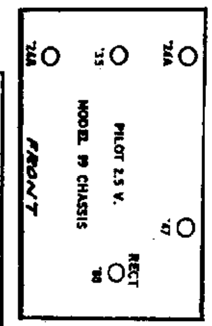
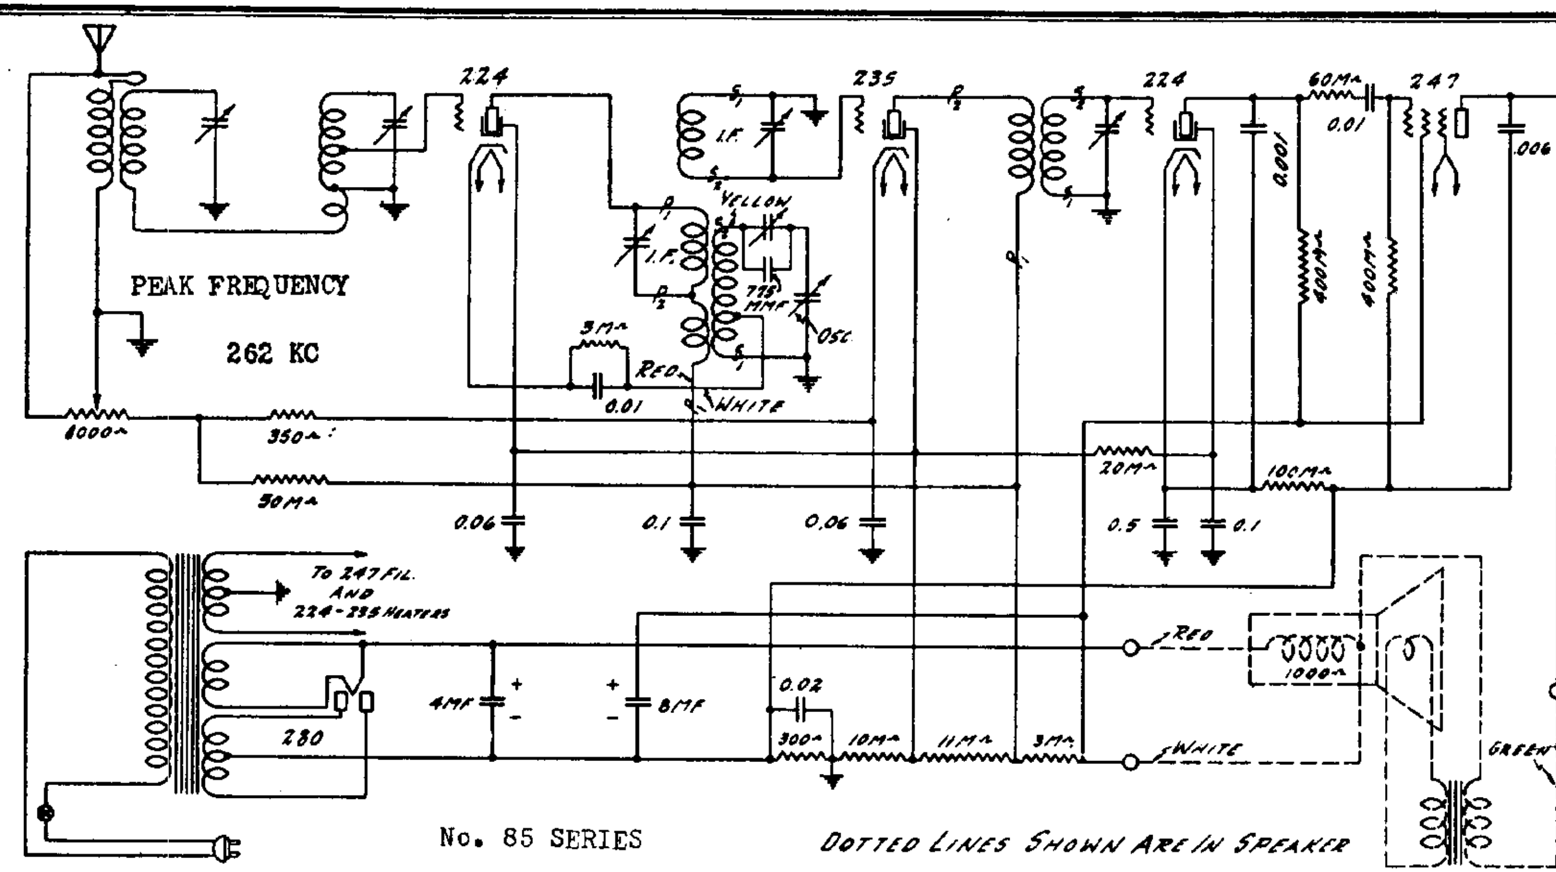
In the second type of installation a single 5¼ inch or 8 inch roof speaker is used. The third type of installation is the dual speaker mounting using two 5¼ inch speakers, one in the car roof and the other on the chassis cover. (The 8 inch and 5¼ inch speakers cannot be used together).

The electrical connections of the different speaker installations are shown in the schematic—Fig. 1. Complete information regarding the method of making the installations and the kits of parts required are in the installation manual packed with each radio.

MODEL 85
Schematic
Socket

GAMBLE-SKOGMO, INC.





There are certain features to be noted in this receiver. The mixer is of the autodyne type, wherein it functions as a mixer (1st detector) and also as an oscillator. Also that the grid lead from the mixer tube joins the grid coil at a tap upon this winding. This tap is so apportioned that the circuit acts to suppress the tranmission of image frequency signals, in this case 524 KC higher than the frequency setting of the tuned circuit. The IF transformer is also of special structure combining the coupling transformer and also the oscillator system. The structure of this transformer-oscillator is illustrated upon the next page.

280	5	Rect.	4.9						27. Per Plate	

(1) Varies with frequency setting of dial approximately as shown.
(2) Voltage as measured with 600,000 ohm meter.
(3) Measured across 300 ohm section of voltage divider resistor.

CONDENSER ALIGNMENT

Aligning Intermediate Condensers—A non-metallic screw driver is necessary for aligning the intermediate condensers. A signal of 262 K.C. is required. Remove the grid cap from the grid connection of the 224 1st detector tube and connect the lead from the signal generator to the grid of the 224 1st detector. The tube shield should be left on. One way to make this connection is to bring the antenna lead from the signal generator through the slot in the shield for the grid wire. A grid cap on the end of the antenna lead of the signal generator will facilitate making this connection. This lead, of course, should be insulated.

The oscillator coil must be shorted out by grounding the lead from the tap on the secondary. This is the white lead which comes through the porcelain base of the oscillator and I.F. assembly. This lead terminates at a lug on a vertically mounted bakelite terminal strip. Connect the jumper from this lug to the ground. Connect the ground lead from the signal generator to the ground post of the chassis.

The intermediate condenser adjusting screws are reached from the bottom of the chassis. There are two on the porcelain base of the oscillator and 1st I.F. transformer assembly, Part No. 3382 and one on the porcelain base of the 2nd I.F. transformer assembly, Part No. 3388. The volume control should be at maximum setting. Then adjust the three intermediate condenser screws until maximum output is obtained on the output meter. After all three have been adjusted the first time, go over them again and check the setting for maximum output.

Aligning R.F. and Oscillator Condensers—For adjusting the R.F. and oscillator condensers the signal input from the signal generator should be made to the antenna post. Adjust the signal generator for a signal of exactly 1400 K.C. Then turn the tuning condenser rotor until the pointer is at exactly 1400 on the dial scale. Then adjust the three trimmers on the tuning condenser for maximum output adjusting the oscillator trimmer first (trimmer nearest back of chassis). Turn the screws up or down until greatest deflection on output indicating meter is obtained.

Then set the signal generator for a signal of 600 K.C. and turn the tuning condenser rotor until the output is at maximum. The next step is to adjust the oscillator 600 K.C. trimmer condenser. The adjusting screw for this condenser is in back of the tuning condenser and is reached from the top of the chassis. To correctly adjust this oscillator 600 K.C. trimmer it will be necessary to turn the screw to several different positions using a nonmetallic screw driver. At every position of this adjusting screw turn the tuning condenser rotor until maximum output is obtained. For each position of the adjusting screw there will be a maximum output and the correct position of the adjusting screw is the setting at which the deflection on output indicating meter is the greatest.

Next set the signal generator again for a 1400 K.C. signal and check the adjustment of the tuning condenser trimmers at this frequency for maximum output. Then set the signal generator for a signal of 1000 K.C. and turn the tuning condenser rotor until the output indicating meter shows maximum deflection. Then bend the slotted rotor plate sections of each tuning condenser bank which are last in mesh, in or out until maximum output is obtained. Tune in a signal at 750 K.C. and then at 600 K.C. and follow the same procedure bending the rotor plate sections last in mesh until maximum output is obtained. Do not change the setting of the oscillator 600 K.C. trimmer in any way after it has once been set as indicated above.

FLUTTERING OR MOTORBOATING

Fluttering or motorboating may be due to an open 8 Mfd. electrolytic filter condenser or to low capacity in this condenser. It may also be due to an open or low capacity .06 Mfd. screen by-pass condenser. If the 4 and 8 Mfd. electrolytic condenser units are reversed in position fluttering may result. The correct position of these two units is shown in Fig. 1.

A 224 1st detector with characteristics varying considerably from the standard may cause fluttering. Try out some new 224 tubes in this socket. A defective oscillator and 1st I.F transformer assembly may also be responsible for this type of disturbance. If, after the tubes have been changed and the other possibilities suggested in this article have been investigated, fluttering persists, it may be advisable to secure a new oscillator and 1st I.F. transformer assembly and try it out in the receiver. Motorboating may be due to a poor grid connection to the 235 I.F. tube and to the 224 2nd detector.

ELECTROLYTIC FILTER CONDENSERS

There are two dry electrolytic condenser units in the No. 99 chassis. One of these units is an 8 Mfd., 450 volt condenser, Part No. 2803. The other unit is a 4 Mfd., 450 volt condenser, Part No. 3366.

In replacing the electrolytic condenser units great care should be taken to wire them in with the correct polarity. Tag the leads when they are taken off the old condensers. The positive terminal of the condenser is identified by a + symbol on the box. The positive lead in the chassis can be determined by referring to the schematic circuit diagram.

Alignment Proceedure

Do not attempt the complete alignment of this set without having a reliable test oscillator or signal generator. Before making any adjustments always be sure that everything has been checked that is mentioned in the section above under "Possible Sources of Trouble."

I. F. alignment—connect the signal generator lead to the grid of the 1-C-6 tube. The ground lead from the signal generator should be connected to the chassis. Connect an output meter on the speaker. Turn tuning condenser open. Set signal generator to 456, attenuating enough so that set does not overload. "Peak" I. F. trimmers—using as low a signal as will give a readable output, going over them at least twice.

Padder Condenser.

Place set in operation and connect signal generator to antenna lead. Close tuning condenser. Set signal generator for 530 K. C. and adjust padder for maximum signal.

Trimmer Condensers.

Open tuning condenser. Leave signal generator connected as above and set for 1730 K. C.—adjust oscillator trimmer (rear section) for maximum.

Change signal generator to 1200 K. C. and tune this in on set, then adjust antenna trimmer for maximum.

Possible Sources of Trouble

1. **Weak volume**, antenna lightning arrestor shorted, exhausted batteries either "A" or "B", weak tubes, tube shield on 34 tube not grounded, defective part—in set—check circuits. Set out of alignment—see paragraph below before attempting to align.

2. **Distorted reproduction**—defective tubes, weak batteries, shorted or open condenser or resistor in set. Defective speaker.

3. **Oscillation—set may "whistle"** when tuning in a station and volume may be low,—tube shield on 34 tube not making contact with ground clip, defective 34 tube, speaker wires close to 32 tube.

4. **Set does not operate at all**—If tubes and batteries have been checked, it is probable that some part has failed or some wire is shorted or connection broken—refer to circuit and check for continuity and resistance. Small condensers can be checked for "open" by placing a new condenser of similar capacity in parallel.

NOTE. When testing set with batteries connected—it is a good plan to place a standard 10 Watt 110 Volt lamp in series with the BLUE "B" battery wire to protect the tubes in case of a short circuit.

BROADCAST BAND ALIGNMENT:

1. Set external oscillator to 1720 K.C. and connect it in series with a 200 mmfd. condenser to the antenna and ground posts.
   (a) With variable condenser in its minimum capacity position, plates entirely out of mesh, adjust oscillator trimmer (rear section of variable condenser) to resonance.
   (b) Re-set external oscillator to 1400 K.C. Rotate variable condenser, pick up signal and adjust antenna trimmer (front section of variable condenser) to resonance.
   (c) Re-set external oscillator to 600 K.C., move dial pointer to 600 K.C., and adjust series pad, part number 124-13 (see top view), to resonance. While making this adjustment, slowly rock variable condenser to and fro until maximum output is obtained.
   (d) Check for sensitivity at 800, 1000, 1200 K.C. DO NOT BEND PLATES.

ALIGNING I.F. TRANSFORMERS: (465 K.C.)

1. With volume control full on and with variable condenser at its minimum capacity position, plates entirely out of mesh, and with external oscillator set at 465 K.C. connected in series with a .1 mfd. condenser, to the grid of the 1A6 tube (cap at top of tube), adjust I.F. transformers, parts number 108-41 and 108-43, to resonance. Both of these transformers have two (2) adjustments each, they are accessible from the tops of the cans (for location see top view).

Use as a resonance indicator an output meter connected across the outside terminals of the speaker or by means of an adapter to the plate and screen of the type 33 output tube. Maximum deflection of the volt meter indicates resonance.
Use only enough signal to get a readily readable output.
A low range output meter or the low scale of a multi-range meter should be used.

MODEL 430
BATTERY RADIO

Coronado Model 430

GENERAL: This model is designed for the greatest possible efficiency from the three tubes that the set uses. It is not intended to take the place of the more powerful Coronado models, but is recommended for the customer who is content with reception of stations at a reasonable distance, and wants a compact set at a low price. It is intended for use only on an outside aerial and ground.

TUBE FUNCTIONS: "IA6" first detector-oscillator, "19" one section as second detector regenerative at an IF frequency of 456 K. C., the other section as first audio amplifier, "33" power tube.

CHECKING PARTS: In case of sub-normal performance, check the following in order named: aerial, ground, lightning arrestor, batteries, tubes, speaker, set parts, alignment. The resistance and capacity values of all major parts are shown on the diagram.

ALIGNMENT: Open tuning condenser (high frequency dial setting) connect a signal generator or test oscillator to the grid cap of the IA6 tube, leaving the present cap in place. Use a small condenser .002-.01 in series with the signal generator lead wire. If the second detector is oscillating—causing the set to "squeal"—turn the "regeneration control" screw (on back of chassis) to the "left" until the oscillation stops. Set the signal generator to 456 K.C. and adjust the two trimmer screws in the top of IF transformer to "peak"-reducing the output of the signal generator so that only an audible signal is obtained during final adjustments. Now turn the regeneration control to the "right" until oscillation starts, then back it off until the set is stable and recheck the IF adjustments. It is best practice to use an output meter to indicate "peak".

ANTENNA AND OSCILLATOR ALIGNMENT: Connect signal generator to aerial lead wire from set and adjust oscillator trimmer (rear section of tuning condenser) for 1730 K.C. Adjust antenna trimmer at 1000 K.C.

ADDITIONAL NOTE: If all parts have been checked, the set carefully aligned, and performance is still not comparable to another set of the same model, the trouble is probably due to a defective IF transformer and this should be replaced with a new one.

Schematic circuit diagram AC-DC Superheterodyne, with automatic volume control

Should it be necessary, at any time, to rebalance this set the procedure is as follows: Attach a 456 kilocycle oscillator to the grid of the 6A7 tube in back of the variable condenser and adjust the trimming condensers of the I. F. transformers to maximum deflection on an output meter connected across the primary of the speaker input transformer. While adjusting these trimmers, the variable condenser should be at the maximum capacity position—at the extreme right of its rotation.

Next disconnect the antenna wire and connect an oscillator in series with a 75 mmf. condenser to the antenna coil. Rotate the condenser plates to the minimum capacity position—extreme left turn, and adjust the trimmer condenser of the rear section of the variable condenser to resonance with an oscillator set at 1725 kilocycles, then adjust the condenser of the front section of the variable condenser to resonance. Align at 1400—1200—1000—800—600—530 kilocycles, bend slotted plates of variable condenser if necessary.

I.F. frequency 175 KC.

GAMBLE-SKOGMO, INC.

Model 578—Series A

5-TUBE A. C. SUPERHETERODYNE RECEIVER

DESCRIPTION

Tubes

The Tube complement of this chassis is as follows:

1 Type 6A7—pentagrid electron coupled oscillator and first detector.
1 Type 6D6—remote cut-off pentode as I.F. amplifier.
1 Type 6B7—duplex diode pentode as diode detector, A.V.C. and A.F.
1 Type 42—pentode output tube.
1 Type 80—high vacuum rectifier.

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt. These voltages are clearly indicated on the circuit diagram

All voltages are measured with 119 volts on the primary of the power transformer.

Resistance of coils and transformer windings are indicated in ohms on schematic circuit diagram.

Transformers are available and chassis are sometimes equipped with universal transformers for operation on 40 and 60 cycles and with primary taps for 108, 125, 150, 220 and 250 volts (see illustrations) and also sometimes equipped with 25 cycle transformers with 105-115 volt or 220 volt primaries, not universals.

ALIGNING INSTRUCTIONS

Description of various dummy antennas used and referred to in these instructions:

(1) I.F. Dummy—Consists of a .1 mfd. condenser connected in series with the external oscillator.

(2) Broadcast Dummy—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Resonance Indicator:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer, or by means of an adapter between the plate and screen terminals of the type 42 output tube. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range volt meter should be used.

Alignment

No aligning adjustments should be attempted without first thoroughly checking over all other possible causes of trouble, such as poor installations, open or grounded antenna systems, low line voltages, defective tubes, condensers and resistors. In order to properly align this chassis, an oscillator (generator) is absolutely necessary. No aligning adjustments should be attempted with the chassis in the cabinet. To remove the knobs, pull them off and to take the chassis out of the cabinet, remove the three bolts by which it is fastened and the speaker plug which you will find on the front flange of the chassis panel.

Aligning I. F. Transformers

1. With volume control full on, the extreme right of its rotation, and with variable condenser at its minimum capacity position, plates entirely out of mesh, adjust the I.F. transformers (two adjustments at the top of parts number 108-53 and 108-47)
   (a) Connect external oscillator which has been adjusted to 465 kilocycles in series with I.F. dummy antenna, to the control grid cap of the type 6D6 tube and chassis ground. Adjust output I.F. transformer, part number 108-47, to resonance.
   (b) Move generator output clip from grid of 6D6 to grid cap of 6A7 tube and align input I.F. transformer, part number 108-53.

   (c) With generator connected to grid of type 6A7 tube, readjust output I.F. transformer, part number 108-47, to resonance.

R. F. Alignment—
(530 - 1720 Kilocycles)

1. With gang condenser in its minimum capacity position, plates entirely out of mesh, connect an external oscillator in series with broadcast dummy antenna to tan antenna and black ground leads and make the following adjustments:
   (a) With external oscillator set at 1720 kilocycles, adjust oscillator trimmer, (rear of gang condenser).
   (b) Re-set external oscillator to 1400 kilocycles, rotate condenser, pick up oscillator signal and adjust antenna trimmer to resonance, (front section of gang condenser).
   (c) Re-set external oscillator to 600 kilocycles and adjust series pad to resonance, rotate condenser and move dial pointer to 600 kilocycles by gently rocking condenser to and fro. Pick up oscillator signal while adjusting series pad to resonance, maximum deflection on an output meter. This adjustment is accessible from the top of the chassis and is located between variable condenser and power transformer.

25 Cycle Chassis differ only from 60 cycle chassis in that part number 104-18 transformer is used in place of 50/60 cycle transformer, part number 104-14.

Service Notes

To check for open by-pass condensers, shunt each condenser with another of similar capacity and of the same voltage rating, which is known to be good, until the defective unit is located. Open by-pass condensers frequently cause oscillation and distorted tone. Defective and shorted electrolytic filter condensers cause excessive hum, motor-boating, low volume and a reduction in all D.C. voltages. Open or shorted electrolytic and by-pass condensers (across bias resistor of type 42 tube) will cause low volume and distorted tone.

Replacement Parts

NOTICE—A change has been made in our parts numbering system. Old parts which are used in new receivers will have a new number assigned to them. For your convenience we are listing below the new part number and the corresponding old part number, should there be one. **Order by new part number only.**

There is a large letter on the chassis which identifies the set as to major part changes. When ordering parts please be sure to mention the series number and this large letter.

New Part No.	Old Part No.	Description	List Price
P-3A126	2022	Type 76 Glass Tube Socket	$0.10
P-3A113	1855	Type 6D6 Glass Tube Socket	.10

10 Tube - 3 Band

All-Wave High Fidelity Receiver

This model is a three band receiver with a tuning range in each band as shown in the specifications above. Three band coverage is accomplished by means of three sets of R. F. and oscillator coils and a three section triple throw switch.

Referring to the schematic circuit diagram, Fig. 2, T1 and T2 are the antenna and interstage R. F. transformer assemblies and T9 is the oscillator coil assembly. The standard wave, 1st and 2nd short wave coils in each assembly are indicated by the letters B, C and D respectively. The three sections of the band switch are designated in the schematic as the antenna, interstage and oscillator sections.

The band switch completes connections to the coils in use. It also short circuits the R. F. transformer secondary and oscillator coil of lower frequency not in use.

The antenna transformer with tuned secondary feeds into a type 6K7 R. F. amplifier tube. The output of this tube is fed through the interstage R. F. transformer with tuned secondary into another 6K7 tube which functions as the 1st detector.

A separate type 76 tube is employed in the oscillator circuit. Referring to the oscillator assembly T9, Fig. 2, B, C and D refer to the standard wave, 1st short wave and 2nd short wave oscillator coils respectively. The oscillating circuit is always resonant at 456 KC above the frequency to which the R. F. amplifier is tuned.

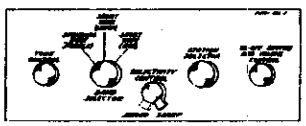

Fig. 1—Arrangement of Controls

The oscillator potential is fed into the cathode circuit of the 6K7 first detector tube. This results in the intermediate or beat frequency of 456 KC being present in the plate circuit of this tube.

Two stages of I. F. amplification are employed using 6K7 tubes. The primaries and secondaries of the first and second I. F. transformers and the primary of the 3rd I. F. transformer are tuned by small trimmer condensers.

Selectivity Control—Referring to the 1st and 2nd I. F. transformers T3 and T4 in Fig. 2, it will be noted that there are coupling windings shown in the illustration below the primaries.

When the selectivity control is in the sharp position, the coupling winding is open circuited and the loose coupling which exists between the primary and secondary of this transformer results in high selectivity.

When the selectivity control is in the broad position, the coupling winding which is wound under the primary is connected in series with the secondary. This provides overcoupling which results in a greatly widened resonance curve. Passage of a wide range of audio frequencies is thus obtained.

Dual Volume Control—A dual manual volume control is employed. In one section the audio voltage applied to the 76 1st audio tube is varied (R10). In the other section the R. F. and 1st I. F. bias is varied (R3). The purpose of the latter section is to reduce the sensitivity of the receiver at low volume settings in order to cut down noise pick-up between stations. The variable section R3 is shorted out through contact No. 4 of the interstage section of the band selector when in the 2nd short wave position.

A type 76 tube functions as a diode second detector. AVC voltage is applied through isolating resistors to the control grid circuits of the R. F. and 1st I. F. tubes. The audio voltage developed across volume control resistor R10 is applied through the movable arm to the control grid of the Type 76 1st audio tube. Transformer coupling is used between the first audio stage and the output stage which employs two type 45 tubes. A type 80 full wave rectifier tube is used in the power unit.

Alignment and Calibration

Correct alignment is extremely important in connection with all wave receivers. The receivers are all properly aligned at the factory with precision instruments and realignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment.

A signal generator that will provide an accurately calibrated signal at 456, 1730, 1500, 600, 5800, 5000, 18,300, 15,000 and 6000 KC and an output indicating meter are required. It will be practically impossible to align the receiver if unsatisfactory apparatus is used. If a station is tuned in with the selectivity control in the broad position and this control is then turned to the sharp position, the station may disappear. This is not an indication that the receiver is out of alignment.

Use a non-metallic screwdriver for the adjustments. The complete procedure is as follows:

I. F. Adjustment

Set the signal generator for a signal of 456 KC.

Connect the output of the signal generator through a 0.1 mf. condenser to the grid of the 1st detector.

Connect the ground lead of the receiver to the ground post of the signal generator.

Turn the band selector to the Range B position (standard wave band—purple dial color).

Turn the selectivity control to the sharp position and keep it in this position for all adjustments.

Turn the volume control to the maximum position.

Attenuate the signal from the signal generator to prevent the levelling-off action of the A.V.C.

Then adjust the five I.F. trimmers until maximum output is obtained. The adjusting screws for these condensers are reached from the top of the chassis, and the location is shown in Fig. 5.

Range B Alignment

1730 KC Adjustment

Set the signal generator for 1730 KC.

Turn the rotor of the tuning condenser to the full open position.

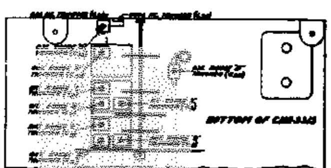

Fig. 3—Location of Trimmers

Keep the band selector in the standard wave position.

Connect the antenna lead of the receiver through a 200 mmf. condenser to the output of the signal generator.

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the oscillator Range B trimmer (C32) until maximum output is obtained. The location of this trimmer is shown in Fig. 3.

1500 KC Adjustment

Set the signal generator for 1500 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Loosen the pointer set screw and set the large pointer at the 1500 KC mark on the standard wave band scale. Retighten the set screw.

Adjust the interstage Range B trimmer (C7) and antenna Range B trimmer (C2) to maximum.

Do not change the setting of the oscillator Range B trimmer.

600 KC Adjustment

Set the signal generator for 600 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 600 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

Range C Alignment

5800 KC Adjustment

Set the signal generator for 5800 KC.

Connect the antenna lead of the receiver through a 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band selector to the Range C position (1st short wave band—green dial color).

Adjust the oscillator Range C trimmer (C30) until maximum output is obtained. See Fig. 3 for location of this trimmer.

5000 KC Adjustment

Set the signal generator for 5000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the interstage Range C trimmer (C8) and antenna Range C trimmer (C3) to maximum.

Do not change the setting of the oscillator Range C trimmer.

Range D Alignment

18,300 KC Adjustment

Set the signal generator for 18,300 KC.

Keep the antenna lead of the receiver connected through the 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band selector to the Range D position (2nd short wave band—red dial color).

Adjust the oscillator Range D trimmer (C29) until maximum output is obtained. See Fig. 3 for location of this trimmer.

15,000 KC Adjustment

Set the signal generator for 15,000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the interstage Range D trimmer (C9) and antenna Range D trimmer (C4) to maximum.

When adjusting the interstage Range D trimmer, it will be necessary at the same time to turn the tuning condenser rotor slowly back and forth until the peak of greatest intensity is obtained.

Then go back and repeat the procedure as given for the 18,300 KC adjustment. If it is found necessary to make any appreciable change in the setting of the oscillator Range D trimmer, the 15,000 KC adjustment must be repeated.

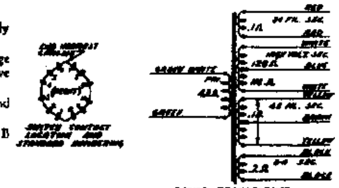
Do not make any further change in the setting of the oscillator Range D trimmer.

6000 KC Adjustment

Set the signal generator for 6000 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 6000 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.



Power Transformer

Changes in Early Models

In the early models of this receiver the tone control resistor (R11) was connected as a series variable resistor connecting in series through the condenser C23 between the grids of the 45 tubes in the audio output stage. In the later models it is employed as a potentiometer in the manner shown in Fig. 2.

The 100,000 ohm resistor (R18) was not used in the early models. Condenser C21 was connected directly to resistor R7.

The type 6K7 metal tubes replace the type 6D6 glass tubes which were used in the early models.

Condenser C35 was added to the oscillator coil standard wave section in later models. It is not, however, used in all cases but only when this capacity is required in this circuit.

Phonograph Connections

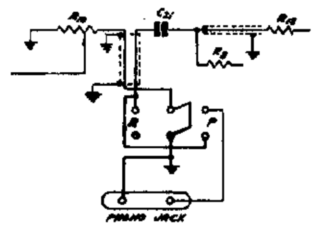


Fig. 7—Phonograph Connections

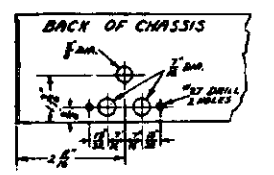

Fig. 8—Details of Panel Drilling for Phono Assembly

Twenty-five Cycle Receivers

The twenty-five cycle receiver differs from the sixty cycle receiver only in the fact that a different power transformer is used. The correct power transformer is shown in the parts list.

The twenty-five cycle receiver can be operated satisfactorily from a sixty cycle power supply. However, the reverse is not true, the sixty cycle receiver cannot be operated from a twenty-five cycle power supply.

A 115-230 Volt, 40 to 60 cycle as well as other power transformers with special power ratings are also available for this model.

INSTALLATION AND SERVICE INSTRUCTIONS

MODEL 580

FIVE TUBE-SUPERHETERODYNE AUTO RADIO

TUBE COMPLEMENT:

1—Type 6D6—remote cut-off pentode as an R. F. amplifier.
1—Type 6A7—pentode as an oscillator and first detector.
1—Type 75 —duplex diode triode second detector automatic volume control and first audio.
1—Type 42 —pentode output tube.
1—Type 84 —high vacuum full wave rectifier.

ACCESSORIES:

The carton of accessories packed with this set contains the following:
1—No. 152-1 shielded plug-in type antenna cable.
1—No. 152-2 plug-in battery cable.
1—No. 149-18 flexible volume control shaft (slotted fitting).
1—No. 150-18 flexible selector shaft (key fitting).
2—No. 146-2 brackets for anchoring flexible shafts to set container.
2—No. 135-5—3" x 5/16" carriage bolts and nuts for mounting set to bulk head.
2—No. 134-1—5/16" x 1" iron washers.
3—No. 134-2—5/16" lockwashers.
6—No. 154-2 set screws, 4 for attaching flexible cables to set, 2 for anchoring cables to brackets.
4—No. 155-6—No. 6 x 3/8" binding head self-tapping screws for attaching brackets (No. 146-2).
6—168-1—Spark plug type suppressors.
1—168-2—Distributor type suppressor.
1—No. 148-1 generator condenser.
1—No. 148-3 ammeter condenser.
1—No. 151-3 remote control head.
1—No. 116-6 pilot light assembly complete.
1—No. 146-8 Die cast mounting bracket.
1—No. 146-12 Steering column strap.
1—No. 116-5 6-8 volt bulb.
1—No. 169-1 15 amp. fuse.
1—No. 152-3 Fuse insulating sleeve.

RECEIVER INSTALLATION:

Determine most satisfactory or desirable mounting position. In most cases it will be found that the receiver can be mounted on the car bulk head, above and to the right of the steering post.

Use the paper template included with these instructions and which is the same size as the set. Mark location for two mounting bolts if mounted on the long side and for one mounting bolt if mounted on the short side.

Then drill two (2) one-half inch (1/2") holes, making certain that the paint around the hole on the engine side of fire wall or bulk head is scraped clean to insure a good ground connection between receiver and the frame of the car. Assemble brackets number 146-2 to case with self-tapping screws.

Insert bolts through dash, assemble plain, lockwashers and nuts on engine side, then hang receiver over bolt heads and tighten nuts securely.

Mount the remote control unit on steering column by means of mounting bracket or attach to instrument panel or under dash (see illustration).

Two flexible shafts are furnished, one with a slotted fitting on one end, which is the volume control shaft (number 149-18), the other is the selector shaft, with key fitting at one end (number 150-18).

Make certain that the outer casings of flexible shafts go into remote control bushings for approximately five-sixteenths of an inch and tighten set screws to secure cables. If cables are pushed too far into remote control head, shafts will not turn freely. Always try to install drive shafts in as straight a line as possible from remote control to set. AVOID SHARP BENDS IN CABLES.

IMPORTANT—READ CAREFULLY:

We are *prepared* to exchange, without charge, our standard number 149-18 and 150-18, eighteen inch cables for *twenty-four* inch cables, number 149-24 and 150-24. You will find that 99% of the installations can be made with the standard eighteen inch cables, and bear in mind that the shorter the cable, the smoother the drive.

DASH MOUNTING FOR THE REMOTE CONTROL HEAD:

The majority of the new 1935 model automobiles have provisions made for mounting the remote control head of an auto radio on the dash. We have available special escutcheon plates for this purpose which can be secured upon request at an additional cost of $1.00. *When requesting escutcheon plates specify make and model of the car, also the finish of the dash.*

Following is a list of 1935 model automobiles which contain removable ash tray receivers and which are able to accommodate the *remote control head of our model 580 auto receiver.*

Chrysler Airstream	Nash	Reo
Dodge	Packard	Ford V-8
Plymouth	Graham DeLuxe	
De Soto Airstream	Hupmobile	

Following is a list of 1935 model automobiles which do not contain ash tray receivers but with the aid of the special drilling dimensions furnished herewith the left hand panel on the dash may be drilled to accommodate our regular remote control head.

La Fayette (Nash)	Graham (Standard)
Franklin	Studebaker

For installation of our remote control head on the following cars we recommend standard steering column or dash mounting with the aid of a bracket:

Auburn	Terraplane	De Soto & Chrysler Airflow
Buick	Pontiac	Hudson
Cadillac	Chevrolet—Standard	Lincoln
La Salle	& De Luxe	Oldsmobile

Many of the 1934 model automobiles contain the same size ash tray receiver as the 1935 models and naturally installation of the remote control head can be made on these models.

We have found that our model 580 auto receiver will fit above the steering column on the fire wall of 75% of the late model automobiles and for dash mounting of the remote control head this location works out very satisfactorily.

The Cadillac, La Salle, Chevrolet, Pontiac and Oldsmobile 1935 automobiles have special blank escutcheon plates on the dash which are intended for remote control heads for auto receivers. The cut-out behind these blank escutcheons will not accommodate our remote control head and for installation in these models we recommend using standard steering column mounting for the remote control head or dash mounting using a bracket as illustrated in drawings contained herein.

DIAL ADJUSTMENT:

Mount control head to steering column by means of bracket and strap or under dash by means of bracket or to instrument panel (see illustrations). Attach cables as above. Tune set to some station of a known frequency (between 800 and 1200 K.C.), hold selector knob, then with a screw driver adjust the slotted screw on back of the control head, and in that way adjust the dial pointer to the correct frequency setting.

CONNECTIONS TO BATTERY:

The battery cable, number 152-2, (red wire with fuse receptacle at one end and terminal lug at other end) must be connected to battery terminal of ammeter. At the same time connect ammeter capacitor, number 148-3, to battery terminal of ammeter, other end of condenser to any convenient grounded screw on back of instrument panel. Make certain that insulating sleeve is slipped over fuse when fuse is placed in receptacle, *before* inserting in receiver (see illustration). All bypass leads should be as short as possible.

When connected properly, the discharge due to current drawn by the receiver should not indicate on the ammeter. This is important, since if improperly connected, as shown by the deflection of ammeter, additional motor interference may be encountered.

PILOT LIGHT:

Pilot light assembly, part number 116-6, a shielded cable, plugs into the set and to the rear of the remote control unit (see illustrations).

ANTENNA CONNECTION:

The antenna is connected to the receiver by means of the antenna cable, number 152-1. The antenna wire is the single black wire projecting from the end of the cable. Splice this wire to the roof antenna lead and ground the pig-tail shielding as close to the corner post of the car as possible.

OPERATION:

Place key (knob) in lock of left hand control of the remote control unit. After waiting approximately 45 seconds for tubes to heat up, rotate station selector, right hand knob, until a desirable program is heard. De-tuning will very seriously affect the tone quality of this receiver.

MOTOR NOISE SUPPRESSION:

The ignition system of every automobile generates high frequency electrical interference. This high frequency interference arising from the ignition coil, the distributor and the spark plugs must be properly suppressed in order to obtain satisfactory reception. Each car will present more or less an individual problem but there is a definite procedure to follow which holds true in every case.

This first essential procedure is to disconnect the high tension leads to the spark plugs and attach the spark plug suppressors (168-1) (for V 8 Fords 168-4) the special distributor type suppressor (168-2) which is inserted in the center contact of the distributor as indicated in the illustration of a typical installation. (NOTE V 8 FORD USES NO DISTRIBUTOR SUPPRESSOR.) For cap type distributor, exchange the standard plug type distributor suppressor (168-2) for a special cable type suppressor (168-3) from your dealer. In some few cases, such as Buicks it is sometimes necessary to use cable type (168-3) suppressors. This type of suppressor is inserted in the leads running from the distributor to the spark plugs and which are concealed underneath the metal plate which covers the spark plugs.

After the spark and distributor suppressors have been properly fastened the next in importance is the generator condenser (148-1), this filters a high pitched whining noise which would otherwise be heard as the motor is accelerated.

It is sometimes necessary in cars where the ignition coil is located under the dash, to use an additional capacitor (144-1) obtainable from your dealer. It must be installed between the battery side of the ignition coil and the frame of the car. Next connect capacitor (148-3) from the battery side of ammeter to frame of car. This is necessary in practically every installation and a good connection to the frame of the car is of utmost importance.

After standard suppression has been applied and the hood clamped down to prevent radiation, the receiver should be turned on and the dial turned off a station, with the volume control at maximum. If motor noise is still objectionable the next step is to determine whether the interference is originating through chassis pickup or from the antenna.

To check for chassis pickup, disconnect the antenna from the antenna cable and ground the antenna lead to shield of cable, or remove antenna cable. Chassis pickup can be reduced by reducing the gap between plug contacts and the rotating arm in the distributor head. To do this, apply solder to the end of the rotor arm. Replace the rotor in the distributor and turn the engine over slowly with the crank in order to clean the excess solder. The rotor should not brush or wipe the contacts inside the distributor cap, but should just clear them. As an additional precaution check the breaker points. They should be thoroughly cleaned and adjusted or new points installed if they are badly worn. The ignition system of a car must be kept in good condition and leaky cracked high tension wires and bad spark plugs should be replaced. In many cars the low tension battery leads, etc., are grouped together with the high tension wires. These leads will very often pick up motor noise and feed it into the receiver through the battery circuit. In cases such as these it will be necessary to separate the low tension from the high tension wires and run them through another hole if they run from the engine compartment up to the instrument panel. This condition is particularly true on the V 8 Ford as the battery and primary leads run through a special tube which also houses the high tension leads. Shield and ground these leads. It is also necessary on V 8 Fords to install a capacitor between the primary terminal of the coil and ground.

Cars with floating power must have the motor bonded to the bulkhead and again to the frame to provide a direct path for the high frequency interference developed in the ignition system. 1/4" copper braid will be necessary, SMALL DIAMETER WIRE WILL NOT DO. Bond flexible shaft leads, such as free wheeling, choke wires, etc., which pick up motor noise and reradiate it into the car. In extreme cases it has been found necessary to ground the steering column. Free wheeling cables should be grounded at the point at which they go through the fire wall of the car.

On cars which have a wooden bulkhead it is necessary to line the motor side with thin sheet metal and ground. This will prevent interference from entering the inside of the car and from there being picked up by the antenna. It is also necessary in some installations to connect a capacitor from the hot side of the dome light wire to frame of the car. This lead can usually be found by referring to the electrical wiring diagram of the car. If the ignition coil is mounted inside the driving compartment, it may be necessary to shield the high tension lead running from the coil to the distributor. This cannot be done effectively, however, if the wire has rubber insulation. Where the car is so equipped this wire should be replaced with a good quality high tension wire such as Packard cable. When applying the shield over this wire be sure that it terminates at least an inch from both ends of the lead and that the shield is grounded at both ends; one end under the dash and the other to the engine. It may be necessary to by-pass the electrical connections of all gauges such as oil, water, gas (Hudson-Terraplane).

The foregoing rules should remove any trace of chassis pickup. Now connect the antenna to the receiver and test for motor noise pickup. It is entirely probable that if any noise is present it will be very slight and only noticeable between stations.

No absolute rule for complete motor noise elimination can be specified inasmuch as many times two cars of the same make present entirely different problems and require bonding or shielding at different points.

A word or two concerning antennas; naturally the performance of any radio depends on the effectiveness of the antenna. The later model cars are coming through with very good Antennas already installed and no trouble should be experienced from this angle with of course an occasional exception. The older cars present a more difficult problem and naturally the service man will have to take cases of this nature into consideration. Many of the older cars on the market today have a wire network in the roof which is nothing more than ordinary chicken wire.

This wire network acts as a support to the roof and is in the majority of cases grounded directly to the body of the car at the point at which the roof meets the sides of the body. Service men frequently tack antennas to the underside of the top material in these cars, this is not satisfactory. There are but two things to do. Either an underslung (plate or strap) antenna must be used or the wire network must be cut from all grounds to the car. If this is done this network will in itself make a very good antenna, but it will be necessary to cut the wire network back for a distance of at least three inches from all sides of the car.

When running the lead-in up the corner post of the car to the roof antenna ground it every few inches to the frame of the body of the car. If this is not possible insulate it, otherwise scratchy noises will result.

Shield high tension leads.

The ignition system of car must be kept in good condition.

It is advisable to advance the generator charging rate in order to compensate for the additional drain of the receiver on car storage battery. THIS SHOULD BE DONE BY A COMPETENT SERVICE STATION.

BALANCING SET TO ANTENNA:

When this set has been installed and is ready for operation it may be found necessary (depending on antenna) to balance set to this antenna. This is accomplished as follows:

With the receiver tuned to a very weak station, about 130 to 140 (1300 to 1400 kilocycles) on the dial, adjust the antenna trimmer with a screw driver until maximum volume is attained. To reach the antenna trimmer remove the plug button from the top of the case.

SERVICE NOTES:

Model 580 is a five tube superheterodyne receiver with an intermediate frequency of 175 kilocycles and a tuning range of from 530 to 1550 kilocycles.

This receiver has been carefully designed to facilitate servicing, the top and bottom covers are both removable, any part is replaceable without removing the chassis from the cabinet. All adjustments are made without removing the chassis from the cabinet.

Should it ever become necessary or desirable to re-align this receiver, the proper method is as follows:

I. F. ALIGNMENT:

1. With variable condenser at its maximum capacity position and with volume control full on, connect in series with a .1 mfd. condenser, an oscillator set at 175 kilocycles to the grid cap of the 6A7 tube.

2. Adjust trimming condensers of I. F. transformer, part number 100-32 (two adjustments) to resonance, as indicated on an output meter connected across the primary terminals of the speaker input transformer or between the plate and screen terminals of the type 42 output tube. The connection to the tube can be made by means of an adapter. Maximum deflection of the meter indicates resonance.

Note: I. F. transformer adjustments are accessible from the bottom of the chassis—the bottom cover must be removed.

R. F. ALIGNMENT:

1. Attach oscillator connected in series with a 200 mmfd. condenser to the antenna lead and with the variable condenser at its minimum capacity position (extreme right of its rotation) and with an oscillator set at 1550 kilocycles, adjust condenser trimmer of oscillator section (Front shaft end) to resonance.

2. Re-set oscillator to 1400 kilocycles, rotate variable condenser to pick up signal, adjust antenna (center section) and R. F. (rear section) trimmers to resonance.

3. Check alignment at 1400-1000-600-530 kilocycles by setting oscillator to these frequencies and picking up signal by rotating condenser.

4. Bend slotted plates of antenna and R. F. sections only if necessary. UNDER NO CIRCUMSTANCES BEND PLATES OF OSCILLATOR SECTION.

NOTES:

Voltages from chassis to different points are indicated on schematic circuit diagram, and should be measured with a voltmeter having a resistance of 1000 ohms per volt.

Failure to operate, noisy or weak reception, may be due to defective tubes or poor contact between cap on top of tube and grid clip.

Tubes may be checked by replacing with another tube which is known to be good.

If fuse blows out frequently, and insulating sleeve has been properly placed over fuse, the trouble probably is in the vibrator and vibrator should be replaced.

NEVER ATTEMPT TO ADJUST VIBRATOR POINTS.

Case rattles may be due to one or more of the following:

Loose screws in top or bottom covers. Loose elements in tubes. Loose tube shield. Loose R. F. coil shield. Loose grill cloth.

MODEL 550
BATTERY RADIO

GENERAL: Always eliminate all possible sources of trouble external to the receiver itself, such as: defective aerial, ground, or lightning arrestor, tubes, batteries, loud speaker.

TUBE FUNCTIONS: "1A6" First detector—oscillator, "34" IF amplifier, "30" diode second detector, "32" first audio amplifier, "33" power tube.

CHECKING PARTS: The resistance of coils and resistors is shown on the circuit diagram together with condenser capacities. Any defective part, either shorted or open or greatly different in value than that specified will result in week reception or none at all.

ALIGNMENT: If all tubes, batteries, and set parts check OK and sensitivity is still low it is probably due to the set being out of alignment. It is necessary to use a reliable test oscillator or signal generator having accurate calibration and positive attenuation.

IF ALIGNMENT 456 K. C.: Open tuning condenser (dial at high frequency end) connect signal generator to grid cap of 1A6 tube leaving present cap in place. Use a small condenser .002—.01 in series with the signal generator lead. Adjust all four IF trimmers, two in top of each IF can. Go over the adjustments several times—reducing the output of the signal generator to as low an output as will give an audible signal. It is best practice to use an output meter connected across the speaker to indicate "peak".

ANTENNA & OSCILLATOR ALIGNMENT:—Connect signal generator to antenna lead of set, with tuning condenser open, adjust oscillator trimmer (rear section of tuning condenser) to peak on a 1730 K. C. signal from generator, close tuning condenser and adjust padder condenser (under chassis) on 540 K. C. signal, then recheck 1730 K. C. adjustment. Adjust antenna trimmer on 1000 K. C. signal.

Note: a strip of bakelite about three-sixteenths thick, one inch wide, and about six inches long with a slot sawed in one end will facilitate adjustment of padder screw.

DISTORTION: On sets bearing serial numbers below J 3604 a decided improvement can be made by the following changes:

1. Change R-7, 250,000 Ohm resistor to 100,000 Ohm resistor.
2. Remove R-4 500,000 Ohm resistor.
3. Short out C-9 .01 200 Volt condenser.
4. Change C-15, .002 800 Volt condenser, to .0005 Mica or 800 Volt paper.

Equivalent changes were made in circuit on models having serial numbers higher than J 3604.

DESCRIPTION

Tubes

The Tube complement of this chassis is as follows:

1 Type 6F7—triode pentode as oscillator and first detector.
1 Type 6D6—remote cut-off pentode as I.F. amplifier.
1 Type 75—duplex diode triode as diode detector, A.V.C. and A.F.
1 Type 42—pentode output tube.
1 Type 80—high vacuum rectifier.

Series "A" chassis are equipped with dry electrolytic filter condensers and are serially numbered on paper tags which are attached to the line cord and to the inside of the cabinet.

Series "B" and "C" chassis are serially numbered on the back flange of the chassis, series "B" beginning with number "5A100510B" and up; series "C" chassis, beginning with number "5B105635C", differs only from series "B" in that the I.F. frequency was changed from 370 to 465 kilocycles.

Series "B" and "C" may be identified by the letter "B" and "C" at the end of the serial numbers.

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt. These voltages are clearly indicated on the circuit diagrams of series "A," "B," and "C."

All voltages are measured with 119 volts on the primary of the power transformer.

Resistance of coils and transformer windings are indicated in ohms on schematic circuit diagram.

Transformers are available and chassis are sometimes equipped with universal transformers for operation on 40 and 60 cycles and with primary taps for 108, 125, 150, 220 and 250 volts (see illustrations) and also sometimes equipped with 25 cycle transformers with 105-115 volt or 220 volt primaries, not universals.

MODEL 585
Series A,B,C
Alignment

GAMBLE-SKOGMO, INC.

ALIGNING INSTRUCTIONS—SERIES A

Description of various dummy antennas used and referred to in these instructions:

(1) I.F. Dummy—Consists of a .1 mfd. condenser connected in series with the external oscillator.

(2) Broadcast Dummy—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

(3) Intermediate and Short Wave Dummy—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

Resonance Indicator:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer, or by means of an adapter between the plate and screen terminals of the type 42 output tube. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range volt meter should be used.

SERIES A

Alignment

No aligning adjustments should be attempted without first thoroughly checking over all other possible causes of trouble, such as poor installations, open or grounded antenna systems, low line voltages, defective tubes, condensers and resistors. In order to properly align this chassis, an oscillator (generator) is absolutely necessary. No aligning adjustments should be attempted with the chassis in the cabinet. To remove the knobs, pull them off and to take the chassis out of the cabinet, remove the three bolts by which it is fastened and the speaker plug which you will find on the front flange of the chassis.

Aligning I. F. Transformers

1. With volume control full on, the extreme right of its rotation, and with wave changing switch in the broadcast position, extreme left of its rotation, and with variable condenser at its minimum capacity position, plates entirely out of mesh, adjust the I.F. transformers (adjustments at the top of parts number 108-26 and 108-27—see top view).

(a) Connect external oscillator in series with I.F. dummy antenna. With external oscillator adjusted to 370 kilocycles, in series with I.F. dummy antenna to the control grid cap of the type 6D6 tube and chassis ground, adjust output I.F. transformer, part number 108-27, to resonance.

Note: Output I.F. transformer, part number 108-27, has only one adjustment.

(b) Move generator output clip from grid of 6D6 to grid cap of type 6F7 tube and align input I.F. transformer, part number 108-26, to resonance. NOTE: IT IS EXTREMELY NECESSARY TO ALIGN BOTH I.F. STAGES SEPARATELY.

Broadcast Band Alignment—
(540 - 1720 Kilocycles)

1. With wave changing switch in the broadcast position, extreme left of its rotation, and with gang condenser in its minimum capacity position, plates entirely out of mesh, and with external oscillator connected in series with broadcast dummy antenna to tan antenna lead and black ground lead, make the following adjustments:

(a) Set external oscillator to 1720 kilocycles and adjust oscillator trimmer to resonance. This adjustment is the rear adjustment of a group of three located next to the variable condenser.

(b) Readjust external oscillator to 600 kilocycles and adjust broadcast series pad to resonance by rotating condenser to approximately 600 kilocycles, rocking it slowly to and fro until by adjusting pad maximum output is attained. This adjustment is located at the front of the chassis next to the variable condenser and wave changing switch.

(c) Check for tracking and sensitivity at 1400 and 1000 kilocycles. NOTE: It is extremely necessary in making all of the above adjustments that the fundamental signal of the oscillator be tuned in and not the image frequency, which will fall below the fundamental.

Short Wave Band Alignment—
(7.5 - 23.0 Megacycles)

1. This band is aligned after the I.F. adjustments have been completed. Set wave selector switch in the short wave position, extreme right of its rotation, set pointer of dial to 21 megacycles.

(a) With external oscillator set at 21 megacycles, and connected to the tan antenna lead in series with the short wave dummy and to the black ground lead, adjust the oscillator short wave trimmer until generator signal is picked up. This trimmer is the one closest to the front of the chassis of the group of three trimmers located next to the gang condenser (see top view of chassis).

(b) Adjust short wave antenna trimmer to resonance. This adjustment is to the right of the 6F7 tube and is the one closest to the front of the chassis (see top view).

(c) Re-set external oscillator to 9 megacycles and pick up oscillator signal by rotating variable condenser, moving dial pointer. Check for tracking and sensitivity and do not bend plates. NOTE: It is extremely necessary in making all of the above adjustments that the fundamental signal of the oscillator be tuned in and not the image frequency, which will fall below the fundamental.

Intermediate Band Alignment—
(2.3 - 7.6 Megacycles)

1. With wave selector switch in the center position and with dial pointer set to 7 megacycles, makes the following adjustments:

(a) With external oscillator set at 7 megacycles and connected in series with the short wave dummy antenna to the tan antenna lead and black ground lead, same as for short wave adjustments, adjust center trimmer of oscillator coil, part number 110-15, until 7 megacycle signal is picked up. This is the center adjustment of a group of three located next to the gang condenser (see top view).

(b) Adjust antenna trimmer to resonance, this adjustment is the rear of a group of two located at the right of the chassis next to the 6F7 tube (see top view).

(c) Re-set external oscillator to 2.5 megacycles (2500 kilocycles), pick up signal by rotating condenser and moving dial pointer. Check for tracking and sensitivity. Do not bend plates. NOTE: It is extremely necessary in making all of the above adjustments that the fundamental signal of the oscillator be tuned in and not the image frequency, which will fall below the fundamental.

Service Notes

To check for open by-pass condensers, shunt each condenser with another of similar capacity and of the same voltage rating, which is known to be good, until the defective unit is located. Open by-pass condensers frequently cause oscillation and distorted tone. Defective and shorted electrolytic filter condensers cause excessive hum, motor-boating, low volume and a reduction in all D.C. voltages. Open or shorted electrolytic and by-pass condensers (across bias resistor of type 42 tube) will cause low volume and distorted tone.

Should the planetary vernier dial drive mechanism fail to function properly, it will probably be found to be due to a cracked or broken compression spring. The drive may be disassembled to replace the compression spring (part number 112-31) by removing the two screws which fasten it to the dial bracket. Before reassembling all parts should be carefully cleaned and a small amount of vaseline applied to the ball bearings. All other dial parts are hardened and should cause no trouble.

Notes—(Series "A" Only)

25 Cycle chassis differ from regular 60 cycle and 40 cycle chassis in that a larger electrolytic filter condenser is used. The regular condenser is part number 119-11 and the larger unit for the 25 cycle chassis is part number 119-12.

Part number 106-10, a metal clad resistor, consists of the following sections with resistances and wattages as noted: one, 500 ohms; one, 35 ohms, one, 300 ohms, all 1/3 watt, plus or minus 10%.

ALIGNING INSTRUCTIONS—SERIES "B" & "C"

NOTE: These instructions are written for series "C". The instructions are identical for series "B", except that for series "B" the I.F. frequency is 370 kilocycles and for series "C", 465 kilocycles. Also, the I.F. transformers are different:

Series "B"
Part No. 108-26—Input I. F. Trans.
Part No. 108-28—Output I. F. Trans.
Series "C"
Part No. 108-38—Input I. F. Trans.
Part No. 108-40—Output I. F. Trans.

Description of various dummy antennas used and referred to in these instructions:

(1) I.F. Dummy—Consists of a .1 mfd. condenser connected in series with the external oscillator.

(2) Broadcast Dummy—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

(3) Intermediate and Short Wave Dummy—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

Resonance Indicator:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer, or by means of an adapter between the plate and screen terminals of the type 42 output tube. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range volt meter should be used.

Alignment

No aligning adjustments should be attempted without first thoroughly checking over all other possible causes of trouble, such as poor installations, open or grounded antenna systems, low line voltages, defective tubes, condensers and resistors. In order to properly align this chassis, an oscillator (generator) is absolutely necessary. No aligning adjustments should be attempted with the chassis in the cabinet. To remove the knobs, pull them off and to take the chassis out of the cabinet, remove the three bolts by which it is fastened and the speaker plug which you will find on the front flange of the chassis panel.

Aligning I. F. Transformers

1. With volume control full on, the extreme right of its rotation, and with wave changing switch in the broadcast position, extreme left of its rotation, and with variable condenser at its minimum capacity position, plates entirely out of mesh, adjust the I.F. transformers (two adjustments at the top of parts number 108-38 and 108-40—see top view).

(a) Connect external oscillator which has been adjusted to 465 kilocycles in series with I.F. dummy antenna, to the control grid cap of the type 6D6 tube and chassis ground. Adjust output I.F. transformer, part number 108-40, to resonance.

(b) Move generator output clip from grid of 6D6 to grid cap of 6F7 tube and align input I.F. transformer, part number 108-38.

(c) With generator connected to grid of type 6F7 tube, readjust output I.F. transformer, part number 108-40, to resonance.

Broadcast Band Alignment—
(530 - 1720 Kilocycles)

1. With wave changing switch in the broadcast position, extreme left of its rotation, and with gang condenser in its minimum capacity position, plates entirely out of mesh, connect an external oscillator in series with broadcast dummy antenna to tan antenna and black ground leads and make the following adjustments:

(a) With external oscillator set at 1720 kilocycles, adjust oscillator trimmer to resonance, for location of this adjustment, number 6, see diagram.

(b) Re-set external oscillator to 1400 kilocycles, rotate condenser, pick up oscillator signal and adjust antenna trimmer to resonance. For location of this adjustment, number 3, see diagram.

(c) Re-set external oscillator to 600 kilocycles and adjust series pad to resonance, rotate condenser and move dial pointer to 600 kilocycles by gently rocking condenser to and fro. Pick up oscillator signal while adjusting series pad to resonance, maximum deflection on an output meter. This adjustment is accessible from the top of the chassis and is located between variable condenser and power transformer, see top view—part number 124-16.

(d) Check for tracking and sensitivity at 1000 kilocycles.

NOTE (Series "B" and "C" Only)

25 Cycle Chassis differ only from 60 cycle chassis in that part number 104-18 transformer is used in place of 50/60 cycle transformer, part number 104-14.

Short Wave Band Alignment—
(7.6 - 19.0 Megacycles)

1. This band is aligned after the I.F. adjustments have been completed. Set wave changing switch to short wave position, extreme right of its rotation, set dial pointer to 18 megacycles.

(a) With external oscillator adjusted to 18 megacycles and connected in series with short wave dummy antenna to tan antenna and black ground leads, adjust the oscillator short wave trimmer until generator signal is picked up. For location of this adjustment, number 4, see diagram.

(b) Adjust short wave antenna trimmer to resonance. For location of this adjustment, number 1, see diagram.

(c) Re-set external oscillator to 9 megacycles, rotate condenser, move dial pointer to 9 megacycles and check for tracking and sensitivity. Do not bend plates. NOTE: It is extremely necessary in making all of the above adjustments that the fundamental signal of the oscillator be tuned in and not the image frequency, which will fall below the fundamental.

Intermediate Band Alignment—
(2.35 - 7.7 Megacycles)

1. With wave changing switch in center position, and with dial pointer set to 7 megacycles, make the following adjustments:

(a) With external oscillator set at 7 megacycles and connected in series with short wave dummy antenna, as for short wave adjustments, adjust trimmer of oscillator coil, part number 110-22 until 7 megacycle signal is picked up. For location of this adjustment, number 5, see diagram.

(b) Adjust antenna trimmer to resonance, adjustment number 2, see diagram.

(c) Re-set external oscillator to 2.5 megacycles (2500 kilocycles), rotate variable condenser, move pointer, pick up oscillator signal and check for tracking and sensitivity. NOTE: It is extremely necessary in making all of the above adjustments that the fundamental signal of the oscillator be tuned in and not the image frequency, which will fall below the fundamental.

Service Notes

To check for open by-pass condensers, shunt each condenser with another of similar capacity and of the same voltage rating, which is known to be good, until the defective unit is located. Open by-pass condensers frequently cause oscillation and distorted tone. Defective and shorted electrolytic filter condensers cause excessive hum, motor-boating, low volume and a reduction in all D.C. voltages. Open or shorted electrolytic and by-pass condensers (across bias resistor of type 42 tube) will cause low volume and distorted tone.

Should the planetary vernier dial drive mechanism fail to function properly, it will probably be found to be due to a cracked or broken compression spring. The drive may be disassembled to replace the compression spring (part number 112-31) by removing the two screws which fasten it to the dial bracket. Before re-assembling all parts should be carefully cleaned and a small amount of vaseline applied to the ball bearings. All other dial parts are hardened and should cause no trouble.

OPERATION

CONTROLS.—The three control knobs on the front of the cabinet, in sequence from left to right are (see illustration):

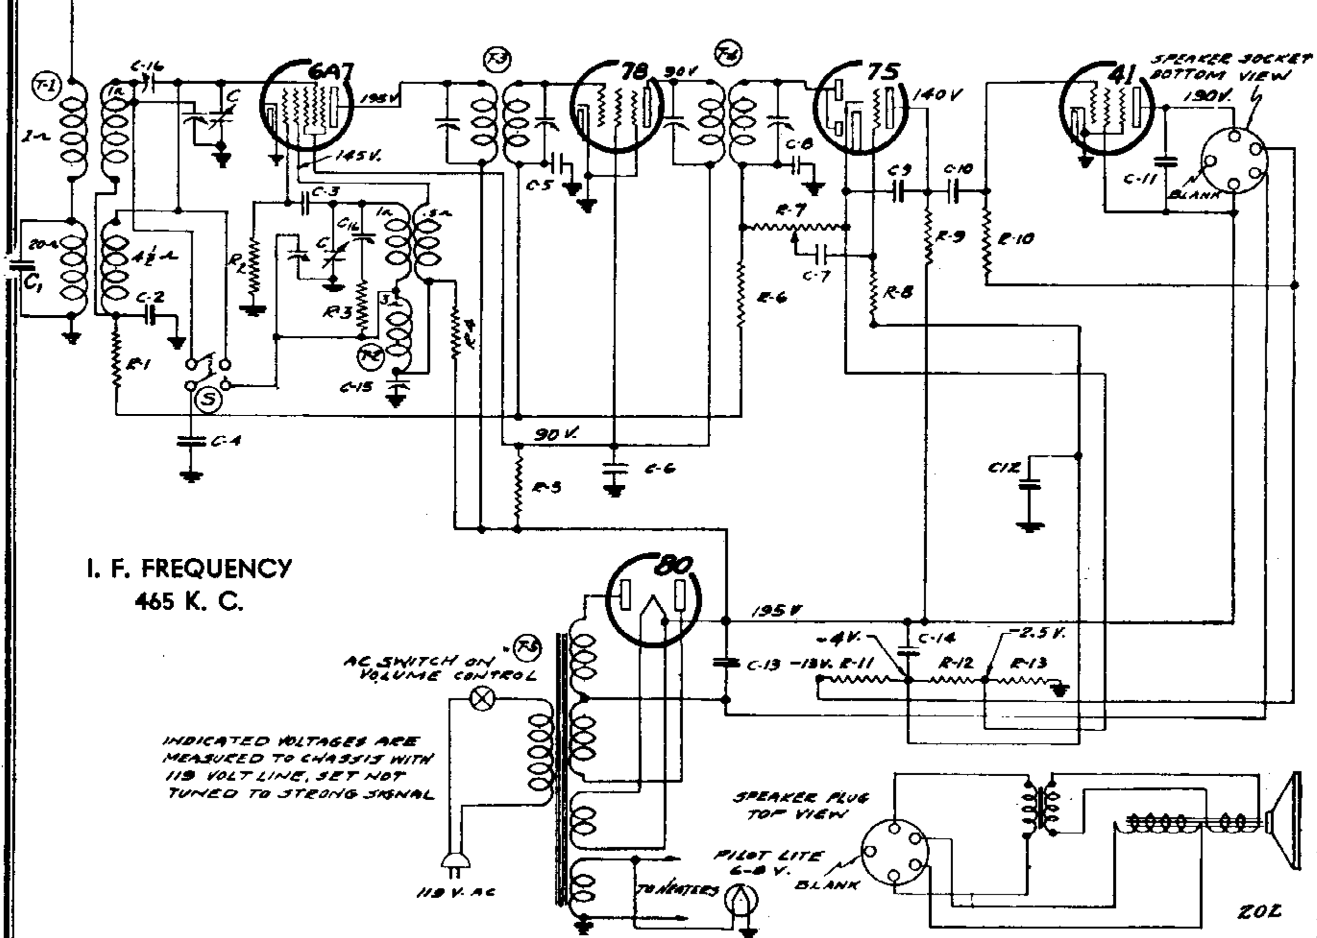
KNOB 1.—*Volume Control and "On-Off" Switch Are Combined.* When turning on, a click will be heard and the dial will light. Wait approximately 45 seconds for the tubes to heat up. Turn knob all the way to the left to turn set off.

KNOB 2.—*Tuning.* The upper end of the pointer covers the standard broadcast band scale, which is marked in kilocycles, the lower end of the pointer covers the intermediate and short wave bands. The lower scale is the short wave band, marked in megacycles, the short heavy lines on this scale are marked in meters. It is at these points that many foreign broadcasters may be heard. The inner scale, marked in megacycles, includes the 49 meter broadcasting channel, which is shown by the short heavy line, it also includes amateurs and police calls.

KNOB 3.—*Wave Changing Switch.* The knob is marked with three dots and the cabinet with a pin. When the right hand dot is in line with the pin, the switch is set in the broadcast band position, when center dot is opposite pin, the intermediate band is in position and when the left dot is opposite pin, the short wave band is connected. Switch turned all the way left—broadcast position, center intermediate, all the way right—short wave.

GAMBLE-SKOGMO, INC.

MODEL 586—SERIES A



TUNING RANGE—

Standard Broadcast Band
535-1720 Kilocycles.

Short Wave Band
2280-6600 Kilocycles

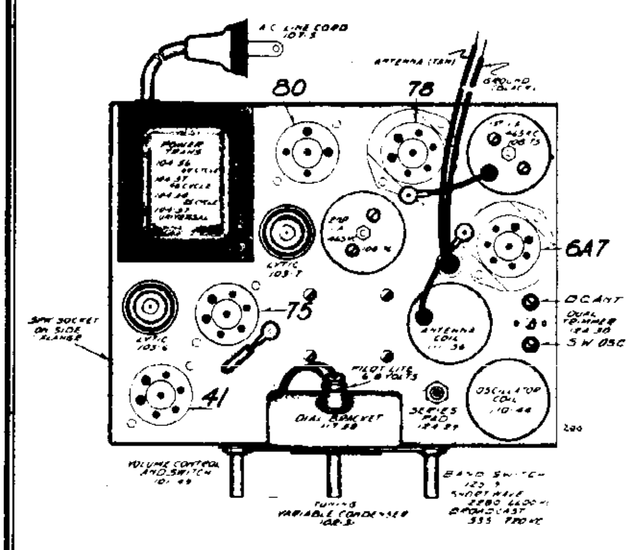


FIG. 1—TOP VIEW

TUBES:

The tube complement of this chassis consists of the following tubes.

The type and function of each tube is as follows:

1—Type 6A7 Pentagrid Mixer, First Detector-oscillator

1—Type 78 Remote Cut-Off Pentode, I. F. Amplifier (465 K.C.)

1—Type 75 Duplex Diode Triode Second Detector, A.V.C. and First Audio.

1—Type 41 Pentode Output Amplifier.

1—Type 80 High Vacuum Rectifier.

Transformers are available and chassis are sometimes equipped with universal transformers for operation on 40 and 60 cycles and with primary taps for 108, 125, 150, 220 and 250 volts (see parts list) and also sometimes equipped with 25 cycle transformers with 105-115 volt or 220 volt primaries, not universals.

131-49		Drive Belt	1	.03
134-9		Compression Spring	1	.01

All adjustments should be made with a non-metalic screw driver.

RESONANCE INDICATOR:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer, or by means of an adapter between the plate and screen terminals of the type 41 output tube. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used.

ALIGNING I.F. TRANSFORMERS: (465 K.C.):

Part No. 108-76 Output I.F. Transformer
Part No. 108-75 Input I.F. Transformer

These I.F. transformers have two adjustments, both of which are accessible from the top of chassis (see top view).

1. With volume control full on (the extreme right of its rotation), the band changing switch in the broadcast position, (extreme left of its rotation), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:

(a) Connect external oscillator set at 465 kilocycles, in series with "Dummy 1," to the control grid cap of the type 78 tube, and adjust the output I.F. transformer (No. 108-76) to resonance.

(b) With "Dummy 1" still connected, move oscillator output clip from grid of 78 to grid cap to 6A7 and adjust input I.F. transformer (No. 108-75) to resonance.

(c) With oscillator still connected to 6A7, readjust output I.F. transformer (108-76) if necessary.

DUMMY ANTENNAS:

The following dummy antennas are used in aligning and are referred to in the following alignment instructions as "Dummy 1," "Dummy 2," and "Dummy 3."

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.

Dummy 2: (Broadcast)—Consists of a 200 mmfd condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

SHORT WAVE BAND ANTENNA ADJUSTMENT:

1. With the band switch in the short wave position, and with external oscillator connected in series with "Dummy 3," to the tan antenna lead and black ground lead, make following adjustment:

(a) Set external oscillator to 6 megacycles and adjust the short-wave antenna trimmer to resonance. This adjustment is the trimmer mounted on the rear section of the variable gang condenser.

BROADCAST AND SHORT WAVE BAND ALIGNMENT

Broadcast Band: 535 to 1720 Kilocycles.
Short Wave Band:—2280 to 6600 Kilocycles.

Important:—These adjustments must be made in the following order:

SHORT WAVE OSCILLATOR ADJUSTMENT:

1. With band switch in the short wave band position, extreme right of its rotation, and with the gang condenser in its minimum capacity position, plates entirely out of mesh, and with the external oscillator connected in series with "Dummy 1" to grid cap of the 6A7 tube, make the following adjustment:

(a) Set external oscillator to 6.6 megacycles and adjust short wave oscillator trimmer to resonance. This adjustment is marked "S.W. Osc." (see top view of chassis, Fig. 1, for location of this adjustment).

NOTE: Make certain that the fundamental 6.6 megacycles signal has been tuned in and not the image frequency, noting that the image appears when the tuning knob is moved to approximately 5.7 megacycles.

BROADCAST BAND OSCILLATOR ADJUSTMENT:

1. With band switch in the broadcast position, extreme left of its rotation, and with the gang condenser in its minimum capacity position, plates entirely out of mesh, and with external oscillator connected in series with "Dummy 1" to grid cap of the 6A7 tube, make the following adjustment:

(a) Set external oscillator to 1720 K.C. and adjust broadcast oscillator trimmer to resonance. This adjustment is the trimmer mounted on the front section of the variable gang condenser.

BROADCAST BAND ANTENNA ADJUSTMENT:

1. With the band switch still in the broadcast position, move the external oscillator from the grid cap of the 6A7 tube to the tan antenna lead and black ground lead, in series with "Dummy 2" and make the following adjustments:

(a) Set external oscillator to 1550 K.C., rotate variable gang condenser and pick up signal. Adjust broadcast antenna trimmer to resonance. This adjustment is marked "B.C. Ant." (See top view of chassis, Fig. 1, for location of this adjustment.)

(b) Re-set external oscillator to 600 K.C. and adjust broadcast series pad to resonance by rotating condenser to approximately 600 K.C., rocking it slowly to and fro until, by adjusting series pad, maximum output is attained. This adjustment is located on the top of the chassis directly in front of the antenna coil. (See top view of chassis, Fig. 1).

(c) Repeat adjustments "a" and "b" until sensitivity is at its maximum.

SERVICE NOTES

Voltages taken from different points of the circuit are measured with a voltmeter having a resistance of 1000 ohms per volt and are made between the points indicated and the chassis pan. These voltages are indicated on the circuit diagram.

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

Excessive hum, stuttering, low volume and a reduction in all D.C. voltages is usually caused by a shorted electrolytic condenser, open by-pass condensers frequently cause oscillation and distorted tone.

ALIGNMENT:

No aligning adjustments should be made until the set has been thoroughly checked for all other possible causes of trouble, such as poor installations, low line voltages, defective tubes, condensers and resistors.

ALIGNING I.F. TRANSFORMERS:

1. With volume control full on, at the extreme right of its rotation, and with wave selector switch in the broadcast position, extreme left of its rotation, and with variable condenser at its minimum capacity position, extreme left of its rotation, plates entirely out of mesh, adjust the I.F. transformers (parts number 108-15 and 108-16) in the following manner:
   (a) Connect an external oscillator which has been adjusted to 370 kilocycles, in series with a .1 mfd. condenser to the control grid cap of the type 57 first detector tube (see diagram and chassis).
   (b) Adjust trimming condensers of both I.F. transformers (Parts number 108-15 and 108-16) to resonance. Use as a resonance indicator an output meter connected across the primary of the speaker input transformer or by means of an adapter between plate and screen terminals of type 2A5 output tube. Maximum deflection of the meter indicates resonance. Care should be taken to use only enough signal to give a readily readable output.

   Note: The two adjustments on each transformer are accessible through holes in the transformer cans from the back of the chassis.

BROADCAST BAND ALIGNMENT:

1. Shift frequency of external oscillator to 535 kilocycles and connect in series with a 200 mmfd. condenser to the tan antenna wire and the black ground wire.
   (a) Set the variable condenser in its maximum capacity position, extreme right of its rotation.
   (b) Adjust the broadcast oscillator series trimmer to resonance with oscillator. This trimmer is located between the gang condenser and the power transformer (see top view).
2. Shift frequency of external oscillator to 1712 kilocycles and set variable condenser in its minimum capacity position, extreme left of its rotation, plates entirely out of mesh.
   (a) Adjust the broadcast oscillator shunt trimmer to resonance. This adjustment is the top adjustment in the oscillator coil can, part number 110-8.

SHORT WAVE BAND ALIGNMENT:

1. Set the wave changing switch in the short wave position, extreme right of its rotation, and change external oscillator frequency to 15 megacycles.
   (a) Adjust variable condenser with selector knob so that pointer is opposite the 15 megacycle calibration on the dial.
   (b) Adjust the short wave oscillator shunt trimmer to resonance with the signal (use extreme care and make certain that you do not adjust to resonance with the image instead of the signal). This trimmer is the bottom trimmer (closest to the chassis) on the oscillator coil, part number 110-8, and is accessible from the side of the chassis.
   (c) Adjust the short wave antenna trimmer to resonance (single trimmer in antenna can, part number 111-11, accessible from the side of the chassis, between type 27 and 57 tubes).

NOTES:

Should the planetary vernier dial drive mechanism fail to function properly, it will probably be found to be due to a cracked or broken compression spring. This drive may be dis-assembled by removing the two screws which fasten it to the dial bracket. The part number of the compression spring is 112-31. All of the other dial parts are hardened and should cause no trouble.

MODEL 670A
AUTO RECEIVER

MODEL 670-A
Alignment
Installation Data

GAMBLE-SKOGMO, INC.

BALANCING SET TO ANTENNA:

When this set has been installed and is ready for operation it may be found necessary (depending on antenna) to balance set to this antenna. This is accomplished as follows:

With the receiver tuned to a very weak station, about 130 to 140 (1300 to 1400 kilocycles) on the dial, adjust the antenna trimmer with a screw driver until maximum volume is attained. To reach the antenna trimmer remove the plug button from the top of the case.

I. F. ALIGNMENT:

1. With variable condenser at its maximum capacity position and with volume control full on, connect in series with a .1 mfd. condenser, an oscillator set at 175 kilocycles to the grid cap of the 6C6 tube.

2. Adjust trimming condensers of both input and output I. F. transformers, parts number 108-20 and 108-21 (see top view of chassis) to resonance with an oscillator, as indicated on an output meter connected across the primary terminals of the speaker input transformer or between the plate and screen terminals of the type 42 output tube. The connection to the tube can be made by means of an adapter. Maximum deflection on the output meter indicates resonance.

Note: Each I. F. transformer has two adjustments, both of these adjustments on both transformers are accessible through holes located in the back of the case between the two mounting plates and directly under the louvres.

R. F. ALIGNMENT:

1. Attach oscillator connected in series with a 200 mmfd. condenser to the antenna lead and with the variable condenser at its minimum capacity position (extreme right of its rotation) and with an oscillator set at 1550 kilocycles, adjust condenser trimmer of oscillator section (Front shaft end) to resonance.

2. Re-set oscillator to 1400 kilocycles, rotate variable condenser to pick up signal, adjust antenna (center section) and R. F. (rear section) trimmers to resonance.

3. Check alignment at 1500-1000-800-600-530 kilocycles by setting oscillator to these frequencies and picking up signal by rotating condenser.

4. Bend slotted plates of antenna and R. F. sections only if necessary. UNDER NO CIRCUMSTANCES BEND PLATES OF OSCILLATOR SECTION.

NOTES:

Voltages from chassis to different points are indicated on schematic circuit diagram, and should be measured with a voltmeter having a resistance of 1000 ohms per volt.

Failure to operate, noisy or weak reception, may be due to defective tubes or poor contact between cap on top of tube and grid clip.

Tubes may be checked by replacing with another tube which is known to be good.

If fuse blows out frequently, and insulating sleeve has been properly placed over fuse, the trouble probably is in the vibrator and vibrator should be replaced.

NEVER ATTEMPT TO ADJUST VIBRATOR POINTS.

Case rattles may be due to one or more of the following:

Loose screws in top or bottom covers. Loose elements in tubes. Loose tube shield. Loose R. F. coil shield. Loose grill cloth.

RECEIVER INSTALLATION:

Determine most satisfactory or desirable mounting position. In most cases it will be found that the receiver can be mounted on the car bulk head, above and to the right of the steering post.

Use the cardboard template which is the same size as set and mark location for two mounting bolts, if mounted on the long side and one bolt if on the short side.

Then drill two (2) one-half inch (½") holes, making certain that the paint around the hole on the engine side of fire wall or bulk head is scraped clean to insure a good ground connection between receiver and the frame of the car. Assemble brackets number 146-2 to case with self-tapping screws.

Insert bolts through dash, assemble plain, lockwashers and nuts on engine side, then hang receiver over bolt heads and tighten nuts securely.

Mount the remote control unit on steering column by means of mounting bracket or attach to instrument panel or under dash (see illustration).

Two flexible shafts are furnished, one with a slotted fitting on one end, which is the volume control shaft (number 149-18), the other is the selector shaft, with key fitting at one end (number 150-18).

Make certain that the outer casings of flexible shafts go into remote control bushings for approximately five-sixteenths of an inch and tighten set screws to secure cables. If cables are pushed too far into remote control head, shafts will not turn freely. Always try to install drive shafts in as straight a line as possible from remote control to set. AVOID SHARP BENDS IN CABLES.

IMPORTANT—READ CAREFULLY:

We are prepared to exchange, without charge, our standard number 149-18 and 150-18, eighteen inch cables for twenty-four inch cables, number 149-24 and 150-24. You will find that 99% of the installations can be made with the standard eighteen inch cables, and bear in mind that the shorter the cable, the smoother the drive.

DIAL ADJUSTMENT:

Mount control head to steering column by means of bracket and strap or under dash by means of bracket or to instrument panel (see illustrations). Attach cables as above. Tune set to some station of a known frequency (between 800 and 1200 K.C.), hold selector knob, then with a screw driver adjust the slotted screw on back of the control head, and in that way adjust the dial pointer to the correct frequency setting.

CONNECTIONS TO BATTERY:

The battery cable, number 152-2, (red wire with fuse receptacle at one end and terminal lug at other end) must be connected to battery terminal of ammeter. At the same time connect ammeter capacitor, number 148-3, to battery terminal of ammeter, other end of condenser to any convenient grounded screw on back of instrument panel. Make certain that insulating sleeve is slipped over fuse when fuse is placed in receptacle, before inserting in receiver (see illustration). All bypass leads should be as short as possible.

When connected properly, the discharge due to current drawn by the receiver should not indicate on the ammeter. This is important, since if improperly connected, as shown by the deflection of ammeter, additional motor interference may be encountered.

PILOT LIGHT:

Pilot light assembly, part number 116-6, a shielded cable, plugs into the set and to the rear of the remote control unit (see illustrations).

TONE CONTROL:

The tone control assembly, part number 101-12, attaches to the back of the remote control head by means of a special screw and plugs into the set (see illustrations).

ANTENNA CONNECTION:

The antenna is connected to the receiver by means of the antenna cable, number 152-1. The antenna wire is the single black wire projecting from the end of the cable. Splice this wire to the roof antenna lead and ground the pig-tail shielding as close to the corner post of the car as possible.

OPERATION:

Place key (knob) in lock of left hand control of the remote control unit. After waiting approximately 45 seconds for tubes to heat up, rotate station selector, right hand knob, until a desirable program is heard. De-tuning will very seriously affect the tone quality of this receiver. Tone control knob located between two black knobs (see illustrations) is a BASS and TREBLE switch, it is not a variable tone control. Turning it to the right makes the BASS connection, turning it to the left makes the TREBLE connection. You will note that the BASS position assists materially in reducing interference from static, street car lines and other high pitched disturbances.

MOTOR NOISE SUPPRESSION:

The ignition system of every automobile generates high frequency electrical interference. This high frequency interference arising from the ignition coil, the distributor and the spark plugs must be properly suppressed in order to obtain satisfactory reception. Each car will present more or less an individual problem but there is a definite procedure to follow which holds true in every case.

This first essential procedure is to disconnect the high tension leads to the spark plugs and attach the spark plug suppressors (168-1) (for V 8 Fords 168-4) the special distributor type suppressor (168-2) which is inserted in the center contact of the distributor as indicated in the illustration of a typical installation. (NOTE V 8 FORD USES NO DISTRIBUTOR SUPPRESSOR.) For cap type distributor, exchange the standard plug type distributor suppressor (168-2) for a special cable type suppressor (168-3) from your dealer. In some few cases, such as Buicks it is sometimes necessary to use cable type (168-3) suppressors. This type of suppressor is inserted in the leads running from the distributor to the spark plugs and which are concealed underneath the metal plate which covers the spark plugs.

After the spark and distributor suppressors have been properly fastened the next in importance is the generator condenser (148-1), this filters a high pitched whining noise which would otherwise be heard as the motor is accelerated.

It is sometimes necessary in cars where the ignition coil is located under the dash, to use an additional capacitor (148-1) obtainable from your dealer. It must be installed between the battery side of the ignition coil and the frame of the car. Next connect capacitor (148-3) from the battery side of ammeter to frame of car. This is necessary in practically every installation and a good connection to the frame of the car is of utmost importance.

Voltages taken from points indicated to chassis ground. Vol. control on full, no signal.

Serial No. 60001 and up.

DUMMY ANTENNAS:

The dummy antennas referred to in the following instructions are:

"I.F. Dummy" —A .1 mfd. condenser connected in series with the test oscillator output lead.

"Broadcast Dummy"—A 200 mmfd. condenser connected in series with the output lead of the test oscillator.

RESONANCE INDICATOR:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer, or by means of an adapter between the plate and the screen of the type 42 output tube. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used.

I.F. ALIGNMENT:

1. With variable condenser in its minimum capacity position (plates entirely out of mesh) and with volume control full on, connect test oscillator set at 175 K.C., in series with I.F. dummy antenna, to the grid cap of the type 6A7 tube.
2. Adjust trimmer condensers of both input (108-33) and output (108-34) I.F. transformers to resonance with oscillator. See top view for location of these transformers. There are two adjustments on each and they are accessible from the top of the transformer shield and should be adjusted with an insulated screw driver.

BROADCAST ALIGNMENT:

1. With variable condenser in its minimum capacity position, connect test oscillator set at 1550 K.C. and in series with broadcast dummy, to the antenna lead of receiver.
2. Adjust oscillator trimmer of variable condenser to resonance (this adjustment is on the end section of the three gang condenser—see top view).
3. Shift test oscillator to 1400 K.C. and pick up signal by rotating condenser and adjust R.F. (center) and antenna (front) trimmers to resonance, see top view.

TUBE COMPLEMENT

The tube complement of the model 686 and model 786 consists of the latest "Metal-Glass" tubes which are interchangeable with metal tubes. They are as follows:

1-Type 6L7 Pentagrid Mixer, First Detector.
1-Type 6C5 Oscillator.
1-Type 6K7 Remote Cut-off Pentode, I.F. Amplifier (465 K.C.).
1-Type 6Q7 Duplex Diode Triode Second Detector, A.V.C. and First Audio.
1-Type 6F6 Pentode Output Amplifier.
1-Type 5Y3 or 5W4 High Vacuum Rectifier. (Note: 5Y3 available in "Metal-Glass" only.)
1-Type 6G5 Cathode-Ray Tuning Indicator. (Note: 6G5 available in all glass only, and only with model 786.)

The tube complement of the model 685 is as follows:

1-Type 6L7 Pentagrid Mixer, First Detector.
1-Type 6C5 Oscillator.
1-Type 6K7G Remote Cut-off Pentode, I.F. Amplifier (465 K.C.).
1-Type 6Q7G Duplex Diode Triode Second Detector, A.V.C. and First Audio.
1-Type 6F6G Pentode Output Amplifier.
1-Type 5Y3 High Vacuum Rectifier.

ALIGNING INSTRUCTIONS:

CAUTION:—No aligning adjustments should be attempted without first thoroughly checking over all other possible causes of trouble, such as poor installations, open or grounded antenna systems, low line voltages, defective tubes, condensers and resistors. In order to properly align this chassis, an oscillator (generator) is absolutely necessary. No aligning adjustments should be attempted with the chassis in the cabinet. Remove the knobs and the four bolts which are used to fasten the chassis.

All adjustments should be made with a non-metallic screw driver.

DUMMY ANTENNAS:

The following dummy antennas are used in aligning and are referred to in the following alignment instructions as "Dummy 1," "Dummy 2," and "Dummy 3."

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.

Dummy 2: (Broadcast)—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Middle and Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

RESONANCE INDICATOR:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer, or by means of an adapter between the plate and screen terminals of the type 6F6 output tube. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used.

ALIGNING I.F. TRANSFORMERS; (465 K.C.):

Part No. 108-73 Output I.F. Transformer.
Part No. 108-74 Input I.F. Transformer.

These I.F. transformers have two adjustments, both of which are accessible from the top of chassis (see top view).

1. With volume control full on (the extreme right of its rotation), the band changing switch in the broadcast position, (extreme left of its rotation), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:
   (a) Connect external oscillator set at 465 kilocycles, in series with "Dummy 1," to the control grid cap of the type 6K7 tube, and adjust the output I.F. transformer (No. 108-73) to resonance.
   (b) With "Dummy 1" still connected, move oscillator output clip from grid of 6K7 to grid cap to 6L7 and adjust input I.F. transformer (No. 108-74) to resonance.
   (c) With oscillator still connected to 6L7, readjust output I.F. transformer (108-73) if necessary.

ALIGNMENT PROCEDURE

The following adjustments to be made after the I.F.'s have been aligned as explained above.

BROADCAST BAND ALIGNMENT:

535 to 1720 Kilocycles

1. With band changing switch in the broadcast position, extreme left of its rotation, and with gang condenser in its minimum capacity position, plates entirely out of mesh, and with external oscillator connected in series with "Dummy 2" to tan antenna lead and black ground lead, make following adjustments:
   (a) Set external oscillator to 1720 K.C. and adjust broadcast oscillator trimmer to resonance (adjustment number 1; see bottom view of coil assembly. Fig. 3.)
   (b) Re-set external oscillator to 1550 K.C., rotate variable gang condenser and pick up signal. Adjust broadcast antenna trimmer (Adjustment number 4) to resonance; also adjust preselector trimmer which is mounted on the top of the rear section of the three gang variable tuning condenser to resonance. (See top view of chassis, Fig. 1, for location of this adjustment.)
   (c) Re-set external oscillator to 600 K.C., and adjust broadcast series pad to resonance by rotating condenser to approximately 600 K.C., rocking it slowly to and fro until by adjusting series pad maximum output is attained. This adjustment is located on the bottom of the chassis directly under the variable gang condenser. (See bottom view of chassis, Fig. 3.)
   (d) Repeat adjustments "a" and "b" until sensitivity is at its maximum.
   (e) Check for tracking and sensitivity at 1000 kilocycles. Under no circumstances bend plates of variable condenser sections to correct tracking.

SHORT WAVE BAND ALIGNMENT:

5.2 to 18.3 Megacycles

1. With band changing switch in the short wave position, extreme right of its rotation, and with external oscillator set at 17 megacycles and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:
   (a) Move dial pointer to 17 megacycles and adjust short wave oscillator (Adjustment number 3) and short wave antenna (Adjustment number 6) to resonance.
   (b) Re-set external oscillator to 6 megacycles and pick up signal by rotating variable condenser and check sensitivity.
   (c) Re-set external oscillator and check set at 18.1 megacycles and 5.3 megacycles for band coverage.

NOTE: It is extremely necessary in making all of these adjustments that the fundamental oscillator signal be tuned in and not the image frequency which will fall below the fundamental. An example of this is an image of a fundamental 18.3 megacycle signal appears near 17.4 megacycles.

MIDDLE WAVE BAND ALIGNMENT:

1695 to 5500 Kilocycles

1. With band changing switch in the middle wave position, center of its rotation, and with external oscillator set at 5000 kilocycles and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:
   (a) Move dial pointer to 5000 kilocycles and adjust middle wave oscillator (Adjustment number 2) and middle wave antenna (Adjustment number 5) to resonance.
   (b) Re-set external oscillator to 1800 kilocycles and pick up signal by rotating variable condenser and check sensitivity.
   (c) Re-set external oscillator and check set at 5400 kilocycles and 1700 kilocycles for band coverage.

LIST OF REPAIR PARTS

GAMBLE-SKOGMO, INC.

SERVICE MANUAL SEVEN TUBE SUPERHETERODYNE WITH A.V.C. AND SHORT WAVE

105-115 Volts Alternating Current, 50-60 Cycles, 80 Watts. 530-1720 Kilocycles - 1700-4500 Kilocycles.

SERVICE NOTES

Should it be at any time necessary to rebalance this set, the correct procedure is as follows:

1. Volume and tone controls on full during all alignment.
2. Squelch switch in "no squelch" position (counter-clockwise (left) rotation) during all alignment.
3. Adjust variable squelch control on rear flange of chassis to maximum counter-clockwise (left) position.
4. Set variable condenser in minimum capacity position (plates open) at the start of all aligning.

I.F. ALIGNMENT

The intermediate frequency of model 750 is 175 kilocycles, and is aligned as follows:

1. Connect oscillator (set at 175 kilocycles) to I.F. grid (second 58 tube) and adjust both trimmers of second I.F. transformer (underneath chassis) to resonance (maximum deflection on an output meter connected across the primary of the speaker input transformer).
2. Connect oscillator output to converter grid (2A7 tube) and adjust both trimmers of first I.F. transformer to resonance. Under no conditions touch the trimmers of the second I.F. transformer after adjusting them (see No. 1).

The four trimmers of the two I.F. transformers are all adjusted from the bottom of the chassis (one nut and one screw adjustment on each I.F. transformer trimmer).

BROADCAST BAND ALIGNMENT

Wave changing switch in clockwise (right) position.

1. Connect an oscillator in series with a 200 mmfd. condenser to the Tan (antenna) lead and Black (ground) lead. With the oscillator set at 1720 kilocycles and the variable condenser at its minimum position (extreme right of its rotation), adjust trimmer of oscillator (rear) section to resonance.
2. Change oscillator to 1400 kilocycles, rotate variable to this frequency and adjust R.F. and antenna trimmers (center and front trimmers respectively) to resonance. Do not touch the oscillator trimmer.
3. Check tracking at the following points only: 1200-1000-800-600-534 kilocycles. NOTE: This receiver will be slightly out of track at 534 kilocycles - do not bend plates in an attempt to track it at this frequency. Rotor plates of condensers should not be bent, except if absolutely necessary, and then only on the center and front sections.

SHORT WAVE BAND ALIGNMENT

Wave changing switch in counter-clockwise (left) position.

1. The frequency range of this short wave band is approximately 1700 to 4500 kilocycles.
2. Peak short wave antenna coil to resonance with oscillator set at 1720 kilocycles by slipping primary.
3. Check for sensitivity at the following frequencies only: 1720 and 3700 kilocycles - under no conditions touch trimmers or plates of variable condenser while checking short wave band.

NOTES:

For failure to operate over both bands, check 2A7 tube and connections to and contacts of wave changing switch.

Condenser shaft to which pointer is attached is rotated by means of a celluloid dial attached to the condenser shaft and a bronze friction drive assembly, to which is attached the selector knob. Should this drive ever slip or become rough, it can be adjusted for smooth operation by sliding the bronze washer drive assembly either closer to the variable shaft or farther away from it in the slot in which it is mounted, to insure smooth operation.

Parts List

GAMBLE-SKOGMO, INC.

MODEL 770 - Series A

7-Tube All Wave Superheterodyne with Avc.

SERVICE NOTES

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt. These voltages are clearly indicated on the circuit diagrams of series A and B.

IN ORDER TO PREVENT SIGNAL FROM ACTING UPON AVC AND AFFECTING ACCURACY OF VOLTAGE MEASUREMENTS, AERIAL AND GROUND LEADS SHOULD BE SHORT CIRCUITED WHILE MAKING MEASUREMENTS.

All voltages are to be measured with 119 volts on the primary of the power transformer.

Resistances of coils and transformer windings are indicated in ohms on schematic circuit diagrams.

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

Excessive hum, stuttering, low volume and a reduction in all D.C. voltages is usually caused by a shorted electrolytic condenser, open by-pass condensers frequently cause oscillation and distorted tone.

ALIGNING INSTRUCTIONS

Dummy Antennas

The following dummy antennas are used in aligning and are referred to in the following alignment instructions as "Dummy 1", "Dummy 2", and "Dummy 3".

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.

Dummy 2: (Broadcast)—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Intermediate and Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

Resonance Indicator:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer, or by means of an adapter between the plate and screen terminals of the type 42 output tube. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used.

CAUTION:

No aligning adjustments should be attempted without first thoroughly checking over all other possible causes of trouble, such as poor installations, open or grounded antenna systems, low line voltages, defective tubes, condensers and resistors. In order properly to align this chassis, an oscillator (generator) is absolutely necessary. No aligning adjustments should be attempted with the chassis in the cabinet. To remove the knobs, pull them off and to take the chassis out of the cabinet, remove the four bolts by which it is fastened.

ALIGNING I.F. TRANSFORMERS (465 K.C.)

Part No. 108-54 Output I.F. Transformer
Part No. 108-56 Input I.F. Transformer

These I.F. transformers have two adjustments, both of which are accessible from the underside of chassis (see bottom view).

1. With volume control full on, (the extreme right of its rotation), the wave changing switch in the broadcast position, (extreme left of its rotation), the tone control on "Hi" part of the sharp position (as much right rotation as possible without operating the Hi Fidelity switch), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:
   (a) Connect external oscillator set at 465 kilocycles, in series with "Dummy 1", to the control grid cap of the type 6K7 tube, located between the two I.F. transformers, and adjust the output I.F. transformer to resonance.
   (b) With "Dummy 1" still connected, move oscillator output clip from grid of 6K7 to grid cap to 6C6 and adjust input I.F. transformer to resonance.
   (c) With oscillator still connected to 6C6, re-adjust output I.F. transformer.

ALIGNMENT PROCEDURE

The following adjustments to be made after the I.F.'s have been aligned as explained above.

BROADCAST BAND ALIGNMENT:

1. With wave changing switch in the broadcast position, extreme left of its rotation, and with external oscillator set at 600 kilocycles and connected in series with "Dummy 2" to the tan antenna and black ground lead, make the following adjustments:
   (a) Adjust broadcast series pad to resonance with oscillator. Keep set in tune with oscillator by slowly rocking to and fro the variable condenser until maximum output is obtained. Note: This adjustment is accessible from the top of the chassis and is located between the variable condenser and the electrolytic condenser. See top view.
   (b) Re-set external oscillator to 1400 K.C.; move dial pointer to 1400 K.C. and adjust oscillator (adjustment number 3), R.F. (adjustment number 2) and antenna (adjustment number 1) to resonance. See bottom view for location of these adjustments.
   (c) Repeat adjustments "a" and "b" until sensitivity is at its maximum.

NOTE: IT IS EXTREMELY NECESSARY IN MAKING ALL OF THESE ADJUSTMENTS THAT THE FUNDAMENTAL OSCILLATOR SIGNAL BE TUNED IN AND NOT THE IMAGE FREQUENCY WHICH WILL FALL BELOW THE FUNDAMENTAL.

SHORT WAVE BAND ALIGNMENT:

1. With wave changing switch in the short wave position, extreme right of its rotation, and with external oscillator set at 17 megacycles and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:
   (a) Move dial pointer to 17 megacycles and adjust short wave oscillator (adjustment number 8), short wave R.F. (adjustment number 7) and short wave antenna (adjustment number 6) to resonance.
   (b) Re-set external oscillator to 6 megacycles and pick up signal by rotating variable condenser and check for sensitivity.

INTERMEDIATE BAND ALIGNMENT:

1. With wave changing switch in the intermediate wave position, center of its rotation, and with external oscillator set at 1800 K.C. and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:
   (a) Rotate variable condenser to approximately 1800 K.C., tune in oscillator signal and adjust M.W. series pad (see top view) to resonance. Slowly rock condenser to and fro while making this adjustment to be sure maximum output is obtained.
   (b) Set external oscillator at 5 M.C., rotate condenser, pick up signal and adjust intermediate wave R.F. (adjustment number 5), intermediate wave antenna (adjustment number 4) and intermediate wave oscillator (adjustment number 9) to resonance.
   (c) Re-check broadcast alignment and if it is found necessary to re-adjust either R.F. or antenna trimmers, repeat the 17 M.C. short wave and 5 M.C. intermediate wave adjustments.

MODELS 777C, 777L
Series A & B
Alignment

GAMBLE-SKOGMO, INC.

NOTE: IN SERIES B THE TYPE 75 WAS REPLACED BY TYPE 6B7, DUPLEX DIODE PENTODE AS A SECOND DETECTOR, A.V.C. AND AUDIO.

Series A and B chassis are serially numbered on the back flange of the chassis, series A beginning with number "5B104021A" and up, series B chassis beginning with number "5D114175B" and up. Series A and B may be identified by the letter "A" and "B" at the end of the serial numbers.

Transformers are available and chassis are sometimes equipped with universal transformers for operation on 40 and 60 cycles and with primary taps for 105, 125, 150, 220 and 250 volts (see instructions) and also sometimes equipped with 25 cycle transformers with 105-115 volt or 220 volt primaries, not universals.

SERVICE NOTES

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt. These voltages are clearly indicated on the circuit diagrams of series A and B.

IN ORDER TO PREVENT SIGNAL FROM ACTING UPON AVC AND AFFECTING ACCURACY OF VOLTAGE MEASUREMENTS, AERIAL AND GROUND LEADS SHOULD BE SHORT CIRCUITED WHILE MAKING MEASUREMENTS.

All voltages are to be measured with 119 volts on the primary of the power transformer.

ALIGNING INSTRUCTIONS

Dummy Antennas

The following dummy antennas are used in aligning both series A and B and are referred to in the following alignment instructions as "Dummy 1", "Dummy 2", and "Dummy 3".

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.

Dummy 2: (Broadcast)—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Intermediate and Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

Resonance Indicator:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer, or by means of an adapter between the plate and screen terminals of the type 42 output tube. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used.

ALIGNMENT PROCEDURE SERIES A ONLY

The following adjustments to be made after the I.F.'s have been aligned as explained above.

BROADCAST BAND ALIGNMENT:

1. With wave changing switch in the broadcast position, extreme left of its rotation, and with external oscillator set at 550 kilocycles and connected in series with "Dummy 2" to the tan antenna and black ground lead, make the following adjustments:
   (a) Adjust broadcast series pad to resonance with oscillator. Keep set in tune with oscillator by slowly rocking to and fro the variable condenser until maximum output is obtained. Note: This adjustment is accessible from the top of the chassis and is located between the variable condenser and the electrolytic condenser. See top view.
   (b) Re-set external oscillator to 1500 K.C., move dial pointer to 1500 K.C. and adjust oscillator (adjustment number 3), R.F. (adjustment number 2) and antenna (adjustment number 1) to resonance. See bottom view for location of these adjustments.
   (c) Repeat adjustments "a" and "b" until sensitivity is at its maximum.

NOTE: IT IS EXTREMELY NECESSARY IN MAKING ALL OF THESE ADJUSTMENTS THAT THE FUNDAMENTAL OSCILLATOR SIGNAL BE TUNED IN AND NOT THE IMAGE FREQUENCY WHICH WILL FALL BELOW THE FUNDAMENTAL.

SHORT WAVE BAND ALIGNMENT:

1. With wave changing switch in the short wave position, extreme right of its rotation, and with external oscillator set at 17 megacycles and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:
   (a) Move dial pointer to 17 megacycles and adjust short wave oscillator (adjustment number 8), short wave R.F. (adjustment number 7) and short wave antenna (adjustment number 6) to resonance.
   (b) Re-set external oscillator to 6 megacycles and pick up signal by rotating variable condenser and check for sensitivity.

INTERMEDIATE BAND ALIGNMENT:

1. With wave changing switch in the intermediate position center of its rotation, and with external oscillator set at 5 megacycles and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:
   (a) Move dial pointer to 5 megacycles and adjust intermediate wave oscillator (adjustment number 9), intermediate wave R.F. (adjustment number 5) and intermediate antenna (adjustment number 4) to resonance.
   (b) Re-set external oscillator to 1800 K.C. and pick up signal by rotating variable condenser and check for sensitivity.
   (c) Re-check broadcast sensitivity as outlined under "Broadcast Band Alignment".

Series "A" chassis have no intermediate band series oscillator pad adjustment.

ALIGNMENT PROCEDURE SERIES B ONLY

The following adjustments to be made after the I.F.'s have been aligned as explained above.

BROADCAST BAND ALIGNMENT:

1. With wave changing switch in the broadcast position, extreme left of its rotation, and with external oscillator set at 600 kilocycles and connected in series with "Dummy 2" to the tan antenna and black ground lead, make the following adjustments:
   (a) Adjust broadcast series pad to resonance with oscillator. Keep set in tune with oscillator by slowly rocking to and fro the variable condenser until maximum output is obtained. Note: This adjustment is accessible from the top of the chassis and is located between the variable condenser and the electrolytic condenser. See top view.
   (b) Re-set external oscillator to 1400 K.C., move dial pointer to 1400 K.C. and adjust oscillator (adjustment number 3), R.F. (adjustment number 2) and antenna (adjustment number 1) to resonance. See bottom view for location of these adjustments.
   (c) Repeat adjustments "a" and "b" until sensitivity is at its maximum.

NOTE: IT IS EXTREMELY NECESSARY IN MAKING ALL OF THESE ADJUSTMENTS THAT THE FUNDAMENTAL OSCILLATOR SIGNAL BE TUNED IN AND NOT THE IMAGE FREQUENCY WHICH WILL FALL BELOW THE FUNDAMENTAL.

SHORT WAVE BAND ALIGNMENT:

1. With wave changing switch in the short wave position, extreme right of its rotation, and with external oscillator set at 17 megacycles and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:
   (a) Move dial pointer to 17 megacycles and adjust short wave oscillator (adjustment number 8), short wave R.F. (adjustment number 7) and short wave antenna (adjustment number 6) to resonance.
   (b) Re-set external oscillator to 6 megacycles and pick up signal by rotating variable condenser and check for sensitivity.

INTERMEDIATE BAND ALIGNMENT:

1. With wave changing switch in the intermediate wave position, center of its rotation, and with external oscillator set at 1800 K.C. and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:
   (a) Rotate variable condenser to approximately 1800 K.C., tune in oscillator signal and adjust M.W. series pad (see top view) to resonance. Slowly rock condenser to and fro while making this adjustment to be sure maximum output is obtained.
   (b) Set external oscillator at 5 M.C., rotate condenser, pick up signal and adjust intermediate wave R.F. (adjustment number 5), intermediate wave antenna (adjustment number 4) and intermediate wave oscillator (adjustment number 9) to resonance.
   (c) Re-check broadcast alignment and if it is found necessary to re-adjust either R.F. or antenna trimmers, repeat the 17 M.C. short wave and 5 M.C. intermediate wave adjustments.

ALIGNING I.F. TRANSFORMERS (465 K.C.)

Series A and B.

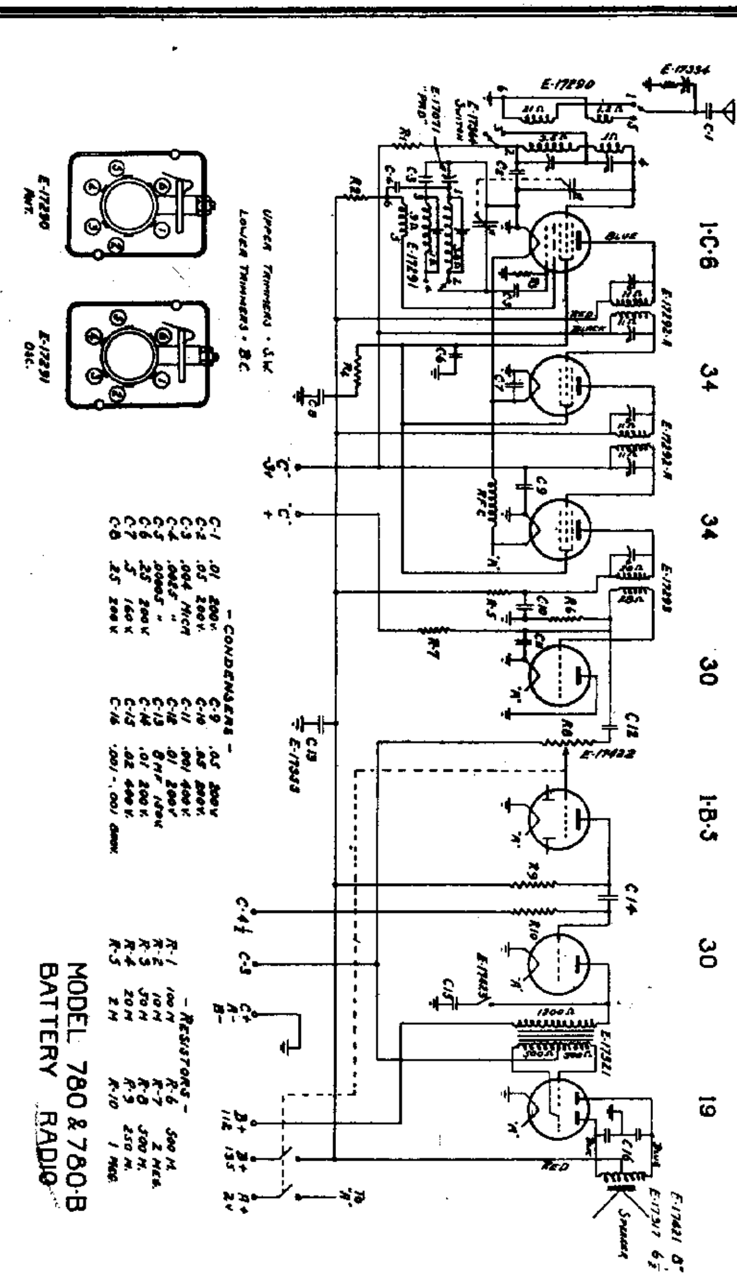
Series A—Part No. 108-35 Output I.F. Transformer
Series A—Part No. 108-36 Input I.F. Transformer
Series B—Part No. 108-35 Output I.F. Transformer
Series B—Part No. 108-36 Input I.F. Transformer

These I.F. transformers have two adjustments, both of which are accessible from the underside of chassis (see bottom view).

1. With volume control full on, the extreme right of its rotation, and with wave changing switch in the broadcast position, extreme left of its rotation, and with variable condenser set to approximately 1400 kilocycles, make the following adjustments:
   (a) Connect external oscillator set at 465 kilocycles, in series with "Dummy 1", to the control grid cap of the type 6D6 tube, located between the two I.F. transformers, and adjust the output I.F. transformer to resonance.
   (b) With "Dummy 1" still connected, move oscillator output clip from grid of 6D6 to grid cap to 6C6 and adjust input I.F. transformer to resonance.
   (c) With oscillator still connected to 6C6, re-adjust output I.F. transformer.

MODEL 780
Schematic
Alignment
Parts List

GAMBLE-SKOGMO, INC.



GENERAL Always eliminate all possible sources of trouble external to the receiver itself such as: Defective aerial, ground, or lightning arrestor, tubes, batteries, loud speakers

TUBE FUNCTIONS "1-C-6" First detector—oscillator, "34" first I F amplifier, "34" second I F amplifier, "30" diode second detector, "1-B-5" first audio, "30" audio driver, "19" class B power tube.

CHECKING PARTS....The resistance of coils and resistors is shown on the circuit diagram together with condenser capacities. Any defective part—either shorted or open—will result in either weak or distorted reception or none at all.

ALIGNMENT....If all parts check OK and sensitivity is still low it is probably due to the set being out of alignment. It is necessary to use a reliable test oscillator or signal generator having accurate calibration and positive attenuation.

I F ALIGNMENT 456 K. C.....Open tuning condenser (High Frequency dial setting). Connect signal generator to grid cap of 1-C-6 tube leaving present cap in place. Use a small condenser .002-.01 in series with signal generator lead wire. Adjust all five trimmers—two in top of each square I F transformer and the one in the top of the round (output) I F transformer. Go over these adjustments several times—it is best to use an output meter to indicate "peak". Reduce the output of the signal generator for final adjustments.

WAVE TRAP With the signal generator still on 456 K. C.—connect to antenna wire of set and adjust wave trap condenser to minimum signal.

The above will usually bring the set back to normal, check operation on stations and if satisfactory do not make any further adjustments.

BROADCAST BAND With the tuning condenser open and the signal generator set on 1735 K. C.—adjust B. C. Oscillator trimmer. Next—close tuning condenser and set signal generator to 540 K. C. adjust variable padding condenser for maximum signal. Adjust B. C. Antenna coil trimmer for maximum at 1400 K. C.

SHORT WAVE This is the most difficult for the service man and unless it is certain that the set does not compare favorably with a similar model under the same conditions of operation—the alignment should be left unchanged. If the service man feels that the short wave operation could be improved—proceed as follows. Connect signal generator to antenna and ground leads using a 300 ohm resistor in series with the antenna lead as a "dummy antenna". Set signal generator at 15,500 K. C. and tune in on the set (wave change switch in Short Wave Position—left). Adjust S. W. oscillator trimmer—see diagram—using a fibre screw driver, move the point of response to the highest frequency setting possible on the dial or near the end of the 19 M. band. Then without moving the tuning dial turn the trimmer screw tighter and you should be able to find a second point of response (the image). Move trimmer back to "loose" position. If the image response cannot be found move the dial and readjust trimmer until it can be heard. Be sure to return to the "loose" or fundamental setting. Next adjust the S. W. antenna coil trimmer for best response retuning the dial at the same time. The low frequency end of the short wave band is fixed by the .004 mica padding condenser and will not change unless this condenser becomes defective.

3-Band High Fidelity Superheterodyne Receiver

DESCRIPTION

The tube complement of this chassis is as follows:

1—Type 6K7 Remote cut-off pentode R.F. amplifier
1—Type 6J7—pentode first detector.
1—Type 6C5 Oscillator
1—Type 6K7 Remote cut-off pentode I.F. amplifier (465 K.C.)
1—Type 6Q7 duplex diode pentode second detector, A.V.C. and audio.
1—Type 6F6—pentode output amplifier.
1—Type 5Y3 or 5W4—high vacuum rectifier.

Transformers are available and chassis are sometimes equipped with universal transformers for operation on 40 and 60 cycles and with primary taps for 105, 125, 150, 220 and 250 volts (see instructions) and also sometimes equipped with 25 cycle transformers with 105-115 volt or 230 volt primaries, not universals.

SERVICE NOTES

NOTE: Chassis with serial numbers from 6C229300 to 6D242726 were equipped with a fuse in the primary circuit of the power transformer and supplied with a type 5Z4 rectifier tube.

This fuse is made accessible for replacement by removing fuse cover located on back flange of chassis, replace only with a 2 ampere fuse. If replacement fuse blows out, check tubes, (particularly 5Z4 rectifier) circuit, repair or replace defective tubes or parts.

NEVER ATTEMPT TO REPLACE FUSE WITHOUT FIRST DISCONNECTING POWER.

NEVER REPLACE WITH FUSE OTHER THAN 2 AMPERE RATING.

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt. These voltages are clearly indicated on the circuit diagram.

IN ORDER TO PREVENT SIGNAL FROM ACTING UPON AVC AND AFFECTING ACCURACY OF VOLTAGE MEASUREMENTS, AERIAL AND GROUND LEADS SHOULD BE SHORT CIRCUITED WHILE MAKING MEASUREMENTS.

All voltages are to be measured with 119 volts on the primary of the power transformer.

Resistances of coils and transformer windings are indicated in ohms on schematic circuit diagrams.

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

Excessive hum, stuttering, low volume and a reduction in all D.C. voltages is usually caused by a shorted electrolytic condenser, open by-pass condensers frequently cause oscillation and distorted tone.

ALIGNING INSTRUCTIONS

Dummy Antennas

The following dummy antennas are used in aligning and are referred to in the following alignment instructions as "Dummy 1", "Dummy 2", and "Dummy 3".

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.

Dummy 2: (Broadcast)—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Intermediate and Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

Resonance Indicator:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer or by means of an adapter between the plate and screen terminals of the type 6F6 output tube. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used.

CAUTION:

No aligning adjustments should be attempted without first thoroughly checking over all other possible causes of trouble, such as poor installations, open or grounded antenna systems, low line voltages, defective tubes, condensers and resistors. In order to properly align this chassis, an oscillator (generator) is absolutely necessary. No aligning adjustments should be attempted with the chassis in the cabinet. To remove the knobs, pull them off and to take the chassis out of the cabinet, remove the four bolts by which it is fastened.

ALIGNING I.F. TRANSFORMERS (465 K.C.)

Part No. 108-63 Output I.F. Transformer
Part No. 108-64 Input I.F. Transformer

These I.F. transformers have two adjustments, both of which are accessible from the underside of chassis (see bottom view).

1. With volume control full on, (the extreme right of its rotation), the wave changing switch in the broadcast position, (extreme left of its rotation), the tone control on "Hi" part of the sharp position (as much right rotation as possible without operating the Hi Fidelity switch), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:

(a) Connect external oscillator set at 465 kilocycles, in series with "Dummy 1", to the control grid cap of the type 6K7 tube, located between the two I.F. transformers, and adjust the output I.F. transformer (108-63) to resonance.

(b) With "Dummy 1" still connected, move oscillator output clip from grid of 6K7 to grid cap to 6J7 and adjust input I.F. transformer (108-64) to resonance.

(c) With oscillator still connected to 6J7, re-adjust output I.F. transformer if necessary.

ALIGNMENT PROCEDURE

The following adjustments to be made after the I.F.'s have been aligned as explained above.

BROADCAST BAND ALIGNMENT:

1. With wave changing switch in the broadcast position, extreme left of its rotation, and with external oscillator set at 600 kilocycles and connected in series with "Dummy 2" to the tan antenna and black ground lead, make the following adjustments:

(a) Adjust broadcast series pad (adjustment number 5) to resonance with oscillator. Keep set in tune with oscillator by slowly rocking to and fro the variable condenser until maximum output is obtained. Note: This adjustment is accessible from the top of the chassis and is located between the variable condenser and the 108-63 output I.F. transformer. See top view, Fig. 3.

(b) Re-set external oscillator to 1400 K.C., move dial pointer to 1400 K.C. and adjust oscillator (adjustment number 4), R.F. (adjustment number 6) and antenna (adjustment number 7) to resonance. See bottom view for location of these adjustments, Fig. 1.

(c) Repeat adjustments "a" and "b" until sensitivity is at its maximum.

NOTE: IT IS EXTREMELY NECESSARY IN MAKING ALL OF THESE ADJUSTMENTS THAT THE FUNDAMENTAL OSCILLATOR SIGNAL BE TUNED IN AND NOT THE IMAGE FREQUENCY WHICH WILL FALL BELOW THE FUNDAMENTAL.

SHORT WAVE BAND ALIGNMENT:

1. With wave changing switch in the short wave position, extreme right of its rotation, and with external oscillator set at 17 megacycles and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:

(a) Move dial pointer to 17 megacycles and adjust short wave oscillator (adjustment number 1), short wave R.F. (adjustment number 8) and short wave antenna (adjustment number 9) to resonance.

(b) Re-set external oscillator to 6 megacycles and pick up signal by rotating variable condenser and check for sensitivity.

INTERMEDIATE BAND ALIGNMENT:

1. With wave changing switch in the intermediate wave position, center of its rotation, and with external oscillator set at 1800 K.C. and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:

(a) Rotate variable condenser to approximately 1800 K.C. tune in oscillator signal and adjust M.W. series pad (adjustment number 3) (see top view) to resonance.

Slowly rock condenser to and fro while making this adjustment to be sure maximum output is obtained.

(b) Set external oscillator at 5 M.C., rotate condenser, pick up signal and adjust intermediate wave R.F. (adjustment number 10), intermediate wave antenna (adjustment number 11) and intermediate wave oscillator (adjustment number 2) to resonance.

(c) Re-check broadcast alignment and if it is found necessary to re-adjust either R.F. or antenna trimmers, repeat the 17 M.C. short wave and 5 M.C. intermediate wave adjustments.

SERVICE MANUAL TEN TUBE SUPERHETERODYNE WITH A.V.C., SQUELCH AND SHORT WAVE

105-115 Volts Alternating Current, 50-60 Cycles, 105 Watts. 530-1720 Kilocycles - 1700-4500 Kilocycles.

SERVICE NOTES

Should it be at any time necessary to rebalance this set, the correct procedure is as follows:

1. Volume and tone controls on full during all alignment.
2. Squelch switch in "no squelch" position (counter-clockwise (left) rotation) during all alignment.
3. Adjust variable squelch control on rear flange of chassis to maximum counter-clockwise (left) position.
4. Set variable condenser in minimum capacity position (plates open) at the start of all aligning.

I.F. ALIGNMENT

The intermediate frequency of model 1050 is 175 kilocycles, and is aligned as follows:

1. Connect oscillator (set at 175 kilocycles) to I.F. grid (second 58 tube) and adjust both trimmers of second I.F. transformer (underneath chassis) to resonance (maximum deflection on an output meter connected across the primary of the speaker input transformer).
2. Connect oscillator output to converter grid (2A7 tube) and adjust both trimmers of first I.F. transformer to resonance. Under no conditions touch the trimmers of the second I.F. transformer after adjusting them (see No. 1).

The four trimmers of the two I.F. transformers are all adjusted from the bottom of the chassis (one nut and one screw adjustment on each I.F. transformer trimmer).

BROADCAST BAND ALIGNMENT

Wave changing switch in clockwise (right) position.

1. Connect an oscillator in series with a 200 mmfd. condenser to the Tan (antenna) lead and Black (ground) lead. With the oscillator set at 1720 kilocycles and the variable condenser at its minimum position (extreme right of its rotation), adjust trimmer of oscillator (rear) section to resonance.
2. Change oscillator to 1400 kilocycles, rotate variable to this frequency and adjust R.F. and antenna trimmers (center and front trimmers respectively) to resonance. Do not touch the oscillator trimmer.
3. Check tracking at the following points only: 1200-1000-800-600-534 kilocycles. NOTE: This receiver will be slightly out of track at 534 kilocycles - do not bend plates in an attempt to track it at this frequency. Rotor plates of condensers should not be bent, except if absolutely necessary, and then only on the center and front sections.

SHORT WAVE BAND ALIGNMENT
Wave changing switch in counter-clockwise (left) position.
1. The frequency range of this short wave band is approximately 1700 to 4500 kilocycles.
2. Peak short wave antenna coil to resonance with oscillator set at 1720 kilocycles by slipping primary.
3. Check for sensitivity at the following frequencies only: 1720 and 3700 kilocycles - under no conditions touch trimmers or plates of variable condenser while checking short wave band.

Tun-a-lite. VISUAL TUNING CHECK
The visual tuning indicator (tun-a-lite tube) is mounted horizontally on the front of the variable condenser assembly and its operation in this respect can be checked as follows:

1. Normally there will be a small continuous glow in the base of the tube when no signal is being received.
2. With a strong oscillator input at 1000 kilocycles, the tun-a-lite should glow to approximately the end of the bulb, varying slightly with different tun-a-lites. If the glow "travel" is short, or none at all, remove the tun-a-lite tube and check its socket connections and contacts. If the tube still fails to indicate satisfactorily, replace the tube.

SQUELCH CHECK
The tun-a-lite tube is also used for noise suppression between stations. Its operation can be checked as follows:

1. Squelch switch adjusted to squelch (clockwise (right) position).
2. Disconnect oscillator, connect antenna, tune set to a position where no signal is received. Noise level at this position should be quite high.
3. Rotate set screw of squelch control on rear flange of chassis, and at some point the noise should cease and the set sound "dead", indicating that the tun-a-lite is squelching and eliminating between station noise.

NOTES: For failure to operate over both bands, check 2A7 tube and connections to and contacts of wave changing switch.

Condenser shaft to which pointer is attached is rotated by means of a celluloid dial attached to the condenser shaft and a bronze friction drive assembly, to which is attached the selector knob. Should this drive ever slip or become rough, it can be adjusted for smooth operation by sliding the bronze washer drive assembly either closer to the variable shaft or farther away from it in the slot in which it is mounted, to insure smooth operation.

Dual-Wave Super-Heterodyne

ALIGNMENT

The necessity for realignment of the receiver circuits will usually be indicated by a lack of sensitivity accompanied by poor selectivity, but realignment should not be attempted until all other causes for this same condition, such as defective tubes, poor antenna installation, partially shorted condensers or loose connections at some point in the chassis, have been investigated.

Aligning Intermediate Condensers — Place the receiver in operation with the band selector switch in the broadcast position. Connect the output lead from the signal generator to the control grid connection of the 57 first detector tube and place the signal generator in operation at 455 K. C.

The oscillator coil must be shorted out by grounding the lead from the tap on the secondary. This is the white lead which comes through the porcelain base of the oscillator and I. F. assembly. This lead terminates at a lug on a vertically mounted bakelite terminal strip. Connect the jumper from this lug to the ground.

Then set the signal generator for a signal of 600 K. C. and turn the tuning condenser rotor until the output is at maximum. The next step is to adjust the oscillator 600 K. C. trimmer condenser. The adjusting screw for this condenser is between the tuning condenser and intermediate frequency shield on top of the chassis. To correctly adjust this oscillator 600 K. C. trimmer it will be necessary to turn the screw to several different positions using a non-metalic screw driver. At every position of this adjusting screw turn the tuning condenser rotor until maximum output is obtained. For each position of the adjusting screw there will be a maximum output and the correct position of the adjusting screw is the setting at which the deflection of the output indicating meter is the greatest.

Next set the signal generator again for a 1400 K. C. signal and check the adjustment of the tuning condenser trimmers at this frequency for the maximum output. Then set the signal generator for a signal of 1000 K. C. and turn the tuning condenser rotor until the output indicating meter shows maximum deflection. Then bend the slotted rotor plate sections of each tuning condenser bank which are last in mesh, in or out until maximum output is obtained. Tune in a signal at 750 K. C. and then at 600 K. C. and follow the same procedure, bending the rotor plate sections last in mesh until maximum output is obtained. Do not change the setting of the oscillator 600 K. C. trimmer in any way after it has once been set as indicated above.

After the foregoing adjustments are carefully made with the receiver in operation in the broadcast band, the same adjustments will be correct for operation of the receiver in the short wave band and no further adjustments are necessary to obtain maximum efficiency of operation on short wave signals.

The intermediate condenser adjusting screws on the first I. F. transformer are reached from the bottom of the chassis. The tuning condensers of this transformer are mounted on the porcelain base of the oscillator I. F. assembly and the adjusting screws protrude through this base. The intermediate condenser adjustments on the second I. F. transformer mounted on top of the chassis are both accessible from above the chassis and adjustment is made by means of the screw and nut on the top of the I. F. transformer. Turning the screw varies the capacity of the I. F. secondary trimmer and turning the nut changes the capacity of the I. F. primary trimmer. Adjust all four intermediate condensers until maximum output is obtained on the output meter. After all four have been adjusted the first time go over them again and check the setting for maximum output.

Aligning R. F. and Oscillator Condensers— The R. F. and oscillator condensers are adjusted with the receiver in operation in the broadcast band and the signal input from the signal generator should be made to the antenna post. Adjust the signal generator for a signal of exactly 1400 K. C. Then turn the tuning condenser rotor until the pointer is at exactly 1400 on the dial scale. Then adjust the two trimmers on the tuning condenser for maximum output adjusting the oscillator trimmer first (trimmer nearest front of chassis). Turn the screws up or down until greatest deflection on output indicating meter is obtained.

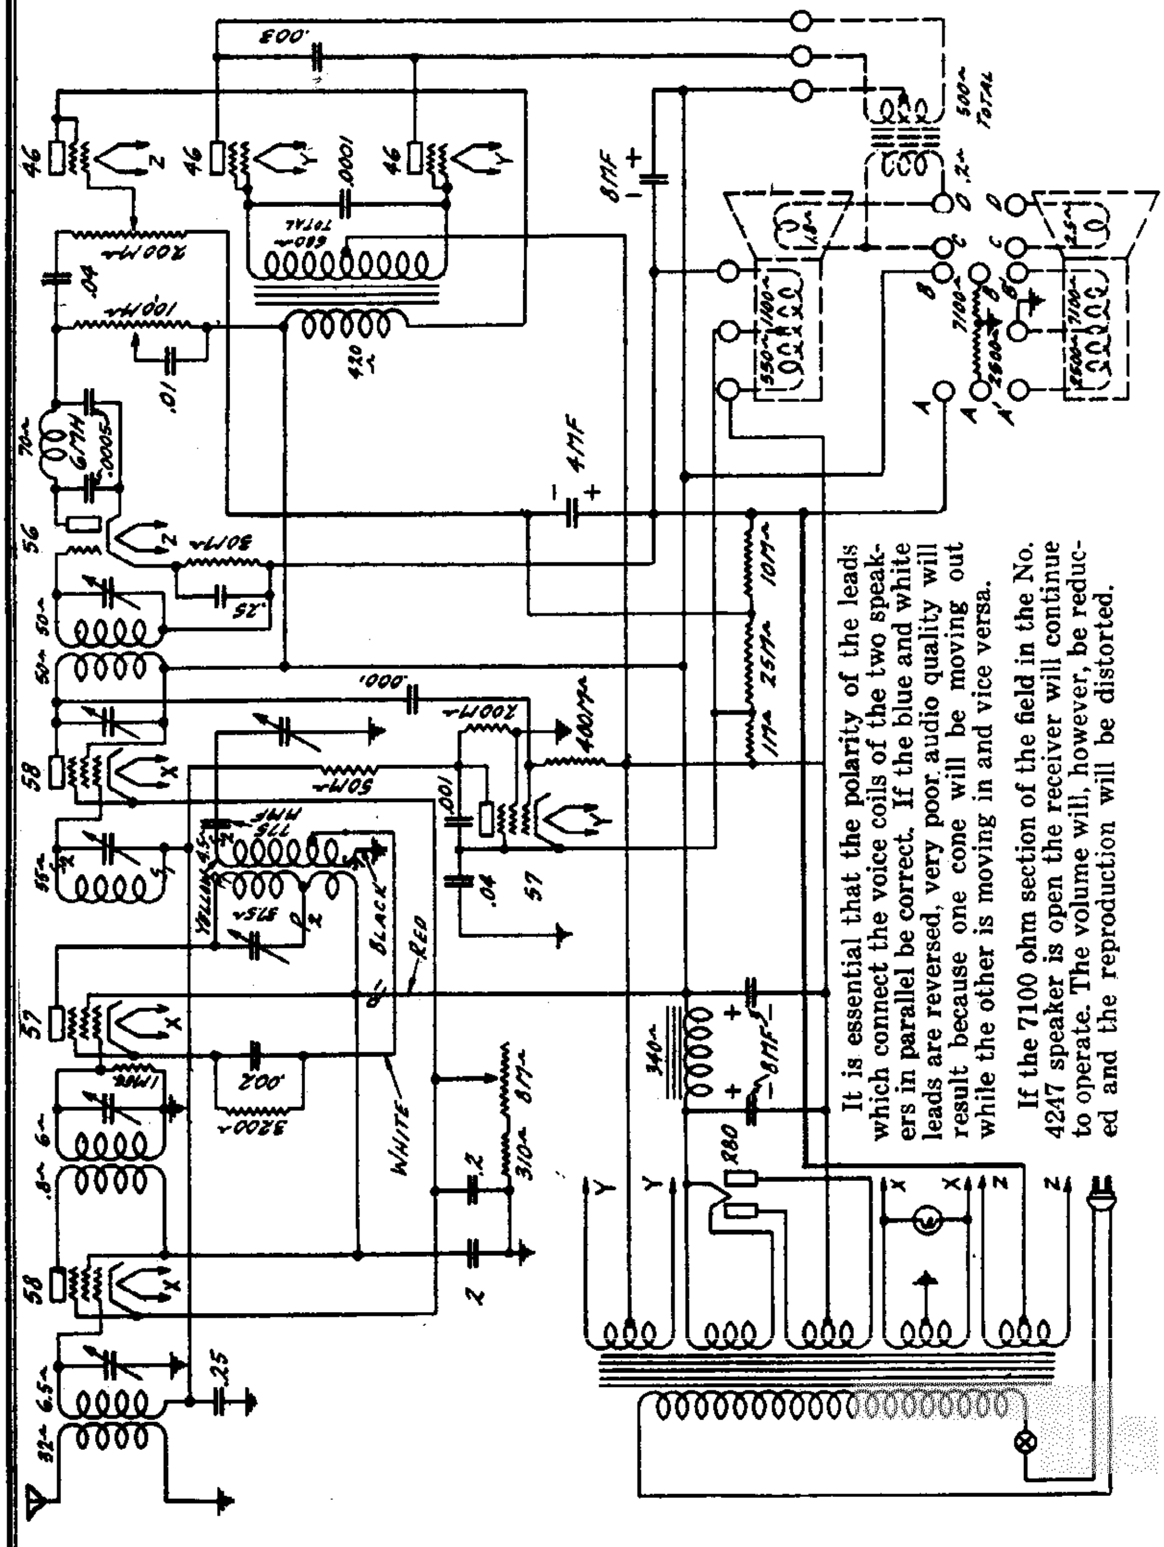
Notes

GAMBLE-SKOGMO, INC.

CONNECT A TO A AND B TO B FOR SINGLE SPEAKER.
CONNECT A' TO A, B' TO B, C TO C AND D TO D FOR DUAL SPEAKERS.



It is essential that the polarity of the leads which connect the voice coils of the two speakers in parallel be correct. If the blue and white leads are reversed, very poor audio quality will result because one cone will be moving out while the other is moving in and vice versa.

If the 7100 ohm section of the field in the No. 4247 speaker is open the receiver will continue to operate. The volume will, however, be reduced and the reproduction will be distorted.

"CORONADO" Model 2090

Super-Heterodyne Receivers

No. 900 Chassis

CIRCUIT

The complete circuit consists of an R.F. amplifier, an Oscillator-1st detector unit in which the local signal is generated and combined with the R.F. signal to form the intermediate or beat frequency, the I.F. amplifier, the 2nd detector or demodulator, the AVC and "Q" Control, the audio stages, and the power system from which the required voltages are obtained.

An R.F. amplifier or similar circuit is necessary because of the tendency of the Super-Heterodyne towards image or double frequency response. Image response is due to the fact that two different R.F. signals can be combined with the oscillator signal at the same time to form the intermediate or beat frequency. One of the R.F. signals is above the oscillator signal by an amount equal to the intermediate frequency and the other R.F. signal is below the oscillator signal by the same amount.

In the No. 900 chassis is included the Quiet Automatic Volume Control (Q.A.V.C.) This is a sensitivity control working in conjunction with the AVC tube to provide quiet operation of the receiver whether or not it is tuned to a station. Control of the receiver sensitivity is obtained by means of a variable biasing resistor in the cathode circuit of the R.F. and I.F. tubes making it possible to adjust the sensitivity of the receiver to a point below the noise level prevailing at the point of reception.

A type 56 tube is used as the 2nd detector or demodulator tube. This detector is of the bias type, the bias voltage being obtained from the drop established by the plate current flowing through the 30,000 ohm resistor in the cathode circuit of the tube. The grid return of this tube is brought to the low potential end of the biasing resistor.

A low-pass filter consisting of a 6-millihenry choke and two 500 Mmf. condensers is placed in the plate circuit of the 2nd detector to prevent I.F. voltage from being applied to the grid of the 46 1st audio or "Driver" tube. This filter offers a very high impedance to intermediate frequency but allows audio frequency to pass readily.

The 2nd detector is coupled to the driver stage by means of resistance coupling, the 100,000 ohm tone blender resistor providing the necessary impedance so that the audio voltage is developed across it and impressed upon the grid of the 46 driver tube through the .04 Mfd. coupling condenser.

A .01 Mfd. condenser is connected between the lower end of the tone blender resistor and the movable arm. As the movable arm is moved so that the .01 Mfd. condenser shunts more of the resistor, the impedance of the plate circuit to high audio frequencies is lowered and less high frequency voltage is impressed upon the grid of the driver tube. The tonal output of the receiver is varied accordingly.

A 200,000 ohm variable resistor is connected as a potentiometer in the grid circuit of the 46 driver tube and serves to control the volume of the receiver. One end of this resistor is connected to the .04 Mfd. coupling condenser and the other end to the source of the grid bias voltage for the 46 driver tube. The grid of this tube is connected to the movable arm. As the position of the movable arm is changed, the A.F. voltage impressed on the grid of the 46 driver tube is varied, thus controlling the volume.

The outer grid of the 46 tube is connected to the plate and the tube functions as a low impedance audio amplifier. Bias voltage for this tube is obtained by using a portion of the voltage drop across the 1100 ohm section of the speaker field. The drop across this section is 45 volts and by means of a voltage dividing system consisting of a 10,000 ohm resistor and a 25,000 ohm resistor in series across the 1100 ohm section, the proper bias voltage of 19 volts is applied to the inner grid of the tube, through the 200,000 ohm volume control resistor. The grid biasing system is bypassed by a 4 mfd. dry electrolytic condenser which completes the audio circuit to the tube and avoids the degenerative effect which would be present if the audio frequencies were forced to flow through the biasing system.

The driver stage is transformer coupled to the two 46 tubes which are used in the Class "B" output amplifier. Owing to the fact that current flows in the grid circuits of these tubes during the time the positive half of the cycle is applied to the dual-grid connection, it is necessary to utilize a specially designed audio transformer with a low impedance secondary. If this is not done the audio wave applied to the dual-grids of the tubes will be distorted due to voltage drop in the transformer secondary winding caused by the grid current.

No grid bias voltage is applied to the dual grids of the 46 tubes as the plate impedance is very high due to the dual-grid connection. The plate current is practically at cut-off, being only 5 MA at no signal.

A 8000 Mmf. condenser is connected between the plates of these tubes and acts as a bypass for high audio frequency harmonics.

A type 57 tube is used as an automatic volume control in this chassis. Grid bias voltage for this tube is obtained by using the voltage drop across the 550 ohm section of the speaker field which is shunted by a 1000 ohm resistor. The plate voltage is developed across the 1100 ohm section of the speaker field and the 7100 ohm section of the Candohm shunt resistor. The AVC controls the signal strength after it has been picked up by the antenna by varying the bias voltage on the 58 R.F. and I.F. tubes. The grid circuits of the tubes are connected through a 50,000 ohm resistor to the plate of the AVC tube. The cathodes of the R.F. and I.F. tubes are connected to ground through the "Q" control and 310 ohm biasing resistor. The 200,000 ohm resistor in the plate circuit of the 57 AVC tube is also connected to ground and when a signal of sufficient magnitude to overcome the initial D.C. bias on the AVC tube is applied to its control grid through the 100 Mmf. coupling condenser, current will flow in the plate circuit, establishing a voltage drop across the 200,000 ohm resistor. This voltage adds to the bias voltage already applied to the grids of the R.F. and I.F. tubes by the drop across the "Q" control and 310 ohm resistor and decreases the sensitivity of the receiver in proportion to the strength of the signal being received.

Previous Super-Heterodyne receivers operated noisily when tuning from one station to another. This was due to the action of the AVC tube in allowing the receiver to operate at maximum sensitivity when no station signal was applied to the receiver. As the Super-Heterodyne is a very sensitive receiver its operation is naturally noisy under such conditions. In the No. 900 chassis a variable resistor is placed in series with the fixed biasing resistor in the cathode circuit of the R.F. and I.F. tubes. This makes possible the manual variation of the sensitivity of the receiver. In practice this 8,000 ohm resistor or "Q" control is adjusted to the point where local interference or static is reduced to an unobjectionable minimum when the receiver is not tuned to a station. This adjustment will make stations which are below the noise level inaudible and may introduce slight fading in the reception of stations whose signal strength goes below the noise level at times but in any case such stations cannot be received with any degree of satisfaction as their signal strength is no greater than the noise level prevailing at the point of reception.

The power system consists of the conventional power transformer, full wave rectifier, filter choke and filter condensers. The speaker field serves as an additional choke as well as a part of the voltage dividing system. The voltage dividing system which provides proper plate, and screen voltages for the different tubes is completed through a 9600 ohm resistor which is tapped at 2500 ohms.

The R.F. amplifier reduces this form of interference by selecting and amplifying the desired signal, at the same time attenuating unwanted signals. Additional freedom from image response is obtained by the selection of a high intermediate frequency.

The R.F. amplifier is a stage of tuned radio frequency coupled to the antenna and ground by a high impedance primary coil. The primary winding is resonant to a frequency below the broadcast band permitting the use of varying antenna lengths without disturbing the alignment. The secondary of this transformer is tuned by the first section of the three-gang tuning condenser. The 2nd R.F. or detector transformer which couples the plate circuit of the 58 R.F. tube to the grid circuit of the 57 1st detector is also inductively coupled. The secondary of this transformer is tuned by the second section of the three-gang tuning condenser.

The grid bias voltage for the 58 R.F. amplifier is variable and depends upon two factors, the current flowing in the plate circuit of the AVC and the position at which the "Q" control is set. Referring to Fig. 2, it will be seen that the resistance in the cathode circuit of the 58 R.F. and I.F. tubes will vary between 310 and 8,310 ohms depending upon the setting of the "Q" control. The voltage drop established by the plate and screen currents flowing through this resistance is applied to the grids of these tubes and is the grid bias voltage at low signal strengths. When higher signal strengths are applied, the AVC will draw plate current, setting up a voltage drop across the 200,000 ohm AVC plate resistor which will add to the voltage drop across the 310 ohm resistor and the section of the "Q" control between this resistor and the movable arm of the control.

The first 57 tube functions both as an oscillator and as the 1st detector. Referring to Fig. 2, there are four coils shown to the right of this tube, all of these coils being in an inductive relation. These coils and the two I.F. tuning condensers make up the Oscillator-1st I.F. Assembly, the wiring of which is shown in Fig. 4.

The tuned circuit P_1, P_2 is resonant at a frequency of 262 K.C. Circuit S_1, S_2 (at the top) is also resonant at this frequency. The two coils P_1, P_2 and S_1, S_2 are the primary and secondary respectively of the first I.F. transformer. Circuit P_1, P_3, P_4 constitutes the primary of the oscillator and circuit S_1, S_3, (below) the secondary. Circuit S_1, S_3, the oscillator secondary, is tuned by the third section of the three-gang tuning condenser and is always resonant at a frequency of 262 K.C. above the frequency to which the R.F. circuits are tuned.

A surge of energy fed into the secondary of the oscillator, inductively, causes this circuit to begin to oscillate at its resonant frequency of 262 K.C. above the radio frequency. This oscillator frequency is fed back through the tap in the secondary coil into the grid circuit of the 1st detector. There the oscillator signal is amplified and fed inductively through the primary system in the plate circuit of the tube back into the secondary, thus sustaining the oscillations at the frequency to which the oscillator secondary circuit is tuned.

The first 57 tube also functions as the 1st detector or mixer and is of the bias type. Bias voltage for this tube is established by the plate and screen currents flowing through the 3,200 ohm resistor in the cathode circuit. This resistor is bypassed by a .002 Mfd. condenser. The bias voltage is influenced to a slight extent by the oscillatory current and will vary within a small range, depending on the frequency to which the receiver is tuned.

There are two frequencies present in the grid circuit of the 57 1st detector. One is the radio frequency and the other is the oscillator frequency which is always 262 K.C. above the radio frequency. This results in the beat or intermediate frequency being present in the plate circuit of the tube. Since circuit P_1, P_2, the primary of the first I.F. transformer, is resonant at 262 K.C., the maximum I.F. voltage will be developed across this circuit. This voltage is then induced in the secondary of the first I.F. transformer, S_1, S_2, the latter circuit also being tuned to 262 K.C.

In order to provide satisfactory tracking with the R.F. and 1st detector tuned circuits, the oscillator is provided with a 1400 K.C. trimmer condenser and a 775 Mmf. series condenser. The 1400 K.C. trimmer condenser is located on top of the tuning condenser and is connected across the oscillator tuning condenser. The 775 Mmf. series condenser is connected between the tuning condenser and the oscillator secondary coil.

The I.F. amplifier provides the high degree of sensitivity and selectivity for which the Super-Heterodyne is noted. The tuned circuits in the primary and secondary of both I.F. transformers afford a high degree of selectivity. High amplification is obtained by using the high mutual conductance 58 tube in a low frequency circuit which permits great amplification without instability.

Bias voltage for the I.F. amplifier tube is the same as the bias voltage for the 58 R.F. tube.

The I.F. transformers are small universal wound coils mounted on tubing. The I.F. tuning condensers are of the same type as the R.F. trimmer condensers and use mica dielectric. The coil tubing and the condensers are mounted on porcelain bases and are enclosed in aluminum cans located on top of the chassis. The adjusting screws of the four I.F. tuning condensers are reached from the bottom of the chassis.

CONDENSER ALIGNMENT

In the No. 900 chassis the R.F. and oscillator trimmer condensers are located on the variable tuning condenser assembly, one on each section. The tube shield cover plate extends over the top of the tuning condenser but need not be removed during readjustment of the trimmers as access to these is given by three circular holes in the cover plate. These trimmers are used to adjust the alignment at the high frequency end of the receiver.

There are also four I.F. trimmer condensers and in order to correct any misalignment of the I.F. transformers it is necessary to remove the chassis from the cabinet. The I.F. trimmer adjusting screws are located on the under side of the chassis subpanel and protrude through the porcelain bases of the I.F. transformers. The adjusting screws of the I.F. transformer trimmers as well as the R.F. trimmers should not be tampered with or changed unless it is apparent that they are out of adjustment. The I.F. trimmers are used to adjust the I.F. transformer circuits to 262 K.C.

An accurately calibrated signal generator and an output indicating meter are essential in order to align the R.F. and I.F. circuits correctly. This signal generator must provide a signal at the broadcast frequencies of from 550 to 1500 K.C. and an intermediate frequency signal at 262 K.C. The broadcast band signals of the signal generator must be accurately known as the dial scale of the receiver is calibrated in kilocycles and the alignment of the gang tuning condenser must be made at definite frequencies in order to have the pointer at the correct location on the scale for the various frequencies. The intermediate frequency signal of the signal generator must also be accurate in order to align the I.F. circuits at 262 K.C.

The companies manufacturing test equipment including Weston-Jewell Electrical Instruments Company, Radio Products Company and Supreme Instruments Corporation have combination R.F. and I.F. signal generators, suitable for servicing this chassis, available to the Radio Trade, which have incorporated in them copper oxide meters for reading the receiver output. The output meter is connected across the voice coils of the speaker or across the primary of the speaker input transformer if it is of sufficient range. The output meter should always be used for alignment as the method of alignment by using the ear to determine maximum output is essentially inaccurate.

During all of the following alignment procedure a "dummy" 57 tube (one which has one filament prong removed) should be inserted in the AVC socket. This will remove any possibility of AVC action which would make the determination of the output peak very difficult. Alignment should never be attempted without any tube in the AVC socket as the lack of the tube capacity in the circuits will cause an incorrect alignment to be made. Attenuate the signal generator output to as low a value as will give a satisfactory reading on the output meter. This will eliminate the possibility of overloading the 2nd detector.

Aligning Intermediate Condensers—It is essential that the I.F. transformers be correctly tuned for maximum deflection on the output meter before the R.F. and oscillator circuits can be correctly aligned. Connect the lead from the signal generator to the control grid of the 57 1st detector. The tube shield should be in position and the chassis grounded but the tube shield cover may be removed to facilitate making the control grid connection. A small battery clip on the signal generator lead makes for convenience in making this connection. Connect the ground lead of the signal generator to the ground post on the back of the chassis. The oscillator must be shorted out by grounding the lead from the tap on the secondary. This can be done conveniently by connecting a jumper from ground to the lug on the 3200 ohm resistor at the end which connects to the oscillator-I.F. assembly.

Then adjust the four intermediate frequency condenser screws until maximum output is obtained on the output meter. After all four of them have been adjusted the first time, go over them again and check the setting for maximum output.

Aligning R.F. and Oscillator Condensers—For adjusting the R.F. and oscillator condensers, the signal input should be made to the antenna post on the back of the receiver chassis.

Loosen the drive plate set screws and turn the tuning condenser rotor until the rotor plates are fully meshed with the stator plates. Turn the drive plate until the dial pointer is directly over the lowest frequency mark. Then tighten one set screw.

Set the signal generator for a signal of 1400 K.C. and turn the drive plate until the pointer

MODEL 2090
Alignment, Part 2
Socket, Voltage
Speaker Connections
Notes, Transformer Data

GAMBLE-SKOGMO, INC.

is directly over the 1400 K.C. mark. Adjust the three trimmers at this frequency for maximum output, adjusting the oscillator trimmer first (trimmer nearest back of chassis).

Set the signal generator for a signal of 600 K.C. and tune the receiver exactly to this signal. Carefully note the dial mark which is under the pointer. If the pointer is not at 600 K.C. on the dial loosen the drive plate set screw and adjust the dial pointer until it is set on the other side of the 600 K.C. mark an amount equal to one-half the frequency difference between the former setting and 600 K.C., being careful not to move the tuning condenser rotor during this change. For instance, if the dial pointer was at 580 K.C. when the 600 K.C. signal was tuned in, it should be moved to read 610 K.C. If the 600 K.C. signal was tuned in at 610 K.C. on the dial, the pointer should be moved to read 595 K.C. Then tighten the drive plate set screw lightly.

Set the signal generator again for a frequency of 1400 K.C. and adjust the tuning condenser so that the dial pointer is at 1400 K.C. on the dial. Readjust the trimmer condensers until maximum output is obtained on the output meter.

Recheck the calibration at 600 K.C. for maximum output. The dial reading should now be correct but in case it is still off slightly, the foregoing procedure should be gone through again. When maximum output is obtained with the pointer at 600 K.C. on the dial tighten both drive plate set screws tightly, taking care that the rotor shaft does not slip.

Then set the signal generator for signals of 1000, 750 and 600 K.C. and check the two R.F. condensers for resonance. Bend the slotted rotor plate sections of each of these two condensers which are last in mesh, in or out until maximum output is obtained. Do not adjust the oscillator condenser slotted rotor plate sections (condenser nearest back of chassis).

ISOLATION OF DEFECTS

The signal generator described in the preceding section provides a convenient and simple method of locating and isolating defects in the R.F. and I.F. circuits. This method consists of introducing a signal into the grid circuit of each tube starting with the 2nd detector and working on to the R.F. stage.

First set the signal generator for a signal of 262 K.C. and connect the ground lead of the signal generator to the ground post of the chassis. Touch the signal lead from the signal generator to the grid contact of the 2nd detector socket. It will, of course, be necessary to have the chassis removed from the cabinet for this test. If the receiver is in good condition from the 2nd detector on through the audio stages the signal will be reproduced at the loudspeaker.

Next connect the signal generator to the grid of the 58 I.F. tube. If the receiver is in operating condition from the I.F. tube through the output stage the signal will be heard at the speaker. Check the magnitude of the output with the output meter and, in order to determine if it is sufficient, make the same test on another receiver of the same type which is known to be in good working order. Then connect the signal generator lead to the grid of the 57 1st detector, ground the oscillator tap and read the output. If signal output is obtained it is an indication that the circuit through the 1st I.F. transformer, but not including the oscillator, is in good order.

Next set the signal generator for a signal in the broadcast band and connect the signal generator lead to the grid of the 57 1st detector. Remove the grounding lead from the oscillator tap. A deflection should be read on the output meter when the receiver is tuned to the frequency of the generator signal. This indicates that the chassis starting with the 1st detector and including the oscillator is in good condition. Then, still using the R.F. signal, connect the signal generator lead to the grid of the 58 R.F. tube. If the receiver is in good order starting with the R.F. tube, a deflection will be had on the output meter. If such is the case, the trouble can only be in the antenna input transformer.

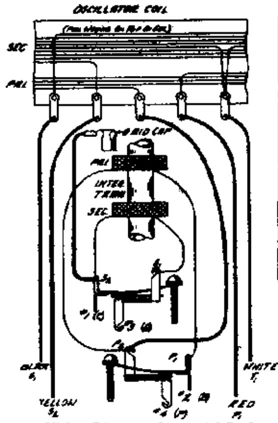

Fig. 4—Wiring Diagram, Osc. and I.F. Assembly

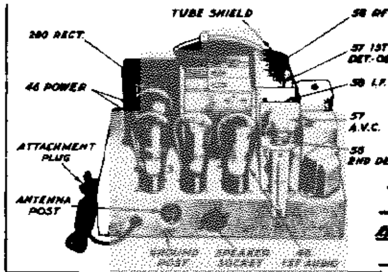
ANTENNA AND 1st DETECTOR TRANSFORMERS

The antenna and 1st detector transformers are matched at the factory in sets of two and should it be necessary to replace one of these it is desirable from the standpoint of efficient operation of the receiver to replace both of them. To replace only one transformer may result in a loss of performance unless the one replaced is of the correct value.

The two transformers are contained in shielding cans under the chassis subpanel. It is not necessary to remove these cans in order to replace the transformers. Unscrew and remove the screw holding the transformer mounting bracket to the subpanel. Bring the transformer out as far as the leads will permit and unsolder the leads to the transformer terminal lugs. Next put the new transformer in position and solder the leads to the lugs. Then replace the screw holding the transformer mounting bracket to the subpanel. After the two transformers have been installed, realign the tuning condensers in accordance with the instructions in the section on "Alignment."

OSCILLATOR AND 1st I.F. ASSEMBLY

The oscillator and I.F. assembly is made up in one compact unit contained in a shielding can. As explained in the article on the circuit, this unit has four coils, all in inductive relation. The primary and secondary of the intermediate frequency transformer in this unit are small universal wound coils. The primary is under the oscillator coil form, while the secondary is mounted in a lower position on the standard. The oscillator is wound on a coil form placed at the top of the unit. The primary winding is on top of the secondary. At the bottom of the unit on the porcelain base are the two I.F. tuning condensers. Complete wiring of the unit is shown in Fig. 4. The unit is carefully adjusted at the factory before assembly in the receiver. If it becomes defective in any way other than a break in the wiring connections which can readily be repaired, it is suggested that the whole unit be replaced rather than attempt replacement of the component parts.



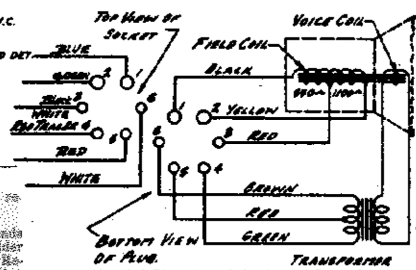
To replace this assembly, unsolder the leads to the lugs on the porcelain base and unsolder the four leads extending through the base. Remove the two nuts from the studs extending through the chassis subpanel, after which the assembly may be removed. The new assembly may then be put on and the leads soldered in.

If the oscillator current is too high, grid current may flow in the 57 1st detector and 58 I.F. grid circuits. Grid current in the case of the 58 will manifest itself as a decrease in volume after the "Q" control has been increased past a certain setting. Grid current in the case of the 57 will manifest itself in weak action and as a whistle with no signal under certain conditions. The causes of oscillation being too strong are 3200 ohm biasing resistor being too low in value, .002 Mfd. bypass condenser being too high in value, too many turns on oscillator primary and oscillator primary wound too low on coil with respect to the secondary, or a 57 1st detector tube which has a characteristic high plate current.

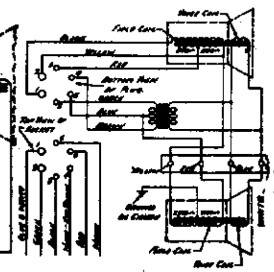
If the oscillations are too weak, this manifests itself as a flutter, usually at low frequencies. In extreme cases, oscillation may cease entirely, causing inoperation of the receiver at all frequencies. Weak oscillations are caused by the reverse of the conditions mentioned above, namely, 3200 ohm biasing resistor being too high in value, .002 Mfd. bypass condenser being too low in value, too few turns on oscillator primary, oscillator primary wound too high on the coil with respect to the secondary, or a low emission 57 1st detector tube.

BYPASS CONDENSERS

The correct testing of bypass condensers of the paper dielectric type for open or short circuits is of the utmost importance. This may be accomplished by using a direct reading ohmmeter. The application of the test prods to the condenser under test will cause a momentary deflection of the meter (the extent of the deflection depending upon the capacity of the condenser and the voltage used with the ohmmeter and in general, the larger the capacity the greater the deflection) after which the meter needle will drop back to infinity if the condenser is in good electrical condition. In the event the condenser circuit is open, there will be no deflection on the meter. A shorted condenser, on the other hand, will give a full scale deflection or zero resistance reading. A leaky condenser will give a partial reading depending upon the extent of the leak or the internal resistance. Bypass condensers of very small capacity in the order of .05 Mfd. or .002 Mfd. or less cannot be successfully tested by this method except for a shorted or leaky condition and if a condenser of this type is suspected of being open, simple trial replacement is the best procedure.



No. 4245 Electrodynamic Speaker and Connections



No. 4246 and 4247 Electrodynamic Speakers and Connections

FLUTTERING OR MOTORBOATING

The tube shield and cover must be on, otherwise motorboating may result. Still other causes are open or defective grid circuits or open bypass condensers. Fluttering is very often due to I.F. oscillation and the causes for such a condition should be investigated in line with the information given in the section on "Oscillation."

Remove the 56 oscillator tube during I.F. alignment.

Alignment of the R.F. and oscillator circuits is made at 1400 K.C. by means of the trimmer condensers mounted on the main tuning condenser. These should be adjusted to give maximum output on a 1400 K.C. oscillator signal with the receiver dial indicator set exactly at 1400. When maximum output has been obtained the oscillator is next set for a signal of 600 K.C. and the receiver tuned to this signal. The dial reading should then be 600 but, if it is not exact, may be corrected by loosening the set screws which hold the drive disc and turning the disc until correct reading is obtained. Alignment at 1400 K.C. will then have to be repeated.

OSCILLATION

A common cause of oscillation is open bypass condensers and these should be checked by simple trial replacement. Coupling between I.F. grid and plate leads may cause the trouble and these leads should be separated and pushed close to the chassis. Too great R.F. gain in the receiver may cause instability or oscillation and is corrected by removing four or five turns from the primary of the 1st detector transfomer. This should not be done, however, until all other causes of oscillation have been investigated.

DISTORTION

Distorted reproduction may be brought about by defective tubes and in any case of distortion these should be checked first. An inoperative 46 output tube will especially cause distortion due to harmonics in the output of the good tube not being balanced out by the other tube. Leaky or open bypass condensers may also cause distortion.

The connections to the voice coil of one speaker being reversed will cause a very noticeable distortion and these should be checked at the terminal strip. Open field windings in either speaker will allow the receiver to continue operation but at reduced volume and with some distortion.

At low volume, distortion may be caused by a tone control rheostat having a resistance higher than the normal value of 50,000 ohms. Other resistors which will bring about distortion if they are high in value are the 20,000 ohm 2nd detector bias resistor and the 7,000 ohm resistor in the voltage dividing circuit which provides grid bias for the AVC tube. In case of distortion at low volume, therefore, these resistors should be checked with an ohmmeter and replaced if not within normal 10% limits.

EXCESSIVE HUM

Excessive hum may be brought about by an open filter condenser or by an open circuit in one half of the 280 plate winding of the power transformer.

Heater-cathode shorts in the 56 or 58 tubes will cause the hum to be higher than normal and new tubes should be tried in any case of excessive hum. Certain 46 tubes, when used in the driver stage, will produce a hum much greater than normal and the tube in this socket should be inter-changed with the other two 46 tubes in the receiver.

Shorted turns in the filter choke or 1,650 ohm speaker field will cause the receiver to hum as will various shorts, opens or grounds at different points in the chassis.

CHASSIS No. 2092

Chassis No. 2092 is practically the same as chassis No. 2094, except that it is designed for single speaker operation. A speaker having a 1,650 ohm field is used with this chassis and a tapped wire wound resistor is substituted for the field of the second speaker.

GAMBLE-SKOGMO, INC.

MODEL 6968-A
Alignment

SERVICE NOTES
for the
SIX TUBE SUPERHETERODYNE RECEIVER
TWO BAND
1720 to 530 Kilocycles
15.8 to 5.6 Megacycles
THIRTY-TWO VOLT

This receiver is designed for operation on 32 volt battery plants only and must not be used on battery plants of a higher rated voltage than 32 volts without a voltage regulator. If the rating is higher than 32 volts consult your dealer, who will supply the proper voltage regulator.

ALIGNMENT PROCEDURE: Realignment of this receiver should never be necessary unless one of the oscillator, antenna, or RF coils has been replaced. Lack of sensitivity, selectivity, and poor tone quality may be due to any one or a combination of causes such as weak or defective tubes or speaker, inadequate or excessively long antenna, open or grounded bias resistor, bypass condenser, etc. Under no circumstances should realignment be attempted until all other possible sources have been first thoroughly investigated and have been definitely proven not to be the cause. If an IF tube is replaced it is adviseable to realign the IF amplifier particularly if the replacement tube is one of a different manufacture than the one in the receiver. It is important when aligning to carefully follow the procedure in the order given, otherwise the receiver will lack sensitivity and the dial calibration will be incorrect. IT IS IMPERATIVE THAT AN ACCURATELY CALIBRATED OSCILLATOR BE USED WITH SOME TYPE OF OUTPUT MEASURING DEVICE.

INTERMEDIATE ALIGNMENT:

1. Connect the high side of the oscillator output to the control grid of the 6A7 tube. Leave the grid cap disconnected and connect a 1 meg ohm resistor from the modulator grid to the chassis base. Connect the ground side of the oscillator to the receiver ground lead.

2. Set the test oscillator frequency to 465 kilocycles (this must be accurate).

3. Align the first intermediate transformer by turning one of the trimmer screws up and down (increasing and decreasing capacity) until maximum reading is obtained on the output meter, after which adjust the other trimmer screw of the same transformer for maximum sensitivity.

4. Adjust the other intermediate transformers in the same manner.

NOTE: Two types of intermediate transformer trimmers have been used in this receiver. One type has two parallel holes in the top of the shield, one for each trimmer. The other type has a brass hex nut for adjusting one trimmer, the other intermediate trimmer being adjusted with the trimmer screw located inside of the brass hex nut. Regardless of which type trimmer is used the procedure is the same.

5. Adjust the IF regeneration trimmer located underneath the chassis for maximum 465 kilocycle signal sensitivity. If adjustment of this trimmer causes the receiver to oscillate always adjust to a point where oscillation just stops, and then back off 1/8 turn.

TO ALIGN THE VARIABLE CONDENSER: It is important when aligning the gang condenser and padding and trimmer condensers to follow the procedure given carefully, otherwise the receiver will be insensitive and the dial calibration will be incorrect. The two coils located on the underside of the chassis which have trimmer condensers mounted on them will be referred to by their function as indicated on the circuit diagram.

1. Connect the high output side of the test oscillator through a .00025 Mfd. condenser to the set antenna lead and the ground to the set ground.

2. Place the band selector switch for operation on the 15.8 to 5.6 megacycle band, tune the receiver to EXACTLY 14 MEGACYCLES on the dial, and set the test oscillator frequency to EXACTLY 14 MEGACYCLES. THEN BRING IN THE 14 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING THE TRIMMER CONDENSER LOCATED ON TOP OF THE OSCILLATOR SECTION OF THE GANG CONDENSER. Looking at the front of the receiver the oscillator section is the rear section of the gang condenser. When adjusting this trimmer two peaks, the fundamental and the image peak, will be noticed. CARE MUST BE TAKEN SO THAT THE FUNDAMENTAL PEAK AND NOT THE IMAGE PEAK IS USED FOR ALIGNING THE RECEIVER AT 14 MEGACYCLES. First back off the trimmer to minimum capacity, next screw down the trimmer (add capacity) until the first peak, which is the fundamental and the one you are to use, is tuned in. If the trimmer is screwed down beyond the point where this first peak is received the incorrect image peak will be tuned in. When the first peak has been located adjust the trimmer to bring in the 14 megacycle signal to maximum output. After completing this adjustment always check to see if the proper peak has been used. To do this leave the test oscillator frequency at 14 megacycles, increase the output of the test oscillator and then tune the receiver dial to approximately 13 megacycles. Vary the receiver dial slightly to the right and left of 13 megacycles and if the fundamental peak was used in aligning at 14 megacycles the test oscillator signal will be heard at approximately 13 megacycles on the receiver dial. If it is not possible to receive the signal then the fundamental peak was not used and the 14 megacycle adjustment of the trimmer on top of the oscillator section of the gang condenser must be gone over and properly adjusted.

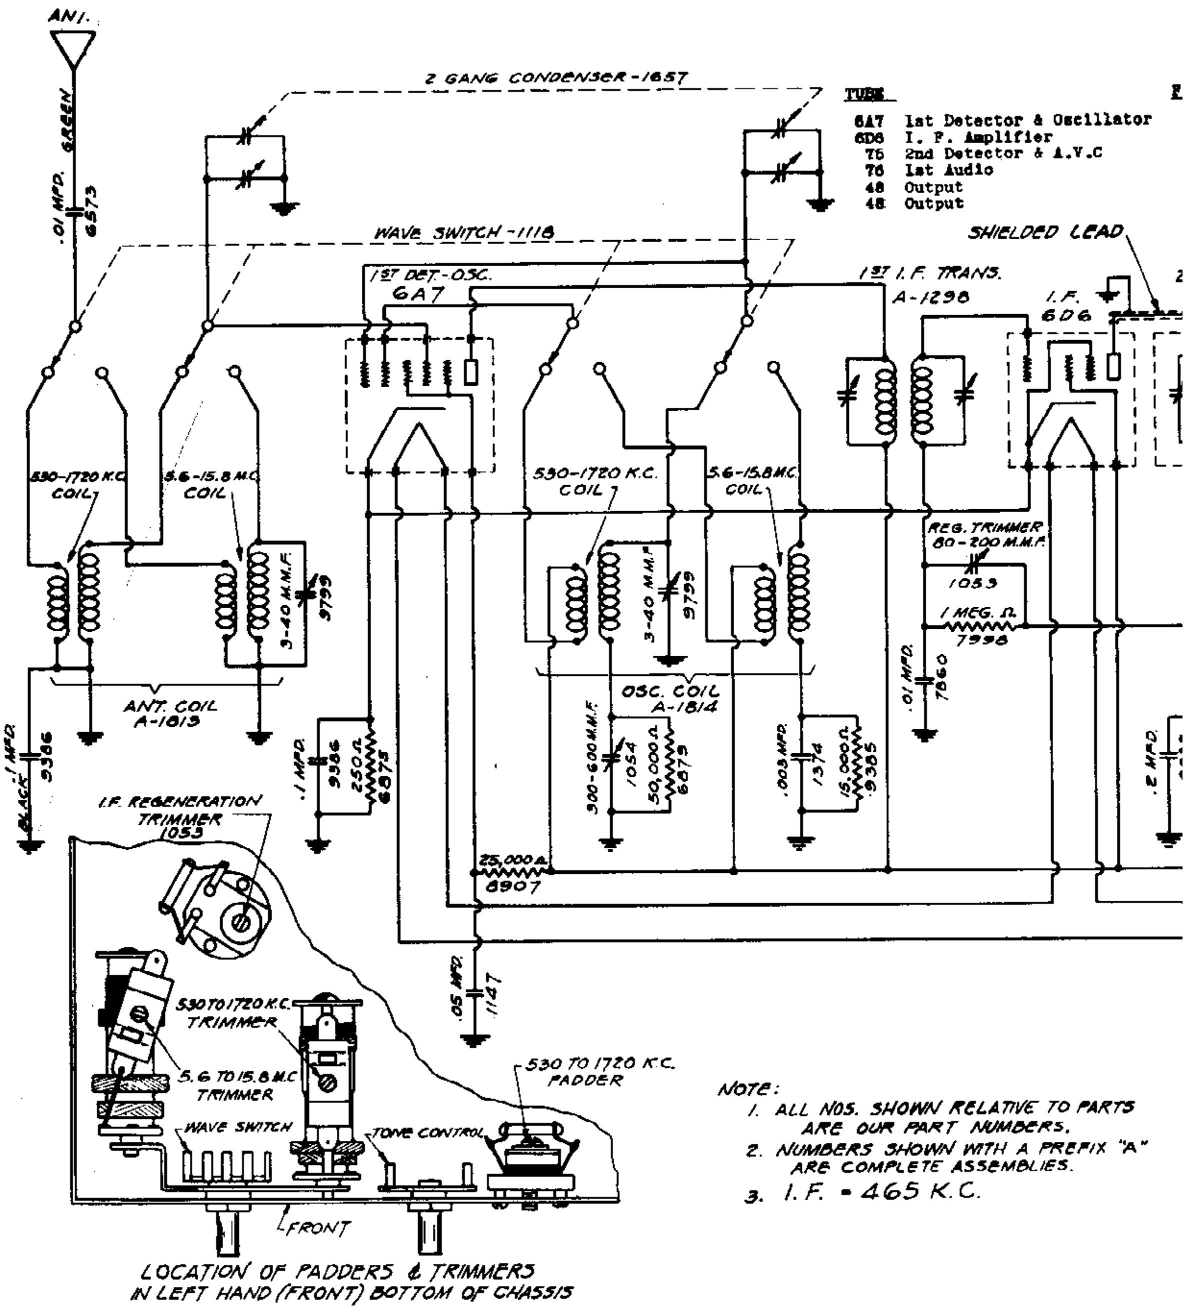
3. Set the band selector switch for operation on the broadcast band (1720-530 K.C.) adjust the test oscillator frequency to EXACTLY 1400 KILOCYCLES and the receiver dial to EXACTLY 1400 KILOCYCLES. THEN BRING IN THE 1400 KILOCYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING THE 1720-530 KILOCYCLE TRIMMER (see circuit diagram) mounted on one of the coils located underneath the chassis. Next adjust the trimmer located on the front section of the gang condenser for maxim m 1400 kilocycle signal sensitivity.

4. Leave the band selector switch for operation on the broadcast band (1720-530 K.C.), tune the receiver dial and set the test oscillator frequency to approximately 600 kilocycles. While rocking the gang condenser slightly to the right and left adjust the 1720-530 kilocycle padder condenser which is located on and accessible through the small hole in the front of the chassis, for maximum sensitivity.

5. Recheck the 1400 kilocycle signal adjustment.

6. Place the band selector switch for operation on the short wave 15.8 to 5.6 megacycle band, set the test oscillator frequency to EXACTLY 14 MEGACYCLES and tune the receiver to EXACTLY 14 MEGACYCLES. While rocking the gang condenser slightly to the right and left adjust the 5.6 to15.8 megacycle trimmer (see circuit diagram) mounted on one of the coils underneath the chassis.

This completes the alignment and it is recommended that all the adjustments be gone over again, as generally it will be found that improved results can be obtained if this is done. Assuming that all tubes and component parts of the set are okeh, then extreme inaccuracies in the dial calibration, low sensitivity, and poor selectivity are indications that the alignment procedure has not been followed.



The power plug attached to the end of the power cord must be inserted correctly in the 32 volt power supply outlet or receptacle, otherwise the set will not operate. If after inserting the plug and turning the receiver on the set does not operate after approximately two minutes, remove the plug and turn it half way around and reinsert it in the power receptacle.

FUSE: A 3 ampere fuse is located on the back of the chassis adjacent to the speaker plug and protects the receiver from damage should a defect occur in the set or if it is connected to the improper power supply. Continued burning out of fuses on the proper power supply is indicative of some defect and the receiver shou be referred to your dealer for examination. THE WARRANTY IS VOID IF THE RECEIVER IS OPERATED WITH THE FUSE SHORTED OUT OR WITH A FUSE LARGER THAN 3 AMPERES.

ANTENNA: Always make the antenna as long as possible consistent with satisfactory selectivity. In most installations an antenna from 35 to 75 feet in length including lead-in will be ample. In isolated communitie where distant daylight reception is desired it may be necessary to increase this so as to obtain good satisfactory daylight reception. As considerable radio interference (static noise) may be picked up when the generator is charging the battery if the aerial or lead-in are run parallel to the 32 volt power lines, the aerial and the lead-in should always be placed as far away from the 32 volt lighting lines as possible. This is not a reflection on the receiver nor does it indicate a defect, as the interference is caused by the generator. Some plant generators have built-in traps which effectively eliminate this interference. The aerial should be connected to the green lead coming out at the rear of the chassis.

GROUND: It is important that a good ground be used. A good ground clamp should be attached to a cold water pipe, or if no cold water pipe is available an iron pipe driven in the ground three or four feet in a place where it is moist will be satisfactory. Connect the ground to the black lead coming out at the rear of the chassis.

SERVICE NOTES
FOR THE
BATTERY OPERATED
SEVEN TUBE SUPERHETERODYNE RECEIVER

ALIGNMENT PROCEDURE: FOR PROPERLY ALIGNING EITHER THE INTERMEDIATE TRANSFORMER OR THE GANG CONDENSER IT IS NECESSARY THAT AN ACCURATELY CALIBRATED TEST OSCILLATOR BE USED WITH SOME TYPE OF OUTPUT MEASURING DEVICE.

INTERMEDIATE ALIGNMENT:

1. CONNECT THE HIGH SIDE OF THE TEST OSCILLATOR OUTPUT TO THE CONTROL GRID OF THE 1C6 TUBE LEAVING THE GRID CAP DISCONNECTED. CONNECT THE GROUND SIDE OF THE TEST OSCILLATOR TO THE RECEIVER CHASSIS.

2. SET THE TEST OSCILLATOR FREQUENCY TO 465 KILOCYCLES (THIS MUST BE ACCURATE).

3. ALIGN THE FIRST INTERMEDIATE TRANSFORMER BY TURNING ONE OF THE TRIMMER SCREWS UP AND DOWN UNTIL MAXIMUM READING IS OBTAINED ON THE OUTPUT METER, AND THEN ADJUST THE OTHER TRIMMER SCREW OF THE SAME TRANSFORMER FOR MAXIMUM SENSITIVITY.

4. ADJUST THE SECOND INTERMEDIATE TRANSFORMER IN THE SAME MANNER.

NOTE: TWO TYPE INTERMEDIATE TRANSFORMER TRIMMERS HAVE BEEN USED IN THIS RECEIVER. ONE TYPE HAS TWO PARALLEL HOLES IN THE TOP OF THE SHIELD, ONE FOR EACH TRIMMER. THE OTHER TYPE HAS A BRASS HEX NUT FOR ADJUSTING ONE TRIMMER, THE OTHER INTERMEDIATE TRIMMER BEING ADJUSTED WITH THE SCREW LOCATED INSIDE OF THE BRASS HEX NUT. REGARDLESS OF WHICH TYPE TRIMMER IS USED THE PROCEDURE IS THE SAME.

TO ALIGN THE VARIABLE CONDENSER: IT IS IMPORTANT WHEN ALIGNING TO FOLLOW THE PROCEDURE CAREFULLY, OTHERWISE THE RECEIVER WILL LACK SENSITIVITY AND THE DIAL CALIBRATION WILL BE INCORRECT.

1. CONNECT THE HIGH OUTPUT SIDE OF THE TEST OSCILLATOR TO THE RECEIVER ANTENNA LEAD AND THE GROUND TO THE CHASSIS.

2. PLACE THE BAND SELECTOR SWITCH FOR OPERATION ON THE SHORT WAVE BAND, TUNE THE RECEIVER TO EXACTLY 15 MEGACYCLES ON THE DIAL, AND SET THE TEST OSCILLATOR FREQUENCY TO EXACTLY 15 MEGACYCLES. THEN TUNE IN THE 15 MEGACYCLE SIGNAL BY ADJUSTING THE TRIMMER MOUNTED ON TOP OF THE OSCILLATOR SECTION OF THE GANG CONDENSER TO MAXIMUM OUTPUT. LOOKING AT THE FRONT OF THE RECEIVER THE OSCILLATOR SECTION IS THE REAR SECTION OF THE GANG CONDENSER.

3. SET THE BAND SELECTOR SWITCH FOR OPERATION ON THE BROADCAST BAND, ADJUST THE TEST OSCILLATOR FREQUENCY TO 1400 KILOCYCLES AND SET THE RECEIVER DIAL TO EXACTLY 1400 KILOCYCLES. NEXT, BRING IN THE 1400 KILOCYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING THE TRIMMER LOCATED UNDERNEATH AND NEAR THE CENTER FRONT OF THE CHASSIS.

4. AFTER MAKING THIS ADJUSTMENT TUNE THE DIAL TO 1720 KILOCYCLES AND SET THE TEST OSCILLATOR FREQUENCY TO 1720 KILOCYCLES. IF THE 1720 KILOCYCLE SIGNAL CANNOT BE RECEIVED REDUCE THE 1400 KILOCYCLE TRIMMER CAPACITY UNTIL THE 1720 KILOCYCLE SIGNAL IS BROUGHT IN.

5. NEXT, SET THE RECEIVER DIAL AND TEST OSCILLATOR TO EXACTLY 1400 KILOCYCLES, AND ADJUST THE TRIMMER LOCATED ON THE FRONT SECTION OF THE GANG CONDENSER FOR MAXIMUM SENSITIVITY.

6. LEAVE THE BAND SELECTOR SWITCH FOR OPERATION ON THE BROADCAST BAND, TUNE THE RECEIVER, AND SET THE TEST OSCILLATOR TO APPROXIMATELY 600 KILOCYCLES. THEN ADJUST THE 600 KILOCYCLE PADDING CONDENSER, WHICH IS LOCATED ON AND ACCESSIBLE THROUGH THE SMALL HOLE IN THE FRONT OF THE CHASSIS, FOR MAXIMUM SENSITIVITY. AS THIS ADJUSTMENT IS QUITE CRITICAL IT IS NECESSARY TO ROCK THE CONDENSER SLIGHTLY TO THE RIGHT AND LEFT TO FIND THE POINT OF GREATEST SENSITIVITY.

7. PLACE THE BAND SELECTOR SWITCH FOR OPERATION ON THE SHORT WAVE BAND, ADJUST THE TEST OSCILLATOR FREQUENCY TO EXACTLY 15 MEGACYCLES AND SET THE RECEIVER DIAL TO 15 MEGACYCLES. TURN THE RECEIVER ON ITS BACK WITH THE DIAL UP AND ADJUST THE TRIMMER, WHICH IS MOUNTED ON THE TOP OF THE COIL UNDERNEATH AND NEAR THE RIGHT HAND SIDE OF THE CHASSIS, FOR MAXIMUM OUTPUT. BE SURE TO ROCK THE CONDENSER SLIGHTLY TO THE RIGHT AND LEFT WHEN MAKING THIS ADJUSTMENT.

THIS COMPLETES THE ALIGNMENT PROCEDURE. IT IS RECOMMENDED THAT ALL OF THE ADJUSTMENTS BE GONE OVER AGAIN. GENERALLY IT WILL BE FOUND THAT IMPROVED RESULTS CAN BE OBTAINED IF THIS IS DONE.

VOLTAGE TABLE

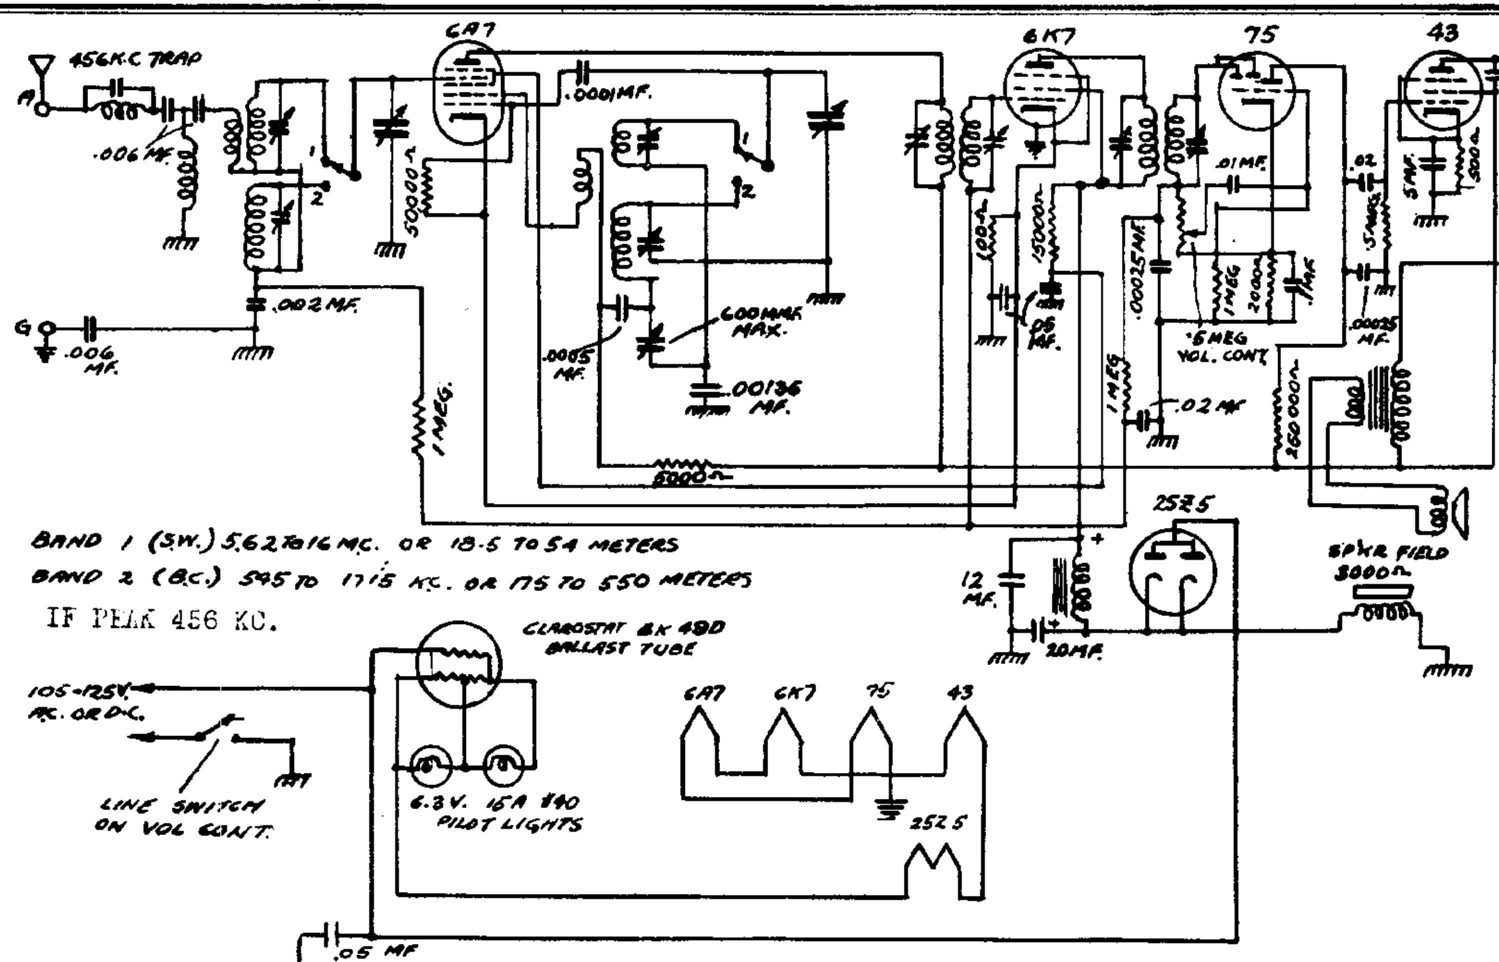
43	audio outp.	20.2	94.0	100.0	12.3	----
25Z5	rectifier	21.0	114.0	---	---	----

NOTE: Fil. voltages measured with a low impedance A.C. voltmeter. Actually, the voltages at 110V line are approximately 6 volts and 23 volts for the 6.3, and 25 volt tubes respectively.



I.F. ADJUSTMENT - The signal generator is set at 456 kc. The "hot" lead from the signal generator is connected to the grid cap on the 1st detector (6A7) tube, the clip having first been removed from the tube cap. The ground lead is connected to the receiver chassis. The oscillator section (front) of the gang tuning condenser is short-circuited and the volume control turned on full. The i.f. trimmers are then adjusted for maximum gain in the receiver. These trimmers are located on top of the i.f. transformer shield cans, which are situated in the rear of the chassis. The one towards the right is the 1st. i.f. transformer and the left one is the 2nd i.f. transformer.

15 MEGACYCLE ADJUSTMENT - The short-circuit is removed from the oscillator condenser and the grid clip replaced in its normal position on the cap of the 6A7 tube. The "hot" lead from the signal generator is connected to the antenna lead of the receiver and the ground lead to the ground of the receiver.With the volume control set at maximum and a minimum input signal from the signal generator, the band switch is turned to the left and the receiver dial set at 15 mc. The oscillator trimmer is adjusted so as to bring the signal in at this setting. The oscillator coil is underneath the chassis and is located directly under the variable gang condenser. The short wave trimmer is over the short wave winding (Heavy spaced wire).

After the oscillator is set, the antenna trimmer is adjusted for maximum output as indicated by the output meter. (Again the S. W. antenna trimmer is located over the heavy spaced winding on the antenna coil, and is accessible from the top of the chassis). There are no other adjustments on this band.

1400 KC KILOCYCLE ADJUSTMENT Turn the Wave Band Switch to the right. Set the signal generator to 1400 kc. and turn the dial pointer to correspond to this frequency. Adjust the oscillator trimmer for this band so that the signal is received exactly at this setting. (This trimmer is located over the close-wound fine winding on the oscillator coil). Adjust the Broadcast antenna trimmer for maximum output as described previously, (this trimmer is over the small 5 section winding and is accessible from the top).

600 KC PADDER ADJUSTMENT - With all connections as above, the signal generator is set at 600 KC and the signal tuned in on the dial. The padder for this frequency is found on the front sub-panel of the receiver, directly under the dial. This padder should be adjusted for maximum response of the receiver, while the tuning condenser is rocked slightly back and forth. The 1400 kc adjustment should then be rechecked.

SERVICE NOTES FOR THE MODEL 33, 33LW, 31, 31LW, 32, 32LW
7 TUBE 3 BAND A.C.-D.C. SUPERHETERODYNE RECEIVERS
ALIGNMENT PROCEDURE

Realignment of this receiver should not be attempted unless all other possible causes of faulty operation have first been thoroughly investigated. An accurately calibrated signal generator which will cover the various wave-bands, and an output meter for indicating the effects of adjustments, are required.

MODEL 33LW, 31LW, 32LW

I.F.ADJUSTMENT - The signal generator is set at 456 kc. The "hot" lead from the signal generator is connected to the grid cap on the 1st detector (6A7) tube, the clip having first been removed from the tube cap. The ground lead is connected to the receiver gnd. post. The oscillator section (front) of the gang tuning condenser is short-circuited and the volume control turned on full. The i.f. trimmers are then adjusted for maximum gain in the receiver. These trimmers are located on top of the i.f. transformer shield cans, which are situated in the rear of the chassis, to the left. The one nearest the front is the 1st i.f. transformer and the rear one is the 2nd i.f. transformer.

16 MEGACYCLE ADJUSTMENT - The short-circuit is removed from the oscillator condenser and the grid clip replaced in its normal position on the cap of the 6A7 tube. The "hot" lead fron the signal generator is connected to the antenna post of the receiver and the ground lead to the ground post of the receiver. With the volume control set at maximum and a minimum input signal from the signal generator, the band switch is set at position no. 1 and the receiver dial set at 16 mc. The oscillator trimmer is adjusted s as to bring the signal in at this setting. This trimmer is found on the side of the oscillator coil shield can which is located directly in front of the i.f. transformers. The upper trimmer is the one for this wave-band. After the oscillator is adjusted, the antenna trimmer is adjusted for maximum output. This is found on the front of the antenna coil can which is directly in front of the 6A7 tube. The lower trimmer is the one for this band. There are no other adjustments on this band.

1400 KILOCYCLE ADJUSTMENT - With the receiver and signal generator both set at 1400 kc. the procedure outlined above is repeated. The trimmers are adjusted for maximum gain of the receiver. These trimmers are located on the coil shield cans; the oscillator trimmer for this band is the bottom one on the oscillator can; the detector trimmer, is the upper one on the detector or antenna coil can. The 600 kc. padder is on the front sub-panel.

600KC PADDER ADJUSTMENT - With all connections as above, the signal generator is set at 600KC and the signal tuned in on the dial. The paddor for this frequency is found on the front sub-panel of the receiver, directly under the wave band switch. This padder should be adjusted for maximum response of the receiver, while the tuning condenser is rocked slightly back and forth. The 1400 kc adjustment should then be rechecked.

LONG WAVE ADJUSTMENT - With the receiver and signal generator both set at 325 kc. the procedure outlined above is repeated. The trimmers are located on the left side panel of the chassis; the one towards the rear is the oscillator trimmer, and the one near the front is the antenna trimmer. The series padder for this band is located in the lower left hand corner of the front sub-panel.

MODEL 31 - 32 - 33

The alignment procedure for the Model 32 - 32LW is exactly the same as for the model 33LW, 31LW except for the location of the trimmers, and the designation of the bands. These are as follows:

Short wave band - Oscillator trimmer is the upper one on the oscillator coil can.
Antenna trimmer is the lower one on the antenna coil can.
No series padder.

Broadcast band - Oscillator trimmer is the lower one on the antenna coil can.
Antenna trimmer is the upper one on the antenna coil can.
600 kc. series padder is on the top of the chassis directly in front of the oscillator coil.

Police band -- Trimmers are on the left side panel of the chassis. The one towards the rear is the oscillator shunt trimmer; the one towards the front is the antenna shunt trimmer.

NOTE: These bands must be aligned in the sequence shown.

VOLTAGE TABLE

TUBE	FUNCTION	H'T'R	PLATE	SC.GR	CATH.	OSC.PL.
6A7	det.-osc.	4.5	100.2	47.0	---	90.0
6K7	i.f. ampl.	4.3	100.2	47.0	---	---
6H6	diode det.	4.5	---	---	---	---
6F5	1st audio	4.4	40.0	---	---	---
43	audio outp.	20.2	94.0	100.0	12.3	---
25Z5	rectifier	21.0	114.0	---	---	---

NOTE: Fil. voltages measured with a low impedance AC-voltmeter. Actually, the voltages at 110V line are approximately 6 volts and 23 volts for the 6, 3, and 2 volt tubes respectively.

Model 32 exactly same as Model 31, but 600 kc. padder is located on the left front of the chassis. Model 32LW same as 31LW.

SERVICE NOTES FOR THE MODEL 49M
10 TUBE 4 BAND A.C. SUPERHETERODYNE RECEIVER
ALIGNMENT PROCEDURE

Realignment of this receiver should not be attempted unless all other possible causes of faulty operation have been thoroughly investigated. An accurately calibrated signal generator which will cover the necessary wave-bands and an output meter for indicating the effect of adjustments are required.

It is important to remember that in receivers of this kind which are equipped with automatic volume control it is necessary to use the minimum possible signal from the signal generator; otherwise the A.V.C. action will tend to nullify the variations in output as the trimmers are adjusted.

I.F. ADJUSTMENT - The signal generator is set at 456 kc. and is connected to the grid of the first detector (6A7). With the oscillator section of the tuning condenser short-circuited and the receiver volume control at its maximum position, the i.f. trimmers are adjusted for maximum output. These trimmers may be found on the i.f. transformer shield cans in the rear of the chassis to the right and rear of the gang condenser.

18 MEGACYCLE ADJUSTMENT - The high side of the signal generator is connected to the antenna lead of the receiver and the low side to the ground lead. The receiver and the signal are both tuned to a frequency of 18 mc. with the selector switch in position for band no. 1. The oscillator trimmer condenser is adjusted so that the 18 mc signal is tuned in exactly as the 18 mc calibration point, with the volume control on full and the signal generator adjusted for minimum input. The antenna preselector and first detector trimmers are then adjusted in the order named for maximum output. These trimmers are located on the tops of the shield cans at the left side of the chassis; reading from front to back, these coils are as follows: 1. antenna preselector; 2. first detector; 3. oscillator. It will be noted that there are four trimmers on each of these coils. The adjustment screw for the trimmer in the front left hand corner of each is painted red. This denote the trimmer for the no. 1 band.

5 MC. ADJUSTMENT - With the band selector switch in position for operation on band no. 2. and the receiver and signal generator both set at 5 mc. the procedure outlined above is repeated. The oscillator trimmer is found on the rear coil can, and is located to the right of the red painted trimmer. The antenna preselector and interstage coil trimmers are located in the same positions on the corresponding shield cans.

The signal generator is set at 1.7 mc. and the signal tuned in on the dial. The padder condenser for this band is adjusted for maximum gain while the gang tuning condenser is rocked slightly to the right and left. The 5 mc. adjustment should then be rechecked. The 1.7 mc. Padder is located on the sub-base on which the gang tuning condenser is mounted and is the left hand one at the group of three found here.

1400 KC. ADJUSTMENT - The band selector switch is set in position for operation on the no. 4 band. The receiver and signal generator are both set at 1400 kc. and the procedure outlined above is repeated. The oscillator trimmer is found on the rear coil can, and is located diagonally opposite the red painted trimmer. The other trimmers for this band are located in similar positions on the corresponding coil cans.

The signal generator is set at 600 kc. and the signal tuned in on the dial. The padder condenser for this band is adjusted for maximum response while the gang tuning condenser is rocked slightly to the right and left. The 1400 kc. adjustment should then be rechecked. The 600 kc. padder is located on the sub-panel on which the gang tuning condenser is mounted and is the center of the three located at this point.

340 KC. ADJUSTMENT - The band selector switch is set in position for operation on band no. 4. The receiver and generator are both tuned to 340 kc. and the procedure outlined above is repeated. The oscillator trimmer is located on the rear coil can. It is the one directly behind the trimmer marked in red. The other trimmers for this band are located in similar positions on the corresponding shield cans.

The signal generator is set at 150 kc. and the signal is tuned in on the dial. The padder condenser for this band is adjusted for maximum response while the gang tuning condenser is rocked slightly to the right and left. The 340 kc. adjustment should then be rechecked. The 150 kc. padder is located on the sub-panel on which the tuning condenser is mounted and is the right hand one of this group.

ALIGNMENT PROCEDURE

Realignment of this receiver should not be attempted unless all other possible causes of faulty operation have been thoroughly investigated. An accurately calibrated signal generator which will cover the necessary wave-bands and an output meter for indicating the effect of adjustments are required.

It is important to remember that in receivers of this kind which are equipped with automatic volume control it is necessary to use the minimum possible signal from the signal generator; otherwise the A.V.C. action will tend to nullify the variations in output as the trimmers are adjusted.

I.F. ADJUSTMENT - The signal generator is set at 456 kc. and is connected to the grid of the first detector (6A7). With the oscillator section of the tuning condenser short-circuited and the receiver volume control at its maximum position, the i.f. trimmers are adjusted for maximum output. These trimmers may be found on the i.f. transformer shield cans to the right and rear of the gang condenser.

18 MEGACYCLE ADJUSTMENT - The high side of the signal generator is connected to the antenna lead of the receiver and the low side to the ground lead. The receiver and the signal are both tuned to a frequency of 18 mc. with the selector switch in position for band no. 1. The oscillator trimmer condenser is adjusted so that the 18 mc signal is tuned in exactly at the 18 mc calibration point, with the volume control on full and the signal generator adjusted for minimum input. The antenna preselector and first detector trimmers are then adjusted in the order named for maximum output. These trimmers are located on the tops of the shield cans at the left side of the chassis; reading from front to back, these coils are as follows: - 1. antenna preselector; 2. first detector; 3. oscillator. It will be noted that there are four trimmers on each of these coils. The adjustment screw for the trimmer in the front left hand corner of each is painted red. This denotes the trimmer for the no. 1. band.

5 MC. ADJUSTMENT - With the band selector switch in position for operation on band no. 2. and the receiver and signal generator both set at 5 mc. the procedure outlined above is repeated. The oscillator trimmer is found on the rear coil can, and is located to the right of the red painted trimmer. The antenna preselector and interstage coil trimmers are located in the same positions on the corresponding shield cans.

The signal generator is set at 1.7 mc. and the signal tuned in on the dial. The padder condenser for this band is adjusted for maximum gain while the gang tuning condenser is rocked slightly to the right and left. The 5 mc. adjustment should then be rechecked. The 1.7 mc. Padder is located on the subbase on which the gang tuning condenser is mounted and is the left hand one at the group of three found here.

1400 KC. ADJUSTMENT - The band selector switch is set in position for operation on the no. 3. band. The receiver and signal generator are both set at 1400 kc. and the procedure outlined above is repeated. The oscillator trimmer is found on the rear coil can, and is located diagonally opposite the red painted trimmer. The other trimmers for this band are located in similar positions on the corresponding coil cans.

CURRENT: This receiver operates on either alternating or direct current of any frequency.

VOLTAGE: Any line voltage from 105-135 volts may be used, without necessity of any adjustments. An adapter for 210-240 volt operation is available and can be supplied at an additional cost.

The signal generator is set at 600 kc. and the signal tuned in on the dial. The padder condenser for this band is adjusted for maximum response while the gang tuning condenser is rocked slightly to the right and left. The 1400 kc. adjustment should then be rechecked. The 600 kc. padder is located on the sub-panel on which the gang tuning condenser is mounted and is the center of the three located at this point.

340 KC. ADJUSTMENT - The band selector switch is set in position for operation on band no. 4. The receiver and generator are both tuned to 340 kc. and the procedure outlined above is repeated. The oscillator trimmer is located on the rear coil can. It is the one directly behind the trimmer marked in red. The other trimmers for this band are located in similar positions on the corresponding shield cans.

The signal generator is set at 150 kc. and the signal is tuned in on the dial. The padder condenser for this band is adjusted for maximum response while the gang tuning condenser is rocked slightly to the right and left. The 340 kc. adjustment should then be rechecked. The 150 kc. padder is located on the sub-panel on which the tuning condenser is mounted and is the right hand one of this group.

12 TUBE 5 BAND A.C.-D.C. SUPERHETERODYNE RECEIVER
ALIGNMENT PROCEDURE

Realignment of this receiver should not be attempted unless all other possible causes of faulty operation have been thoroughly investigated. An accurately calibrated signal generator which will cover the necessary wave-bands and an output meter for indicating the effect of adjustments are required.

It is important to remember that in receivers of this kind which are equipped with automatic volume control it is necessary to use the minimum possible signal from the signal generator; otherwise the avc action will tend to nullify the variations in output as the trimmers are adjusted. A surer method is to make the avc tube inoperative. This may be done by shorting return of RF trimmers to ground.

I.F. ADJUSTMENT - The signal generator is set at 456 kc. and is connected to the grid of the first detector (6A7). With the oscillator section of the tuning condenser short-circuited and the receiver volume control at its maximum position, the i.f. trimmers are adjusted for maximum output. These trimmers may be found on the i.f. transformer shield cans in the rear of the chassis. The third i.f. transformer has only one trimmer. This is the one at the left rear of the chassis. The other two transformers have two trimmers each.

18 MEGACYCLE ADJUSTMENT - The high side of the signal generator is connected to the antenna lead of the receiver and the low side to the ground lead. The receiver and the signal are both tuned to a frequency of 18 mc. with the selector switch in position for band no. 2. The oscillator trimmer condenser is adjusted so that the 18 mc. signal is tuned in exactly at the 18 mc. calibration point, with the volume control on full and the signal generator adjusted for minimum input. The antenna preselector and first detector trimmers are then adjusted in the order named for maximum output. These trimmers are located on the tops of the shield cans at the left side of the chassis; reading from front to back, these coils are as follows: 1. antenna preselector; 2. first detector; 3. oscillator. It will be noted that there are four trimmers on each of these coils. The adjustment screw for the trimmer in the front left hand corner of each is painted red. This denotes the trimmer for the no. 2 band.

36 MEGACYCLE ADJUSTMENT - With the band switch in position for the no. 1 band, the receiver and signal generator are both set at 36 mc. and the procedure outlined above is repeated. There is no oscillator trimmer for this band, a harmonic from the no. 2 band of the oscillator being used. The trimmer for the preselector stage is located on the underside of the chassis near the front and center. The first detector or interstage trimmer is located behind the band selector switch, also on the underside of the chassis.

5 MC. ADJUSTMENT - With the band selector switch in position for operation on band no. 3, and the receiver and signal generator both set at 5 mc. the procedure outlined above is repeated. The oscillator trimmer is found on the rear coil can, and is located to the right of the red painted trimmer. The antenna preselector and interstage coil trimmers are located in the same positions on the corresponding shield cans

The signal generator is set at 1.7 mc. and the signal tuned in on the dial. The padder condenser for this band is adjusted for maximum gain while the gang tuning condenser is rocked slightly to the right and left. The .5 mc. adjustment should then be rechecked. The 1.7 mc. Padder is located on the subbase on which the gang tuning condenser is mounted and is the left hand one at the group of three found here.

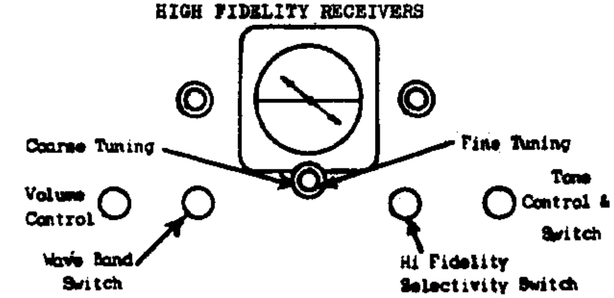
1400 KC. ADJUSTMENT - The band selector switch is set in position for operation on the no. 4 band. The receiver and signal generator are both set at 1400 kc. and the procedure outlined above is repeated. The oscillator trimmer is found on the rear coil can, and is located diagonally opposite the red painted trimmer. The other trimmers for this band are located in similar positions on the corresponding coil cans.

The signal generator is set at 600 kc. and the signal tuned in on the dial. The padder condenser for this band is adjusted for maximum response while the gang tuning condenser is rocked slightly to the right and left. The 1400 kc. adjustment should then be rechecked. The 600 kc. padder is located on the sub-panel on which the gang tuning condenser is mounted and is the center of the three located at this point.

340 KC. ADJUSTMENT - The band selector switch is set in position for operation on band no. 4. The receiver and generator are both tuned to 340 kc. and the procedure outlined above is repeated. The oscillator trimmer is located on the rear coil can. It is the one directly behind the trimmer marked in red. The other trimmers for this band are located in similar positions on the corresponding shield cans.

The signal generator is set at 150 kc. and the signal is tuned in on the dial. The padder condenser for this band is adjusted for maximum response while the gang tuning condenser is rocked slightly to the right and left. The 340 kc. adjustment should then be rechecked. The 150 kc. padder is located on the sub- panel on which the tuning condenser is mounted and is the right hand one of this group.

MODELS #511 "A" and #511 "G" CONSOLE and #511 "P" COMBINATION HIGH FIDELITY RECEIVERS



INSTRUCTIONS FOR INSTALLATION AND OPERATION

CURRENT: This receiver operates on AC (Alternating Current) only, on frequencies from 50 to 60 cycles.

VOLTAGE: Any line voltage from 105 to 260 volts may be used. This model is equipped with a universal Transformer, with five taps marked as follows:- 110, 135, 150, 220, 260. Access to this tap changer is obtained by lifting off the box-like black cover on top of the transformer. The lug attached to the flexible lead is then moved to the point which corresponds most nearly to the line voltage available. The cover is then snapped back into place. Unless otherwise specified, the receiver is always connected to the 110 volt tap (suitable for 105 to 125 volts). Before inserting the line plug, be sure to ascertain what the line voltage is and connect to the correct tap.

PHONOGRAPH OPERATION: When the radio volume control is turned all the way to "OFF" position the phonograph pickup automatically connected into circuit. Turn motor switch ON, and the phonograph is ready for operation. Phonograph volume is regulated by means of a separate control located in the base of the phonograph pickup arm. The tone of the phonograph reproduction may be controlled in the same way as for radio operation.

SERVICE NOTES FOR THE MODEL 514
14 TUBE 5 BAND A.C.-D.C. SUPERHETERODYNE RECEIVER

ALIGNMENT PROCEDURE

I.F.ADJUSTMENT - The signal generator is set at 456 kc. and is connected to the grid of the first detector (6A7). With the oscillator section of the tuning condenser short-circuited and the receiver volume control at its maximum position, the i.f. trimmers are adjusted for maximum output. These trimmers may be found on the i.f. transformer shield cans in the rear of the chassis. The third i.f. transformer has only one trimmer. This is the one at the left rear of the chassis. The other two transformers have two trimmers each.

18 MEGACYCLE ADJUSTMENT - The high side of the signal generator is connected to the antenna lead of the receiver and the low side to the ground lead. The receiver and the signal are both tuned to a frequency of 18 mc. with the selector switch in position for band no. 2. The oscillator trimmer condenser is adjusted so that the 18 mc signal is tuned in exactly as the 18 mc calibration point, with the volume control on full and the signal generator adjusted for minimum input. The antenna preselector and first detector trimmers are then adjusted in the order named for maximum output. These trimmers are located on the tops of the shield cans at the left side of the chassis; reading from front to back, these coils are as follows: - 1. antenna preselector; 2. first detector; 3. oscillator. It will be noted that there are four trimmers on each of these coils. The adjustment screw for the trimmer in the front left hand corner of each is painted red. This denote the trimmer for the no. 2 band.

36 MEGACYCLE ADJUSTMENT - With the band switch in position for the no. 1 band, the receiver and signal generator are both set at 36 mc. and the procedure outlined above is repeated. There is no oscillator trimmer for this band, a harmonic from the no. 2 band of the oscillator being used. The trimmer for the preselector stage is located on the underside of the chassis near the front and center. The first detector or interstage trimmer is located behind the band selector switch, also on the underside of the chassis.

5.2 MC. ADJUSTMENT - With the band selector switch in position for operation on band no. 3. and the receiver and signal generator both set at 5.2 mc. the procedure outlined above is repeated. The oscillator trimmer is found on the rear coil can, and is located to the right of the red painted trimmer. The antenna preselector and interstage coil trimmers are located in the same positions on the corresponding shield cans.

The signal generator is set at 1.7 mc. and the signal tuned in on the dial. The padder condenser for this band is adjusted for maximum gain while the gang tuning condenser is rocked slightly to the right and left. The 5.2 mc. adjustment should then be rechecked. The 1.7 mc. Padder is located on the subbase on which the gang tuning condenser is mounted and is the left hand one at the group of three found here.

1400 KC. ADJUSTMENT - The band selector switch is set in position for operation on the no. 4 band. The receiver and signal generator are both set at 1400 kc. and the procedure outlined above is repeated. The oscillator trimmer is found on the rear coil can, and is located diagonally opposite the red painted trimmer. The other trimmers for this band are located in similar positions on the corresponding coil cans.

The signal generator is set at 600 kc. and the signal tuned in on the dial. The padder condenser for this band is adjusted for maximum response while the gang tuning condenser is rocked slightly to the right and left. The 1400 kc. adjustment should then be rechecked. The 600 kc. padder is located on the sub-panel on which the gang tuning condenser is mounted and is the center of the three located at this point.

340 KC. ADJUSTMENT - The band selector switch is set in position for operation on band no. 4. The receiver and generator are both tuned to 340 kc. and the procedure outlined above is repeated. The oscillator trimmer is located on the rear coil can. It is the one directly behind the trimmer marked in red. The other trimmers for this band are located in similar positions on the corresponding shield cans.

The signal generator is set at 140 kc. and the signal is tuned in on the dial. The padder condenser for this band is adjusted for maximum response while the gang tuning condenser is rocked slightly to the right and left. The 340 kc. adjustment should then be rechecked. The 140 kc. padder is located on the sub-panel on which the tuning condenser is mounted and is the right hand one of this group.

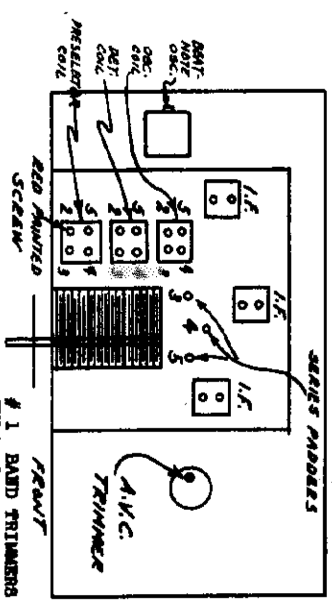
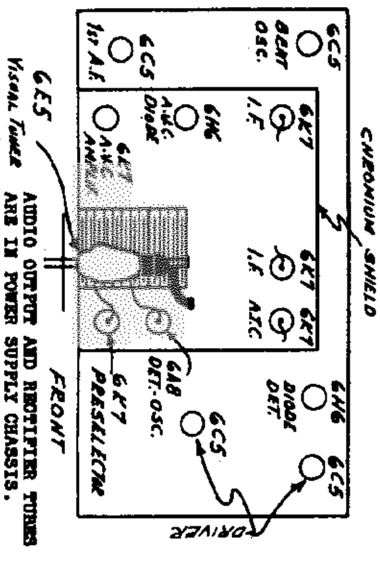
TOP VIEW OF CHASSIS SHOWING LOCATION OF ALIGNING TRIMMERS



1 BAND TRIMMERS UNDER CHASSIS

TOP VIEW OF CHASSIS SHOWING LOCATION OF TUBES



AUDIO OUTPUT AND RECTIFIER TUBES ARE IN POWER SUPPLY CHASSIS.

20 TUBE 5 BAND A.C. HIGH FIDELITY SUPERHETERODYNE RECIEVER.

CIRCUIT

The receiver consists of two separate units, one the power supply and audio output stage and the other the tuned stages and control unit.

Visual tuning is obtained by means of the 6E5 cathode-ray tuning indicator. Resonance is indicated when the darkened area of this tube is narrowest; that is, when the green illuminated area is greatest.

The beat oscillator, used for c.w. reception and for beat note tuning, makes use of a type 6C5 tube.

For power supply, two transformers are used. The plate supply transformer is a separate unit and is tapped for 115, 135, 150, 220 and 250 volts. The filament supply transformer is similarly tapped, and contains all three filament windings, as well as the grid bias winding. Two type 5Z3 tubes are used for rectification, in a full wave parallel connection. Grid bias is obtained by means of a type 45 tube connected as a half-wave rectifier and fed by a separate winding on the filament transformer. The speaker field is connected in the filter ciruit.

ALIGNMENT PROCEDURE

Realignment of this receiver should not be attempted except by an experienced serviceman and only after all other possible causes of faulty operation have first been thoroughly investigated. An accurately calibrated signal generator which will cover the necessary wave bands is required. Either a suitable output meter or the cathode-ray tuning indicator may be used for indicating the effects of adjustments. It is necessary, in all of the ensuing procedure, that the signal generator be attenuated as much as possible.

I.F. ADJUSTMENT - The i.f. transformers are housed in the polished metal shield on the chassis. The location of these transformers is indicated in the accompanying diagram. The trimmers are on the tops of the transformer cans. The first and second i.f. transformers have two trimmers each and the detector coupling transformer has only one trimmer. These trimmers are adjusted at 456 kc. for maximum gain. In making this adjustment, the oscillator (rear) section of the tuning condenser should be short-circuited and the signal generator connected between the grid cap of the 6A8 and the ground post of the receiver. The selectivity switch should of course be in the high selectivity position.

SHORT WAVE BAND - With the output from the signal generator connected across the aerial and ground terminals of the receiver, and the volume control in position for maximum volume, the oscillator trimmer for this band is adjusted for maximum response as indicated by the 6E5. This adjustment must be made with the dial set at exactly 17 mc., otherwise the calibration will be off. The series padder for this band should then be adjusted by setting the signal generator at a frequency of 5.5 megacycles and tuning the signal in on the receiver. The tuning condenser is rotated slightly back and forth as the padder screw is adjusted for maximum output. The 17 mc. adjustment should then be re-checked. If the dial calibration is off, the procedure should be repeated again.

ULTRA SHORT WAVE BAND - The trimmers for this band are adjusted at 36 megacycles in the manner described above. They are located on the under side of the chassis and are not shown on the chassis layout diagram. There are only two trimmers for this band, the oscillator operating on harmonics of the short wave band.

POLICE BAND ADJUSTMENT - The trimmers for this band are adjusted at 4.8 megacycles in the manner described and the series padder at 1.7 mc. exactly as indicated in the SHORT WAVE BAND ADJUSTMENT procedure.

BROADCAST BAND The adjustments for this band are as described above. The trimmers are adjusted at 1400 kc. and the padder at 600 kc.

LONG WAVE BAND - The adjustments for this band are made in the prescribed manner, the trimmers being adjusted at 340 kc. and the padder at approximately 150 kc.

A.V.C. AMPLIFIER ADJUSTMENT - The a.v.c. has a separate amplifier which is tuned as follows: The signal generator is set at 1400 kc. and the signal tuned in on the receiver, as indicated by the minimum opening in the 6E5 beam. The a.v.c. trimmer is then adjusted to give the WIDEST opening in the beam. The receiver is then carefully retuned and the adjustment repeated.

BEAT NOTE OSCILLATOR ADJUSTMENT - A weak unmodulated signal from the signal generator is tuned in on the receiver as indicated by the minimum opening in the 6E5 beam. The beat oscillator switch is then turned on. An audible note should be heard whose pitch may be varied by adjusting the screw on the small square can on the left side of the chassis. This should be so adjusted that when the station is tuned in exactly, no beat is heard (zero beat). If no beat note is audible when first turned on, rotation of this same screw should bring in the note.

DESCRIPTION OF ELECTRICAL CIRCUIT

The signal from the antenna is applied to the control grid of the 6A8 tube through the R.F. coil, the secondary of which is tuned to the incoming signal by the rear section of the main tuning condenser. In the 6A8 tube the incoming signal is combined with the local oscillator signal which is 465 kc. higher in frequency. The local signal is generated by the oscillator section of this tube, and the proper frequency difference is maintained throughout the tuning range by the front section of the tuning condenser in conjunction with the oscillator coil and padding capacitors.

The combination of the two signals produces the intermediate frequency of 465 kc. This particular frequency is chosen to reduce image response and improve short-wave performance. The intermediate frequency amplifier consists of a 6K7 tube and two transformers, the first of which has both primary and secondary tuned.

The second transformer is unshielded and has the primary tuned to 465 kc. The secondary is self-resonant to 465 in conjunction with its associated circuit capacities.

The output of the I.F. amplifier is rectified by the diode section of the 6Q7 tube, providing automatic control bias as well as detection. The audio frequency voltage developed across R-4 is applied through C-27 to the grid of the triode section of this tube from the variable arm of R-4 which constitutes the volume control of the receiver. The d-c voltage developed across R-4 is applied to the control grids of the 6A8 and 6K7 tubes for automatic volume control.

The output of the 6Q7 amplifier section is resistance coupled to the grid of the 6F6 power amplifier pentode. The plate circuit of the 6F6 is suitably matched to the loudspeaker by means of a step-down output transformer.

The tone control circuit consists of a .03 mfd. capacitor which is connected from the plate of the 6F6 tube to ground through the tone control switch. When it is desired to reduce the high frequency output of the receiver the tone control switch is closed by turning the tone control knob to the right.

Plate and grid voltages for all tubes are supplied by the power supply system employing a 5Z4 full-wave rectifier tube and utilizing the loudspeaker field as a filter reactor which together with a suitable network of resistors and capacitors supplies the required voltages and filtering action.

ALIGNMENT PROCEDURE

Before making any adjustments to the R.F. circuits, it is wise to determine the correctness of the existing alignment. This may be done by supplying a signal from the test oscillator to the receiver and inserting a "tuning wand" into the antenna coil. The "tuning wand" consists of a bakelite rod having a brass cylinder attached to one end, and a small core of finely divided iron compacted into the opposite end. By inserting the brass cylinder end into the antenna coil, the inductance is lowered, increasing its resonant frequency. Inserting the iron-filled end into the coil raises its inductance, lowering its resonant frequency. If the circuits are in exact alignment, inserting either end of the tuning wand in the coil will result in a decrease in output. When an increase in signal is obtained with the iron-filled end of the wand at the 1500 kc. point or the 6.0-mc. point, a decrease in resonant frequency of that circuit by increasing the antenna trimmer capacity is indicated. When an increase in signal is obtained with the brass cylinder, a decrease in antenna trimmer capacity is indicated. In the event that the brass cylinder end causes an increase in output at the 580-kc. point when inserted in the antenna coil, it is necessary to increase the oscillator padder capacity, meanwhile rocking the tuning dial. An increase in output, resulting from inserting the iron-filled end, indicates a decrease in oscillator padder capacity.

ALIGNMENT FREQUENCIES

I.F.	Broadcast	Short-wave
465 kc.	580 kc.	6000 kc.
	1500 kc.	

In order to properly align this receiver, it will be necessary to have the following service tools:

1. Test Oscillator capable of producing the above alignment frequencies.
2. Non-metallic alignment screwdriver.
3. Output meter.

Trimmer locations as well as socket voltages are illustrated in Fig. 2.

(1) *I.F. Alignment*

The I.F. amplifier should be tuned to 465 kc.; set the test oscillator dial at this frequency. Set the volume control at maximum and short-circuit the antenna and ground leads. Tune the receiver to a point where no signal comes in and ground the chassis.

Connect the test oscillator output between the 6A8 converter tube control grid and the chassis. Connect the output meter across the cone coil of the speaker and adjust the oscillator output until a small deflection is observed in the output meter.

The three I.F. trimmers are adjusted in the following sequence:

1. Primary trimmer on second I.F. transformer.
2. Secondary trimmer on first I.F. transformer.
3. Primary trimmer on first I.F. transformer.

Throughout all adjustments the output should be maintained at a low level by decreasing the test oscillator output as the various stages are brought in line. After these adjustments have been made the same procedure should be repeated as a final check. The I.F. alignment will then be complete.

(2) *Wave Trap Alignment*

With the test oscillator still tuned to 465 kc. connect its output terminals to the antenna and ground leads of the receiver. Increase the output from the test oscillator until a reading is obtained on the output meter. Then adjust the wave trap trimmer for minimum output.

This adjustment may be changed slightly in actual operation if it is necessary to tune out a code station which is not exactly at 465 kc. This is done by adjusting the wave trap trimmer with the receiver connected to antenna and ground until the offending signal is reduced to a minimum. This adjustment should always be made with the frequency band switch in the broadcast position and with no station tuned in so that extraneous signals may not interfere with the adjustment.

(3) *R.F. Alignment*

The R.F. and oscillator transformers are aligned at 580, 1500, and 6000 kc. With the tuning condenser plates fully meshed, line up the pointer and dial by adjusting the dial set screws so that the line at the extreme end of the dial is indicated.

BROADCAST BAND

With the band switch in the clockwise position, set the tuning dial to 1500 kc. Set the test oscillator at 1500 kc. and, have its output connected to the antenna and ground leads of the receiver. Adjust the oscillator trimmer for the broadcast band for maximum output. Next, set the R.F. trimmer for maximum output, taking care that the output from the test oscillator is not high enough to overload any part of the set. After these adjustments, tune the set and the test oscillator to 580 kc. Adjust the broadcast padding capacitor for maximum output while rocking the tuning condenser back and forth until maximum output is obtained. The dial setting after this adjustment may not agree exactly with the frequency, but this is not important.

To complete the broadcast band line-up, repeat the adjustment at 1500 kc. as before.

Short-Wave Band

With the frequency band switch in the counterclockwise position, set the receiver dial to 6.0 mc. Set the test oscillator at 6000 kc. and adjust the short-wave oscillator trimmer for maximum output. Next, set the short-wave R.F. trimmer for maximum output. Repeat these adjustments a second time. After aligning the S.W. band, turn the test oscillator to approximately 6930 kc. with the receiver dial still at 6 mc. Increase the test oscillator output until a signal is heard in the neighborhood of 6930 kc. This is the image frequency and if the set has been properly aligned the sensitivity at this point will be much less than at 6000 kc. In the event the image frequency cannot be found, the alignment should be rechecked at 6.0 mc. It will be noticed that the oscillator trimmer will have two positions at which the signal will give maximum output. The position which gives the lower trimmer capacitance obtained by turning the trimmer screw counter-clockwise is the proper adjustment.

When these adjustments have been completed the receiver will be in alignment.

DESCRIPTION OF ELECTRICAL CIRCUIT

The signal from the antenna is applied to the control grid of the 6A8 tube through the R.F. transformer, the secondary of which is tuned to the incoming signal by the rear section of the main tuning condenser. In the 6A8 tube the incoming signal is combined with the local oscillator signal which is 465 kc. higher in frequency. The local signal is generated by the oscillator section of this tube, and the proper frequency difference is maintained throughout the tuning range by the front section of the tuning condenser in conjunction with the oscillator coils and padding capacitors.

The combination of the two signals produces the intermediate frequency of 465 kc. This particular frequency is chosen to reduce image response and improve short-wave performance. The intermediate frequency amplifier consists of a 6K7 tube and two transformers, both of which have tuned primaries and secondaries.

The output of the I.F. amplifier is rectified by the diode section of the 6Q7 tube, providing automatic volume control bias as well as detection. The audio frequency voltage developed across R-7 is applied through C-18 to the grid of the triode section of this tube from the variable arm of R-7 which constitutes the volume control of the receiver. The D.C. voltage developed across R-7 is applied to the control grids of the 6A8 and 6K7 tubes for automatic volume control.

The output of the 6Q7 amplifier section is resistance coupled to the grid of the 25A6 power amplifier pentode. The plate circuit of the 25A6 is suitably matched to the loud-speaker by means of a step-down output transformer.

The tone control circuit consists of a .05-mfd. capacitor which is connected from the plate of the 25A6 tube to "B-" lead through the tone control switch. When it is desired to reduce the high frequency output of the receiver the tone control switch is closed by turning the tone control knob to the right.

When the receiver is used on alternating current, plate and grid voltages and loud-speaker field current are supplied by a 25Z6 rectifier tube and its associated filter circuits. Each section of the 25Z6 tube acts as a separate half-wave rectifier, one for speaker field current, and one for plate and grid voltages, and each section has its own filter circuit.

When the receiver is used on a D.C. supply the 25Z6 rectifier tube remains in the circuit and serves two purposes. If the power cord should be plugged in with incorrect polarity, the 25Z6 tube protects the filter condensers from damage. On correct D.C. polarity the 25Z6 tube aids the filter circuits in smoothing the supply, thus minimizing line noise.

The heaters of all tubes and the dial light with its shunt ballast resistor (the 30-ohm section of R12) are all in series and are furnished current from the power line through a dropping resistor (the 150-ohm section of R12).

Note that the chassis is not connected directly to either the ground lead or to the power supply, but is by-passed to the "B-" lead by various condensers.

ALIGNMENT PROCEDURE

Before making any adjustments to the R.F. circuits, it is wise to determine the correctness of the existing alignment. This may be done by supplying a signal from the test oscillator to the receiver and inserting a "tuning wand" into the antenna coil. The "tuning wand" consists of a bakelite rod having a brass cylinder attached to one end, and a small core of finely divided iron compacted into the opposite end. By inserting the brass cylinder end into the antenna coil, the inductance is lowered, increasing its resonant frequency. Inserting the iron-filled end into the coil raises its inductance, lowering its resonant frequency. If the circuits are in exact alignment, inserting either end of the tuning wand in the coil will result in a decrease in output. When an increase in signal is obtained with the iron-filled end of the wand at the 1500-kc. point or the 6.0-mc. point, a decrease in resonant frequency of that circuit by increasing the antenna trimmer capacity is indicated. When an increase in signal is obtained with the brass cylinder, a decrease in antenna trimmer capacity is indicated. In the event that the brass cylinder end causes an increase in output at the 580-kc. point when inserted in the antenna coil, it is necessary to increase the oscillator padder capacity, meanwhile rocking the tuning dial. An increase in output, resulting from inserting the iron-filled end, indicates a decrease in oscillator padder capacity.

ALIGNMENT FREQUENCIES

I.F.	Broadcast	Short-wave
465 kc.	580 kc.	6000 kc.
	1500 kc.	

In order to properly align this receiver, it will be necessary to have the following service tools:

1. Test Oscillator capable of producing the above alignment frequencies.
2. Non-metallic alignment screwdriver.
3. Output meter.

Trimmer locations as well as socket voltages are illustrated in Fig. 3.

(1) I.F. Alignment

The I.F. amplifier should be tuned to 465 kc.; set the test oscillator dial at this frequency. Set the volume control at maximum and short-circuit the antenna and ground leads. Tune the receiver to a point where no signal comes in.

Connect the test oscillator output between the 6A8 converter tube grid (with the grid cap on) and the chassis. Connect the output meter across the cone coil of the speaker and adjust the oscillator output until a small deflection is observed in the output meter.

The four I.F. trimmers are adjusted in the following sequence:

1. Secondary trimmer on second I.F. transformer.
2. Primary trimmer on second I.F. transformer.
3. Secondary trimmer on first I.F. transformer.
4. Primary trimmer on first I.F. transformer.

Throughout all adjustments the output should be maintained at a low level by decreasing the test oscillator output as the various stages are brought in line. After these adjustments have been made, the same procedure should be repeated as a final check. The I.F. alignment will then be complete.

(2) R.F. Alignment

The R.F. and oscillator transformers are aligned at 580, 1500, and 6000 kc. With the tuning condenser plates fully meshed, line up the pointer and dial by adjusting the dial set screws so that the line at the extreme end of the dial is indicated.

(a) Broadcast Band

With the band switch in the clockwise position, set the tuning dial to 1500 kc. Set the test oscillator at 1500 kc. and adjust the oscillator trimmer for the broadcast band for maximum output. Next, set the R.F. trimmer for maximum output, taking care that the output from the test oscillator is not high enough to overload any part of the set. After these adjustments, tune the set and the test oscillator to 580 kc. Adjust the broadcast padding capacitor for maximum output while rocking the tuning condenser back and forth until maximum output is obtained. The dial setting after this adjustment may not agree exactly with the frequency, but this is not important.

To complete the broadcast band line-up, repeat the adjustment at 1500 kc. as before.

(b) Short-wave Band

With the frequency band switch in the counterclockwise position, set the receiver dial to 6.0 mc. Set the test oscillator at 6000 kc. and adjust the short-wave oscillator trimmer for maximum output. Next, set the short-wave R.F. trimmer for maximum output. Repeat these adjustments a second time. After aligning the S. W. band, turn the test oscillator to approximately 6930 kc. with the receiver dial still at 6.0 mc. Increase the test oscillator output until a signal is heard in the neighborhood of 6930 kc. This is the image frequency and if the set has been properly aligned the sensitivity at this point will be much less than at 6000 kc. In the event the image frequency cannot be found, the alignment should be rechecked at 6.0 mc. It will be noticed that the oscillator trimmer will have two positions at which the signal will give maximum output. The position which gives the lower trimmer capacitance obtained by turning the trimmer screw counterclockwise is the proper adjustment.

When these adjustments have been completed the receiver will be in alignment.

6 Tube Automobile Radio — MODEL N-60

SPECIFICATIONS

Power Consumption	7.0 Amperes at 6.0 Volts	Tuning Frequency Range	530 to 1650 KC
Power Output (Undistorted)	3 Watts	Intermediate Frequency	175 KC
Power Output (Maximum)	4 Watts	Speaker	6 Inch Dynamic

Circuit

This model is a 6 tube automobile receiver covering the standard wave band. It has a tuning range as shown in the specifications above. The signal is fed through an antenna transformer with tuned secondary into a 6K7 tube which functions as an R.F. amplifier. The output of this tube is fed through another R.F. transformer with tuned secondary into a 6J7 tube which functions as the first detector and oscillator. The oscillating circuit is tuned by the oscillator section of the gang condenser and is always resonant at a frequency 175 KC above the frequency to which the R.F. circuits are tuned.

One stage of I.F. amplification is employed using a 6K7 tube. The primary and secondary of the first I.F. transformer and the primary of the second I.F. transformer are tuned by small trimmer condensers.

A 6Q7 dual diode-triode tube functions as a diode 2nd detector, AVC tube and a one stage audio amplifier. AVC voltage is applied to the control grid circuits of the 6K7 R.F. and I.F. tubes. The manual volume control varies the audio voltage applied to the grid of the 6Q7 tube.

In the output stage a 6F6 tube is employed. A dynamic reproducer is used.

The vibrator in the power unit interrupts the current through the primary of the power transformer. The use of a vibrating interrupter in the primary circuit and a high ratio transformer results in the application of high voltage AC to the rectifier tube plates. The 6X5 full wave rectifier tube, filter choke, and filter condensers convert this high voltage AC into high voltage DC for the plate and screen circuits.

Alignment and Calibration

Misalignment or mistracking of condensers generally manifests itself as broad tuning and lack of volume at portions or all of the standard wave band. The receivers are all properly aligned at the factory with precision instruments and realignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment.

A signal generator that will provide accurately calibrated signals over the standard wave band and at the intermediate frequency, and an output meter are required for indicating the effect of adjustments.

Use a non-metallic screwdriver for the adjustments. The complete procedure is as follows:

I. F. Adjustment

Set the signal generator for a signal of 175 KC.

Connect the antenna lead of the signal generator thru a .05 mf. condenser to the stator of the 1st detector section of the tuning condenser. (See Fig. 2 for location of this section.) This can be done by pushing a wire or conductor between the stator plates or by extending an insulated wire thru the hole in the shield over the stator and pushing the wire thru the hole in the lug which extends up from the insulated stator assembly.

Connect the ground lead of the signal generator to the chassis ground.

Short out the oscillator section of the tuning condenser.

Set the volume control at the maximum position.

Attenuate the signal from the signal generator to prevent the levelling-off action of the AVC.

Then adjust the three I.F. trimmers until maximum output is obtained. The location of these trimmers is shown in Fig. 2.

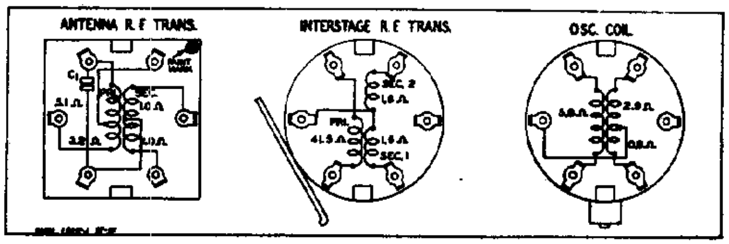

Fig. 3—R. F. and Oscillator Coil Base Terminal Arrangement and D. C. Resistance of Windings

1650 KC Adjustment

Set the signal generator for 1650 KC.

Turn the rotor of the tuning condenser to the full open position.

If a low capacity antenna is used connect the shielded antenna lead from the chassis through a 150 mmf. condenser to the antenna post of the signal generator. (If high capacity, use 1500 mmf.)

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent AVC action.

Adjust the trimmer of the oscillator section of the three gang condenser until maximum output is obtained—see Fig. 2 for location of this trimmer.

1400 KC. Adjustment

Set the signal generator for 1400 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the 1st detector and antenna trimmers for maximum output.

Do not change the setting of the oscillator trimmer.

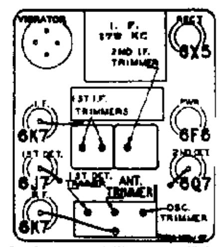

Fig. 2—Location of Tubes and Trimmers

D. C. Resistance of Windings

Following are the D. C. resistances of the various windings in the chassis. The values given below will vary slightly in different sets.

Code	Winding	D. C. Resistance in Ohms

L4	Filament Reactor	.20
L5	Power Reactor	300.0
L6	R. F. "B" Plate Reactor	4.0
L7	Vibrator Filter Reactor	Small

Adjusting Antenna Trimmer

After the receiver is installed and the car antenna is connected it will be necessary to adjust the antenna trimmer. Tune in a weak signal between 1200 and 1400 KC with the volume control about three-fourths on. Remove the cover of the chassis case. The antenna trimmer is on the center tuning condenser section—see Fig. 2. Turn the adjusting screw of this condenser up or down until maximum output is obtained. CAUTION—Do not turn any of the other trimmer adjusting screws for this adjustment.

Calibrating the Receiver

To calibrate the receiver, tune in a station of known frequency. At the back of the control head is the calibration screw. Remove the pilot lamp assembly. Insert a fine blade screwdriver and turn this screw until the pointer on the dial scale is at the frequency of the station being received. The knob must be held during this adjustment.

If the control head is inaccessible it may be calibrated by setting the pointer from the front. Remove the crystal by inserting a knife blade under the lower edge. Loosen the pointer screw, set the pointer and retighten.

GENERAL ELECTRIC CO.

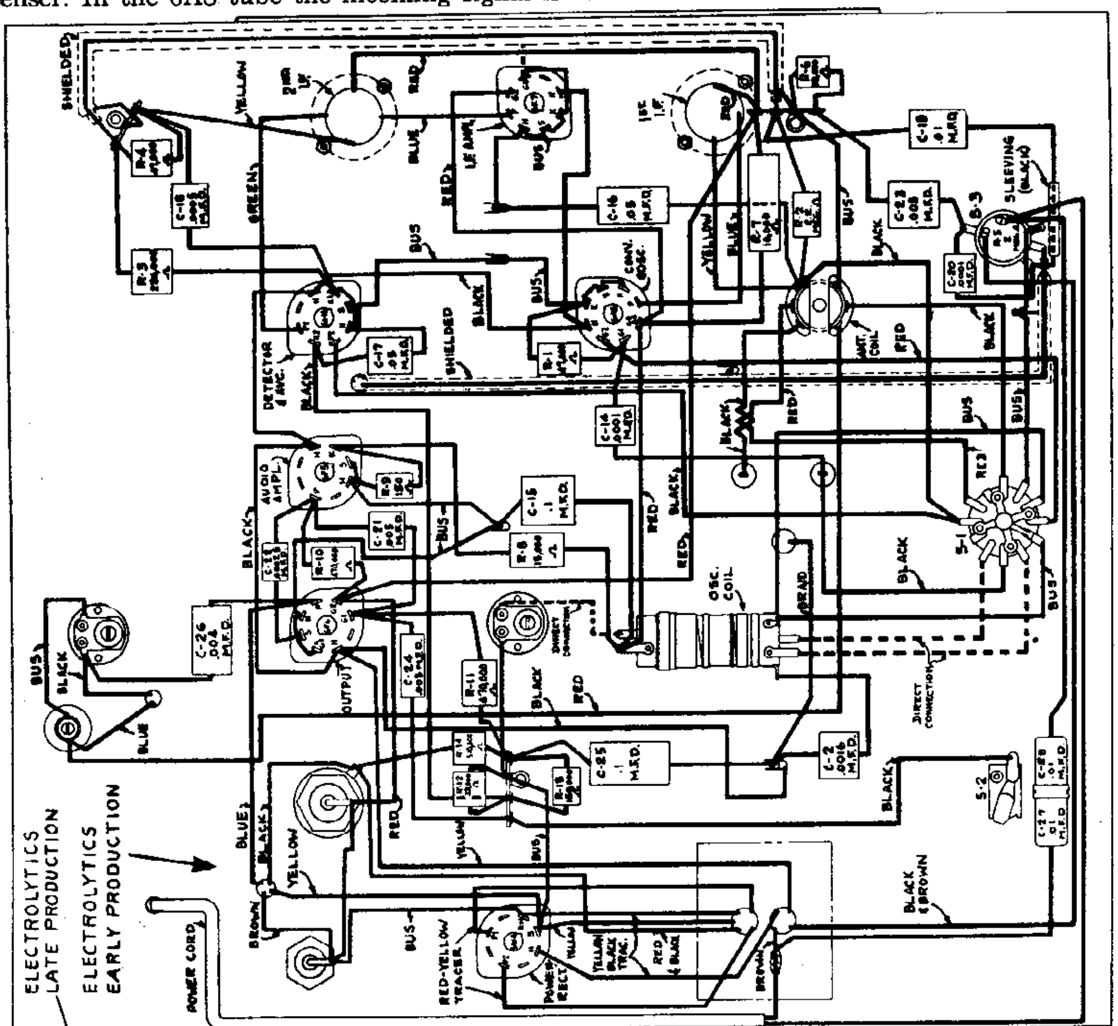
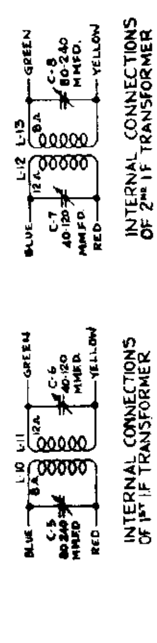
DESCRIPTION OF ELECTRICAL CIRCUIT

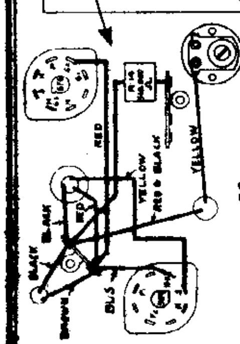
Models E-61, E-62 and E-68 employ six metal envelope tubes in a superheterodyne circuit giving the excellent selectivity and sensitivity inherent in this type circuit. Ample undistorted output is obtained through diode detection and two high gain audio amplifier stages.

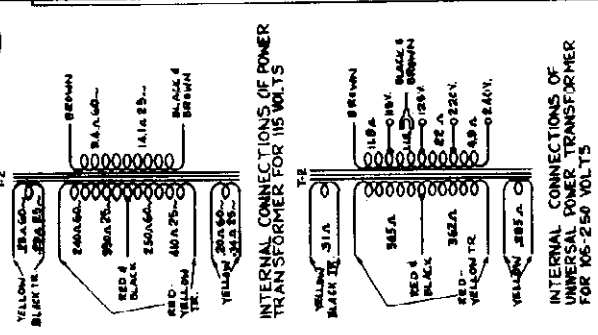
The signal from the antenna is applied to the control grid of the 6A8 tube through the R. F. coil, the secondary of which is tuned to the incoming signal by the rear section of the main tuning condenser. In the 6A8 tube the incoming signal is combined with the local oscillator signal which is 465 KC higher in frequency. The local signal is generated by the oscillator elements of this tube, and the proper frequency difference is maintained throughout the tuning range by the front section of the main tuning condenser in conjunction with the oscillator coil and padding capacitors.

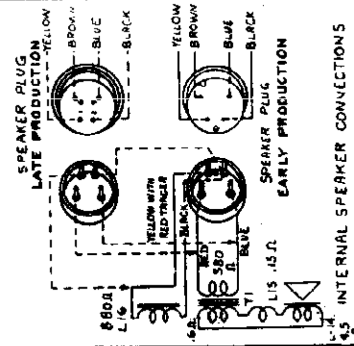
The combination of the two signals produces the intermediate frequency of 465 kilocycles. This particular intermediate frequency is chosen to reduce image response and improve short-wave performance. The intermediate frequency amplifier consists of a 6K7











tube and two I. F. transformers, each with two tuned circuits. An I. F. wave trap is provided across the antenna and ground terminals to eliminate interfering signals of the intermediate frequency.

The output of the I. F. amplifier is applied to one plate of the 6H6 diode rectifier, which is a combined detector, initial bias and automatic volume control tube. The direct-current component of the rectified signal, through one diode of the 6H6, produces a voltage drop across R-3. This voltage drop provides automatic bias for the converter and I. F. amplifier tubes and so gives automatic volume control action. The other diode of the 6H6 provides an initial bias for the tubes on the automatic volume control circuit under conditions of little or no signal. This initial bias diode, under conditions of small signal, draws current which flows through resistors R-2 and R-3. The resulting voltage is the required minimum operating bias for the controlled tubes. Upon receiving signals above the level of the initial bias, the initial bias diode stops drawing current and the automatic volume control diode takes over the controlling bias.

The manual volume control, R-5, selects the amount of audio signal applied to the grid of the 6F5 audio amplifier tube, and this regulates the output of the receiver. The output of the 6F5 tube is resistan coupled to the grid of the 6F6 power amplifier pentod The plate circuit of the 6F6 is suitably matched the loud-speaker by means of a step-down outp transformer.

The tone control circuit consists of a .003 mf capacitor, connected in series with a two poi grounding switch, S-2, in the grid circuit of the 6F power pentode. When it is desired to reduce the hig frequency output of the receiver, the switch, S-2, turned to its counterclockwise grounding position.

Plate and grid voltages for all tubes are supplied b the power supply system employing a 5W4 full-wa rectifier tube which, together with a suitable netwo of resistors and capacitors, supplies the required vol ages and filtering action.

ALIGNMENT PROCEDURE

The receiver should first be allowed to run for fifteen minutes in order to reach its approximate normal operating temperature. Before making any adjustments, it is wise to determine the correctness of the existing alignment. This may be done by supplying a signal to the receiver from the test oscillator at the alignment frequency and inserting a "Tuning Wand" into the coil involved. The "Tuning Wand" consists of a rod of insulating material having a ring of nonmagnetic metal attached to one end, and a small core of finely divided iron compacted into the opposite end. By inserting the metal ring end into the center of the R. F. coil, the inductance of this coil is lowered, increasing its resonant frequency. Inserting the iron-filled end into the coil raises its inductance, lowering its resonant frequency. If the R. F. circuits are in exact alignment, inserting either end of the tuning wand into the coil will result in a decrease in output. When an increase of signal is obtained with the iron-filled end of the wand, a decrease in resonant frequency of that circuit by increasing its trimmer capacity is indicated. When an increase of signal is obtained with the metal ring, a decrease in trimmer capacity is indicated.

Changes Indicated by Wand

Wand	Signal	Trimmer Adjustment Required
Metal Ring Iron Filings	Decrease Decrease	None
Metal Ring Iron Filings	Increase Decrease	Decrease capacity
Metal Ring Iron Filings	Decrease Increase	Increase capacity

In order to align these receivers properly it is necessary to have available:

1. A modulated test oscillator capable of producing the above alignment frequencies.
2. An output indicator, such as a high resistance a-c voltmeter with a maximum scale reading of 3 to 5 volts, or a neon lamp indicator.
3. An alignment tool consisting of an insulating shaft with a small screwdriver blade.

The location of all alignment trimmer capacitors, as well as socket voltages, is shown in Fig. 3.

SOCKET VOLTAGES

Tube No.		Plate to Ground Volts D-c	Screen Grid to Ground Volts D-c	Cathode to Ground Volts D-c	Cathode Current M.A.	Heater Volts A-c
6A8	Oscillator	98	...	0	...	...
	Converter	250	96	...	12.0	6.3

5W4 Power Rectifier		625/314 RMS	...	250	64.0	5.0

Measured at 115 volts supply. No signal input. Volume control maximum. Voltmeter 1000 ohms per volt; measurements taken on highest scale giving accurate readable deflection.

* Supply voltage minus drop in load resistor, measured on 1000 volt scale.

1. I. F. Alignment

Set the frequency band switch of the receiver to the broadcast position and turn the volume control to maximum (extreme clockwise position). Tune the receiver to some point above 1500 KC so that no signal is heard, short-circuiting the antenna and ground terminals if necessary, and ground the chassis.

Remove the control grid clip from the 6A8 tube and connect the test oscillator output between chassis and the dome terminal of the 6A8 tube. The I. F. amplifier is tuned to 465 KC; set the oscillator dial at this frequency. Make sure that a d-c path exists between the output terminals of the test oscillator; if an ohmmeter does not show continuity between the test oscillator terminals, connect a resistor of fairly high resistance between the 6A8 dome terminal and chassis to provide a d-c grid return path.

Connect the output meter across the cone coil of the speaker and adjust the test oscillator output control so that, with the volume control at maximum, a small indication is observed on the output indicator.

Adjust the secondary trimmer of the second I. F. transformer until a peak output reading is obtained. Maintaining a small output indication, adjust next the primary trimmer of the second I. F. transformer for maximum output. Continue this procedure, adjusting the secondary trimmer of the first I. F. transformer, and lastly, the primary trimmer of the first I. F. transformer. After completing this procedure, repeat it a second time for final alignment. The I. F. alignment will then be complete.

During both I. F. and R. F. alignments, the test oscillator signal should be maintained at the lowest level that will give a good output indication, keeping the receiver volume control at maximum and adjusting the test oscillator output control to give the required indication.

I. F. Wave Trap Alignment

After completion of the I. F. alignment, with the test oscillator still set on 465 KC, apply this frequency to the antenna post of the receiver through a dummy antenna. This dummy antenna consists of a 400 ohm resistor in series with a 250 mmfd. capacitor and should be connected in series between the test oscillator output and the receiver antenna post. With the 465 KC signal applied to the receiver antenna post, adjust the I. F. Wave Trap trimmer for minimum output indication.

2. R. F. Alignment

The R. F. and Oscillator trimmers are aligned at 580 and 1500 KC. First of all, check the position of the dial pointer. To do this, rotate the gang condenser to the maximum capacity position, i.e., plates fully meshed. While in this position, align the pointer with the last black line on the scale by loosening the dial drum set screws and rotating the drum on the gang shaft. Make sure the antenna and ground terminals of the receiver are not short-circuited and connect to them the output of the test oscillator, preferably using the dummy antenna described above between the test oscillator and the receiver antenna terminal. Connect the output indicator across the speaker cone coil.

Broadcast 540-1750 Kc

Set the frequency band switch to the broadcast position. Tune the test oscillator to 1500 KC and set the dial pointer on the receiver to this frequency. Adjust the broadcast oscillator trimmer on the front section of the gang condenser for maximum output, keeping the receiver volume control at its extreme clockwise position and adjusting the test oscillator output to maintain a small reading on the output indicator. When optimum adjustment on the broadcast oscillator trimmer is obtained, adjust the broadcast R. F. trimmer on the rear section of the gang for maximum output.

Now set the test oscillator at 580 KC and tune the receiver to that frequency. Slowly, rocking the tuning condenser back and forth through the signal, adjust the 580 KC padding capacitor for maximum output. When this has been done, return to 1500 KC on the receiver and test oscillator and recheck the alignment at that frequency for maximum output. The broadcast band should now be in alignment.

Short Wave—2.2—7.0 M.C (2,200-7,000 Kc)

No separate short wave trimmers are provided on this receiver. The correct adjustment of the broadcast band at 580 and 1500 KC automatically aligns the short wave band.

DESCRIPTION OF ELECTRICAL CIRCUIT

Models E-71, E-72, and E-76 employ seven metal envelope tubes to perform the above functions in a superheterodyne circuit, giving the excellent selectivity and sensitivity inherent in this type circuit. The "B" and "C" band coils are wound on a common form, while the "D" band coils have individual forms. Ample undistorted output is obtained through diode detection and two audio amplifier stages.

The signal from the antenna is applied to the control grid of the 6A8 converter tube through the antenna coil, the secondary of which is tuned to the incoming signal by the rear section of the main tuning condenser. The secondary of the coil for the band next lower in frequency to the one in use is short-circuited through a capacitor to prevent absorption of energy at its resonant frequency which falls in the next higher band. (NOTE.—On the schematic diagram, Fig. 1, the center portion of the wave band switch supporting the two shorting lugs rotates simultaneously with the four contact pins.) In the 6A8 tube the incoming signal is combined with the local oscillator signal which is 465 kc. different in frequency. The local signal is generated by the oscillator elements of this tube and the proper frequency difference is maintained throughout the tuning range by the front section of the main tuning condenser in conjunction with the oscillator coil and padding capacitors.

The combination of the signal frequency with the local oscillator frequency in the converter tube produces the intermediate frequency of 465 kilocycles. This particular intermediate frequency is chosen to reduce image response and improve short-wave performance. The intermediate frequency amplifier consists of two 6K7 tubes and three transformers, each with two tuned circuits.

The output of the I. F. amplifier is applied to the 6H6 diode rectifier, which is a combined detector and automatic volume control tube. The direct current component of the rectified signal produces a voltage drop across R-14. This voltage drop provides automatic bias for the R. F. and I. F. amplifier and converter tubes and so gives automatic volume control action. Full automatic bias voltage is applied to the pentagrid converter tube and to the first I. F. amplifier tube. The second I. F. tube is operated on self bias, obtained by the drop through R-8. This enables the second I. F. tube to provide maximum power to the 6H6 diode rectifier.

MODELS E-71, E-72 AND E-76

The manual volume control, R-13, selects the amount of audio signal applied to the grid of the 6F5 audio amplifier tube and this regulates the output of the receiver. The output of the 6F5 tube is resistance coupled to the grid of the 6F6 power amplifier pentode. The plate circuit of the 6F6 is suitably matched to the loud-speaker by means of a step-down output transformer.

The tone control circuit consists of a .003-mfd. capacitor connected in series with a grounding switch S-3 in the grid circuit of the 6F6 output tube. When it is desired to reduce the high frequency output of this receiver the switch S-3 is closed to ground.

Plate and grid voltages for all tubes are supplied by the power supply system employing a 5W4 full-wave rectifier tube which, together with a suitable network of resistors and capacitors, supplies the required voltages and filtering action.

1. *I. F. Alignment*

Set the frequency band switch of the receiver to Band "B," short-circuit the antenna and ground terminals and tune the receiver to some point where no signal is heard. Set the volume control at its maximum position and ground the chassis.

The I. F. amplifier is tuned to 465 kc.; set the test oscillator dial at this frequency. Connect the test oscillator output between the converter tube (6A8) control grid and chassis. Connect the output meter across the cone coil of the speaker and adjust the test oscillator output control so that, with the receiver volume control at maximum, a small deflection is observed on the output meter. During both I. F. and R. F. alignment, the test oscillator signal should be maintained at the lowest level that will give a good readable output indication.

Adjust the secondary trimmer of the third I. F. transformer until a maximum output reading is obtained. Maintain a small deflection on the output meter throughout alignment by adjusting the test oscillator output. Next, adjust the primary trimmer of the third I. F. transformer for maximum output. Continue this procedure, adjusting the secondary and primary trimmers, respectively, of the second I. F. transformer. The secondary trimmer of the first I. F. transformer may then be adjusted and, lastly, the primary trimmer of the first I. F. transformer. After completing this procedure, repeat it a second time for final alignment. The I. F. alignment will then be complete.

I. F. Wave Trap Alignment

After completion of the I. F. alignment, with the test oscillator still set on 465 kc., apply this frequency to the antenna post of the receiver through a dummy antenna. This dummy antenna consists of a 400-ohm resistor in series with a 250-mmfd. capacitor and should be connected in series between the test oscillator output and the receiver antenna post. With the 465-kc. signal applied to the receiver antenna post, adjust the I. F. Wave Trap trimmer for *minimum* output indication.

2. *R. F. Alignment*

First of all, check the position of the dial pointer. To do this, rotate the gang condenser to the maximum capacity position, i.e., plates fully meshed. While in this position, align the pointer with the last black line on the scale by loosening the dial drum set screws and rotating the drum on the gang shaft. Make sure the antenna and ground terminals of the receiver are not short-circuited and connect to them the output of the test oscillator, preferably using the dummy antenna described above between the test oscillator and the receiver antenna terminal. Connect the output indicator across the speaker cone coil.

"D" Band (5.6-18.0 mc.)

Because of the R. F. circuit used in this receiver, the "D" band must be aligned first. Set the frequency band switch to the "D" band position by rotating it to its most clockwise position. Tune the test oscillator to 18,000 kc. (18 mc.) and set the dial pointer on the receiver at this frequency. Adjust the "D" band oscillator trimmer, located on the front section of the gang condenser, for maximum output. (NOTE.—The oscillator operates on the *low* frequency side of the incoming signal; therefore adjust the trimmer until the second oscillator peak is reached as the trimmer is *increased* in capacity. A check for the correctness of this adjustment may be made by rotating the gang to the 17,070 kc. calibration mark. If, with increased input from the test oscillator, no signal is detected, the correct oscillator peak has been used.) Keep the receiver volume control at its extreme clockwise position and adjust the test oscillator output to maintain a small reading on the output indicator. When the optimum adjustment on the oscillator trimmer has been obtained, adjust the "D" band antenna trimmer on the rear section of the gang for maximum output while rocking the tuning condenser through the signal.

"C" Band (1.56-5.80 mc.)

No separate trimmers are provided for adjustment of this band. The correct adjustment of the "D" band and "B" band automatically aligns the "C" band. The adjustment procedure for the "B" band follows immediately.

"B" Band (540-1600 kc.)
