The various diagrams of this bulletin contain such information as will be needed to isolate causes for defective operation when such a condition develops. Values of the resistors, capacitors, coils, etc., are indicated adjacent to the symbols signifying these parts on the diagrams. Identification titles, such as R-3, L-2, C-1, etc., are provided for reference between the diagrams and the replacement parts list. Locating of the parts in the schematic circuit is facilitated by the fact that the numerical titles increase from left to right on the diagram. The coils, reactors, and transformer windings are rated in terms of their d-c resistances only. Resistances of less than one ohm are generally omitted.

Alignment Procedure

Precise alignment is vital to the proper functioning of this receiver. There are four trimming adjustments provided in the i-f system, three in the oscillator coil system, two in the detector coil system, and two in the antenna coil system. Each of these trimmers has been accurately adjusted during manufacture and should remain properly aligned unless affected by abnormal conditions of climate or have been altered for service purposes. Incorrect alignment is usually evidenced by loss of sensitivity, improper tone quality, and poor selectivity. These indications will generally be present together.

The correct performance of the receiver can only be obtained when the alignment is performed with adequate and reliable test apparatus. The manufacturer of this instrument has a complete assortment of such service equipment available. This equipment, illustrated and described on a separate page of this booklet, may be purchased from authorized distributors and dealers.

An oscillator (signal generator) is required as a source of the specified alignment frequencies. Visual indication of the receiver output during the adjustments is necessary to enable the serviceman to obtain an accuracy of alignment which is not possible by listening to the signal. **The RCA Victor Stock No. 9595 Full-Range Oscillator and the RCA Victor Stock No. 4317 Neon Output Indicator are especially suitable and fulfill the above requirements.**

The following procedure should be followed in adjusting the various trimmer capacitors:

I-F Trimmer Adjustments

The four trimmers of the two i-f transformers are located as shown by Figure 6. Each must be aligned to a basic frequency of 460 kc. To do this, attach the Output Indicator across the voice coil circuit or across the output transformer primary. Connect the output of the test oscillator between the control-grid of the RCA-6A8 first detector tube and chassis-ground. Tune the oscillator to 460 kc. Advance the receiver volume control to its full-on position and adjust the receiver tuning control to a point within its range where no interference is encountered either from local broadcast stations or the heterodyne oscil

MODEL D7-7
Alignment, Part 2
Parts List

RCA MFG. CO., INC.

later. Increase the output of the test oscillator until a slight indication is apparent on the output indicator. Then adjust the two trimmers, C-25 and C-26, of the second i-f transformer to produce maximum (peak) indicated receiver output. Then, adjust the two trimmers, C-23 and C-24, of the first i-f transformer for maximum (peak) receiver output as shown by the indicating device. During these adjustments, regulate the test oscillator output so that the indication is always as low as possible. By doing so, broadness of tuning due to a.v.c. action will be avoided. It is advisable to repeat the adjustment of all i-f trimmers a second time to assure that the inter-action between them has not disturbed the original adjustment.

R-F Trimmer Adjustments

The seven trimmers associated with the r-f, first detector, and oscillator tuned circuits have their locations shown by Figure 1. The three trimmers which are at all times directly in shunt with the variable tuning condenser necessitate that the high-frequency range (Band C) be aligned first. The range selector switch should, therefore, be turned to its Band C position for the first adjustment. The Output Indicator should be left connected to the output system. Attach the output terminals of the test oscillator to the antenna and ground terminals of the receiver.

Calibrate the dial by rotating the tuning control until the variable condenser plates are in their full mesh (maximum capacity) position and adjusting the dial pointer so that its end points to the *horizontal* graduation (530 kc.) at the low frequency end of the Band A scale.

Proceed further as follows:

(a) Adjust the test oscillator to 18,000 kc. and set the receiver tuning control to a dial reading of 18,000 kc.

(b) Regulate the output of the test oscillator until a slight indication is perceptible at the receiver output. Then adjust the trimmer, C-20, on the oscillator section of the variable condenser to the point at which it produces maximum indicated receiver output. Two points may be found, each of which produces such a maximum. The one of *maximum trimmer capacitance* is correct and should be used. (The oscillator will be 460 kc. below the signal frequency at this adjustment point.)

(c) Adjust the trimmer, C-12, of the detector section of the variable condenser, simultaneously rocking the receiver tuning control backward and forward through the 18,000 kc. input signal, until maximum receiver output results from these combined operations. Rocking of the variable condenser will prevent inaccurate adjustment which would otherwise be caused by the inter-action between the heterodyne oscillator circuit and the detector tuned circuit.

(d) With the receiver tuning control set to 18,000 kc. adjust the trimmer, C-6, on the antenna section of the variable condenser to the point which produces maximum (peak) indicated receiver output.

(e) Change the receiver range selector to its Band A position and set the receiver tuning control to a dial reading of 1,400 kc. Tune the test oscillator to 1,400 kc. and regulate its output to produce a slight indication on the receiver output indicating device.

(f) Adjust the high frequency trimmers of the Band A oscillator, detector, and antenna coils, C-15, C-9, and C-4 respectively, to the points at which each produces maximum indicated receiver output.

(g) Shift the test oscillator frequency to 600 kc. and tune the receiver to pick up this signal, disregarding the dial reading at which it is best received.

(h) Tune the low frequency trimmer, C-18, of the oscillator Band A coil, simultaneously rocking the tuning control of the receiver backward and forward through the signal, until maximum indicated receiver output results from these combined operations. The adjustment of C-20, C-12, and C-6 should be corrected at 18,000 kc. as in (b), (c), and (d); also C-15, C-9, and C-4 should be corrected at 1,400 kc. as in (f) to compensate for any changes caused by the adjustment of the low frequency oscillator coil trimmer.

Radiotron Socket Voltages

The voltage values indicated from the Radiotron socket contacts to chassis on Figure 6 will assist in the location of causes for faulty operation. Each value as specified should hold within ±20% when the receiver is normally operative at its rated supply voltage. Variations in excess of this limit will usually be indicative of trouble in the basic circuits. The voltages given are actual operating values and do not allow for inaccuracies which may be caused by the loading effect of a voltmeter's internal resistance. This resistance should be duly considered for all readings. The amount of circuit resistance shunting the meter during measurement will determine the accuracy to be obtained, the error increasing as the meter resistance becomes comparable to or less than the circuit resistance. For the majority of readings, a meter having an internal resistance of 1000 ohms per volt will be satisfactory when the range used for each reading is chosen as high as possible consistent with good readability.

Universal Transformer

The special transformer used on some receivers of this type is adaptable to several ranges of voltage as given under Rating C of Electrical Specifications. Its schematic and wiring are shown by Figure 5. Terminals are provided at the top of the transformer case for changing the primary connections to suit the voltage available. Note that a 110-volt tap is brought out separately for supplying a phonograph motor.

Wave-Trap Adjustment

With the receiver in operation using its normal antenna, tune station selector to the point at which the intermediate frequency interference is most intense. Then adjust the wave trap trimmer to the point which causes maximum suppression of the interference. This trimmer is adjusted to 460 kc. during manufacture, however, local conditions may require a readjustment, depending upon the interfering frequency.

Phonograph Mechanism

The phonograph motor is of the synchronous type and designed to be simple and foolproof. Under normal operating conditions, service difficulties should be negligible. Occasionally, however, certain adjustments may be required. These adjustments are illustrated and explained in Figure 8.

Magnetic Pickup

The pickup used in the phonograph unit is of an improved design. The horseshoe magnet is rigidly welded to the pole pieces and is irremovable. There is a centering spring attached to the armature to maintain proper adjustment and to provide a limiting effect on the movement of the armature. The frequency response is substantially uniform over a wide range. Service operations which may be necessary on the pickup are as follows:

Centering Armature

Refer to Figure 9 showing the pickup inner structure. The armature is shown in its proper relation to the magnet pole pieces, i. e., exactly centered. Whenever this centering adjustment has been disturbed it will be necessary to remove the pickup mechanism from the tone arm by removing the needle holding screw and the two mounting screws from the front of the tone arm, holding the pickup assembly to keep it from dropping. Unsolder the two leads from the lugs on the terminal board at the rear of the pickup. Insert a small rod or nail into the armature needle hole and replace the needle holding screw, tightening it to hold the rod securely. If the armature clamping screws A and B have not been disturbed, screw C should be loosened which will permit the armature to be moved from side to side, the rod acting as a lever to perform this operation. The proper adjustment is obtained when the armature is moved to the extreme position on each side (the movement being limited by the armature striking the pole pieces) and then brought to the mid position between these two extremes. Screw C should then be tightened. The armature position should then be central between the pole pieces and at right angles to them. With a little practice, the correct adjustment of the armature will be obtained. The air gap between the pole pieces and the armature should be kept free from dust, filings, and other foreign material which would obstruct the movement of the pickup armature.

Damping Block

The viscoloid damping block which is attached to the front end of the armature shank serves as a mechanical filter to eliminate undesirable resonances and to cause the frequency response to be uniform. Should it be necessary to replace this damping block, the pickup mechanism should be removed from the tone arm as explained above. Then unsolder the pickup coil leads from the two lugs on the pickup terminal board and remove the terminal board mounting screw and the terminal board. Then remove screw D and the damping block from the pickup assembly. Make sure that the shaft of the armature which contacts the viscoloid is clean. Then insert the new damping block so that it occupies the same position as that of the original block, and is in correct vertical alignment with the armature. The hole in the block is somewhat smaller than the diameter of the armature in order to permit a snug fit. With the damping block properly aligned on the armature, screw D with its washer should then be replaced. Heat should be applied to the armature (viscoloid side) so that the damping block will fuse at the point of contact and become rigidly attached to the armature. A special-tip soldering iron, constructed as shown in Figure 10, will be found very useful in performing this operation. The iron should be applied only long enough to slightly melt the block, causing a small bulge on both sides.

Replacing Coil

Whenever there is defective operation due to an open or shorted pickup coil, this coil should be replaced. Remove the pickup mechanism and terminal board as described above. Remove screws A and B and the magnet assembly. Remove the bakelite coil support (with coil attached) and insert the new coil support assembly in its place, after which replace the magnet assembly and center the armature as described above, then reassemble the remainder of the unit. Only rosin core solder should be used for soldering the coil leads and pickup leads to the pickup terminal board. This same type of solder should be used when necessary for soldering the centering spring to the armature.

Magnetizing

Loss of magnetization will not usually occur when the pickup has received normal care due to the fact that the magnet and pole pieces are one unit and the magnetic circuit remains closed at all times. When the pickup has been mishandled, subjected to a strong a-c field, jolted, or dropped, there may be an appreciable loss of magnetic strength, in which case it will be necessary to remagnetize the entire structure. To do this, it will be necessary to first remove the pickup mechanism from the tone arm, and then remove the magnet assembly. Place the magnet assembly on the poles of a standard pickup magnetizer such as the **RCA Stock No. 9549 Pickup Magnetizer** and charging the magnet in accordance with the instructions accompanying the magnetizer. It is preferable to check the polarity of the pickup magnet and to remagnetize it so that the same polarity is maintained.

Mechanical Specifications

Height	39¼ inches
Width	23⅛ inches
Depth	14⅛ inches
Weight (Net)	65 pounds
Weight (Shipping)	85 pounds
Chassis Base Dimensions	13⅞ inches x 7⅝ inches x 2½ inches

REPLACEMENT PARTS

Insist on genuine factory tested parts, which are readily identified and may be purchased from authorized dealers

Stock No.	Description	List Price
	RECEIVER ASSEMBLIES	
5237	Bushing—Variable tuning condenser mounting bushing assembly—Package of 3	$0.43
11759	Cable—Two-conductor shielded cable—complete with four-contact female connector	.92
11758	Cable—Three-conductor shielded cable complete with four-contact male connector and grid contact cap—connects phonograph volume control to chassis cable	1.04
11350	Cap—Contact cap Package of 5	.20
11463	Capacitor—Adjustable capacitor—(C18)	.48
11289	Capacitor—50 MMfd. (C37)	.36
5116	Capacitor—175 MMfd.—(C31)	.18
11290	Capacitor—400 MMfd.—(C2, C7, C13, C38)	.25
11401	Capacitor—4000 MMfd.—(C3)	.38
4868	Capacitor—.005 Mfd.—(C29, C34)	.20
4906	Capacitor—.017 Mfd.—(C33)	.25
11395	Capacitor—.01 Mfd.—(C28)	.18
4858	Capacitor—.01 Mfd.—(C32)	.25
11414	Capacitor—0.1 Mfd.—(C43)	.20
4839	Capacitor—0.1 Mfd.—(C14)	.28
4841	Capacitor—0.1 Mfd.—(C21)	.23
5170	Capacitor—0.25 Mfd.—(C8)	.25
11240	Capacitor—10 Mfd.—(C36)	1.08
11387	Capacitor—10 Mfd.—(C22)	.86
5212	Capacitor—18 Mfd.—(C35)	1.16
5238	Clip—Antenna terminal board with clip, insulating strip and rivets	.14
11600	Coil—Antenna coil—(L2, L3, L4, L5, C4, R1)	1.78
11601	Coil—Detector coil—(L6, L7, L8, L9, C9, R3)	1.78
11602	Coil—Oscillator coil—(L10, L11, L12, L13, L14, L15, C15, C16)	2.15
6123	Connector—Four-contact male connector for cable, Stock No. 11758	.30
4153	Connector—Four-contact female connector for cable, Stock No. 11759	.48
11385	Condenser—Three gang variable tuning condenser—(C5, C6, C11, C12, C19, C20)	5.02
11675	Dial—Station selector dial	.78
11394	Foot—Chassis foot assembly—Package of 2	.70
11396	Indicator—Station selector indicator pointer	.25
5226	Lamp—Dial lamp—Package of 5	.70
11393	Resistor—Voltage divider resistor—comprising one 3,500 ohm and one 13,000 ohm sections—(R15, R20)	.74
11329	Resistor—Voltage divider resistor—comprising one 85 ohm, one 148 ohm, one 32 ohm sections—(R16, R17, R18)	.52
11369	Resistor—12 ohms—flexible type complete with contact cap—(R22)	.22
11324	Resistor—560 ohms—Carbon type—¼ watt—(R24)—Package of 5	1.00
3066	Resistor—12,000 ohms—Carbon type—1 watt—(R5*)—Package of 5	1.10
8072	Resistor—33,000 ohms—Carbon type—½ watt—(R5*)—Package of 5	1.00
11322	Resistor—39,000 ohms—Carbon type—¼ watt—(R10)—Package of 5	1.00
11282	Resistor—56,000 ohms—Carbon type—1/10 watt—(R19*)—Package of 5	.75
11365	Resistor—82,000 ohms—Carbon type—¼ watt—(R23)—Package of 5	1.00
3118	Resistor—100,000 ohms—Carbon type—¼ watt—(R19*)—Package of 5	1.00
11325	Resistor—270,000 ohms—Carbon type—¼ watt—(R13)—Package of 5	1.00
11172	Resistor—470,000 ohms—Carbon type—¼ watt—(R14)—Package of 5	1.00
11397	Resistor—560,000 ohms—Carbon type—1/10 watt—(R2, R4)—Package of 5	.75
11626	Resistor—2.2 megohms—Carbon type—¼ watt—(R9)—Package of 5	1.00
11603	Shield—Antenna or detector coil shield	.36
11604	Shield—Oscillator coil shield	.24
11383	Shield—Rectifier Radiotron shield	.20
11390	Shield—Intermediate frequency transformer shield	.25
11199	Socket—Dial lamp socket	.14
4794	Socket—4-contact rectifier Radiotron socket	.15
11198	Socket—7-contact 6K7—6F5—or 6H6 Radiotron socket	.15
11196	Socket—8-contact 6A8 or 6F6 Radiotron socket	.15
11386	Switch—Range switch—(S1)	1.16
11392	Switch—Tone control and power switch assembly—(S2, S3)	1.14
11388	Transformer—First intermediate frequency transformer—(L16, L17, C23, C24)	1.90
11389	Transformer—Second intermediate frequency transformer—(L18, L19, C25, C26, C27, R7, R8)	3.02
11384	Transformer—Power transformer—105-125 volts—50-60 cycles—(T1)	4.65
11725	Transformer—Power transformer—105-125 volts—25-30 cycles	6.60
11727	Transformer—Power transformer—105-130, 140-160, 195-250 volts—40-60 cycles	6.60
11391	Trap—Wave trap—(L1, C1)	1.72
11237	Volume Control—(R11)	1.20
	PICKUP AND ARM ASSEMBLY	
11731	Armature—Pickup armature	.64
11730	Cable—Pickup cable	.14
11732	Coil—Pickup coil (L23)	.60
4543	Damper—Pickup damper block complete with damper plate	.10
11728	Pickup and Arm Assembly—Complete	8.15
3811	Screw—Needle holding screw—Package of 10	.46
	MOTOR ASSEMBLY	
10394	Ball—Steel ball bearing—Package of 20	.25
11740	Base—Motor base and bearing assembly	1.45
11745	Cap—Turntable spindle cap—Package of 5	.30
11733	Coil—Stator assembly—comprising coil and laminations—105-125 volt, 60 cycle operation	2.98
11734	Coil—Stator assembly—comprising coil and laminations—105-125 volt, 50 cycle operation	3.00
11735	Coil—Stator assembly—comprising coil and laminations—105-125 volt, 25 cycle operation	3.08
11748	Damper—Motor damper assembly—comprising one damper, one damper plate, one screw, two rubber washers and one "C" washer	.20
11741	Motor—105-125 volts—60 cycle motor complete (M1)	11.10
11742	Motor—105-125 volts—50 cycle motor complete	11.10
11743	Motor—105-125 volts—25 cycle motor complete	11.60
11746	Tripper—Automatic brake tripper—located on rotor laminations	.16
11737	Turntable—Turntable assembly—complete with rotor laminations—60 cycle operation	4.80
11738	Turntable—Turntable assembly—complete with rotor laminations—50 cycle operation	4.80
11739	Turntable—Turntable assembly—complete with rotor laminations—25 cycle operation	5.05
4083	Washer—Leather washer—Package of 10	.20
4084	Washer—Metal washer—Package of 10	.26
	MOTOR BOARD ASSEMBLY	
11752	Brake—Automatic brake and switch—complete	2.50
11751	Bushing—Motor mounting bushing and spring assembly—comprising one bushing, one large washer, one cup washer, one spring, one small washer and two nuts	.74
4577	Connector—Two-contact male connector for power supply cable	.30
2947	Leather—Automatic brake friction leather—Package of 20	.50
11749	Lever—Brake mechanism actuating lever—fastens to pivot shaft under base of pickup arm	.28
11754	Lever—Friction lever assembly—complete	.38
11753	Plunger—Automatic brake trip plunger	.18
3261	Rest—Pickup rubber rest—Package of 5	.40
11750	Screw—No. 4-40x9/32-in. cone pointed headless set screw for brake mechanism actuating lever, Stock No. 11749—Package of 10	.22
11756	Spring—Automatic stop mechanism trip lever spring—Package of 10	.22
11757	Spring—Automatic stop mechanism brake lever spring—Package of 10	.20
11755	Switch—Automatic brake switch (S4)	.75
	REPRODUCER ASSEMBLIES	
11232	Board—Terminal board assembly with two lead wire clips	.18
11231	Bolt—Yoke and core assembly bolt and nut	.16
8060	Bracket—Output transformer mounting bracket	.14
11237	Clamp—Cone center suspension clamping nut and screw assembly—Package of 5	.25
11254	Coil—Field coil—(L22)	2.00
11233	Coil—Hum neutralizing coil—(L21)	.30
11258	Cone—Reproducer cone—(L20)—Package of 5	3.85
5118	Connector—3-contact male connector for reproducer	.25
5119	Connector—3-contact female connector plug for reproducer cable	.35
9619	Reproducer—Complete	6.05
11253	Transformer—Output transformer—(T2)	1.36
11884	Washer—spring washer used to hold speaker field coil securely—Package of 5	.20
	MISCELLANEOUS ASSEMBLIES	
11762	Box—Used needle box	.25
11764	Cable—Two-conductor shielded cable approximately 28-in. long, connects phonograph volume control to compensator pack	.56
11760	Compensator—Phonograph compensator pack—Comprising one 470 ohm and one 1,000 ohm resistors, one .01 Mfd., one 0.1 Mfd. and one 1.0 Mfd. capacitors, and one 0.25H reactor—(R25, R26, C39, C40, C41, L24)	3.85
11376	Escutcheon—Station selector escutcheon and crystal	.70
11582	Knob—Range switch knob—Package of 5	.50
11347	Knob—Volume control, power switch or phonograph volume control knob—Package of 5	.75
11610	Knob—Station selector knob assembly—comprising one large and one small knob—Package of 5	1.00
11763	Receptacle—Needle receptacle	.38
11210	Screw—Chassis mounting screw assembly—Package of 4	.28
11761	Screw—Motor board screw and finishing washer assembly—Package of 10	.28
11349	Spring—Retaining spring for knobs, Stock No. 11347, No. 11582 and small knob in Stock No. 11610—Package of 5	.15
4982	Spring—Retaining spring for large knob in Stock No. 11610—Package of 10	.26
11695	Volume Control—Phonograph volume control (R27, S5)	1.60

The prices quoted above are subject to change without notice.

—NOTES—

(1) Beat notes or heterodyning (whistles) may be encountered in some instances on these receivers due to excessive antenna capacitance. This condition may be corrected by reducing the size of the antenna or by inserting a 150 mmfd. capacitor in series with the antenna lead. This may be accomplished in the receiver by removing the brown lead which connects from the antenna terminal to the wave trap inductance L-1 and inserting the condenser between these points. Interference in the form of "beats" from a local station may frequently be remedied by tuning the antenna wave trap to that station. The wave trap will tune up to 700 kc.

General Description

These two models are similar to RCA Victor Models T6-1 and C6-2 respectively. The changes consist of (1) the addition of an RCA-6E5 Tuning Indicator, (2) an RCA-5Z4 all-metal rectifier used in place of the RCA-80, and (3) new cabinet design. All service data for Models T6-1 and C6-2 are directly applicable to these instruments except as follows:

Secondary resistance of Universal Transformer, 355 ohms total.

Tuning Tube Cable voltages: Yellow, 0 v.; Brown, 6.4 v. a-c; Red, 263 v.; and Green, 0 v.

The following parts listed for Models T6-1 and C6-2 are not required: Stock Nos. 4841 (C23), 11615, 11376, 11396, 11283, 5158, 11383, 11458, 11585, 11584, and 11230.

The parts listed below are required in addition to the remaining parts for Models T6-1 and C6-2 :

Stock No.	Description	List Price
11996	Bracket—Tuning tube mounting bracket and clamp assembly	.22
11888	Cable—Tuning tube cable, complete with socket	1.06
4836	Capacitor—.05 Mfd. (C35)	.30
11894	Dial—Station selector dial scale	.65
11276	Escutcheon—Tuning tube escutcheon	.40
11893	Indicator—Station selector indicator pointer	.28
11455	Knob—Volume control or power switch knob—Package of 5	.48
11609	Knob—Range switch knob—Package of 5	.52
11610	Knob—Station selector knob assembly, comprising one large and one small knob—Package of 5	1.00

Alignment

RCA MFG. CO., INC.

GENERAL FEATURES

These two instruments are alike in chassis construction and design. The table model employs an 8 inch loudspeaker while the console model uses a 12 inch unit. The following features are of outstanding interest:—

Metal Tubes

This receiver uses the new metal tubes which are much smaller in size than the corresponding glass types. The high frequency efficiency of these metal tubes is greater, because of; the shorter lengths of leads, lesser interelectrode capacitance and the more complete shielding of the metallic envelopes. Their rugged construction prevents breakage and reduces microphonic tendencies. The bases and sockets of all types have a standardized arrangement of connecting prongs.

Dial Drive

An open face airplane type of dial is used. Each scale has a band of color adjacent to its graduations and three short strips of corresponding colors at the lower part of the dial for index purposes. An index pointer, which moves as the band switch is rotated, points to one of these colors to identify the band in use. The drive mechanism is variable, there being either a 50 to 1 or 10 to 1 ratio available between the tuning knob and condenser drive shaft.

Tuning Condenser

The variable tuning condenser is supported by a new design of shock-proof mount which has been developed by our engineers to prevent chassis vibration from producing audio frequency "howl"

Plug-in Loudspeaker

A readily detachable plug type of connection is used in the chassis to loudspeaker cable. This permits ready removal for service.

First Detector

This stage has unusually good high frequency mixing efficiency. The tube used, an RCA-6L7, is a new hexode type. The signal is supplied to the first control grid and the oscillator voltage is fed in on a second control grid, a screen grid separating the two. The arrangement of the grids prevents degenerative diffi-

CIRCUIT FEATURES

The circuit is based upon the Superheterodyne principle. The three ranges of tuning are covered by three sets of coils. A single r-f stage provides the desired selectivity and gain ahead of the hexode first detector tube. The oscillator stage operates separately from the first detector. A single stage i-f system is employed. Its basic frequency is 460 kc. Diode detection is performed by a double diode RCA-6H6 Radiotron. Automatic volume control is provided by this same tube. The audio system consists of two stages, one an RCA-6F5, and the output, an RCA-6F6. High voltages for plate and bias supplies are obtained from an RCA-5Z3 full wave rectifier through an efficient filter. The field of the loudspeaker acts as a reactor in the filter circuit. Further details of the circuit are as follows:—

Oscillator

The oscillator circuit has extreme stability of frequency and good uniformity of output over the tuning ranges. These qualities assure that the tuning of the receiver will not drift as the line voltage varies or the receiver heats. The action of the circuit is such that when the cathode emission tends to change with line voltage or because of other reasons, the variation of voltage drop in the plate and screen resistor restores the operating characteristics of the tube to normal and thus maintains constancy of the generated signal.

culties, particularly at the higher frequencies. The second grid is direct-connected to the cathode of the oscillator and has no d-c bias.

Compensated Volume Control

The variation in response of the human ear with different degrees of volume is compensated for by a resistor and condenser network in the manual volume control circuit. The volume control itself is an acoustically tapered potentiometer which provides equal changes of sound intensity for the listener per degree of rotation.

Range Switch

The band change switch has several functions. It exchanges the antenna, detector and oscillator coils in order to select the range desired. At the same time, it shorts out the unused coils so as to eliminate their absorptive effects. It also varies the fidelity by shorting a coupling condenser in the audio system to provide the desired reproduction for short as well as long wave reception.

Tone Control

Provision is included for variable reduction of high frequencies. This consists of a resistor and condenser combination across the primary winding of the output transformer, the resistor being the variable element. As it is decreased, the high frequency response limit is lowered.

Power System

The power transformer has its primary winding capacitively shielded from its secondary windings to eliminate transfer of line disturbances into the receiver and to stop any tendency for the circuit to radiate into the line. Rectification is performed in the usual manner by a full wave tube.

Detection and A.V.C.

The modulated signal as obtained from the output of the i-f system is detected by an RCA-6H6 double diode tube. The audio frequency secured by this process is passed on to the a-f system for amplification and final reproduction. The d-c voltage which results from detection of the signal is used for automatic volume control. This voltage, which develops across resistor R-8, is applied as automatic control grid bias to the r-f, first detector and i-f tubes through suitable resistance-capacitance filter circuits. The second diode of the RCA-6H6 is used to supply residual bias for these controlled tubes under conditions of little or no signal. This diode, under such conditions, draws current, which flows through R-9 and R-8, thereby maintaining the desired minimum operating bias on such tubes. On application of signal energy above a certain low level, however, the auxiliary bias diode ceases to draw current and the a.v.c. diode takes over the biasing function.

SERVICE DATA

The various diagrams of this booklet contain such information as will be needed for servicing the receiver. The ratings of all resistors, capacitors, coils, etc., are indicated adjacent to the symbols signifying these parts on the diagrams. The coils, reactors and transformer windings are rated in terms of their d-c resistance only and where the value is less than one ohm, no rating is given. Identification titles such as R-1, L-2, C-1, etc., are provided for reference between the illustrations and replacement parts list.

Alignment Procedure

There are a total of fourteen adjustments necessary for obtaining proper alignment when such a process becomes necessary. Four of these are involved with the i-f system and the remainder are associated with the antenna, first detector and oscillator coils.

Correct performance of the receiver can only be obtained when the trimmer adjustments have been made by a skilled service man with the use of adequate and reliable test equipment. Such apparatus as may be required for this particular instrument is illustrated and described on a separate page of this booklet.

Two methods of alignment are applicable. One utilizes a Cathode-Ray Oscillograph as a means of output indication and the other follows former procedure where a glow type indicator or meter is used. The oscillographic method is much to be preferred, since greater accuracy is possible and the time required is lessened. There are no approximations necessary as with the meter or aural method, but each adjustment can be made with excellent precision. Both methods are hereinafter outlined so that alignment operations may be made according to the equipment available.

It is wise to determine the necessity for alignment as well as the direction of misalignment before making adjustments. The RCA Tuning Wand is an instrument designed particularly for such a purpose.

The Tuning Wand consists of a bakelite rod having a small brass cylinder at one end and a core of finely divided iron at the other. It may be inserted into a tuned coil while a signal of the normal resonant frequency is being supplied to such coil to obtain an indication of the tuning. Holes are provided at the top of each shield can for entrance of the Wand. The presence of either end of the Wand will cause a change in tuning which will be indicated at the receiver output as an increase or decrease in signal level. If there is a decrease of output when either end is inserted, the tuning is correct and will require no adjustment. However, should there be an increase of output due to the iron core and decrease with the brass cylinder, an increase in inductance or capacitance is indicated as necessary to bring the circuit into line. The trimmer involved should therefore be increased accordingly. If the brass cylinder end causes an increase in output while the iron end causes a decrease, reduction of inductance will be necessary to place the circuit in alignment. This is equivalent to decreasing the trimmer concerned. The following tabulation gives the various changes and the adjustments required:—

WAND	SIGNAL	INDICATES
Brass	Decrease	None
Iron	Decrease	
Brass	Increase	Decrease
Iron	Decrease	
Brass	Decrease	Increase
Iron	Increase	

(1) CATHODE-RAY ALIGNMENT

Equipment

A standard source of the specified alignment frequencies is required. Such a source should consist of an RCA Full Range Oscillator, Stock No. 9595. Output indication should be by means of an RCA Stock No. 9545 Cathode-Ray Oscillograph. An RCA Stock No. 9558 Frequency Modulator will be needed to sweep the generated signal and synchronize it with the Oscillograph in order to make possible the visual representation of the resonant characteristic of the circuit being tuned on the cathode-ray fluorescent screen.

I-F Trimmer Adjustments

The four trimmers of the two i-f transformers are located as shown by Figure 6. Each must be aligned to a basic frequency of 460 kc. The last transformer must be aligned firstly and the first transformer aligned secondly. For such a process, it is necessary to feed the output of the Full Range Oscillator to the stages in their order of alignment, adjusting the trimmers of each transformer and observing the effect at the second detector output on the Cathode-Ray Oscillograph. The proper point of connection of the Oscillograph is with its vertical "high" input terminal attached to the juncture of R-7, R-8 and R-9 as illustrated in Figure 6, and with the "0" or ground terminal to the chassis. The "Ext. Sync." terminals of the Oscillograph should be connected to the Frequency Modulator as shown by Figure 5. A .001 mfd. capacitor installed in series with the Oscillator "Ant." lead will prevent the voltages of the stage under alignment from becoming upset. The vertical "A" amplifier should be "On" for the ensuing adjustments and the gain control kept at its maximum position. For each adjustment, the Oscillator's output need be regulated so that the image obtained on the Oscillograph screen will be of sufficient size as to be accurately observable. Proceed further as follows:—

(a) Place the receiver, Oscillograph and test Oscillator in operation. Set the receiver range switch to Band "A" and tune the station selector to a point where no interference will be picked up, shorting the antenna and ground terminals if necessary. Set the Oscillograph horizontal "B" amplifier to "Timing" and control its gain so that the luminescent spot sweeps a straight line trace completely across the screen. Place the timing control to "Int." Adjust the intensity and focusing controls of the Oscillograph to produce the correct size and strength of the spot.

(b) Attach the output of the test Oscillator between the control grid cap of the RCA-6K7 i-f tube and chassis ground as shown typically by Figure 5. Tune the Oscillator to 460 kc. and set its modulation switch to "On". Regulate its output until the signal produces a wave pattern on the Oscillograph screen, adjusting the Oscillograph controls to give the desired number of cycles. Cause the image to stand still on the screen by manipulation of the frequency and synchronizing controls. Then carefully tune the two trimmers C-29 and C-30 of the second i-f transformer to produce maximum amplitude (vertical deflection) of the oscillographic image. Under this condition the transformer will be sharply resonated to 460 kc.

(c) The Frequency Modulator should then be placed in operation and interconnected with the Full Range Oscillator by means of the special shielded patch cord. Figure 5 shows the proper arrangement. Set the Frequency Modulator sweep range switch to its "Lo" position and turn the Oscillator modulation switch to "Off". Change the timing control of the Oscillograph to "Ext." and place the range switch to its No. 1 position. Then carefully shift the tuning of the Oscillator so as to increase its frequency, until two distinct and similar waves appear on the Oscillograph screen and become exactly coincident at their highest points. These curves will be found to occur at an Oscillator setting of *approximately 540* kc. They will be identical in shape but appearing in reversed positions. Adjust the frequency control of the Oscillograph in order to cause the waves to conform with the above requirements and to make them remain motionless on the screen. This will require a setting of approximately ½ clockwise rotation of the frequency control. The trimmers C-29 and C-30 should then be re-adjusted so that the two curves move together and become exactly coincident throughout their lengths, maintaining the maximum amplitude at which this condition can be brought about.

(d) Leaving the equipment connected and adjusted as in (c), change the Oscillator output to the control grid cap of the RCA-6L7 first detector tube. Then adjust the first i-f transformer trimmers C-24 and C-25 so that the forward and reverse waves appearing on the Oscillograph coincide throughout their lengths and have maximum amplitude. The shape of the composite wave obtained from this operation is a true representation of the overall tuning characteristic of the i-f system. Each trimmer of the entire group should then be checked to assure that it is in correct alignment as indicated by the degree of coincidence and relative amplitude of the image on the Oscillograph screen.

R-F Trimmer Adjustments

Locations of the various antenna, detector and oscillator coil trimmers are shown by Figure 6. The test Oscillator should be removed from connection with the i-f system and its output connected to the antenna-ground terminals of the receiver. No changes are to be made in the connections of the Oscillograph at the second detector. During the following adjustments, the Oscillator output should be regulated as often as is necessary to keep the oscillographic image as low as is practically observable. Adherence to such a procedure will obviate the broadness of tuning that would result from a.v.c. action on a stronger signal. Proceed with the adjustments as follows:—

Calibration

Set the receiver range switch to Band A and rotate the station selector until the tuning condenser plates are in full mesh (maximum capacitance). Then move the main dial pointer until it points exactly to the horizontal line at the low frequency end of the Band A scale.

Band A

(a) With the receiver range switch in its Band A position, tune the station selector until the dial pointer is at a reading of 1720 kc. Adjust the test Oscillator to 1720 kc. (modulation "On" and Frequency Modulator disconnected) and increase its output to produce a registration on the Oscillograph. Carefully align the oscillator, detector and antenna trimmers C-20, C-10 and C-3 respectively, so that each brings about maximum amplitude of output as shown by the wave on the Oscillograph. It will be necessary to have the timing control of the Oscillograph on "Int." for this operation. After each trimmer has been peaked, the Oscillograph timing control should be set to "Ext." and the Frequency Modulator placed into operation with its connections to the Oscillator and Oscillograph made in accordance with Figure 5. Turn the modulation switch of the Oscillator to "Off" and retune the Oscillator (increase frequency) until the forward and reverse waves show on the Oscillograph and become coincident at their highest points. Adjust the trimmers C-20, C-10 and C-3 again, setting each to the point which produces the best coincidence and maximum amplitude of the wave images.

(b) Remove the Frequency Modulator cable from the Oscillator and shift the signal frequency to 600 kc. Place the modulation switch to "On". Tune the receiver to pick up this signal, disregarding the dial reading at which it is best received. Then insert the Frequency Modulator plug and retune the Oscillator (modulation "Off") until the two similar forward and reverse waves appear on the screen. For this adjustment, it is advisable to shift the Oscillator to its 200—400 kc. range and use the third harmonic of the generated signal in order to obtain the desired range of sweep. The oscillator series trimmer C-19 should then be adjusted to produce maximum amplitude of the images. No rocking will be necessary on the station selector inasmuch as the signal frequency is being "wobbled" by the Frequency Modulator to produce the same effect.

After completing this adjustment the trimmer C-20 should be re-aligned as in (a) to correct for any change brought about by the adjustment of C-19.

Band B

(a) Advance the receiver range switch to its Band B position and tune the station selector to a dial reading of 6132 kc. Set the test Oscillator to this same frequency (modulation "On" and Frequency Modulator disconnected) and increase its output until a suitable indication is apparent on the Oscillograph. The Oscillograph should be adjusted for "Int." timing. Then adjust the oscillator trimmer C-18 to the point at which maximum amplitude of the image is obtained. Two positions will be found for this trimmer which gives such a maximum. The one of least capacitance is correct and should be used. This can be checked by tuning the "image" signal, which will be received at 5212 kc. on the dial if the adjustment of C-18 has been properly made. An increase in test Oscillator output may be necessary for this test, however, *its frequency should not be changed from 6132 kc. nor any trimmer adjustments made on the receiver.*

(b) Return the station selector to the 6132 kc. reading and align the detector and antenna coil trimmers, C-9 and C-2 respectively, for maximum (peak) output as shown by the Oscillograph. No further adjustments are to be made on this band.

Band C

(a) Turn the range switch of the receiver to its Band C position and tune the station selector until the dial pointer reads 18,000 kc. Set the test Oscillator to the same frequency (modulation "On" and Frequency Modulator disconnected) and regulate its output to the level required for convenient observation. Adjust the trimmer C-16 to the point producing maximum output as indicated on the Oscillograph. Check for the presence of the proper "image" signal by tuning the receiver to 17,080 kc. The 18,000 kc. signal of the Oscillator will be received at this point if the adjustment of C-16 has been properly made using the position of least capacitance which gives maximum receiver output. It may be necessary to increase the output of the Oscillator in order to get an indication of the "image". *No adjustments should be made during this check.*

(b) Return the receiver tuning to 18,000 kc., re-align C-16 if necessary, and then adjust the detector and antenna trimmers, C-8 and C-1, for maximum signal output as evidenced by the oscillographic image. No further adjustments are to be made on this band.

(2) ALIGNMENT WITH OUTPUT METER

To align the receiver by means of an output indicator other than a Cathode-Ray Oscillograph will require the use of a standard test Oscillator such as that recommended above for the source of signals and means of indication for the output. The RCA Neon Output Indicator, Stock No. 4317 will be found very satisfactory for such use. It should be connected across the voice coil circuit of the loudspeaker or across the output transformer primary.

I-F Alignment

Connect the test Oscillator to the control grid cap of the i-f tube. Advance the volume control of the receiver, to its full-on position. Tune the test Oscillator accurately to 460 kc, and align the trimmers C-29 and C-30 to give maximum receiver output. Regulate the Oscillator output during this adjustment so that the output indication is as small as can be conveniently observed. After completing the adjustments of these trimmers re-connect the Oscillator so that it will feed into the control grid circuit of the RCA-6L7 first detector. Then tune the first i-f transformer trimmers C-24 and C-25 for maximum receiver output.

R-F Alignment

After completing the i-f adjustments, it is advisable to correct the line-up of the circuits ahead of the first detector. The test Oscillator should be connected to the antenna-ground terminals of the receiver and the manual volume control kept at its maximum position. For each adjustment the Oscillator output should be maintained as low as possible in order to avoid broadness of tuning which would result from a.v.c. action on a stronger signal. Band A should be aligned by supplying a 1720 kc. signal to the receiver, tuning the station selector to a dial reading of 1720 and adjusting the trimmers C-20, C-10 and C-3 to produce maximum receiver output. The Oscillator should then be shifted to 600 kc. and the receiver tuned to resonate this signal, disregarding the reading at which it is best received. Trimmer C-19 must then be adjusted, simultaneously while rocking the station selector backward and forward through the signal until the maximum output results from the combined operations. C-20 should be rechecked to assure that its adjustment has not changed because of the trimming of C-19. Band B must be aligned at 6132 kc. by tuning the test Oscillator to such a frequency and turning the station selector to the same dial reading. Tune the trimmer C-18 to produce maximum receiver output, using the setting of least capacitance which causes same. The presence of the proper "image" may be checked by tuning the receiver to 5212 kc. at which point the 6132 kc. signal will be heard if the trimmer C-18 has been properly set to the position of least capacitance for maximum (peak) output. It may be necessary to increase the Oscillator output for this check. *No adjustments are to be made.* Return the station selector to the 6132 kc. dial marking and trim capacitors C-9 and C-2 for maximum receiver output. No other adjustments are necessary on Band B. Change the receiver so that it is operative and the dial reads 18,000 kc. on the "C" Band. Tune the test Oscillator to this same frequency. Then adjust the oscillator trimmer C-16 to produce maximum (peak) output. Two positions of this trimmer will be found which conform with this requirement. The one of least capacitance is correct. Check for the presence of "image" response at 17,080 kc. by shifting the receiver tuning. If it is received at such a point, the trimmer C-16 has been correctly adjusted to the right peak. *No adjustments are to be made during this check.* Tune the receiver back to the 18,000 kc. dial marking, re-adjust C-16 if necessary, and then tune the detector and antenna capacitors C-1 and C-8 for maximum receiver output. No further adjustments are necessary.

Radiotron Socket Voltages

The voltage values indicated from the Radiotron Socket contacts to chassis on Figure 6 will serve to assist in the location of causes for faulty operation. Each value as specified should hold within ± 20% when the receiver is normally operative at its rated supply voltage. Variations in excess of this limit will usually be indicative of trouble in the basic circuits. The voltages given are actual operating values and do not allow for inaccuracies which may be caused by the loading effect of a voltmeter's internal resistance. This resistance should be duly considered for all readings. The amount of circuit resistance shunting the meter during measurement will determine the accuracy to be obtained, the error increasing as the meter resistance becomes comparable to or less than the circuit resistance. For the majority of readings, a meter having an internal resistance of 1000 ohms per volt will be satisfactory when the range used for each reading is chosen as high as possible consistent with good readability.

Universal Transformer

The transformer used on some models of these receivers is adaptable to several ranges of voltage as given under rating C of Electrical Specifications. Its schematic and wiring are shown by Figure 7. Terminals are provided at the top of the transformer case for changing the primary connections to suit the voltage being used.

SERVICE NOTES

On receiver Models T 7-5 and T 8-14, three different type speakers are used. They can be readily identified by the following numbers stamped on them: (1) RL 63-4, (2) 76365-1, and (3) 76365-3.

On receiver Models T 10-1 and T 10-3, two different type speakers are used: (1) RL 63-5 and (2) 76365-2.

On receiver Model T 8-16, two different type speakers are used: (1) RL 63-4 and (2) 76365-3.

The internal connections and replacement parts for speakers RL 63-4 and RL 63-5 are given in the Service Notes, while the schematic diagrams given below indicate the color code and wiring to the plug and connector for speakers: (1) 76365-1, (2) 76365-2, and (3) 76365-3. The replacement parts appear opposite the respective speakers.

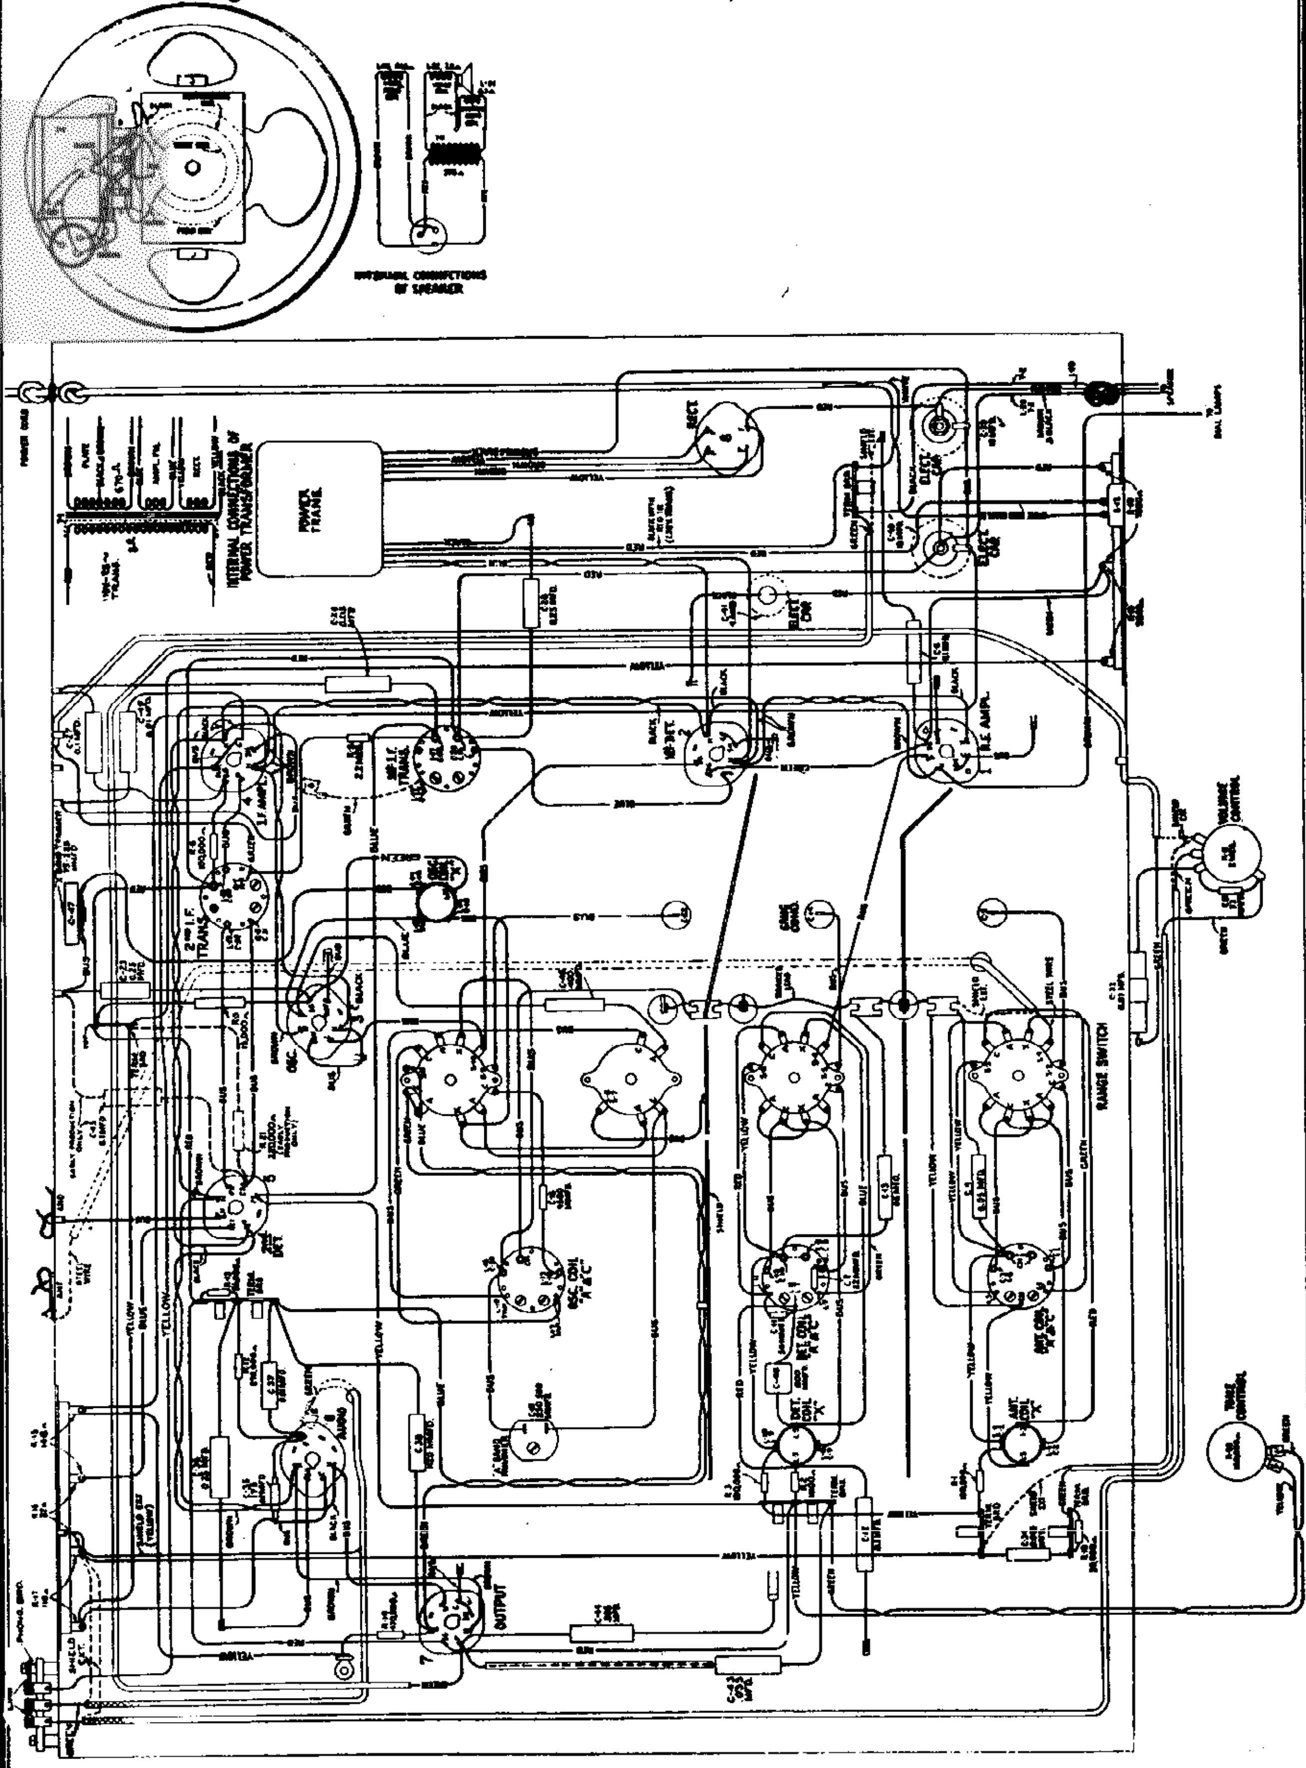

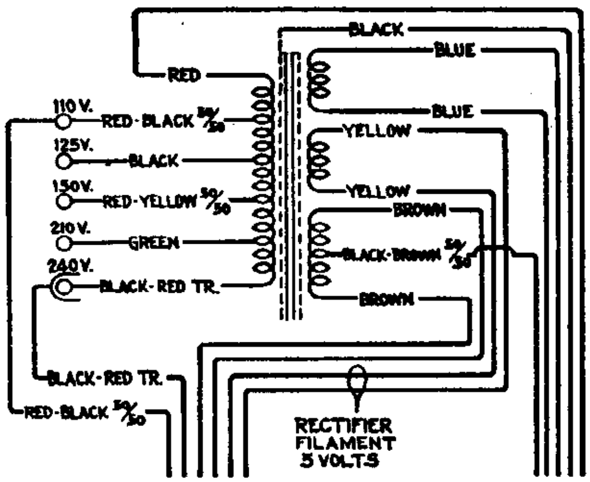

Figure 7—Universal Power Transformer Connections

Pri. Res.—10.3 Ohms, Total
Sec. Res.—383 Ohms, Total

Radiotron Socket Voltages

The voltage values indicated from the Radiotron socket contacts to chassis on Figure 6 will serve to assist in the location of causes for faulty operation. Each value as specified should hold within ± 20% when the receiver is normally operative at its rated supply voltage. Variations in excess of this limit will usually be indicative of trouble in the basic circuits. The voltages given are actual operating values and do not allow for inaccuracies which may be caused by the loading effect of a voltmeter's internal resistance. This resistance should be duly considered for all readings.

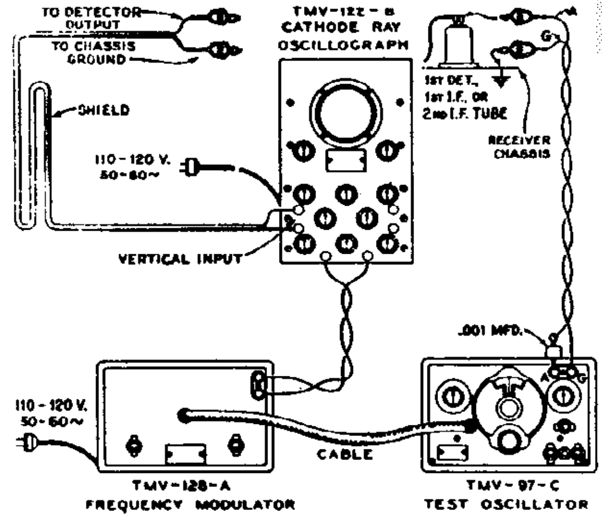

Figure 5—Alignment Apparatus Connections

The amount of circuit resistance shunting the meter during measurement will determine the accuracy to be obtained, the error increasing as the meter resistance becomes comparable to or less than the circuit resistance.

Universal Transformer

The transformer used on some models of these receivers is adaptable to several ranges of voltage as given under rating C of Electrical Specifications. Its schematic and wiring are shown by Figure 7. Terminals are provided at the top of the transformer case for changing the primary connections to suit the voltage being used.

Measured at 115 volts A.C.—No Signal—Volume Control Maximum

RCA MFG. CO., INC.

(1) CATHODE-RAY ALIGNMENT

Equipment

A standard source of the specified alignment frequencies is required. Such a source should consist of an RCA Full Range Oscillator, Stock No. 9595. Output indication should be by means of an RCA Stock No. 9545 Cathode-Ray Oscillograph. An RCA Stock No. 9558 Frequency Modulator will be needed to sweep the generated signal and synchronize it with the Oscillograph in order to make possible the visual representation of the resonant characteristic of the circuit being tuned on the cathode-ray fluorescent screen.

I-F Trimmer Adjustments

The four trimmers of the two i-f transformers are located as shown by Figure 6. Each must be aligned to a basic frequency of 460 kc. The last transformer must be aligned firstly and the first transformer aligned secondly. For such a process, it is necessary to feed the output of the Full Range Oscillator to the stage in their order of alignment, adjusting the trimmers of each transformer and observing the effect at the second detector output on the Cathode-Ray Oscillograph. The proper point of connection of the Oscillograph is with its vertical "high" input terminal attached to the juncture of R-7, R-8 and R-9 as illustrated in Figure 6, and with the "0" or ground terminal to the chassis. The "Ext. Sync." terminals of the Oscillograph should be connected to the Frequency Modulator as shown by Figure 5. A .001 mfd. capacitor installed in series with the Oscillator "Ant." lead will prevent the voltage of the stage under alignment from becoming upset. The vertical "A" amplifier should be "On" for the ensuing adjustments and the gain control kept at its maximum position. For each adjustment, the Oscillator output need be regulated so that the image obtained on the Oscillograph screen will be of sufficient size as to be accurately observable. Proceed further as follows:—

(a) Place the receiver, Oscillograph and test Oscillator in operation. Set the receiver range switch to Band "A" and tune the station selector to a point where no interference will be picked up, shorting the antenna and ground terminals if necessary. Set the Oscillograph horizontal "B" amplifier to "Timing" and control its gain so that the luminescent spot sweeps a straight line trace completely across the screen. Place the timing control to "Int." Adjust the intensity and focusing controls of the Oscillograph to produce the correct size and strength of the spot.

(b) Attach the output of the test Oscillator between the control grid cap of the RCA-6K7 i-f tube and chassis ground as shown typically by Figure 5. Tune the Oscillator to 460 kc. and set its modulation switch to "On". Regulate its output until the signal produces a wave pattern on the Oscillograph screen, adjusting the Oscillograph controls to give the desired number of cycles. Cause the image to stand still on the screen by manipulation of the frequency and synchronizing controls. Then carefully tune the two trimmers C-29 and C-30 of the second i-f transformer to produce maximum amplitude (vertical deflection) of the oscillographic image. Under this condition the transformer will be sharply resonated to 460 kc.

(c) The Frequency Modulator should then be placed in operation and interconnected with the Full Range Oscillator by means of the special shielded patch cord. Figure 5 shows the proper arrangement. Set the Frequency Modulator sweep range switch to its "Lo" position and turn the Oscillator modulation switch to "Off". Change the timing control of the Oscillograph to "Ext." and place the range switch to its No. 2 position. Then carefully shift the tuning of the Oscillator so as to increase its frequency, until two distinct and similar waves appear on the Oscillograph screen and become exactly coincident at their highest points. These curves will be found to occur at an Oscillator setting of *approximately* 540 kc. They will be identical in shape but appearing in reversed positions. Adjust the frequency control of the Oscillograph in order to cause the waves to conform with the above requirements and to make them remain motionless on the screen. This will require a setting of approximately ½ clockwise rotation of the frequency control. The trimmers C-29 and C-30 should then be re-adjusted so that the two curves move together and become exactly coincident throughout their lengths, maintaining the maximum amplitude at which this condition can be brought about.

(d) Leaving the equipment connected and adjusted as in (c), change the Oscillator output to the control grid cap of the RCA-6L7 first detector tube. Then adjust the first i-f transformer trimmers C-24 and C-25 so that the forward and reverse waves appearing on the Oscillograph coincide throughout their lengths and have maximum amplitude. The shape of the composite wave obtained from this operation is a true representation of the overall tuning characteristic of the i-f system. Each trimmer of the entire group should then be checked to assure that it is in correct alignment as indicated by the degree of coincidence and relative amplitude of the image on the Oscillograph screen.

R-F Trimmer Adjustments

Locations of the various antenna, detector and oscillator coil trimmers are shown by Figure 6. The test Oscillator should be removed from connection with the i-f system and its output connected to the antenna-ground terminals of the receiver. No changes are to be made in the connections of the Oscillograph at the second detector. During the following adjustments, the Oscillator output should be regulated as often as is necessary to keep the oscillographic image as low as is practically observable. Adherence to such a procedure will obviate the broadness of tuning that would result from a.v.c. action on a stronger signal. Proceed with the adjustments as follows:—

Calibration

Set the receiver range switch to Band A and rotate the station selector until the tuning condenser plates are in full mesh (maximum capacitance). Then move the main dial pointer until it points exactly to the horizontal line at the low frequency end of the Band A scale.

Band A

(a) With the receiver range switch in its Band A position, tune the station selector until the dial pointer is at a reading of 1720 kc. Adjust the test Oscillator to 1720 kc. (modulation "On" and Frequency Modulator disconnected) and increase its output to produce a registration on the Oscillograph. Carefully align the oscillator, detector and antenna trimmers C-20, C-10 and C-3 respectively, so that each brings about maximum amplitude of output as shown by the wave on the Oscillograph. It will be necessary to have the timing control of the Oscillograph on "Int." for this operation. After each trimmer has been peaked, the Oscillograph timing control should be set to "Ext." and the Frequency Modulator placed into operation with its connections to the Oscillator and Oscillograph made in accordance with Figure 5. Turn the modulation switch of the Oscillator to "Off" and retune the Oscillator (increase frequency) until the forward and reverse waves show on the Oscillograph and become coincident at their highest points. Adjust the trimmers C-20, C-10 and C-3 again, setting each to the point which produces the best coincidence and maximum amplitude of the wave images.

(b) Remove the Frequency Modulator cable from the Oscillator and shift the signal frequency to 600 kc. Place the modulation switch to "On". Tune the receiver to pick up this signal, disregarding the dial reading at which it is best received. Then insert the Frequency Modulator plug and retune the Oscillator (modulation "Off") until the two similar forward and reversed waves appear on the screen. For this adjustment, it is advisable to shift the Oscillator to its 200—400 kc. range and use the third harmonic of the generated signal in order to obtain the desired range of sweep. The oscillator series trimmer C-19 should then be adjusted to produce maximum amplitude of the images. No rocking will be necessary on the station selector inasmuch as the signal frequency is being "wobbled" by the Frequency Modulator to produce the same effect.
After completing this adjustment the trimmer C-20 should be re-aligned as in (a) to correct for any change brought about by the adjustment of C-19.

Band X

(a) Disconnect the Frequency Modulator and tune the test Oscillator to a frequency of 400 kc. (Modulation "On"). Place the receiver range switch to its Band X position and tune the station selector until the dial pointer reads exactly 400 kc. Adjust the Oscillograph timing control to "Int." Then align each of the trimmers C-18, C-9 and C-2 to the point producing maximum output at the Oscillograph. Place the Frequency Modulator in operation and attach it to the test Oscillator by means of the shielded cable. Change the Oscillograph timing to "Ext." Increase the frequency of the Oscillator (Modulation "Off" until the two forward and reverse waves appear and become coincident at their highest point, approximately at 462 kc. These waves may be made to remain stationary on the screen by manipulation of the Oscillograph range switch (No. 2 position) and frequency control (mid-position). Re-adjust the three trimmers C-18, C-9 and C-2 to give maximum amplitude and complete coincidence of the waves.

(b) Change the test Oscillator so that it delivers a signal of 150 kc. with the Frequency Modulator disconnected. Tune this signal on the receiver, which should be set to the Band X setting, disregarding the dial reading at which the signal is best received. Then interconnect the Frequency Modulator with the Oscillator and retune the latter to the point at which the two similar waves appear on the screen. Adjust the trimmer C-47 for maximum amplitude of the wave images. Rocking of the tuning condenser will not be necessary for this operation as such is duplicated by the Frequency Modulator. Repeat the alignment of C-18 as in (a) to correct for any error brought about by the adjustment of C-47.

Band C

(a) Turn the range switch of the receiver to its Band C position and tune the station selector until the dial pointer reads 18,000 kc. Set the test Oscillator to the same frequency (modulation "On" and Frequency Modulator disconnected) and regulate its output to the level required for convenient observation. Adjust the trimmer C-16 to the point producing maximum output as indicated on the Oscillograph. Check for the presence of the proper "image" signal by tuning the receiver to 17,080 kc. The 18,000 kc. signal of the Oscillator will be received at this point if the adjustment of C-16 has been properly made using the position of least capacitance which gives maximum receiver output. It may be necessary to increase the output of the Oscillator in order to get an indication of the "image". *No adjustments should be made during this check.*

(b) Return the receiver tuning to 18,000 kc., re-align C-16 if necessary, and then adjust the detector and antenna trimmers, C-8 and C-1, for maximum signal output as evidenced by the oscillographic image. No further adjustments are to be made on this band.

OUTPUT INDICATOR ALIGNMENT

I-F Alignment

Connect the test Oscillator to the control grid cap of the i-f tube. Advance the volume control of the receiver to its full-on position. Tune the test Oscillator accurately to 460 kc. and align the trimmers C-29 and C-30 to give maximum receiver output. Regulate the Oscillator output during this adjustment so that the output indication is as small as can be conveniently observed. After completing the adjustments of these trimmers, re-connect the Oscillator so that it will feed into the control grid circuit of the RCA-6L7 first detector. Then tune the first i-f transformer trimmers C-24 and C-25 for maximum receiver output.

R-F Alignment

After completing the i-f adjustments, it is advisable to correct the line-up of the circuits ahead of the first detector. The test Oscillator should be connected to the antenna-ground terminals of the receiver and the manual volume control kept at its maximum position. For each adjustment the Oscillator output should be maintained as low as possible in order to avoid broadness of tuning which would result from a.v.c. action on a stronger signal. Band A should be aligned by supplying a 1720 kc. signal to the receiver, tuning the station selector to a dial reading of 1720 and adjusting the trimmers C-20, C-10 and C-3 to produce maximum receiver output. The Oscillator should then be shifted to 600 kc. and the receiver tuned to resonate this signal, disregarding the reading at which it is best received. Trimmer C-19 must then be adjusted, simultaneously while rocking the station selector backward and forward through the signal until the maximum output results from the combined operations. C-20 should be rechecked to assure that its adjustment has not changed because of the trimming of C-19. Band X must be aligned at 400 kc. and 150 kc. Tune the test Oscillator to 400 kc. and turn the receiver dial to the same reading. Adjust trimmers C-18, C-9 and C-2 for maximum (peak) receiver output. Then shift the Oscillator to 150 kc. and tune the receiver to pick up this signal, disregarding the dial reading at which it is best received. Adjust trimmer C-47, simultaneously rocking the tuning condenser backward and forward through the signal, until maximum receiver output results from the combined operations. Repeat the alignment of C-18 as above to correct for any change which may have been caused by the adjustment of C-47. Change the receiver so that it is operative and the dial reads 18,000 kc. on the "C" Band. Tune the test Oscillator to this same frequency. Then adjust the oscillator trimmer C-16 to produce maximum (peak) output. Two positions of this trimmer will be found which conform with this requirement. The one of least capacitance is correct. Check for the presence of "image" response at 17,080 kc. by shifting the receiver tuning. If it is received at such a point, the trimmer C-16 has been correctly adjusted to the right peak. *No adjustments are to be made during this check.* Tune the receiver back to the 18,000 kc. dial marking, re-adjust C-16 if necessary, and then tune the detector and antenna capacitors C-1 and C-8 for maximum receiver output. No further adjustments are necessary.

General Description

Magic Brain

The radio receiver incorporates the Junior "Magic Brain" which is a scientifically correct co-ordination of all the parts of the r-f, oscillator, and first detector functions of a Superheterodyne Receiver. This arrangement provides greater efficiency, especially in the short-wave ranges, as all lead lengths are kept as short as possible and all sockets and other parts are located for best possible operation.

Phonograph Mechanism

An improved manually operated phonograph mechanism is used in this model. The 12-inch turntable will accommodate either the 10-inch or the 12-inch phonograph records. The turntable rotates at a speed of 78 r.p.m. A speed regulator is provided for accurate adjustment of this speed. The instrument may be purchased with any one of three ratings as specified under Electrical Specifications. *It is important that a machine of any particular rating be operated at the frequency and voltage for which it is rated.* Attempts to operate at ratings other than specified for the particular instrument may result in damage to both the phonograph motor and the radio receiver. An automatic switch is provided to turn "off" the phonograph motor at the completion of record play when the eccentric-type inside groove record is used.

Tuning Dial

The tuning dial is an illuminated semi-airplane type. Each band is distinctively marked with a separate color for each band. Positions of the range selector knob are plainly marked on the control panel with letters indicating each band position placed over color strips corresponding to the band colors on the dial. The tuning control is of the dual-ratio type which permits fast tuning through a 10-to-1 drive ratio and vernier tuning through a 50-to-1 drive ratio. The latter is especially advantageous for accurate tuning of the short-wave stations. The new shock-proof condenser mounting reduces microphonic tendencies to a minimum.

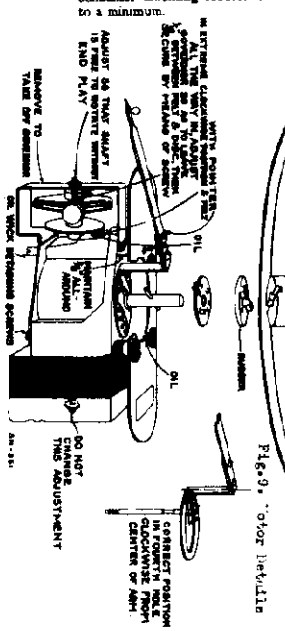

Fig. 9. Motor Details

Circuit Arrangement

The conventional Superheterodyne type of circuit, consisting of an r-f stage, a combined first-detector-oscillator stage, a single i-f stage, a diode-detector-automatic-volume-control stage, an audio voltage amplifier stage, an audio power output stage and a high-voltage rectifier power-supply stage, is used.

Tuned Circuits

The antenna coil system and the detector coil system each consist of a single primary and three series-connected secondary windings to provide the three ranges of tuning. The oscillator coil system is similarly wound on a single form. A range selector switch (S-1) is used for connecting the various sections of these three coil systems into the circuit to provide operation on the band desired. The coils are tuned by a variable three-section gang condenser having trimmer capacitors in shunt with each section. There are additional trimmer capacitors across the section of each coil used for Band "A." A series trimmer is also associated with the Band "A" oscillator coil.

The intermediate frequency amplifier system consists of an RCA-6K7 in a transformer-coupled circuit. This stage operates at a basic frequency of 460 kc. Each winding of both i-f transformers (input and output) is tuned by an adjustable trimmer.

Detector and A.V.C.

The modulated signal as obtained from the output of the i-f stage is detected by an RCA-6H6 twin-diode tube. The audio frequency secured by this process is transferred to the a-f system for amplification and final reproduction. The d-c voltage which results from detection of the signal is used for automatic volume control. This voltage, which develops across resistor R-8, is applied as automatic control-grid bias to the r-f, first-detector, and i-f tubes through a suitable resistance filter circuit. The second (auxiliary) diode of the RCA-6H6 is used to supply residual bias for the controlled tubes under conditions of little or no signal. This diode, under such conditions, draws current which flows through resistors R-8 and R-9, thereby maintaining the desired minimum operating bias on such tubes. On application of signal energy above a certain level, however, the auxiliary bias-diode ceases to draw current and the a.v.c. diode takes over the biasing function.

Audio System

The manual volume control consists of an acoustically tapered potentiometer in the audio circuit between the output of the detector diode and the input grid of the audio-voltage-amplifier tube. This control has a tone compensating filter connected to it so that the correct aural balance will be obtained at different volume settings.

Resistance-capacitance coupling is used between the first audio stage and the power output stage. The output of the power amplifier is transformer-coupled into the dynamic loudspeaker. High-frequency tone control is effected by a capacitor across the plate circuit of the output tube. Speech-music control is effected by a resistor connected to the compensated volume control circuit. Control of tone is obtained by means of the switch (S-2).

Rectifier

The power required for operation of this receiver is supplied through transformer T-1. This transformer has an efficient electrostatic shield between its primary and secondary windings. This shield prevents interference which is on the power-supply circuit from entering the receiver and conversely reduces the tendency of the receiver to re-radiate into the power circuit. An RCA-5Z4 furnishes the d-c voltages necessary for plate, screen, cathode, and grid potentials. The field winding of the loudspeaker is used as a reactor in the filter circuit from which it simultaneously receives its magnetizing current. The heaters of all Radiotrons are supplied from a low voltage (6.3 volt) winding on the power transformer. One side of this winding is at ground potential.

Wave-Trap Adjustment

With the receiver in operation using its normal antenna, tune station selector to the point at which the intermediate frequency interference is most intense. Then adjust the wave trap trimmer to the point which causes maximum suppression of the interference. This trimmer is adjusted to 460 kc. during manufacture, however, local conditions may require a readjustment, depending upon the interfering frequency.

Phonograph Mechanism

The phonograph motor is of the governor induction type and designed to be simple and foolproof. Under normal operating conditions, service difficulties should be negligible. Occasionally, however, certain adjustments may be required. These adjustments are illustrated and explained in Figure 9. Application of oil to the felt pad which rubs against the governor disc will insure smooth operation.

Magnetic Pickup

The pickup used in the phonograph unit is of an improved design, having several variations from the usual type of pickup. The magnetic assembly is one rigid piece. The horseshoe magnet is solidly welded to the pole pieces and is irremovable. There is a centering spring attached to the armature to maintain proper adjustment and provides a damping effect on the movement of the armature. The frequency response is uniform over a wide range.

Service operations which may be necessary on the pickup are as follows:

Centering Armature

Refer to Figure 8 showing the pickup inner structure. The armature is shown in its proper relation to the magnet pole pieces, i. e., exactly centered. Whenever this centering adjustment has been disturbed, the screws A, B, and C should be loosened and the armature clamp adjusted to the point where the vertical axis of the armature is at right angles to the horizontal axis of the pole pieces, and centered between them. This centering operation may be facilitated by inserting a small rod or nail into the armature needle hole, using it as a lever to test the angular movement of the armature. The limitations of the movement in each direction will be caused by the armature striking the pole pieces. The proper adjustment is obtained when there is equal angular displacement of the armature and adjustment rod or nail to each side of the vertical axis of the magnet and coil assembly. The screws A and B should then be secured, observing care not to disturb the adjustment of the armature clamp. Then place the pickup in a vise and secure the centering spring-clamp by means of the screw C, allowing the centering spring to remain in the position at which the armature is exactly centered between the pole pieces. With a little practice, the correct adjustment of the armature may be readily obtained. The air gap between the pole pieces and the armature should be kept free from dust, filings, and other such foreign materials which would obstruct the movement of the pickup armature.

Damping Block

The viscoloid block which is attached to the back end of the armature shank serves as a mechanical filter to eliminate undesirable resonances and to cause the frequency response to be uniform. Should it be necessary to replace this damping block, it may be done by removing screw D and the cover support bracket from the mechanism and taking off the old viscoloid block. The surface of the armature which is in contact with the viscoloid should be thoroughly cleaned with fine emery cloth. Then insert the new block so that it occupies the same position as it did originally. Make certain that the block is in correct vertical alignment with the armature. The hole in the new viscoloid block is somewhat smaller than the diameter of the armature in order to permit a snug fit. With the viscoloid aligned on the armature, screw D and the cover support bracket should then be replaced. Heat should be applied to the armature (viscoloid side) so that the viscoloid block will fuse at the point of contact and become rigidly attached to the armature. A special-tip soldering iron constructed as shown in Figure 10 will be found very useful in performing this operation. The iron should be applied only long enough to slightly melt the block and cause

MODEL D8-28
Alignment, Parts
Loudspeaker, Transformer

RCA MFG. CO., INC.

a small bulge on both sides.

Replacing Coil

Whenever there is defective operation due to an open or shorted pickup coil, this coil should be replaced. The method of replacement will be obvious upon inspection of the pickup assembly and by study of the cut-a-way illustrations. Make sure that the new coil is properly centered with the hole in the support strip and glued securely in that position. It is important to readjust the armature as previously explained after re-assembly of the mechanism. Only rosin core solder should be used for soldering the coil leads in the pickup. This same type of solder should be used when necessary for soldering the centering spring to the armature.

Magnetizing

Loss of magnetization will not usually occur when the pickup has received normal care, due to the fact that the magnet and pole pieces are one unit and the magnetic circuit remains closed at all times. When the pickup has been mishandled, subjected to a strong a-c field, jolted, or dropped, there may be an appreciable loss of magnetic strength, in which case it will be necessary to re-magnetize the entire structure. This should be done by first removing the pickup cover and then placing the pickup assembly on the poles of a standard pickup magnetizer such as the RCA Pickup Magnetizer, Stock No. 9549, and charging the pickup in accordance with the instructions accompanying the magnetizer. It is recommended that the pickup be magnetized with the armature in place. This will require that one pole piece on the pickup magnetizer be rotated 180 degrees. This gives the desired clearance for the armature clamp assembly. It is preferable to check the polarity of the pickup magnet and to re-magnetize it so that the same polarity is maintained.

SERVICE DATA

The various diagrams of this bulletin contain such information as will be needed to isolate causes for defective operation when such a condition develops. Values of the resistors, capacitors, coils, etc., are indicated adjacent to the symbols signifying these parts on the diagrams. Identification titles, such as R-3, L-2, C-1, etc., are provided for reference between the diagrams and the replacement parts list. Locating of the parts in the schematic circuit is facilitated by the fact that the numerical titles increase from left to right on the diagram. The coils, reactors, and transformer windings are rated in terms of their d-c resistances only. Resistances of less than one ohm are generally omitted.

Alignment Procedure

Precise alignment is vital to the proper functioning of this receiver. There are four trimming adjustments provided in the i-f system, three in the oscillator coil system, two in the detector coil system, and two in the antenna coil system. Each of these trimmers has been accurately adjusted during manufacture and should remain properly aligned unless affected by abnormal conditions of climate or have been altered for service purposes. Incorrect alignment is usually evidenced by loss of sensitivity, improper tone quality, and poor selectivity. These indications will generally be present together.

The correct performance of the receiver can only be obtained when the alignment is performed with adequate and reliable test apparatus. The manufacturer of this instrument has a complete assortment of such service equipment available. This equipment illustrated and described on a separate page of this booklet, may be purchased from authorized distributors and dealers.

An oscillator (signal generator) is required as a source of the specified alignment frequencies. Visual indication of the receiver output during the adjustments is necessary to enable the serviceman to obtain an accuracy of alignment which is not possible by listening to the signal. The RCA Victor Stock No. 9595 Full-Range Oscillator and the RCA Victor Stock No. 4317 Neon Output Indicator are especially suitable and fulfill the above requirements.

The following procedure should be followed in adjusting the various trimmer capacitors:

I-F Trimmer Adjustments

The four trimmers of the two i-f transformers are located as shown by Figure 6. Each must be aligned to a basic frequency of 460 kc. To do this, attach the Output Indicator across the voice coil circuit or across the output transformer primary. Connect the output of the test oscillator between the control-grid of the RCA-6A8 first detector tube and chassis-ground. Tune the oscillator to 460 kc. Advance the receiver volume control to its full-on position and adjust the receiver tuning control to a point within its range where no interference is encountered either from local broadcast stations or the heterodyne oscillator. Increase the output of the test oscillator until a slight indication is apparent on the output indicator. Then adjust the two trimmers, C-25 and C-26, of the second i-f transformer to produce maximum (peak) indicated receiver output. Then, adjust the two trimmers, C-23 and C-24, of the first i-f transformer for maximum (peak) receiver output as shown by the indicating device. During these adjustments, regulate the test oscillator output so that the indication is always as low as possible. By doing so, broadness of tuning due to a-v-c action will be avoided. It is advisable to repeat the adjustment of all i-f trimmers a second time to assure that the inter-action between them has not disturbed the original adjustment.

R-F Trimmer Adjustments

The seven trimmers associated with the r-f, first detector and oscillator tuned circuits have their locations shown by Figure 1. The three trimmers which are at all times directly in shunt with the variable tuning condenser necessitate that the high frequency range (Band C) be aligned first. The range selector switch should therefore be turned to its Band C position for the first adjustment. The Output Indicator should be left connected to the output system. Attach the output terminals of the test oscillator to the antenna and ground terminals of the receiver.

Calibrate the dial by rotating the tuning control until the variable condenser plates are in their full mesh (maximum capacity) position and adjusting the dial pointer so that its end points to the horizontal graduation (530 kc.) at the low frequency end of the Band A scale.

Proceed further as follows:

(a) Adjust the test oscillator to 18,000 kc. and set the receiver tuning control to a dial reading of 18,000 kc.

(b) Regulate the output of the test oscillator until a slight indication is perceptible at the receiver output. Then adjust the trimmer, C-20, on the oscillator section of the variable condenser to the point at which it produces maximum indicated receiver output. Two points may be found, each of which produces such a maximum. The one of maximum trimmer capacitance is correct and should be used. (The oscillator will be 460 kc. below the signal frequency at this adjustment point.)

(c) Adjust the trimmer, C-12, of the detector section of the variable condenser, simultaneously rocking the receiver tuning control backward and forward through the 18,000 kc. input signal, until maximum receiver output results from these combined operations. Rocking of the variable condenser will prevent inaccurate adjustment which would otherwise be caused by the inter-action between the heterodyne oscillator circuit and the detector tuned circuit.

(d) With the receiver tuning control set to 18,000 kc. adjust the trimmer, C-6, on the antenna section of the variable condenser to the point which produces maximum (peak) indicated receiver output.

(e) Change the receiver range selector to its Band A position and set the receiver tuning control to a dial reading of 1,400 kc. Tune the test oscillator to 1,400 kc. and regulate its output to produce a slight indication on the receiver output indicating device.

(f) Adjust the high frequency trimmers of the Band A oscillator, detector, and antenna coils, C-15, C-9, and C-4 respectively, to the points at which each produces maximum indicated receiver output.

(g) Shift the test oscillator frequency to 600 kc. and tune the receiver to pick up this signal, disregarding the dial reading at which it is best received.

(h) Tune the low frequency trimmer, C-18, of the oscillator Band A coil, simultaneously rocking the tuning control of the receiver backward and forward through the signal, until maximum indicated receiver output results from these combined operations. The adjustment of C-20, C-12, and C-6 should be corrected at 18,000 kc. as in (b), (c), and (d); also C-15, C-9, and C-4 should be corrected at 1,400 kc. as in (f) to compensate for any changes caused by the adjustment of the low frequency oscillator coil trimmer.

Radiotron Socket Voltages

The voltage values indicated from the Radiotron socket contacts to chassis on Figure 6 will assist in the location of causes for faulty operation. Each value as specified should hold within ± 20% when the receiver is normally operative at its rated supply voltage. Variations in excess of this limit will usually be indicative of trouble in the basic circuits. The voltages given are actual operating values and do not allow for inaccuracies which may be caused by the loading effect of a voltmeter's internal resistance. This resistance should be duly considered for all readings. The amount of circuit resistance shunting the meter during measurement will determine the accuracy to be obtained, the error increasing as the meter resistance becomes comparable to or less than the circuit resistance. For the majority of readings, a meter having an internal resistance of 1000 ohms per volt will be satisfactory when the range used for each reading is chosen as high as possible consistent with good readability.

Standard Transformer

The transformer used on some models of this instrument is adaptable for voltages and frequencies as given under Ratings A and B of Electrical Specifications. Its schematic and wiring are shown by Figure 5.

The resistance values shown between Radiotron socket contacts, grid caps, resistors, and terminals to receiver chassis ground or other pertinent point on figure 6, permit a rapid continuity check of the circuits. The use of this diagram in conjunction with the Schematic Circuit Diagram, figure 2, and Wiring Diagram, figure 3, will permit the location of certain troubles which might otherwise be difficult to ascertain. Each value as specified should hold within ± 20%. Variations in excess of this limit will usually be indicative of trouble in circuit under test. In all cases of measuring the resistance between points of the circuit and ground, it will be necessary to connect the negative terminal of the resistance meter to chassis-ground. If the polarity of the resistance meter is not known, it may be readily ascertained by connecting a d-c voltmeter of indicated polarity across the terminals of the device.

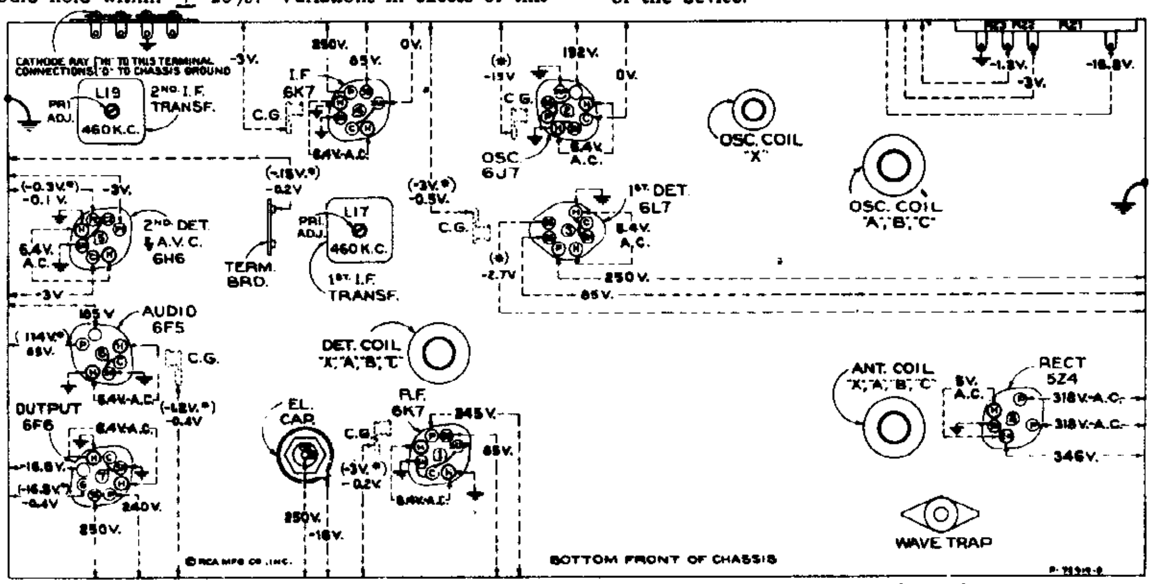

Figure 7—Radiotron Socket Voltages, Coil, and I-F Trimmer Locations

Measured at 115 volts, 60-cycle supply—Tuned to approximately 1,000 kc—No signal being received—Volume control minimum

Note: *Two voltage values are shown for some readings. The higher value shown in parenthesis with asterisk (*) indicates operating conditions without voltmeter loading. The lower value is the actual measured voltage and differs from the higher value because of the additional loading of the voltmeter through the high series circuit resistance.*

The voltage values indicated from the Radiotron socket contacts, grid caps, resistors, and terminals to receiver chassis ground on figure 7 will assist in locating cause for faulty operation. Each value as specified should hold within ± 20% when the receiver is normally operative at its rated line voltage. Variations in excess of this limit will usually be indicative of trouble in the basic circuits. To duplicate the conditions under which the voltages were measured requires a 1,000-ohm-per-volt d-c meter, having ranges of 10, 50, 250, 500, and 1,000 volts. Use the nearest range above the specified measured voltage. A-c voltages were measured with a corresponding a-c meter.

RCA MFG. CO., INC.

General Description

This receiver represents the result of thorough development, design, and substantial manufacture. Noteworthy technical improvements have been applied in achieving marked advantages of operation, and efficiency of performance.

Model 9K is a nine-tube, console-type, superheterodyne receiver with a twelve-inch electrodynamic loudspeaker. Design features incorporated in this receiver include a built-in doublet antenna coupler; improved plunger-type air dielectric adjustable trimming capacitors in the antenna, detector, and oscillator coil circuits, tuned r-f amplifier, high-efficiency first detector (converter) with separate oscillator, magnetite core adjusted i-f transformers, low-frequency oscillator tracking, and wave-trap; two-point aural compensated volume control; music-speech switch; automatic volume control; phonograph terminal board; new selector dial and a dust proof electrodynamic loudspeaker.

Service convenience has been a controlling factor in the layout of the chassis parts and wiring. The assembly of these various elements is such that the number of conductors is minimized, with all important connections being readily accessible. Trimming adjustments are located at accessible points. A double tuning-knob arrangement permits the choice of either a twenty-to-one or a hundred-to-one dial drive ratio. The latter permits ease of tuning, especially in the "Medium wave" and "Short wave" bands.

Circuit Arrangement

The conventional type of superheterodyne circuit is used. It consists of an r-f amplifier stage, a first-detector (converter) stage, a separate oscillator stage, an i-f amplifier stage, a diode detector—automatic-volume-control stage, an audio voltage-amplifier stage, a power-amplifier stage, a tuning indicator "Magic Eye," and a full-wave rectifier.

A single-wire antenna, or a doublet antenna, when connected to the proper input terminals of the receiver, is coupled to the control grid of the RCA 6K7 r-f amplifier tube through the tuned r-f transformer consisting of L6, L5, L4, L3, and L2. A unique method of switching is used. In the "Long wave" (X) band, L6 becomes the primary with L5, L4, L3, and L2 as secondary. In the "Standard broadcast" (A) band, L5 becomes the primary with L4, L3, and L2 as secondary (L6 shorted out). In the "Medium wave" (B) band, L4 becomes the primary with L3 and L2 as secondary (L6 and L5 shorted out). In the "Short wave" (C) band, L3 becomes the primary with L2 as secondary (L6, L5, L4, and tap on L4 shorted out). The tap on L4 is provided to prevent interaction with L3 and L2 when operating receiver in "Short wave" band. This method of switching reduces the total number of coils and leads, and results in having a low-loss primary and secondary winding for each band with high efficiency of operation.

The band switching of the detector circuits is similar to that of the antenna circuits. Coils L11 and L16 are always connected in series with the plate circuit of the RCA-6K7 r-f amplifier tube. In the "Long wave" (X) band, L15, L14, L13, and L12 are connected in series as the secondary circuit. The ground of the coil system is at the low end of L15. L16 acts as the primary which transfers energy to the secondary L15. Capacitor C14 resonates primary L16 at the proper frequency. In the "Standard broadcast" (A) band L14, L13, and L12 are connected in series as the secondary circuit. The ground of the coil system is now between L15 and L14. L15 is used as the primary and is resonated at the proper frequency by capacitors C28 and C19 which are in shunt with this coil. Capacitor C24 is connected to transfer energy to the primary coil L15. In the "Medium wave" (B) band, L13 and L12 are connected in series as the secondary. The ground of the coil system is now between L14 and L13. L14 is used as the primary and is resonated at the proper frequency by capacitor C29 which is in shunt with this coil. L15 is shorted by the range selector. Capacitor C24 transfers the r-f energy from the plate circuit to the primary L14. In the "Short wave" (C) band, L12 is the secondary. The ground of the coil system is now between L13 and L1.. L13 is used as the primary and is resonated to the proper frequency by capacitor C29. In addition, L11 acts as a high-frequency primary which resonates at about 20 mc and improves the gain at the high-frequency end of the "Short wave" band. Coils L15 and L14 are shorted by the range selector.

Separate windings are employed in the oscillator stage for each position of the range selector. The inherent stability of this circuit provides minimum frequency drift which is especially advantageous for high frequency reception. The locally generated signal is capacitance coupled to control grid No. 2 of the RCA 6L7 first detector.

I-F Amplifier

The intermediate-frequency amplifier consists of an RCA-6K7 in a transformer-coupled circuit. The windings of these transformers are resonated with fixed capacitors, and are adjusted by molded magnetite cores (both primary and secondary) to tune to 460 kc.

Detector and A.V.C.

The modulated signal as obtained from the output of the i-f stage is detected by an RCA-6H6 twin-diode tube. The audio frequency secured by this process is transferred to the a f system for amplification and final reproduction. The d c voltage which results from detection of the signal is used for automatic volume control. This voltage which develops across resistors R11 and R12, is applied as automatic control-grid bias to the r-f, first-detector, and i f tubes. The other (auxiliary) diode of the RCA-6H6 is used to supply residual bias to the controlled tubes under conditions of little or no signal. This diode, under such conditions, draws current which flows through resistors R10, R11, and R12, thereby maintaining the desired operating bias on such tubes. On application of signal energy above a certain level, however, the auxiliary bias-diode ceases to draw current and the a.v.c. diode takes over the biasing function.

Audio System

The manual volume control consists of an acoustically tapered potentiometer in the audio circuit between the output of the detector diode and the input grid of the RCA-6F5 audio voltage-amplifier tube. This control has a two-point tone-compensating filter connected to it so that the correct aural balance will be obtained at different volume settings. Phonograph terminals are provided to feed the output of an external phonograph pickup to the control grid of the audio amplifier through this aurally compensated volume control.

The output of the voltage amplifier is resistance-capacitance coupled to the control grid of the RCA-6F6 power-output tube. The output of this stage is transformer coupled to the voice coil of the electrodynamic speaker.

The "Music-speech" control consists of a switch S4 which, in the "Speech" position, places an additional capacitor C45 in shunt with the capacitor C44 in one of the tone compensating filters. This reduces the low-frequency response of the amplifier and provides maximum intelligibility of the voice frequencies.

Continuously variable tone control is effected by means of capacitor C48 and variable resistor R19 shunting the plate circuit of the output tube.

"Magic Eye"

An RCA-6E5 cathode-ray tuning tube is used as a means of visually indicating when the receiver is accurately tuned to the incoming signal. This tube consists of an amplifier section and a cathode-ray section built in the same glass envelope. A portion of the signal voltage developed across resistor R12 is used to actuate the grid of the amplifier section. Maximum voltage is applied to this grid when the receiver is tuned to resonance with an incoming carrier. This condition is evidenced by the minimum width of the dark sector on the fluorescent screen.

SERVICE DATA

The various diagrams in this booklet contain such information as will be needed to locate causes for defective operation if such develops. The values of the various resistors, capacitors, coils, etc., are indicated adjacent to the symbols signifying these parts on the diagram. Identification titles, such as C1, L2, R1, etc., are provided for reference between the illustrations and the Replacement Parts List. The coils, reactors, and transformer windings are rated in terms of their d-c resistance only. Resistance values of less than one ohm are generally omitted.

Alignment Procedure

There are fourteen adjustments required for the alignment of the oscillator, first-detector, and antenna-tuned circuits; one adjustment for the wave-trap; and four adjustments for the i-f system. Twelve of these adjustments are made with plunger-type air trimming capacitors and require the use of an RCA Stock No. 12636 Adjusting Tool. Each of these capacitors has a lock nut for securing the plunger in place after adjustment. The remaining seven adjustments are made by means of screws attached to molded magnetite cores. These cores change the inductance of the particular coils in which they are inserted to provide exact alignment. All of these adjustments are accurately made during manufacture and should remain in proper alignment unless affected by abnormal conditions of climate or purported alterations for servicing, or unless altered by other means. Loss of sensitivity, improper tone quality, and poor selectivity are the usual indications of improper alignment. Such conditions will usually exist simultaneously. Correct performance of this receiver can only be obtained when these adjustments have been made by a skilled service engineer with the use of adequate and reliable test equipment. The manufacturer of this receiver has such test equipment available for sale through its distributors and dealers.

This receiver requires a more or less involved method of alignment. However, if the following directions are carefully applied in the sequence given, normal performance of the instrument will be obtained.

The plunger-type air trimming capacitors have their approximate plunger settings tabulated on figure 5. If the plungers have been disturbed from their original adjustments, they may be roughly set to the specified dimensions prior to alignment.

In performing services on the oscillator, detector, and r-f circuits, the leads should be restored to their original positions, since the lead-dress is important for proper operation and dial calibration.

Precautionary Dressing of Leads Prior to Alignment (Refer to Figure 3)

Band "X"

1. Keep blue lead X of S1 to antenna coil L4-5 dressed away from chassis, and from yellow lead of S1 to antenna coil L5-6.
2. Keep blue lead X of S3 to detector coil L14-15 clear of chassis, coil shield, can, and other leads.
3. Keep bus lead C3 to X of S1 apart from bus lead C6 to A of S1, and from chassis.

Band "A"

1. Keep green lead, terminal of S1 to antenna coil tap L-4, away from chassis, coil shield, and coil.
2. Keep bus lead C6 to A of S1 apart from bus lead C3 to X of S1, and from chassis.

Band "C"

Lead from C18 to oscillator coil L7 should be maintained as short and straight as possible.

For alignment, the test-oscillator frequency should be quite accurate. A convenient and reliable means of accurately checking the frequency of test oscillators, receivers, etc., is the RCA Stock No. 9572 Crystal Calibrator.

If the test-oscillator signal cannot be heard as the receiver (heterodyne) oscillator air-trimmer plunger is changed from its minimum-capacity to maximum-capacity position (receiver dial and test oscillator set to the specified frequencies, and the correct oscillator air-trimmer used) it may be an indication that the test-oscillator frequency is outside the range covered by the air-trimmer. Under such conditions, when a more accurate setting of the test oscillator cannot be determined, set the oscillator air-trimmer plungers to the approximate settings given on figure 5. Tune the test oscillator until the signal is heard in the speaker. Each of two test-oscillator settings (the fundamentals or the harmonics of which are 920 kc ap. rt) produce a signal. The lower-frequency test oscillator setting should be used as this places the test oscillator (signal) frequency 460 kc below the frequency of the receiver heterodyne oscillator.

Holes are provided in the top of the r-f and antenna coil cans on some models to enable a tuning check with the RCA Stock No. 6679 Tuning Wand. The hole in the top of the detector coil can has a cinch button which must be removed before insertion of the tuning wand. When the brass end of the wand is inserted in the coil, the inductance of the coil is decreased. If this results in an increase of output, the respective air-trimmer capacitance should be decreased (plunger pulled out). If inserting the iron end of the tuning wand causes an increase in output, resulting from an increase of inductance of the coil, the respective air trimmer capacitance should be increased (plunger pushed in). If the range of the air trimmer is not sufficient to give the desired results, the lead-dress may be changed in the particular circuit being aligned so as to cause the circuit to resonate within the range of the trimmer. An increase in the capacity-to-ground of the circuit will be required if the iron end of the tuning wand causes an increase of signal output when the air-trimmer plunger is full-in, while a decrease in the capacity-to-ground will be required if the brass end of the tuning wand causes an increase in signal output when the air-trimmer plunger is full-out.

Two methods of alignment are applicable—one requires use of the cathode-ray oscillograph, and the other requires a voltmeter or glow-type indicator. The cathode-ray alignment method is advantageous in that the indication provided is in the form of a wave-image which represents the resonance characteristics of the circuit being tuned. This type of alignment is possible through use of apparatus such as the RCA Stock No. 9558 Frequency Modulator and the RCA Stock No. 9545 Cathode-Ray Oscillograph. The output-indicator method should be performed with an instrument such as the RCA Stock No. 4317 Neon Glow Indicator. Either of these methods require the use of a reliable test oscillator such as the RCA Stock No. 9595. Both of these procedures are outlined below.

Cathode-Ray Alignment

Make alignment apparatus connections shown on figure 4. Remove the plug of the frequency-modulator cable from the test-oscillator jack. Connect the receiver chassis to a good external ground. Connect oscillograph "Vertical" input terminals as indicated on figure 3. Set oscillograph power switch to "On" and adjust "Intensity" and "Focus" controls to give a clearly defined spot, or line, on the screen. Set oscillograph "Ampl. A" switch to "On," "Vertical gain" control full-clockwise, "Ampl. B" switch to "Timing," "Range" switch to No. 2 position, and "Timing" switch to "Int." Place the "Sync." control, "Freq." control, and "Horizontal gain" control to about their mid-positions. For each of the following adjustments, the test-oscillator output must be regulated so that the image obtained on the oscillograph screen will be of the minimum size for accurate observation. The receiver volume-control setting is optional.

I-F Adjustments

(a) Connect the "Ant." output of the test oscillator to the grid cap of RCA-6K7 i-f tube (with grid lead in place) through a .001-mfd. capacitor, with "Gnd." to receiver chassis. Tune the test oscillator to 460 kc and place its modulation switch to "On" and its output switch to "Hi."

(b) Turn on the receiver and test oscillator. Increase the output of the test oscillator until a deflection is noticeable on the oscillograph screen. The figures obtained represent several waves of the detected signal, the amplitude of which may be observed as an indication of output. Cause the wave-image formed (400-cycle waves) to be spread completely across the screen by adjusting the "Horizontal gain" control. The image should be synchronized and made to remain motionless by adjusting the "Sync." and "Freq." controls.

(c) Adjust the two magnetite core screws L20 and L19 (see figures 1 and 7) of the second i-f transformer (one on top and one on bottom) to produce maximum vertical deflection of the oscillographic image. This adjustment places the transformer in exact resonance with the 460-kc signal.

(d) The sweeping operation should follow using the frequency modulator. Shift the oscillograph "Timing" switch to "Ext." Insert plug of frequency-modulator cable in test-oscillator jack. Turn the test-oscillator modulation switch to "Off." Turn on the frequency modulator and place its sweep-range switch to "Hi."

(e) Increase the frequency of the test oscillator by slowly turning its tuning control until two separate, distinct, and similar waves appear on the screen. If only one wave appears, increase the "Freq." control on the oscillograph to obtain two waves. These waves will be identical in shape, totally disconnected, and appear in reversed positions. They will have a common base line, which is discontinuous. Adjust the "Freq." and "Sync." controls of the oscillograph to make them remain motionless on the screen. Continue increasing the test-oscillator frequency until these forward and reverse curves move together and overlap with their highest points exactly coincident. This condition will be obtained at a test-oscillator setting of approximately 575 kc.

(f) With the images established as in (e), re-adjust the two magnetite core screws L20 and L19 on the second i-f transformer so that they cause the curves on the oscillograph screen to become exactly coincident throughout their lengths and have maximum amplitude.

(g) Without altering the adjustments of the apparatus, shift the "Ant." output of the test oscillator to the input of the i f system, i.e., to the RCA-6L7 first-detector grid cap, through a .001-mfd. capacitor (with grid lead in place). Regulate the test-oscillator output so that the amplitude of the oscillographic image is approximately the same as used for adjustment (f) above.

(h) The two first i-f transformer magnetite core screws L18 and L17 (one on top and one on bottom) should then be adjusted so that they cause the forward and reverse curves to become coincident throughout their lengths and have maximum amplitude. The composite wave obtained in this manner represents the resonance characteristic of the total i-f system. Lack of symmetry or irregularity of the resultant image will indicate the presence of a defect in the i-f system.

R-F Adjustments

Make receiver dial adjustments as outlined by "Selector dial," figure 9. Alignment must be made in sequence of "Wave-trap," "Short wave" band, "Medium wave" band, "Standard broadcast" band, and "Long wave" band.

"Wave-Trap" Adjustment

(a) Connect the output of the test oscillator to the antenna terminal "A1" through a 200-mmfd. (important) capacitor. Remove the plug of the frequency-modulator cable from the test-oscillator jack. Turn test-oscillator modulation switch to "On." Shift the oscillograph "Timing" switch to "Int." Place receiver range selector in "Standard broadcast" position. Set the receiver dial to a position of no extraneous signals near 600 kc. Tune the test oscillator to 460 kc. Adjust the wave-trap magnetite core screw L1 to the point which causes minimum amplitude of output (maximum suppression of signal) as shown by the waves on the oscillograph. An increase of the test-oscillator output may be necessary before this point of minimum amplitude, obtained by correct adjustment of wave-trap screw, becomes apparent on oscillograph screen.

"Short Wave" Band

(b) Connect the "Ant." output of the test oscillator to the antenna terminal "A1" of the receiver through a 300-ohm resistor. Set the receiver range selector to its "Short wave" position and its dial pointer to 20,000 kc. Adjust the test oscillator to 20,000 kc. Adjust oscillator air-trimmer C11 until maximum (peak) output is reached. Two peaks may be found with this circuit. The peak with minimum capacitance (plunger near out) should be used. Tighten lock nut. Adjust detector air-trimmer C28 until maximum (peak) output is reached, while slightly rocking the gang tuning condenser back and forth through the signal. Two peaks may be found with this circuit. The peak with maximum capacitance (plunger near in) should be used. Tighten lock nut. Adjust antenna air-trimmer C8 until maximum (peak) output is reached while slightly rocking the gang tuning condenser back and forth through the signal. Two peaks may be found with this circuit. The peak with maximum capacitance (plunger near in) should be used. Tighten lock nut. Check the image frequency by changing the receiver dial setting to 19,080 kc. The image signal should be received at this position indicating that the adjustment of C11 has been correctly made. No adjustments should be made while checking for the image signal.

"Medium Wave" Band

(c) Place receiver range selector to its "Medium wave" position with its dial pointer set to 6,000 kc. Tune the test oscillator to 6,000 kc. Adjust oscillator air-trimmer C12 to produce maximum (peak) output as shown by the waves on the oscillograph. Two peaks may be found with this circuit. The peak with minimum capacitance (plunger near out) should be used. Tighten lock nut. Adjust the detector air-trimmer C27 for maximum (peak) output while slightly rocking the gang tuning condenser back and forth through the signal. Two peaks may be found with this circuit. The peak with maximum capacitance (plunger near in) should be used. Tighten lock nut. Adjust antenna air-trimmer C7 to produce maximum (peak) output. Tighten lock nut.

"Standard Broadcast" Band

(d) Remove the 300-ohm resistor from between the test-oscillator "Ant." post and receiver antenna terminal "A1" and insert a 200-mmfd. capacitor in its place. Place receiver range selector to "Standard broadcast" position with receiver dial pointer set to 600 kc. Tune the test oscillator to 600 kc. Adjust oscillator magnetite core screw L9 (top of large oscillator coil can) for maximum (peak) output as shown by the waves on the oscillograph screen.

(e) Set receiver dial pointer to 1,500 kc. Tune test oscillator to 1,500 kc (1,500–5,100-kc range) and increase its output to produce a registration on the oscillograph screen. Carefully adjust the oscillator, detector, and antenna air-trimmers C10, C26, and C6, respectively, to produce maximum (peak) output as shown by the waves on the oscillograph screen. Shift the oscillograph "Timing" switch to "Ext." Place the frequency modulator sweep-range switch to its "Lo" position and insert plug of the frequency-modulator cable in test-oscillator jack. Turn test-oscillator modulation switch to "Off." Re-tune the test oscillator (increase frequency) until the forward and reverse waves show on the oscillograph screen and become coincident at their highest points. This will occur at a test-oscillator setting of approximately 1,640 kc. Adjust trimmers C10, C26, and C6 again, setting each to the point which produces the best coincidence and maximum amplitude of the images.

(f) Remove the plug of the frequency-modulator cable from the test-oscillator jack. Turn test-oscillator modulation switch to "On." Set oscillograph "Timing" switch to "Int." Tune test oscillator to 200 kc (200–400-kc range). Tune receiver for maximum response to this signal at a dial reading of approximately 600 kc. The third harmonic of the 200-kc signal is used for this adjustment. Shift oscillograph "Timing" switch to "Ext." Insert the plug of the frequency-modulator cable in test oscillator jack. Turn test-oscillator modulation switch to "Off." Re-tune the test oscillator (increase frequency) until the forward and reverse waves show on the oscillograph screen. This will occur at a test-oscillator setting of approximately 230 kc. Disregarding the fact that the two images may or may not come together, adjust the oscillator magnetite core screw L9 (top of large oscillator coil can) to produce

MODEL 9K
Alignment, Part 2
Data, Parts List

RCA MFG. CO., INC.

maximum (peak) amplitude of the images. Shift the oscillograph "Timing" switch to "Int." Remove the plug of the frequency-modulator cable from the test-oscillator jack. Turn the test-oscillator modulation switch to "On." Repeat adjustments in (e) above to compensate for any changes caused by the adjustment of L9 core, tightening lock nuts on C10, C26, and C6, respectively, after each is adjusted.

"Long Wave" Band

(g) Shift the oscillograph "Timing" switch to "Int." Remove the plug of the frequency-modulator cable from the test-oscillator jack. Turn the test-oscillator modulation switch to "On." Place receiver range selector to its "Long wave" position. Set the receiver dial pointer to 175 kc. Tune the test oscillator to 175 kc and increase its output until a deflection is noticeable on the oscillograph screen. Adjust oscillator magnetite core screw L10 (located on top of small oscillator coil can) so that maximum (peak) amplitude of output is shown on the oscillograph screen.

(h) Set receiver dial pointer to 350 kc. Tune test oscillator to 350 kc. Adjust the oscillator, detector, and antenna air-trimmers C16, C25, and C5 to produce maximum (peak) output as shown by the waves on the oscillograph screen. Without disturbing the connections, shift the oscillograph "Timing" switch to "Ext." Place the frequency-modulator sweep-range switch to its "Hi" position and insert plug of frequency-modulator cable in test-oscillator jack. Turn test-oscillator modulation switch to "Off." Re-tune the test oscillator (decrease frequency) until the forward and reverse waves show on the oscillograph screen and become coincident at their highest points. This will occur at a test oscillator setting of approximately 190 kc. This setting places the test-oscillator frequency to 175 kc. The second harmonic is now used for the 350 kc adjustment. Adjust air-trimmers C16, C25, and C5, again, to produce maximum amplitude of the images and best coincidence throughout their lengths.

(i) Re-tune the receiver to approximately 175 kc so that the forward and reverse waves appear on the oscillograph screen. Adjust the oscillator magnetite core screw L10 to produce maximum (peak) amplitude of the waves, disregarding the fact that the two images may or may not come together.

(j) Shift the receiver dial setting to 350 kc without altering any other adjustments (frequency modulator still in operation). Adjust air-trimmers C16, C25, and C5, respectively, to produce maximum amplitude and best coincidence of the waves. These adjustments compensate for any changes caused by the adjustment of the magnetite core screw L10. Tighten lock nuts on C16, C25, and C5, respectively, after each is adjusted.

Output Indicator Alignment

Attach the output indicator across the loudspeaker voice-coil circuit. Advance the receiver "Volume" control to its maximum position, letting it remain in such position for all adjustments. For each adjusting operation, regulate the test-oscillator output so that the signal level is as low as possible and still be observable at the receiver output. Use of such small signal will obviate broadness of tuning which would otherwise result from a.v.c. action on a stronger one.

I-F Adjustments

(a) Connect the "Ant." output of the test oscillator to the grid cap of the RCA-6L7 first detector tube (with grid lead in place) through a .001-mfd. capacitor, with "Gnd." to receiver chassis. Tune the test oscillator to 460 kc. Place its modulation switch to "On" and its output switch to "Hi."

(b) Adjust the two magnetite core screws L20 and L19 (see figures 1 and 7) of the second i-f transformer to produce maximum (peak) output.

(c) Adjust the two first i-f transformer magnetite core screws L18 and L17 to produce maximum (peak) output. It is advisable to repeat the adjustment of all i-f magnetite core screws to assure that the interaction between them has not disturbed the original adjustments.

R-F Adjustments

Make receiver dial adjustments as outlined by "Selector dial," figure 9. Alignment must be made in sequence of "Wave-trap," "Short wave" band, "Medium wave" band, "Standard broadcast" band, and "Long wave" band.

"Wave-Trap" Adjustment

(a) Connect the "Ant." output of the test oscillator to the antenna terminal "A1" on the receiver through a 200-mmfd. (important) capacitor. Place the receiver range selector to its "Standard broadcast" position and set the dial pointer to a position of no extraneous signals near 600 kc. Tune the test oscillator to 460 kc. Adjust the wave-trap magnetite core screw L1 to the point which causes minimum output (maximum suppression of signal). An increase of the test-oscillator output may be necessary before the point of minimum output, obtained by adjustment of wave-trap screw, becomes apparent on the output indicator.

"Short Wave" Band

(b) Connect the "Ant." output of the test oscillator to the antenna terminal "A1" through a 300-ohm resistor. Set the receiver range selector to its "Short wave" position and its dial pointer to 20,000 kc. Adjust the test oscillator to 20,000 kc. Adjust oscillator air-trimmer C11 until maximum (peak) output is reached. Two peaks may be found with this circuit. The peak with minimum capacitance (plunger near out) should be used. Tighten lock nut. Adjust detector air-trimmer C28 until maximum (peak) output is reached, while slightly rocking the gang tuning condenser back and forth through the signal. Two peaks may be found with this circuit. The peak with maximum capacitance (plunger near in) should be used. Tighten lock nut. Adjust antenna air-trimmer C8 until maximum (peak) output is reached, while slightly rocking the gang tuning condenser back and forth through the signal. Two peaks may be found with this circuit. The peak with maximum capacitance (plunger near in) should be used. Tighten lock nut. Check the image frequency by changing the receiver dial setting to 19,080 kc. The signal should be received at this position indicating that the adjustment of C11 has been correctly made. No adjustments should be made while checking for the image signal.

"Medium Wave" Band

(c) Place receiver range selector to its "Medium wave" position with the receiver dial pointer set to 6,000 kc. Tune the test oscillator to 6,000 kc. Adjust oscillator air-trimmer C12 to produce maximum (peak) output. Two peaks may be found with this circuit. The peak with minimum capacitance (plunger near out) should be used. Tighten lock nut. Adjust the detector air-trimmer C27 for maximum (peak) output while slightly rocking the receiver gang tuning condenser back and forth through the signal. Two peaks may be found with this circuit. The peak with maximum capacitance (plunger near in) should be used. Tighten lock nut. Adjust antenna air-trimmer C7 to produce maximum (peak) output. Tighten lock nut.

"Standard Broadcast" Band

(d) Remove the 300-ohm resistor from between the test-oscillator "Ant." post and receiver antenna terminal "A1" and insert a 200-mmfd. capacitor in its place. Place receiver range selector to its "Standard broadcast" position with the receiver dial pointer set to 600 kc. Tune the test oscillator to 600 kc. Adjust the oscillator magnetite core screw L9 (top of large oscillator coil can) for maximum (peak) output.

(e) Set receiver dial pointer to 1,500 kc. Tune test oscillator to 1,500 kc and regulate its output until a slight indication of output is visible. Carefully adjust the oscillator, detector, and antenna air-trimmers C10, C26, and C6, respectively, to produce maximum (peak) output.

(f) Tune test oscillator to 600 kc. Tune the receiver to pick up this signal near 600 kc, disregarding the dial reading at which it is best received. Adjust oscillator magnetite core screw L9 (top of large oscillator coil can) for maximum (peak) output while slightly rocking the gang tuning condenser back and forth through the signal. Repeat adjustments in (e) above to compensate for any change caused by adjustment of L9 magnetite core screw, tightening lock nuts on C10, C26, and C6, respectively, after each is adjusted.

"Long Wave" Band

(g) Place receiver range selector to its "Long wave" position, with dial pointer set to 175 kc. Tune the test oscillator to 175 kc and increase its output until a slight indication of output is visible. Adjust oscillator magnetite core screw L10 (top of small oscillator coil can) for maximum (peak) output.

(h) Set receiver dial pointer to 350 kc. Tune test oscillator to 350 kc. Adjust the oscillator, detector, and antenna air-trimmers C16, C25, and C5, respectively, to produce maximum (peak) output.

(i) Tune test oscillator to 175 kc. Tune receiver to pick up this signal near 175 kc, disregarding the dial reading at which it is best received. Adjust oscillator magnetite core screw L10 (top of small oscillator coil can) for maximum (peak) output while slightly rocking the gang tuning condenser back and forth through the signal. Repeat adjustments in (h) above to compensate for any changes caused by the adjustment of the magnetite core screw L10. Tighten lock nuts on C16, C25, and C5, respectively, after each is adjusted.

Selector Dial

Figure 9 illustrates the relation of the various parts of the dial mechanism when in its "Standard broadcast" position with the range switch likewise turned to its "Standard broadcast" position. In re-assembling the dial after repairs, see that the gears are meshed in accordance with the diagram, at the same time noting that the range switch is in its "Standard broadcast" position and the lever attached to the range-switch shaft placed in the position shown.

To adjust the dial mechanism, set the range switch to its "Standard broadcast" position. Place a straight-edge across the center of the dial so that its edge is even with the lower (end) marking at both the low-frequency and high-frequency ends of the dial. Under such conditions the straight-edge should be parallel with the top of the chassis base. If the straight-edge is not parallel with the top of the chassis base, loosen the nut on the rear of the roller link pivot stud and move the stud up or down until the link roller moves the dial to the desired position so that the end calibration marks obtain the position mentioned above. Tighten the nut on the roller link pivot stud.

Set the gang tuning condenser to its maximum capacity position. Adjust the dial pointer to the low-frequency (end) mark on "Standard broadcast" scale. This is a friction adjustment.

With the gang tuning condenser plates still in full mesh, loosen the two set screws on the vernier-dial hub. Rotate the vernier dial until the "0" marking is in a vertical plane above the center of the shaft. Tighten set screws.

Phonograph Terminal Board

A terminal board is provided for connecting a phonograph into the audio amplifying circuit. Typical methods of connecting a low-impedance pickup, or the RCA Victor Models R-93, R-93-2, and R-93-8 Record Players are shown on the Schematic Diagram (figure 2).

Antenna and Ground Terminals

These receivers are equipped with an antenna-ground terminal board having three terminals. These terminals are marked "A2," "A1," and "G," the latter being the ground terminal and should always be connected to a good external ground. The transmission-line leads of the RCA RK-40A antenna system should be connected to terminals "A2" and "A1." The receiver coupling units of the RCA RK-40 and the RCA Spider-Web antenna systems should be connected to terminals "A1" and "G." Connect a single-wire antenna to terminal "A1."

Loudspeaker

Centering of the loudspeaker voice coil is made in the usual manner with three narrow paper feelers after first removing the front paper dust cover. This may be removed by softening its cement with a very light application of acetone using care not to allow the acetone to flow down into the air gap. The dust cover should be cemented back in place with ambroid upon completion of adjustment.

RADIOTRON COMPLEMENT

(1) RCA-6K7 .... R-F Amplifier
(2) RCA-6J7 .... Oscillator
(3) RCA-6L7 .... First Detector
(4) RCA-6K7 .... I-F Amplifier
(5) RCA-6H6 .... Second Detector and A.V.C.
(6) RCA-6F5 .... Audio Voltage Amplifier
(7) RCA-6F6 .... Power Output
(8) RCA-5Z4 .... Full-Wave Rectifier
(9) RCA-6E5 .... Tuning Tube

Pilot Lamps (4) .... Mazda No. 46, 6.3 volts, 0.25 ampere

POWER SUPPLY RATINGS

Rating A .... 105-125 volts, 50-60 cycles, 95 watts
Rating B .... 105-125 volts, 25-60 cycles, 95 watts
Rating C .... 100-130/140-160/195-250 volts, 40-60 cycles, 95 watts

Mechanical Specifications

Height .... 40½ inches
Width .... 27 inches
Depth .... 14 inches
Weight (net) .... 56 pounds
Weight (shipping) .... 86 pounds
Chassis Base Dimensions .... 14½ inches x 7¾ inches x 3¼ inches
Over-all Height of Chassis .... 9 inches
Operating Controls. (1) Music-Speech—Power Switch, (2) Volume, (3) Tuning, (4) Range Selector, (5) Tone
Tuning Drive Ratios .... 20 to 1 and 100 to 1

REPLACEMENT PARTS

Stock No.	Description	List Price
	RECEIVER ASSEMBLIES	
12806	Board—3-contact antenna and ground terminal board	$0.25
12865	Board—4-contact and 2-link phonograph terminal board	.25
12929	Bracket—Mounting bracket for L.F. tone control or volume control	.15
5237	Bushing—Variable condenser mounting bushing assembly—Package of 3	.43
11625	Cable—Tuning lamp cable and socket	1.26
12521	Cap—Grid contact cap—Package of 5	.15
12884	Capacitor—Adjustable trimmer (C16, C25)	.40
12807	Capacitor—Adjustable trimmer (C11, C27, C28)	.35
12714	Capacitor—Adjustable trimmer (C5, C6, C7, C8, C10, C12, C26)	.38
12896	Capacitor—15 Mmfd. (C29)	.20
12722	Capacitor—18 Mmfd. (C9)	.70
12895	Capacitor—56 Mmfd. (C17)	.30
12723	Capacitor—56 Mmfd. (C2, C21)	.20
12724	Capacitor—120 Mmfd. (C20, C46)	.28
12404	Capacitor—120 Mmfd. (C32, C35, C36, C38)	.26
12725	Capacitor—150 Mmfd. (C1)	.28
12894	Capacitor—180 Mmfd. (C15)	.20
12406	Capacitor—180 Mmfd. (C39)	.26
12727	Capacitor—555 Mmfd. (C14)	.20
12537	Capacitor—560 Mmfd. (C3, C24, C31)	.20
12729	Capacitor—1,550 Mmfd. (C13)	.36
12728	Capacitor—4,500 Mmfd. (C18)	.36
4838	Capacitor—.005 Mfd. (C49)	.20
4858	Capacitor—.01 Mfd. (C23, C40, C47)	.25
5196	Capacitor—.015 Mfd. (C48)	.18
4836	Capacitor—.05 Mfd. (C37)	.30
11282	Resistor—56,000 ohm, carbon type, 1/10 watt—Package of 5 (R6, R15, R3)	.75
11398	Resistor—220,000 ohm, carbon type, 1/10 watt—Package of 5 (R12)	.75
11451	Resistor—270,000 ohm, carbon type, 1/10 watt—Package of 5 (R17)	.75
11172	Resistor—470,000 ohm, carbon type, ¼ watt—Package of 5 (R15)	1.00
11452	Resistor—470,000 ohm, carbon type, 1/10 watt—Package of 5 (R18)	.75
11397	Resistor—560,000 ohm, carbon type, 1/10 watt—Package of 5 (R1, R5)	.75
12013	Resistor—1 Meg., carbon type, 1/10 watt—Package of 5 (R20)	.75
12079	Resistor—2.2 Meg., insulated, ¼ watt—Package of 5 (R10)	1.00
12928	Resistor—3.3 Meg., insulated, ¼ watt—Package of 5 (R8, R9)	1.00
12927	Resistor—Voltage divider resistor, comprising one 16 ohm, one 25 ohm and one 190 ohm sections (R21, R22, R23)	.35
12715	Resistor—Wire wound resistor, comprising one 10,000 ohm and one 27,000 ohm sections (R4, R7)	.86
4669	Screw—No. 8-32-5/32 set screw for link, Stock No. 12868—Package of 10	.25
3903	Screw—No. 8-32-3/16 headless, cup point set screw for Stock No. 12870—Package of 20	.34
12925	Shaft—Range switch and band indicator operating shaft and hub assembly	.25
12651	Shield—Coil shield for Stock Nos. 12923 and 12924	.21
12710	Shield—Coil shield for Stock No. 12709	.18
12883	Shield—Coil shield for Stock No. 12881	.10
12926	Shield—Chassis end shield and rubber mounting foot assembly—Package of 2	.85
12006	Shield—I. F. transformer shield for Stock Nos. 12652 and 12653	.28
12607	Shield—I. F. transformer shield top for Stock No. 12652	.30
12581	Shield—I. F. transformer shield top for Stock No. 12653	.36
5119	Socket—3-contact female connector for speaker leads	.25
11193	Socket—5-contact 5Z4 Radiotron socket	.15
11198	Socket—7-contact 6F5, 6H6, 6K7 or 6L7 Radiotron socket	.15
11196	Socket—8-contact 6F6 or 6J7 Radiotron socket	.15
11232	Socket—Upper right or lower left hand dial lamp socket	.18
13095	Socket—Upper left or lower right hand dial lamp socket	.25
11381	Socket—Tuning lamp socket and cover	.45
12007	Spring—Retaining spring for core, Stock Nos. 12006, 12664, 12800 and 12882—Package of 10	.36
12920	Switch—Range switch (S1, S2, S3)	2.60
12921	Tone Control—High frequency tone control (R19)	.95
12860	Tone Control—Low frequency tone control and power switch (S4, S5)	1.50
12652	Transformer—First I. F. transformer, complete (L17, L18, C32, C33)	1.60
12918	Transformer—Power transformer, 105-125 volt, 50-60 cycle (T1)	4.30
12857	Transformer—Power transformer, 105-125 volt, 25 cycle (T1)	7.10
12919	Transformer—Power transformer, 100-250 volt, 40-60 cycle (T2)	6.20
12653	Transformer—Second I. F. transformer, complete (L19, L20, C36, C38, C39, R11, R12)	2.06
12654	Trap—Wave trap, complete (L1)	.73
12861	Volume Control (R13)	1.00
4841	Capacitor—0.1 Mfd. (C34, C51)	.21
5170	Capacitor—0.25 Mfd. (C22, C52)	.25
4840	Capacitor—0.25 Mfd. (C42, C33)	.30
5212	Capacitor—18 Mfd. (C51)	1.16
12467	Capacitor—30 Mfd. (C50)	1.40
12923	Coil—Antenna coil and shield XABC bands (L2, L3, L4, L5, L6)	1.75
12924	Coil—Detector coil and shield XABC bands (L11, L12, L13, L14, L15, L16)	1.90
12709	Coil—Oscillator coil and shield ABC bands only (L7, L8, L9)	2.02
12881	Coil—Oscillator coil and shield X band only (L10)	.80
12859	Compensator Pack—Comprising two sections .015 Mfd. each, one section .1 Mfd. and two resistors 27,000 ohms each (C43, C44, C45, R14, R16)	1.50
12922	Condenser—3-gang variable tuning condenser (C4, C19, C30)	4.15
12664	Core—Adjustable core and stud for Stock No. 12654	.35
12800	Core—Adjustable core and stud for Stock No. 12709	.30
12882	Core—Adjustable core and stud for Stock No. 12881	.30
12006	Core—Adjustable core and stud for Stock Nos. 12652 and 12653	.22
12870	Dial—Vernier dial and disc assembly	.45
5226	Lamp—Dial lamp—6.3 volt—Package of 5	.70
12868	Link—Range switch and band indicator operating link, complete with set screws	.45
5112	Resistor—1,000 ohm, carbon type, ¼ watt—Package of 5 (R2)	1.00
	REPRODUCER ASSEMBLIES	
12641	Board—3-contact reproducer terminal board	.15
12640	Bracket—Output transformer mounting bracket and clamp	.18
12032	Coil—Field coil (L23)	1.85
11469	Coil—Neutralizing coil (L22)	.20
12467	Cone—Reproducer cone and dust cap (L21)	1.00
5118	Connector—3-contact male speaker cable connector	.25
9694	Reproducer, complete	6.90
11233	Transformer—Output transformer (T2)	1.56
11686	Washer—Spring washer to hold field coil securely—Package of 5	.20
	DRIVE ASSEMBLIES	
10703	Ball—3/32-inch dia. steel ball for planetary drive—Package of 20	.25
10841	Ball—⅛-inch dia. steel ball for planetary drive bearing—Package of 20	.25
12904	Bushing—Plate and bushing assembly for planetary drive mounting	.30
12905	Coupling—Flexible coupling and shaft assembly, complete	.50
12909	Dial—Band indicating dial and cam assembly	1.05
12899	Drive—Variable tuning condenser drive, complete—including mounting bracket, drive, dial scale and indicator, less vernier dial, Stock No. 12870 and link, Stock No. 12868	4.40
12906	Gear—Anti-lash drive gear, complete	.75
12910	Gear—Sector gear and link assembly for band selector	.20
12908	Indicator—Station selector indicator pointer	.20
8051	Link—Link and roller assembly, complete with spring	.10
12911	Screen—Dial lamp screen and light diffuser	.20
4669	Screw—Set screw for flexible coupling or gear, Stock Nos. 12905 and 12906—Package of 10	.25
12901	Shaft—Direct drive shaft and pinion gear for planetary drive	.75
12900	Shaft—Vernier drive shaft for planetary drive	.25
12903	Spring—Tension spring for planetary drive bearing—Package of 10	.10
12907	Spring—Tension spring for gear, Stock No. 12906—Package of 10	.30
8052	Spring—Tension spring for link, Stock No. 8051—Package of 5	.32
	MISCELLANEOUS ASSEMBLIES

The resistance values shown between Radiotron socket contacts, grid caps, resistors, and terminals to receiver chassis ground or other pertinent point on figure 7, permit a rapid continuity check of the circuits. The use of this diagram in conjunction with the Schematic Circuit Diagram, figure 2, and Wiring Diagrams, figures 3 and 4, will permit the location of certain troubles which might otherwise be difficult to ascertain. Each value as specified should hold within ± 20%. Variations in excess of this limit will usually be indicative of trouble in circuit under test. In all cases of measuring the resistance between points of the circuit and ground, it will be necessary to connect the negative terminal of the resistance meter to chassis-ground. If the polarity of the resistance meter is not known, it may be readily ascertained by connecting a d-c voltmeter of indicated polarity across the terminals of the device.

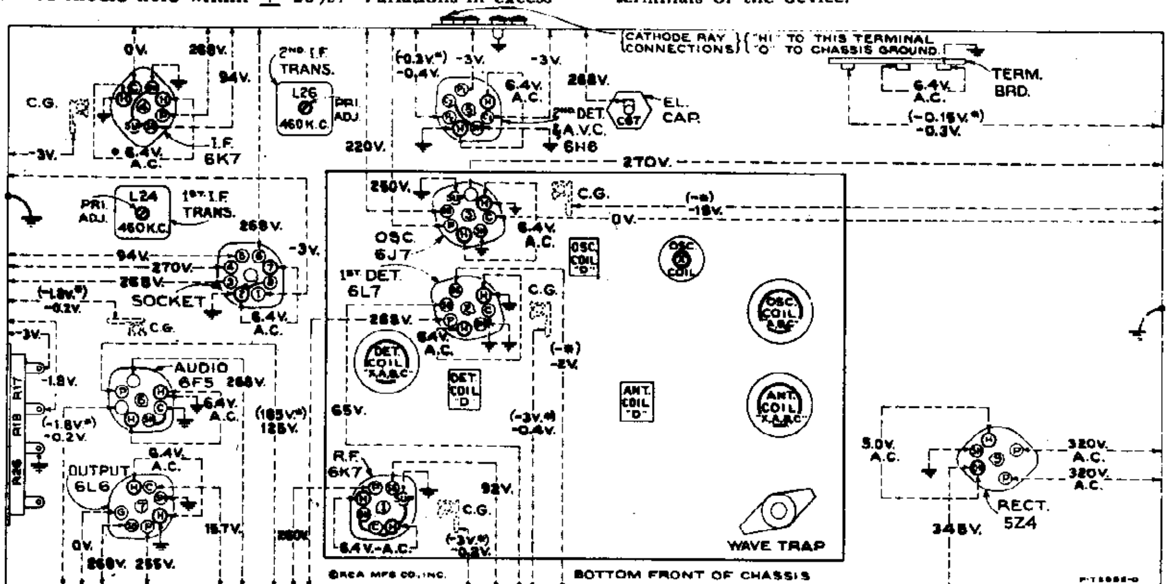

Figure 8—Radiotron Socket Voltages, Coil, and I-F Trimmer Locations

Measured at 115 volts, 60-cycle supply—Tuned to approximately 1,000 kc—No signal being received—Volume control minimum

***Note:** Two voltage values are shown for some readings. The higher value shown in parenthesis with asterisk (*) indicates operating conditions without voltmeter loading. The lower value is the actual measured voltage and differs from the higher value because of the additional loading of the voltmeter through the high series circuit resistance.*

The voltage values indicated from the Radiotron socket contacts, grid caps, resistors, and terminals to receiver chassis ground on figure 8 will assist in locating cause for faulty operation. Each value as specified should hold within ± 20% when the receiver is normally operative at its rated line voltage. Variations in excess of this limit will usually be indicative of trouble in the basic circuits. To duplicate the conditions under which the voltages were measured requires a 1,000-ohm-per-volt d-c meter, having ranges of 10, 50, 250, 500, and 1,000 volts. Use the nearest range above the voltage to be measured. A-c voltages were measured with a corresponding a-c meter.

Alignment,Part 1

RCA MFG. CO., INC.

Circuit Arrangement

The conventional type of superheterodyne circuit is used. It consists of an r-f amplifier stage, first-detector (converter) stage, separate oscillator stage, an i-f amplifier stage, a diode-detector—automatic-volume-control stage, an audio voltage-amplifier stage, a beam-type power-amplifier stage, a tuning indicator "Magic Eye", and a full-wave rectifier.

"Magic Brain"

The new "Magic Brain" is constructed as a separate, self-contained, completely shielded, five-band, oscillator-detector-antenna tuning unit which plugs into the main chassis.

A single-wire antenna, or a doublet antenna, when connected to the proper input terminals of the receiver, is coupled to the control grid of the RCA-6K7 r-f amplifier tube through the tuned r-f transformer consisting of L6, L5, L4, L3, and L2 (except when range selector is in "Ultra short wave" position). The primary coil L13 of the "Ultra short wave" (D) band tuned r-f transformer remains in the antenna circuit at all times. A unique method of switching is used. In the "Long wave" (X) band, L6 becomes the primary with L5, L4, L3, and L2 as secondary. In the "Standard broadcast" (A) band, L5 becomes the primary with L4, L3, and L2 as secondary (L6 shorted out). In the "Medium wave" (B) band, L4 becomes the primary with L3 and L2 as secondary (L6 and L5 shorted out). In the "Short wave" (C) band, L3 becomes the primary with L2 as secondary (L6, L5, L4, and tap on L4 shorted out). The tap on L4 is provided to prevent interaction with L3 and L2 when operating receiver in "Short wave" band. In the "Ultra short wave" (D) band, L6, L5, L4, and L3 are shorted out and grounded, and secondary L14 is placed in shunt with L2. The latter connection prevents undesirable interaction of L2 with L14. This method of switching reduces the total number of coils and leads, and results in having a low-loss primary and secondary winding for each band with high efficiency of operation.

The band switching of the detector circuits is similar to that of the antenna circuits. Coils L15, L21, and L20 are always connected in series with the plate circuit of the RCA-6K7 r-f amplifier tube. In the "Long wave" (X) band, L19, L18, L17, and L16 are connected in series as the secondary circuit. The ground of the coil system is at the low end of L19. L20 acts as the primary which transfers energy to the secondary L19. Capacitor C33 resonates primary L20 at the proper frequency. In the "Standard broadcast" (A) band, L18, L17, and L16 are connected in series as the secondary circuit. The ground of the coil system is now between L18 and L19. L19 is used as the primary and is resonated at the proper frequency by capacitors C34 and C35 which are in shunt with this coil. Capacitor C33 is connected to transfer energy to the primary coil L19. In the "Medium wave" (B) band, L17 and L16 are connected in series as the secondary. The ground of the coil system is now between L17 and L18. L18 is used as the primary and is resonated at the proper frequency by capacitor C34 which is in shunt with this coil. L19 is shorted by the range selector. Capacitor C33 transfers the r-f energy from the plate circuit to the primary L18. In the "Short wave" (C) band, L16 is the secondary. The ground of the coil system is now between L16 and L17. L17 is used as the primary and is resonated to the proper frequency by capacitor C34. In addition, L15 acts as a high-frequency primary which resonates above 20 mc and improves the gain at the high-frequency end of the "Short wave" band. Coils L19 and L18 are shorted by the range selector. L21 is effectively r-f bypassed in this position by capacitor C32. In the "Ultra short wave" (D) band, L22 is the secondary, or grid coil, and consists of approximately a single turn of silver plated strap around a 7/8 inch coil form. The primary coils, L21 and L15 are in series on this band, with L21 acting as a low-frequency primary and L15 as a high-frequency primary. L16 is shunted by L22 instead of being shorted directly by the range selector. Any inductive effect of L16 is thus eliminated. L19, L18, and L17 are shorted directly by the range selector.

Separate windings are employed in the oscillator stage for each position of the range selector. The inherent stability of this circuit provides minimum frequency drift which is especially advantageous for high-frequency reception. The locally generated signal is capacitance coupled to control grid No. 2 of the RCA-6L7 first detector.

The output of the "Magic Brain" is fed to the i-f amplifier through the plug-in cable. This cable also supplies all power required by the "Magic Brain" unit.

I-F Amplifier

The intermediate-frequency amplifier consists of an RCA-6K7 in a transformer-coupled circuit. The windings of these transformers are resonated with fixed capacitors, and are adjusted by molded magnetite cores (both primary and secondary) to tune to 460 kc.

Detector and A.V.C.

The modulated signal as obtained from the output of the i-f stage is detected by an RCA-6H6 twin-diode tube. The audio frequency secured by this process is transferred to the a-f system for amplification and final reproduction. The d-c voltage which results from detection of the signal is used for automatic volume control. This voltage, which develops across resistors R12 and R13, is applied as automatic control-grid bias to the first-detector and i-f tubes. The second (auxiliary) diode of the RCA-6H6 is used to supply residual bias to the controlled tubes under conditions of little or no signal. This diode, under such conditions, draws current which flows through resistors R11, R12, and R13, thereby maintaining the desired operating bias on such tubes. On application of signal energy above a certain level, however, the auxiliary bias-diode ceases to draw current and the a.v.c diode takes over the biasing function.

Audio System

The manual volume control consists of an acoustically tapered potentiometer in the audio circuit between the output of the detector-diode and the input grid of the RCA-6F5 audio voltage-amplifier tube. This control has a two-point tone-compensating filter connected to it so that the correct aural balance will be obtained at different volume settings. Phonograph terminals are provided to feed the output of an external phonograph pickup to the control grid of the audio amplifier through this aurally compensated volume control.

The output of the voltage amplifier is resistance-capacitance coupled to the control grid of the RCA-6L6 power output tube. The output of this stage is transformer coupled to the voice coil of the electro-dynamic speaker.

The "Music-speech" control consists of a switch S5 which, in the "Speech" position, places an additional capacitor C57 in shunt with the capacitor C56 in one of the tone compensating filters. This reduces the low-frequency response of the amplifier and provides maximum intelligibility of the voice frequencies.

Continuously variable tone control is effected by means of capacitor C62 and variable resistor R27 shunting the plate circuit of the output tube.

"Magic Eye"

An RCA-6E5 cathode-ray tuning tube is used as a means of visually indicating when the receiver is accurately tuned to the incoming signal. This tube consists of an amplifier section and a cathode-ray section built in the same glass envelope. A portion of the signal voltage developed across resistor R13 is used to actuate the grid of the amplifier section. Maximum voltage is applied to this grid when the receiver is tuned to resonance with an incoming carrier. This condition is evidenced by the minimum width of the dark sector on the fluorescent screen.

"Magic Voice" (Model 9K2)

Model 9K2 is designed with a cabinet incorporating the "Magic Voice." This is accomplished by having the rear of the speaker compartment completely enclosed by a tight-fitting back.

Five metal open-end pipes of equal diameter but of three different lengths are inserted in holes in the cabinet base and extend upward in the speaker compartment. The effect is to cause the lower-frequency waves, reaching the front of the cabinet through the pipes, to arrive approximately in-phase giving extended low-frequency response without boominess, or cabinet resonance.

SERVICE DATA

The various diagrams in this booklet contain such information as will be needed to locate causes for defective operation if such develops. The values of the various resistors, capacitors, coils, etc., are indicated adjacent to the symbols signifying these parts on the diagram. Identification titles, such as C1, L2, R1, etc., are provided for reference between the illustrations and the Replacement Parts List. The coils, reactors, and transformer windings are rated in terms of their d-c resistance only. Resistance values of less than one ohm are generally omitted.

Alignment Procedure

There are seventeen adjustments required for the alignment of the oscillator, first-detector, and antenna-tuned circuits, one adjustment for the wave-trap; and four adjustments for the i-f system. Fifteen of these adjustments are made with plunger-type air trimming capacitors and require the use of an RCA Stock No. 12636 Adjusting Tool. Each of these capacitors has a lock nut for securing the plunger in place after adjustment. The remaining seven adjustments are made by means of screws attached to molded magnetite cores. These cores change the inductance of the particular coils in which they are inserted to provide exact alignment. All of these adjustments are accurately made during manufacture and should remain in proper alignment unless affected by abnormal conditions of climate or purported alterations for servicing, or unless altered by other means. Loss of sensitivity, improper tone quality, and poor selectivity are the usual indications of improper alignment. Such conditions will usually exist simultaneously. Correct performance of this receiver can only be obtained when these adjustments have been made by a skilled service engineer with the use of adequate and reliable test equipment. The manufacturer of this receiver has such test equipment available for sale through its distributors and dealers.

The extensive frequency range of these receivers necessitates a more or less involved method of alignment. However, if the following directions are carefully applied in the sequence given, normal performance of the instruments will be obtained.

The plunger-type air trimming capacitors have their approximate plunger settings tabulated on figure 6. If the plungers have been disturbed from their original adjustments, they may be roughly set to the specified dimensions prior to alignment.

In performing services on the "Magic Brain", the leads should be restored to their original positions, since the lead-dress is important for proper operation and dial calibration.

Precautionary Dressing of Leads for "Magic Brain" Alignment
(Refer to Figure 4)

Band "X"

1. Keep blue lead A of S1 to antenna coil L4-5 dressed away from chassis, and from yellow lead X of S1 to antenna coil L5-6.
2. Bus lead from C10 to S1 should be as short as possible.
3. Keep blue lead A of S1 to detector coil L18-19 clear of chassis, coil shield, coil, and other leads.
4. Keep spaghetti lead C6 to X of S1 apart from spaghetti lead C5 to A of S1, and from chassis.

Band "A"

1. Keep green lead terminal S1 to antenna coil tap L4 away from chassis, coil shield, and coil.
2. Keep spaghetti lead C5 to A of S1 apart from spaghetti lead C6 to X of S1 and from chassis.

Band "C"

Lead from C19 to oscillator coil L7 should be maintained as short and straight as possible.

For alignment, the test-oscillator frequency should be quite accurate. A convenient and reliable means of accurately checking the frequency of test oscillators, receivers, etc., is the RCA Stock No. 9572 Crystal Calibrator.

If the test-oscillator signal cannot be heard as the receiver (heterodyne) oscillator air-trimmer plunger is changed from its minimum-capacity to maximum-capacity position (receiver dial and test oscillator set to the specified frequencies, and the correct oscillator air-trimmer used) it may be an indication that the test-oscillator frequency is outside the range covered by the air-trimmer. Under such conditions, when a more accurate setting of the test oscillator cannot be determined, set the oscillator air-trimmer plungers to the approximate settings given on figure 6. Tune the test oscillator until the signal is heard in the speaker. Each of two test-oscillator settings (the fundamentals or the harmonics of which are 920 kc apart) produce a signal. The lower-frequency test-oscillator setting should be used as this places the test-oscillator (signal) frequency 460 kc below the frequency of the receiver heterodyne oscillator.

Holes are provided in the top of the r-f and antenna coil cans on some models to enable a tuning check with the RCA Stock No. 6679 Tuning Wand. The hole in the top of the detector coil can has a cinch button which must be removed before insertion of the tuning wand. When the brass end of the wand is inserted in the coil, the inductance of the coil is decreased. If this results in an increase of output, the respective air-trimmer capacitance should be decreased (plunger pulled out). If inserting the iron end of the tuning wand causes an increase in output, resulting from an increase of inductance of the coil, the respective air-trimmer capacitance should be increased (plunger pushed in). If the range of the air trimmer is not sufficient to give the desired results, the lead-dress may be changed in the particular circuit being aligned, so as to cause the circuit to resonate within the range of the trimmer. An increase in the capacity-to-ground of the circuit will be required if the iron end of the tuning wand causes an increase of signal output when the air-trimmer plunger is full-in, while a decrease in the capacity-to-ground will be required if the brass end of the tuning wand causes an increase in signal output when the air-trimmer plunger is full-out.

Two methods of alignment are applicable—one requires use of the cathode-ray oscillograph, and the other requires a voltmeter or glow-type indicator. The cathode-ray alignment method is advantageous in that the indication provided is in the form of a wave-image which represents the resonance characteristics of the circuit being tuned. This type of alignment is possible through use of apparatus such as the RCA Stock No. 9558 Frequency Modulator and the RCA Stock No. 9545 Cathode-Ray Oscillograph. The output-indicator method should be performed with an instrument such as the RCA Stock No. 4317 Neon Glow Indicator. Both of these procedures are outlined below.

Cathode-Ray Alignment

Make alignment apparatus connections shown on figure 5. Remove the plug of the frequency-modulator cable from the test-oscillator jack. Connect the receiver chassis to a good external ground. Connect oscillograph "Vertical" input terminals as indicated on figure 3. Set oscillograph power switch to "On" and adjust "Intensity" and "Focus" controls to give a clearly defined spot, or line, on the screen. Set oscillograph "Ampl. A" switch to "On," "Vertical gain" control full-clockwise, "Ampl. B" switch to "Timing," "Range" switch to No. 2 position, and "Timing" switch to "Int." Place the "Sync." control, "Freq." control, and "Horizontal gain" control to about their mid-positions. For each of the following adjustments, the test-oscillator output must be regulated so that the image obtained on the oscillograph screen will be of the minimum size for accurate observation. The receiver volume-control setting is optional.

I-F Adjustments

(a) Connect the "Ant." output of the test oscillator to the grid cap of RCA-6K7 i-f tube (with grid lead in place) through a .001-mfd. capacitor, with "Gnd." to receiver chassis. Tune the test oscillator to 460 kc and place its modulation switch to "On" and its output switch to "Hi."

(b) Turn on the receiver and test oscillator. Increase the output of the test oscillator until a deflection is noticeable on the oscillograph screen. The figures obtained represent several waves of the detected signal, the amplitude of which may be observed as an indication of output. Cause the wave-image formed (400-cycle waves) to be spread completely across the screen by adjusting the "Horizontal gain" control. The image should be synchronized and made to remain motionless by adjusting the "Sync." and "Freq." controls.

(c) Adjust the two magnetite core screws L27 and L26 (see figures 1 and 8) of the second i-f transformer (one on top and one on bottom) to produce maximum vertical deflection of the oscillographic image. This adjustment places the transformer in exact resonance with the 460-kc signal.

(d) The sweeping operation should follow using the frequency modulator. Shift the oscillograph "Timing" switch to "Ext." Insert plug of frequency-modulator cable in test-oscillator jack. Turn the test-oscillator modulation switch to "Off." Turn on the frequency modulator and place its sweep-range switch to "Hi."

(e) Increase the frequency of the test oscillator by slowly turning its tuning control until two separate, distinct, and similar waves appear on the screen. If only one wave appears, increase the "Freq." control on the oscillograph to obtain two waves. These waves will be identical in shape, usually disconnected, and appear in reversed positions. They will have a common base line, which is discontinuous. Adjust the "Freq." and "Sync." controls of the oscillograph to make them remain motionless on the screen. Continue increasing the test-oscillator frequency until these forward and reverse curves move together and overlap, with their highest points exactly coincident. This condition will be obtained at a test-oscillator setting of approximately 575 kc.

(f) With the images established as in (e), re-adjust the two magnetite core screws L27 and L26 on the second i-f transformer so that they cause the curves on the oscillograph screen to become exactly coincident throughout their lengths and have maximum amplitude.

(g) Without altering the adjustments of the apparatus, shift the "Ant." output of the test oscillator to the input of the i-f system, i.e., to the RCA-6L7 first-detector grid cap, through a .001-mfd. capacitor (with grid lead in place). Regulate the test-oscillator output so that the amplitude of the oscillographic image is approximately the same as used for adjustment (f) above.

(h) The two first i-f transformer magnetite core screws L25 and L24 (one on top and one on bottom) should then be adjusted so that they cause the forward and reverse curves to become coincident throughout their lengths and have maximum amplitude. The composite wave obtained in this manner represents the resonance characteristic of the total i-f system. Lack of symmetry or irregularity of the resultant image will indicate the presence of a defect in the i-f system.

R-F Adjustments

Make receiver dial adjustments as outlined by "Selector dial," figure 11. Alignment must be made in sequence of "Wave-trap," "Ultra short wave" band, "Short wave" band, "Medium wave" band, "Standard broadcast" band, and "Long wave" band.

"Wave-Trap" Adjustment

(a) Connect the output of the test oscillator to the antenna terminal "A1" through a 200-mmfd. (important) capacitor. Remove the plug of the frequency-modulator cable from the test-oscillator jack. Turn test-oscillator modulation switch to "On." Shift the oscillograph "Timing" switch to "Int." Place receiver range selector in "Standard broadcast" position. Set the receiver dial to a position of no extraneous signals near 600 kc. Tune the test oscillator to 460 kc. Adjust the wave-trap magnetite core screw to the point which causes minimum amplitude of output (maximum suppression of signal) as shown by the waves on the oscillograph. An increase of the test-oscillator output may be necessary before this point of minimum amplitude, obtained by correct adjustment of wave-trap screw, becomes apparent on oscillograph screen.

"Ultra Short Wave" Band

(b) Connect the "Ant." output of the test oscillator to the antenna terminal "A1" of the receiver through a 300-ohm resistor. Set the receiver range selector to its "Ultra short wave" position and its dial pointer to 57,000 kc. Adjust the test oscillator to 19,000 kc. The third harmonic of 19,000 kc is used for this adjustment. If the indication on the oscillograph screen is not sufficient for the following adjustments at 57,000 kc, the vertical-input terminals of the cathode-ray oscillograph may be connected thus: "Hi" to the plate contact of the RCA-6L6 power-output tube socket with the "0" terminal to chassis-ground. The receiver should be turned off while making this connection since the plate potential is impressed across the oscillograph input and a severe shock will result if contact is made between these two points. If this connection is made, advance the receiver volume control to its maximum position. Adjust oscillator air-trimmer C23 for maximum (peak) output. Two positions, each producing maximum output, may be found. The position of minimum capacitance (plunger near out) should be used. This places the receiver heterodyne oscillator 460 kc higher in frequency than the incoming signal. Tighten lock nut. Adjust the detector air-trimmer C39, while slightly rocking the gang tuning condenser back and forth through the signal, for maximum (peak) output. Two peaks may be found on this trimmer. The peak of maximum capacitance (plunger near in) should be used. Tighten lock nut. Adjust the antenna air-trimmer C10 for maximum (peak) output while slightly rocking the gang tuning condenser back and forth through the signal. Two peaks may be found on this trimmer which produce maximum output. The peak with maximum capacitance (plunger near in) should be used. Tighten lock nut. Check the image frequency by changing the receiver dial setting to 56,080 kc. If the image signal is received at this position, the adjustment of the oscillator air-trimmer C23 has been correctly made. No adjustments should be made while checking for the image signal.

(c) Re-tune receiver for maximum response to 57,000 kc (not image response) without disturbing test-oscillator adjustments. Change test oscillator to 6,000—14,000 kc range. Tune test oscillator until signal is heard in speaker (should occur at approximately 14,250 kc, fourth harmonic of test oscillator used). Two test-oscillator settings (230 kc apart) will produce a signal at this point. The lower frequency test-oscillator setting should be used, as this places the test oscillator harmonic 460 kc below the frequency of the receiver heterodyne oscillator. Tune receiver for maximum response at a dial setting of approximately 28,500 kc (image should tune in at a dial setting approximately 27,580 kc) without altering test-oscillator adjustment. Test-oscillator second harmonic of 14,250 kc is used for the following check. Check calibration of receiver dial. A receiver-dial reading of less than 28,500 kc indicates that the inductance of the oscillator secondary coil L11 is too low and should be increased. If the receiver dial reading is greater than 28,500 kc, the inductance of L11 is too high and should be decreased. If it is necessary to change the inductance of L11, first remove bottom cover of "Magic Brain" and then set receiver dial pointer to 28,500 kc. To decrease inductance, move the grounded ends (straps) of L11 and L12 (see figure 4) nearer chassis. Do not allow straps to touch chassis except where connected. To increase inductance, move the straps farther away from chassis. Adjust position of straps till maximum (peak) output results. The alignment of the detector tuned circuit should next be checked at 28,500 kc without changing either the receiver or test oscillator adjustments. An increase of output when the brass end of a tuning wand is brought near L22 indicates that L22 is too high in inductance, while an increase when the iron end is brought near the coil indicates that the inductance is too low. The inductance of L22 may be varied by changing the spacing between the grounded end (strap) of L22 and the strap connected from C41 to contact on S2 (figure 4). An increase of spacing will increase the inductance, while a decrease of spacing will decrease the inductance. Adjust the spacing until maximum (peak) output results. Replace "Magic Brain" bottom cover and repeat adjustments in (b) prior to those of "Short wave" band.

"Short Wave" Band

(d) Set the receiver range selector to its "Short wave" position and its dial pointer to 20,000 kc. Adjust the test oscillator to 20,000 kc. If the vertical input cathode-ray connections were changed for adjustment (b) above, they should

RCA MFG. CO., INC.

MODELS 9T, 9K2
Alignment, Part 2
Notes

be restored to their original position as shown on figure 3. Adjust oscillator air-trimmer C13 until maximum (peak) output is reached. Two peaks may be found with this circuit. The peak with minimum capacitance (plunger near out) should be used. Tighten lock nut. Adjust detector air-trimmer C35 until maximum (peak) output is reached, while slightly rocking the gang tuning condenser back and forth through the signal. Two peaks may be found with this circuit. The peak with maximum capacitance (plunger near in) should be used. Tighten lock nut. Adjust antenna air-trimmer C3 until maximum (peak) output is reached while slightly rocking the gang tuning condenser back and forth through the signal. Two peaks may be found with this circuit. The peak with maximum capacity (plunger near in) should be used. Tighten lock nut. Check the image frequency by changing the receiver dial setting to 19,080 kc. The image signal should be received at this position indicating that the adjustment of C13 has been correctly made. No adjustments should be made while checking for the image signal.

"Medium Wave" Band

(e) Place receiver range selector to its "Medium wave" position with its dial pointer set to 6,000 kc. Tune the test oscillator to 6,000 kc. Adjust oscillator air trimmer C14 to produce maximum (peak) output as shown by the waves on the oscillograph. Two peaks may be found with this circuit. The peak with minimum capacitance (plunger near out) should be used. Tighten lock nut. Adjust the detector air-trimmer C36 for maximum (peak) output while slightly rocking the gang tuning condenser back and forth through the signal. Two peaks may be found with this circuit. The peak with maximum capacitance (plunger near in) should be used. Tighten lock nut. Adjust antenna air-trimmer C4 to produce maximum (peak) output. Tighten lock nut.

"Standard Broadcast" Band

(f) Remove the 300-ohm resistor from between the test-oscillator "Ant." post and receiver antenna terminal "A1" and insert a 200-mmfd. capacitor in its place. Place receiver range selector to "Standard broadcast" position with receiver dial pointer set to 600 kc. Tune the test oscillator to 600 kc. Adjust oscillator magnetite core screw L9 (top of large oscillator coil can) for maximum (peak) output as shown by the waves on the oscillograph screen.

(g) Set receiver dial pointer to 1,500 kc. Tune test oscillator to 1,500 kc (1,500–3,100-kc range) and increase its output to produce a registration on the oscillograph screen. Carefully adjust the oscillator, detector, and antenna air-trimmers C16, C37 and C5, respectively, to produce maximum (peak) output as shown by the waves on the oscillograph screen. Shift the oscillograph "Timing" switch to "Ext." Place the frequency modulator sweep-range switch to its "Lo" position and insert plug of the frequency-modulator cable in test-oscillator jack. Turn test-oscillator modulation switch to "Off." Re-tune the test oscillator (increase frequency) until the forward and reverse waves show on the oscillograph screen and become coincident at their highest points. This will occur at a test-oscillator setting of approximately 1,680 kc. Adjust trimmers C16, C37, and C5 again, setting each to the point which produces the best coincidence and maximum amplitude of the images.

(h) Remove the plug of the frequency-modulator cable from the test-oscillator jack. Turn test-oscillator modulation switch to "On." Set oscillograph "Timing" switch to "Int." Tune test oscillator to 200 kc (200–400-kc range). Tune receiver for maximum response to this signal at a dial reading of approximately 600 kc. The third harmonic of the 200-kc signal is used for this adjustment. Shift oscillograph "Timing" switch to "Ext." Insert the plug of the frequency-modulator cable in test-oscillator jack. Turn test-oscillator modulation switch to "Off." Re-tune the test oscillator (increased frequency) until the forward and reverse waves show on the oscillograph screen. This will occur at a test-oscillator setting of approximately 230 kc. Disregarding the fact that the two images may or may not come together adjust the oscillator magnetite core screw L9 (top of large oscillator coil can) to produce maximum (peak) amplitude of the images. Shift the oscillograph "Timing" switch to "Int." Remove the plug of the frequency-modulator cable from the test-oscillator jack. Turn the test-oscillator modulation switch to "On." Repeat adjustments in (g) above to compensate for any changes caused by the adjustment of L9 core, tightening lock nuts on C16, C37, and C5, respectively, after each is adjusted.

Radiotron Cathode Current Readings
Measured with Milliammeter Connected at Tube Socket Cathode Terminal under Conditions Similar to Those of Voltage Measurements

(1) RCA-6K7—R-F	8.0 ma.
(2) RCA-6L7—1st Det.	4.4 ma.
(3) RCA-6J7—Osc.	6.7 ma.
(4) RCA-6K7—I-F	8.0 ma.
(5) RCA-6H6—2nd Det.-A.V.C.	—
(6) RCA-6F5—A-F	0.5 ma.
(7) RCA-6L6 Power	63 ma.
(8) RCA-6E5—Eye	3.0 ma.
(9) RCA-5Z4—Rect.	110 ma.

"Long Wave" Band

(i) Shift the oscillograph "Timing" switch to "Int." Remove the plug of the frequency-modulator cable from the test-oscillator jack. Turn the test-oscillator modulation switch to "On." Place receiver range selector to its "Long wave" position. Set the receiver dial pointer to 175 kc. Tune the test oscillator to 175 kc and increase its output until a deflection is noticeable on the oscillograph screen. Adjust oscillator magnetite core screw L10 (located on top of small oscillator coil can) so that maximum (peak) amplitude of output is shown on the oscillograph screen.

(j) Set receiver dial pointer to 350 kc. Tune test oscillator to 350 kc. Adjust the oscillator, detector, and antenna air-trimmers C18, C38, and C6 to produce maximum (peak) output as shown by the waves on the oscillograph screen. Without disturbing the connections, shift the oscillograph "Timing" switch to "Ext." Place the frequency-modulator sweep-range switch to its "Hi" position and insert plug of frequency-modulator cable in test-oscillator jack. Turn test-oscillator modulation switch to "Off." Re-tune the test oscillator (decrease frequency) until the forward and reverse waves show on the oscillograph screen and become coincident at their highest points. This will occur at a test-oscillator setting of approximately 190 kc. This setting places the test-oscillator frequency to 175 kc. The second harmonic is now used for the 350 kc adjustment. Adjust air-trimmers C18, C38, and C6, again, to produce maximum amplitude of the images and best coincidence throughout their lengths.

(k) Re-tune the receiver to approximately 175 kc so that the forward and reverse waves appear on the oscillograph screen. Adjust the oscillator magnetite core screw L10 to produce maximum (peak) amplitude of the waves, disregarding the fact that the two images may or may not come together.

(l) Shift the receiver dial setting to 350 kc without altering any other adjustments (frequency modulator still in operation). Adjust air-trimmers C18, C38, and C6, respectively, to produce maximum amplitude and best coincidence of the waves. These adjustments compensate for any changes caused by the adjustment of the magnetite core screw L10. Tighten lock nuts on C18, C38, and C6, respectively, after each is adjusted.

Output Indicator Alignment

Attach the output indicator across the loudspeaker voice-coil circuit. Advance the receiver "Volume" control to its maximum position, letting it remain in such position for all adjustments. For each adjusting operation regulate the test-oscillator output so that the signal level is as low as possible and still be observable at the receiver output. Use of such small signal will obviate broadness of tuning which would otherwise result from a.v.c. action on a stronger one.

I-F Adjustments

(a) Connect the "Ant." output of the test oscillator to the grid cap of the RCA-6L7 first detector tube (with grid lead in place) through a .001-mfd. capacitor, with "Gnd." to receiver chassis. Tune the test oscillator to 460 kc. Place its modulation switch to "On" and its output switch to "Hi."

(b) Adjust the two magnetite core screws of the second i-f transformer (one on top and one on bottom) to produce maximum (peak) output.

(c) The two first i-f transformer magnetite core screws (one on top and one on bottom) should be adjusted to produce maximum (peak) output. It is advisable to repeat the adjustment of all i-f magnetite core screws to assure that the interaction between them has not disturbed the original adjustments.

R-F Adjustments

Make receiver dial adjustments as outlined by "Selector dial," figure 11. Alignment must be made in sequence of "Wave-trap," "Ultra short wave" band, "Short wave" band, "Medium wave" band, "Standard broadcast" band, and "Long wave" band.

"Wave-Trap" Adjustment

(a) Connect the "Ant." output of the test oscillator to the antenna terminal "A1" on the receiver through a 200-mmfd. (important) capacitor. Place the range selector to its "Standard broadcast" position and set the receiver dial pointer to a position of no extraneous signals near 600 kc. Tune the test oscillator to 460 kc. Adjust the wave-trap magnetite core screw to the point which causes minimum output (maximum suppression of signal). An increase of the test-oscillator output may be necessary before the point of minimum output, obtained by adjustment of wave-trap screw, becomes apparent on the output indicator.

"Ultra Short Wave" Band

(b) Connect the "Ant." output of the test oscillator to the antenna terminal "A1" through a 300-ohm resistor. Set receiver range selector to its "Ultra short wave" position and its dial pointer to 57,000 kc. Adjust the test oscillator to 19,000 kc. The third harmonic of 19,000 kc is used for this adjustment. Adjust the oscillator air-trimmer C23 for maximum (peak) output. Two positions for maximum output may be found. The position of minimum capacitance (plunger near out) should be used. This places the receiver heterodyne oscillator 460 kc higher in frequency than the incoming signal. Tighten lock nut. Adjust the detector air-trimmer C39 while slightly rocking the gang tuning condenser back and forth through the signal for maximum (peak) output. Two peaks may be found on this trimmer. The peak of maximum capacitance (plunger near in) should be used. Tighten lock nut. Adjust the antenna air-trimmer C10 for maximum (peak) output while slightly rocking the gang tuning condenser back and forth through the signal. Two peaks may be found on this trimmer which produce maximum output. The peak with maximum capacitance (plunger near in) should be used. Tighten lock nut. Check the image frequency by changing the receiver dial setting to 56,080 kc. If the image signal is received at this position, the adjustment of the oscillator air-trimmer C23 has been correctly made. No adjustments should be made while checking for the image signal.

(c) Re-tune receiver for maximum response to 57,000 kc (not image response) without disturbing test-oscillator adjustments. Change test oscillator to 6,800–14,000-kc range. Tune test oscillator until signal is heard in speaker (should occur at approximately 14,250 kc, fourth harmonic of test oscillator used). Two test-oscillator settings (230 kc apart) will produce a signal at this point. The lower frequency test-oscillator setting should be used, as this places the test oscillator harmonic 460 kc below the frequency of the receiver heterodyne oscillator. Tune receiver for maximum response at a dial setting of approximately 28,500 kc (image should tune in at a dial setting of approximately 27,580 kc) without altering test-oscillator adjustment. Test-oscillator second harmonic of 14,250 kc is used for the following check. Check calibration of receiver dial. A receiver-dial reading of less than 28,500 kc indicates that the inductance of the oscillator secondary coil L11 is too low and should be increased. If the receiver-dial reading is greater than 28,500 kc, the inductance of L11 is too high and should be decreased. If it is necessary to change the inductance of L11, first remove bottom cover of "Magic Brain" and then set receiver dial pointer to 28,500 kc. To decrease inductance, move the grounded ends (straps) of L11 and L12 (see figure 4) nearer chassis. Do not allow straps to touch chassis except where connected. To increase inductance, move the straps farther away from chassis. Adjust position of straps till maximum (peak) output results. The alignment of the detector-tuned circuit should next be checked at 28,500 kc without changing either the receiver or test oscillator adjustments. An increase of output when the brass end of a tuning wand is brought near L22 indicates that L22 is too high in inductance, while an increase when the iron end is brought near the coil indicates that the inductance is too low. The inductance of L22 may be varied by changing the spacing between the grounded end strap of L22 and the strap connected from C41 to contact on S2. An increase of spacing will increase the inductance, while a decrease of spacing will decrease the inductance. Adjust the spacing until maximum (peak) output results. Replace "Magic Brain" bottom cover and repeat adjustments in (b) prior to those of "Short wave" band.

"Short Wave" Band

(d) Set the receiver range selector to its "Short wave" position and its dial pointer to 20,000 kc. Adjust the test oscillator to 20,000 kc. Adjust oscillator air-trimmer C13 until maximum (peak) output is reached. Two peaks may be found with this circuit. The peak with minimum capacitance (plunger near out) should be used. Tighten lock nut. Adjust detector air-trimmer C35 until maximum (peak) output is reached, while slightly rocking the gang tuning condenser back and forth through the signal. Two peaks may be found with this circuit. The peak with maximum capacitance (plunger near in) should be used. Tighten lock nut. Adjust antenna air-trimmer C3 until maximum (peak) output is reached, while slightly rocking the gang tuning condenser back and forth through the signal. Two peaks may be found with this circuit. The peak with maximum capacity (plunger near in) should be used. Tighten lock nut. Check the image frequency by changing the receiver dial setting to 19,080 kc. The signal should be received at this position indicating that the adjustment of C13 has been correctly made. No adjustments should be made while checking for the image signal.

"Medium Wave" Band

(e) Place receiver range selector to its "Medium wave" position with the receiver dial pointer set to 6,000 kc. Tune the test oscillator to 6,000 kc. Adjust oscillator air-trimmer C14 to produce maximum (peak) output. Two peaks may be found with this circuit. The peak with minimum capacitance (plunger near out) should be used. Tighten lock nut. Adjust the detector air-trimmer C36 for maximum (peak) output while slightly rocking the receiver gang tuning condenser back and forth through the signal. Two peaks may be found with this circuit. The peak with maximum capacitance (plunger near in) should be used. Tighten lock nut. Adjust antenna air-trimmer C4 to produce maximum (peak) output. Tighten lock nut.

"Standard Broadcast" Band

(f) Remove the 300-ohm resistor from between the test-oscillator "Ant." post and receiver antenna terminal "A1" and insert a 200-mmfd. capacitor in its place. Place receiver range selector to its "Standard broadcast" position with the receiver dial pointer set to 600 kc. Tune the test oscillator to 600 kc. Adjust the oscillator magnetite core screw L9 (top of large oscillator coil can) for maximum (peak) output.

(g) Set receiver dial pointer to 1,500 kc. Tune test oscillator to 1,500 kc and regulate its output until a slight indication of output is visible. Carefully adjust the oscillator, detector, and antenna air-trimmers C16, C37, and C5, respectively, to produce maximum (peak) output.

(h) Tune test oscillator to 600 kc. Tune the receiver to pick up this signal near 600 kc, disregarding the dial reading at which it is best received. Adjust oscillator magnetite core screw L9 (top of large oscillator coil can) for maximum (peak) output while slightly rocking the gang tuning condenser back and forth through the signal. Repeat adjustments in (g) above to compensate for any change caused by adjustment of L9 magnetite core screw, tightening lock nuts on C16, C37, and C5, respectively, after each is adjusted.

"Long Wave" Band

(i) Place receiver range selector to its "Long wave" position, with dial pointer set to 175 kc. Tune the test oscillator to 175 kc and increase its output until a slight indication of output is visible. Adjust oscillator magnetite core screw L10 (top of small oscillator coil can) for that maximum (peak) output.

(j) Set receiver dial position to 350 kc. Tune test oscillator to 350 kc. Adjust the oscillator, detector, and antenna air-trimmers C18, C38, and ~~C6, respectively, to produce maximum (peak)~~ output.

(k) Tune test oscillator to 175 kc. Tune receiver to pick up this signal near 175 kc, disregarding the dial reading at which it is best received. Adjust oscillator magnetite core screw L10 (top of small oscillator coil can) for maximum (peak) output while slightly rocking the gang tuning condenser back and forth through the signal. Repeat adjustments in (j) above to compensate for any changes caused by the adjustment of the magnetite core screw L10. Tighten lock nuts on C18, C38, and C6, respectively, after each is adjusted.

Loudspeaker

Centering of the loudspeaker voice coil is made in the usual manner with three narrow paper feelers after first removing the front paper dust cover. This may be removed either permanently by cutting it away with a sharp knife, or by softening its cement with a very slight application of acetone using care not to allow the acetone to flow down into the air gap. The dust cover may be cemented back in place with ambroid upon completion of adjustment.

Phonograph Terminal Board

A terminal board is provided for connecting a phonograph into the audio amplifying circuit. Typical methods of connecting a low-impedance pickup, or the RCA Victor Models R-93, R-93-2, and R-93-S Record Players are shown on the Schematic Diagram (figure 7).

Selector Dial

Figure 11 illustrates the relation of the various parts of the dial mechanism when in its "Standard broadcast" position with the range switch likewise turned to its "Standard broadcast" position. In re-assembling the dial after repairs, see that the gears are meshed in accordance with the diagram, at the same time noting that the range switch is in its "Standard broadcast" position and the lever attached to the range-switch shaft placed in the position shown.

To adjust the dial mechanism, set the range switch to its "Standard broadcast" position. Place a straight-edge across the center of the dial so that its edge is even with the lower (end) marking at both the low-frequency and high-frequency ends of the dial. Under such conditions the straight-edge should be parallel with the top of the chassis base. If the straight-edge is not parallel with the top of the chassis base, loosen the nut on the rear of the roller link pivot stud and move the stud up or down until the link roller moves the dial to the desired position so that the end calibration marks obtain the position mentioned above. Tighten the nut on the roller link pivot stud.

Set the gang tuning condenser to its maximum capacity position. Adjust the dial pointer to the low-frequency (end) mark on "Standard broadcast" scale. This is a friction adjustment.

With the gang tuning condenser plates still in full mesh, loosen the two set screws on the vernier-dial hub. Rotate the vernier dial until the "0" marking is in a vertical plane above the center of the shaft. Tighten set screws.

Antenna and Ground Terminals

These receivers are equipped with an antenna-ground terminal board having three terminals. These terminals are marked "A2," "A1," and "G," the latter being the ground terminal and should always be connected to a good external ground. The transmission-line leads of the RCA RK-40A antenna system should be connected to terminals "A2" and "A1." The receiver coupling units of the RCA RK-40 and the RCA Spider-Web antenna systems should be connected to terminals "A1" and "G." Connect a single-wire antenna to terminal "A1."

General Description

These receivers represent the result of thorough development, design, and substantial manufacture. Noteworthy technical improvements have been applied in achieving marked advantages of operation, and efficiency of performance.

Model 9T is a nine-tube, table-type, "Magic Brain" superheterodyne receiver with an eight-inch electrodynamic loudspeaker. Model 9K2 employs an identical radio chassis, is of the console-type, has a twelve-inch electrodynamic loudspeaker, and incorporates the newly developed "Magic Voice." Design features incorporated in these receivers include built in doublet antenna coupler; "Magic Brain"; improved plunger-type air-dielectric adjustable trimming capacitors in the antenna, detector, and oscillator coil circuits; tuned r-f amplifier; high-efficiency first detector (converter) with separate oscillator; beam-type power amplifier; magnetite core adjusted i-f transformers, low-frequency oscillator tracking, and wave-trap; two-point aural compensated volume control; music-speech switch; automatic volume control; phonograph terminal board; new selector dial; and a dust-proof electrodynamic loudspeaker.

Service convenience has been a controlling factor in the layout of the chassis parts and wiring. The assembly of these various elements is such that the number of conductors is minimized, with all important connections being readily accessible. Trimming adjustments are located at accessible points. A double tuning-knob arrangement permits the choice of either a twenty-to-one or a hundred-to-one dial drive ratio. The latter permits ease of tuning, especially in the "Medium wave", "Short wave", and "Ultra short wave" bands.

Mechanical Specifications

Cabinet Dimensions	Model 9T	Model 9K2
Height	22½ inches	41 inches
Width	17½ inches	27⁹⁄₁₆ inches
Depth	12⁵⁄₁₆ inches	14½ inches
Weights		
Net	44 pounds	86 pounds
Shipping	53 pounds	129 pounds

Chassis Base Dimensions .... 15 x 9¾ x 3 inches
Over-all Height of Chassis .... 9¼ inches
Tuning Drive Ratios .... 20 to 1 and 100 to 1

Radiotron Complement

(1) RCA-6K7 .... R-F Amplifier
(2) RCA-6L7 .... First Detector
(3) RCA-6J7 .... Oscillator
(4) RCA-6K7 .... I-F Amplifier
Pilot Lamps (4) ....
Mazda No. 46, 6.3 volts, 0.25 ampere
(5) RCA-6H6 .... Second Detector and A.V.C.
(6) RCA-6F5 .... Audio Voltage Amplifier
(7) RCA-6L6 .... Power Output
(8) RCA-6E5 .... Tuning Tube
(9) RCA-5Z4 .... Full-Wave Rectifier

MODELS 9T, 9K2

Parts List

RCA MFG. CO., INC.

Stock No.	Description	List Price
12807	Capacitor—Adjustable trimmer capacitor (C13, C35, C36, C37)	.35
12884	Capacitor—Adjustable trimmer capacitor (C10, C18, C23, C38, C39)	.40
12896	Capacitor—15 Mmfd. (C34)	.20
12722	Capacitor—18 Mmfd. (C15)	.20
12891	Capacitor—36 Mmfd. (C40)	.20
12629	Capacitor—56 Mmfd. (C24)	.20
12895	Capacitor—56 Mmfd. (C17)	.20
12723	Capacitor—56 Mmfd. (C2, C44)	.20
13307	Capacitor—62 Mmfd. (C11)	.20
12724	Capacitor—120 Mmfd. (C25, C28, C29)	.28
12725	Capacitor—150 Mmfd. (C1)	.28
12894	Capacitor—180 Mmfd. (C22)	.20
12727	Capacitor—555 Mmfd. (C21)	.20
12537	Capacitor—560 Mmfd. (C7, C26, C33, C42)	.20
12898	Capacitor—1,500 Mmfd. (C12)	.20
12729	Capacitor—1,550 Mmfd. (C20)	.26
12728	Capacitor—4,500 Mmfd. (C19)	.36
12897	Capacitor—4,700 Mmfd. (C43)	.40
4858	Capacitor—.01 Mfd. (C8, C30, C31, C32)	.25
12879	Coil—Antenna coil and shield XABC bands (L2, L3, L4, L5, L6)	1.90
12888	Coil—Antenna coil "D" band (L13, L14)	.60
12880	Coil—Detector coil and shield XABC bands (L15, L16, L17, L18, L19, L20)	2.05
12709	Coil—Oscillator coil and shield ABC bands (L7, L8, L9)	2.02
12881	Coil—Oscillator coil and shield X band only (L10)	.80
12890	Coil—Oscillator coil "D" band (L11, L12, L23)	.70
12889	Coil—R.F. coil "D" band (L21, L22)	.65
12877	Condenser—3-gang variable tuning condenser (C9, C27, C41)	5.10
12887	Connector—8-contact male connector and cover for power cable Stock No. 12886	.40
12664	Core—Adjustable core and stud for Stock No. 12654	.22
12800	Core—Adjustable core and stud for Stock No. 12709	.20
12882	Core—Adjustable core and stud for Stock No. 12881	.20
11324	Resistor—560 ohms—carbon type—¼ watt (R2)—Package of 5	1.00
5112	Resistor—1,000 ohms—carbon type—¼ watt (R3)—Package of 5	1.00
11298	Resistor—5,600 ohms—carbon type—1 watt (R6)—Package of 5	.22
3998	Resistor—15,000 ohms—carbon type—¼ watt (R5)—Package of 5	1.00
11282	Resistor—56,000 ohms—carbon type—1/10 watt (R4, R9)—Package of 5	.75
8064	Resistor—82,000 ohms—carbon type—½ watt (R8)—Package of 5	1.00
11397	Resistor—560,000 ohms—carbon type—1/10 watt (R1, R7)—Package of 5	.75
12651	Shield—Coil shield for Stock Nos. 12879, 12880	.22
12710	Shield—Coil shield for Stock No. 12709	.28
12883	Shield—Coil shield for Stock No. 12881	.20
11198	Socket—7-contact 6K7 radiotron socket	.15
11279	Socket—7-contact 6L7 radiotron socket	.20
12885	Socket—8-contact 6J7 radiotron socket	.20
12007	Spring—Retaining spring for core Stock Nos. 12664, 12800, 12882—Package of 10	.36
12878	Switch—Range switch and mounting nut (S1, S2, S3)	3.60
12654	Trap—Wave trap complete (L1)	.75
	DRIVE ASSEMBLIES	
10705	Ball—5/32-in. dia. steel ball for planetary drive—Package of 20	.25
10941	Ball—1/8-in. dia. steel ball for planetary drive bearing—Package of 20	.25
12904	Bushing—Plate and bushing assembly for planetary drive mounting	.20
12905	Coupling—Flexible coupling and shaft assembly complete	.50
12909	Dial—Band indicating dial and cam assembly	1.05
12899	Drive—Variable tuning condenser drive complete including mounting bracket, drive, dial scale, and indicator less vernier dial Stock No. 12870 and link Stock No. 12868	4.40
12906	Gear—Anti-lash drive gear complete	.75
12910	Gear—Sector gear and link assembly for band selector	.20
12908	Indicator—Station selector indicator pointer	.20
8051	Link—Link and roller assembly complete with spring	.30
12911	Screen—Dial lamp screen and light diffuser	.20
4669	Screw—Set screw for flexible coupling or gear Stock No. 12905 and 12906—Package of 10	.25
12901	Shaft—Direct drive shaft and pinion gear for planetary drive	.75
12900	Shaft—Vernier drive shaft for planetary drive	.25
12903	Spring—Tension spring for planetary drive bearing—Package of 10	.20
12907	Spring—Tension spring for gear Stock No. 12906—Package of 10	.20
8052	Spring—Tension spring for link Stock No. 8051—Package of 5	.32
	REPRODUCER ASSEMBLIES	
12914	Board—3-contact reproducer terminal board	.25
12640	Bracket—Output transformer mounting bracket and clamp assembly	.18
12912	Coil—Field coil (L30)	1.70
12642	Cone—Reproducer cone and dust cap (L28) (Model 9T)	.94
12667	Cone—Reproducer cone and dust cap (L28) (Model 9K2)	1.00
5118	Plug—3-contact male reproducer plug	.25
9714	Reproducer Complete—(Model 9T)	6.85
9716	Reproducer Complete—(Model 9K2)	7.80
12913	Transformer—Output transformer (T2)	1.45
11886	Washer—Spring washer to hold field coil securely—Package of 5	.20
	MISCELLANEOUS ASSEMBLIES	
11996	Bracket—Tuning lamp mounting bracket and clamp	.22
12915	Crystal—Station selector escutcheon and crystal	1.30
12742	Escutcheon—Tuning lamp escutcheon	.22
12699	Knob—Large station selector knob—Package of 5	.68
11347	Knob—Low frequency tone control and power switch volume control range switch or high frequency tone control knob—Package of 5	.75
12700	Knob—Small (vernier) station selector knob—Package of 5	.58
11377	Screw—Chassis mounting screw assembly for table model only—Package of 4	.12
11210	Screw—Chassis mounting screw assembly for console model only—Package of 4	.28
12916	Shield—Complete R.F. unit shield	.90
11349	Spring—Retaining spring for knob Stock No. 11347 and 12700—Package of 5	.25
4982	Spring—Retaining spring for knob Stock No. 12699—Package of 10	.50
	RECEIVER ASSEMBLIES	
12863	Board—4-contact and 2-link phonograph terminal board	$0.25
4427	Bracket—Mounting bracket for H.F. tone control, L.F. tone control or volume control	.18
12867	Cable—Tuning lamp cable and socket	1.70
12511	Cap—Grid contact cap—Package of 5	.15
12859	Capacitor Pack—Comprising two sections .015 Mfd., one section .1 Mfd., and two resistors 27,000 ohms each (C55, C56, C57, R21, R22)	1.50
12873	Capacitor Pack—Comprising one 3 Mfd. and one 20 Mfd. section used in 25 cycle Model only (C61, C69)	1.20
12724	Capacitor—120 Mmfd. (C59)	.28
12404	Capacitor—120 Mmfd. (C45, C46, C49, C50)	.26
12406	Capacitor—180 Mmfd. (C52)	.26
4624	Capacitor—.01 Mfd. (C51)	.54
4858	Capacitor—.01 Mfd. (C60)	.25
4937	Capacitor—.01 Mfd. (C63)	.25
4836	Capacitor—.05 Mfd. (C53)	.30
4886	Capacitor—.05 Mfd. (C62)	.20
4841	Capacitor—.1 Mfd. (C54)	.22
11414	Capacitor—.1 Mfd. (C47)	.20
4840	Capacitor—.25 Mfd. (C58)	.30
5170	Capacitor—.25 Mfd. (C48, C68)	.25
12741	Capacitor—.5 Mfd. (C64)	.34
5212	Capacitor—18 Mfd. (C67)	1.16
12872	Capacitor—20 Mfd. (C61)	.90
12467	Capacitor—30 Mfd. (C65, C66)	1.40
5119	Connector—3-contact female connector for speaker leads	.25
12006	Core—Adjustable core and stud for Stock No. 12652 and 12653	.22
12870	Dial—Vernier dial and disc assembly	.65
12866	Foot—Chassis mounting bracket and foot assembly—Package of 2	.75
5226	Lamp—Dial lamp—6.3 volt—Package of 5	.70
12868	Link—Range switch and band indicator operating link complete with set screw	.45
12871	Reactor—Filter reactor (L31)	1.50
12865	Resistor—Voltage divider resistor—Comprising one section 250 ohm, one section 17 ohm and one section 11 ohm (R17, R18, R26)	.45
12876	Resistor—10,000 ohms—wire wound, 10 watt (R10)	.55
12864	Resistor—17,000 ohms—wire wound (R19)	.70
11282	Resistor—56,000 ohms—carbon type—1/10 watt (R12)—Package of 5	.75
12875	Resistor—56,000 ohms—carbon type—1 watt (R16)—Package of 5	1.10
11398	Resistor—220,000 ohms—carbon type—1/10 watt (R13)—Package of 5	.75
11453	Resistor—270,000 ohms—carbon type—1/10 watt (R24)—Package of 5	.75
11172	Resistor—470,000 ohms—carbon type—¼ watt (R23)—Package of 5	1.00
11452	Resistor—470,000 ohms—carbon type—1/10 watt (R25)—Package of 5	.75
12013	Resistor—1 Megohm—carbon type—1/10 watt (R28)—Package of 5	.75
11626	Resistor—2.2 Megohm—carbon type—¼ watt (R11)—Package of 5	1.00
12874	Resistor—3.3 Megohm—carbon type—¼ watt (R14, R15)—Package of 5	1.00
4669	Screw—No. 8-32-5/32 set screw for link Stock No. 12868—Package of 10	.25
3903	Screw—No. 8-32-3/16 headless cup point set screw for Stock No. 12870—Package of 20	.36
12869	Shaft—Range switch and band indicator operating shaft and hub assembly	.25
12008	Shield—I.F. transformer shield for Stock No. 12652, 12653	.28
12607	Shield—I.F. transformer shield for Stock No. 12652	.30
12581	Shield—I.F. transformer shield top for Stock No. 12653	.36
13095	Socket—Dial lamp socket	.25
11222	Socket—Dial lamp socket	.18
11381	Socket—Tuning lamp socket and cover	.45
11195	Socket—5-contact 5Z4 radiotron socket	.15
11198	Socket—7-contact 6H6, 6K7, 6L6 or 6F5 radiotron sockets	.15
11196	Socket—8-contact socket for R.F. unit power cable plug	.15
12007	Spring—Retaining spring for Stock No. 12006	.36
12860	Tone Control—Low frequency tone control and power switch (S4, S5)	1.50
12862	Tone Control—High frequency tone control (R27)	1.00
12652	Transformer—First I.F. transformer complete (L24, L25, C45, C46)	1.60
12856	Transformer—Power transformer 105-125 volt, 50-60 cycle (T1)	5.35
12857	Transformer—Power transformer 105-125 volt, 25 cycle (T1)	7.10
12858	Transformer—Power transformer 100-250 volt, 40-60 cycle (T1)	8.75
12653	Transformer—Second I.F. transformer complete (L26, L27, C49, C50, C52, R12, R13)	2.06
12861	Volume Control—(R20)	1.00
	MAGIC BRAIN UNIT ASSEMBLIES	
12806	Board—3-contact antenna and ground terminal board	.25
5237	Bushing—Variable condenser mounting bushing assembly—Package of 3	.43
12886	Cable—Shielded power cable approx. 4-in. long complete with 8-contact male plug	1.50
12511	Cap—Grid contact cap—Package of 5	.15
12714	Capacitor—Adjustable trimmer capacitor (C3, C4, C5, C6, C14, C16)	.38

see Model C9-4

General Description

These two models each employ the same type of chassis and are similar to the original RCA Victor Model C9-4. The main changes consist of the following: (1) An RCA-5Z4 metal rectifier is used in place of the RCA-5Z3 glass rectifier, and (2) a Speech-Music Control is added to the compensated volume control circuit and is actuated by the same knob as the power switch. The Console Model (C9-4) employs a 12-inch dynamic loudspeaker and the Table Model (T9-10) employs an 8-inch dynamic loudspeaker.

Service Data

All Service Data contained in the Service Notes for RCA Victor Model C9-4 are directly applicable to these instruments except the Schematic Diagram, Wiring Diagram, and Replacement Parts. Other differences not illustrated are as follows:

Universal Transformer d-c resistance (Figure 7 of C9-4 Service Note).

Primary Winding 17.3 ohms total.

Secondary Winding 400 ohms total.

Standard Transformer

The transformer used on some models of this instrument is adaptable for voltages and frequencies as given under Ratings A and B of Electrical Specifications. Its schematic and wiring are shown by Figure 7.

Phonograph Attachment

A terminal board is provided for connecting a phonograph attachment into the audio amplifying circuit. Two typical methods of connection are shown on the schematic diagram, Figure 1. The radio volume control must be set to minimum when using phonograph.

General Features

These two models each employ the same nine-tube chassis. The table model (T 9-9) uses an 8-inch dynamic speaker and the console model (C 9-6) uses an improved 12-inch dynamic speaker.

Metal Tubes

The new metal tubes are used in the radio receiver for amplifying and detecting purposes. These tubes make possible a greater range of stable amplification not previously attainable with corresponding glass types. Their metal envelopes form a perfect electrostatic and electromagnetic shield, precluding the former necessity for elaborate shielding by means of cans. The metal tubes are especially adaptable to the modern, extended-range receivers because of their efficient shielding and their favorable internal characteristics.

Dial Drive

An open face airplane-type of dial is used. Each scale has a band of color adjacent to its graduations and three short strips of corresponding colors at the lower part of the dial for index purposes. An index pointer, which moves as the band switch is rotated, points to one of these colors to identify the band in use. The drive mechanism is variable, there being either a 50-to-1 or 10-to-1 ratio available between the tuning knob and condenser drive shaft.

Tuning Indicator

A cathode-ray tube is used as a means of visually indicating when the receiver is accurately tuned to the incoming signal. This tube is of new design and comprises an amplifier section and a cathode-ray section built in the same glass envelope. The cathode-ray section consists of a conically shaped luminescent screen, upon which a pattern is formed by an effect of the detected signal after said effect has been amplified by the amplifier section which is fed from the detector diode circuit. The size of the patterns is determined by the strength of the signal voltage, so, that any change of tuning may be readily observed in order to facilitate tuning to exact resonance.

CIRCUIT FEATURES

The circuit is based upon the Superheterodyne principle. The three ranges of tuning are covered by three sets of coils. A single r-f stage provides the desired selectivity and gain ahead of the hexode first-detector tube. The oscillator stage operates separately from the first detector. A single stage i-f system is employed. Its basic frequency is 460 kc. Diode detection is performed by a double diode RCA-6H6 Radiotron. Automatic volume control is provided by this same tube. The audio system consists of two stages, the driver, an RCA-6F5, and the output, an RCA-6F6. High voltages for plate, screen, and bias supplies are obtained from an RCA-5Z3 full-wave rectifier through an efficient filter. The field of the loudspeaker acts as a reactor in the filter circuit. Further details of the circuit are as follows:

Oscillator

The oscillator circuit has extreme stability of frequency and good uniformity of output over the tuning ranges. These qualities assure that the tuning of the receiver will not drift as the line voltage varies. The action of the circuit is such that when the cathode emission tends to change with line voltage or because of other reasons, the variation of voltage drop in the plate and screen resistor restores the operating characteristics of the tube to normal and thus maintains constancy of the generated signal.

First Detector

This stage has unusually good high frequency mixing efficiency. The tube used, an RCA-6L7, is a new hexode type. The signal is supplied to the first control-grid and the oscillator voltage is fed in on a second control-grid, a screen-grid separating the two. The arrangement of the grids prevents degenerative difficulties, particularly at the higher frequencies. The second grid is direct-connected to the cathode of the oscillator and has no d-c bias.

Compensated Volume Control

The variation in response of the human ear with different degrees of volume is compensated for by a resistor and condenser network in the manual volume control circuit. The volume control itself is an acoustically tapered potentiometer which provides equal changes of sound intensity for the listener per degree of rotation.

Range Switch

The band-change switch has several functions. It exchanges the antenna, detector, and oscillator coils in order to select the range desired. At the same time, it shorts out the unused coils so as to eliminate their absorptive effects. It also varies the fidelity by shorting a coupling condenser in the audio system to provide the desired reproduction for short-wave as well as long-wave reception.

Tone Control

Provision is included for variable reduction of high frequencies. This consists of a resistor and condenser combination across the primary winding of the output transformer, the resistor being the variable element. As it is decreased, the high-frequency response limit is lowered.

Power System

The power transformer has its primary winding capacitively shielded from its secondary windings to eliminate transfer of line disturbances into the receiver and to stop any tendency for the circuit to radiate into the line. Rectification is performed in the usual manner by a full-wave tube.

Detection and A.V.C.

The modulated signal as obtained from the output of the i-f system is detected by an RCA-6H6 twin diode tube. The audio frequency secured by this process is passed on to the a-f system for amplification and final reproduction. The d-c voltage which results from detection of the signal is used for automatic volume control. This voltage, which develops across resistor R-8, is applied as automatic control-grid bias to the r-f, first-detector, and i-f tubes through suitable resistance-capacitance filter circuits. The second diode of the RCA-6H6 is used to supply residual bias for these controlled tubes under conditions of little or no signal. This diode, under such conditions, draws current, which flows through R-9 and R-8, thereby maintaining the desired minimum operating bias on such tubes. On application of signal energy above a certain level, however, the auxiliary bias diode ceases to draw current and the a.v.c. diode takes over the biasing function.

SERVICE DATA

The various diagrams of this booklet contain such information as will be needed for servicing the receiver. The ratings of all resistors, capacitors, coils, etc., are indicated adjacent to the symbols signifying these parts on the diagrams. The coils, reactors, and transformer windings are rated in terms of their d-c resistances only. Ratings of less than one ohm are generally omitted. Identification titles such as R-3, L-7, C-1, etc., are provided for reference between the illustrations and replacement parts.

Alignment Procedure

The extensive frequency range of this receiver necessitates a more or less involved method of alignment. However, if the following directions are carefully applied, the normal performance of the instrument will be obtained.

Correct performance of the receiver can only be obtained when the trimmer adjustments have been made by a skilled service man with the use of adequate and reliable test equipment. Such apparatus as may be required for this particular instrument is illustrated and described on a separate page of this booklet.

Two methods of alignment are applicable. One utilizes a Cathode-Ray Oscillograph as a means of output indication and the other follows former procedure where a glow type indicator or meter is used. The oscillographic method is much to be preferred, since greater accuracy is possible from the type of indication afforded. There are no approximations necessary as with the meter or aural method, but each adjustment can be made with excellent precision. Both methods are hereinafter outlined so that alignment operations may be made according to the equipment available.

It is wise to determine the necessity for alignment as well as the direction of misalignment before making adjustments. The RCA Tuning Wand is an instrument designed particularly for such a purpose.

The Tuning Wand consists of a bakelite rod having a small brass cylinder at one end and a core of finely divided iron at the other. It may be inserted into a tuned coil while a signal of the normal resonant frequency is being supplied to such coil to obtain an indication of the tuning. Holes are provided at the top of the r-f shield cans for entrance of the Wand. The presence of either end of the Wand will cause a change in tuning which will be indicated at the receiver output as an increase or decrease in signal level. If there is a decrease of output when either end is inserted, the tuning is correct and will require no adjustment. However, should there be an increase of output due to the iron core and decrease with the brass cylinder, an increase in inductance or capacitance is indicated as necessary to bring the circuit into line. The trimmer involved should therefore be increased accordingly. If the brass cylinder end causes an increase in output while the iron end causes a decrease, reduction of inductance will be necessary to place the circuit in alignment. This is equivalent to decreasing the trimmer concerned. The following tabulation gives the various changes and the adjustments required:

WAND	SIGNAL	TRIMMER
Brass	Decrease	None
Iron	Decrease	
Brass	Increase	Decrease
Iron	Decrease	
Brass	Decrease	Increase
Iron	Increase	

CATHODE-RAY ALIGNMENT

Equipment

A standard source of the specified alignment frequencies is required. Such a source should consist of an RCA Full Range Oscillator, Stock No. 9595. Output indication should be by means of an RCA Stock No. 9545 Cathode-Ray Oscillograph. An RCA Stock No. 9558 Frequency Modulator will be needed to sweep the generated signal and synchronize it with the Oscillograph in order to make possible the visual representation of the resonant characteristic of the circuit being tuned on the cathode-ray fluorescent screen.

I-F Trimmer Adjustments

The four trimmers of the two i-f transformers are located as shown by Figure 6. Each must be aligned to a basic frequency of 460 kc. The last transformer must be aligned firstly and the first transformer aligned secondly. For such a process, it is necessary to feed the output of the Full-Range Oscillator to the stages in their order of alignment, adjusting the trimmers of each transformer and observing the effect at the second detector output on the Cathode-Ray Oscillograph. The proper point of connection of the Oscillograph is with its vertical "high" input terminal attached to the junction of R-7, R8 and R9 as illustrated in Figure 6, and with the "0" or ground terminal to the chassis. The "Ext. Sync." terminals of the Oscillograph should be connected to the Frequency Modulator as shown by Figure 4. A .001 mfd. capacitor installed in series with the Oscillator "Ant." lead will prevent the voltages of the stage under alignment from becoming upset. The vertical "A" amplifier should be "On" for the ensuing adjustments and the gain control kept at its maximum position. For each adjustment, the Oscillator output need be regulated so that the image obtained on the Oscillograph screen will be of sufficient size as to be accurately observable. Proceed further as follows:

(a) Place the receiver, Oscillograph and test Oscillator in operation. Set the receiver range switch to Band "A" and tune the station selector to a point where no interference will be picked up, shorting the antenna and ground terminals if necessary. Set the Oscillograph horizontal "B" amplifier to "Timing" and control its gain so that the luminescent spot sweeps a straight line trace completely across the screen. Place the timing control to "Int." Adjust the intensity and focusing controls of the Oscillograph to produce the correct size and strength of the spot.

(b) Attach the output of the test Oscillator between the control grid cap of the RCA-6K7 i-f tube and chassis ground as shown typically by Figure 4. Tune the Oscillator to 460 kc. and set its modulation switch to "On". Regulate its output until the signal produces a wave pattern on the Oscillograph screen, adjusting the Oscillograph controls to give the desired number of cycles. Cause the image to stand still on the screen by manipulation of the frequency and synchronizing controls. Then carefully tune the two trimmers C-29 and C-30 of the second i-f transformer to produce maximum amplitude (vertical deflection) of the oscillographic image. Under this condition the transformer will be sharply resonated to 460 kc.

(c) The Frequency Modulator should then be placed in operation and interconnected with the Full-Range Oscillator by means of the special shielded patch cord. Figure 4 shows the proper arrangement. Set the Frequency Modulator sweep range switch to its "Lo" position and turn the Oscillator modulation switch to "Off". Change the timing control of the Oscillograph to "Ext." and place the range switch to its No. 2 position. Then carefully shift the tuning of the Oscillator so as to increase its frequency, until two distinct and similar waves appear on the Oscillograph screen and become exactly coincident at their highest points. These curves will be found to occur at an Oscillator setting of ***approximately* 540 kc.** They will be identical in shape but appearing in reversed positions. Adjust the frequency control of the Oscillograph in order to cause the waves to conform with the above requirements and to make them remain motionless on the screen. This will require a setting of approximately ½ clockwise rotation of the frequency control. The trimmers C-29 and C-30 should then be re-adjusted so that the two curves move together and become exactly coincident throughout their lengths, maintaining the maximum amplitude at which this condition can be brought about.

(d) Leaving the equipment connected and adjusted as in (c), change the Oscillator output to the control-grid cap of the RCA-6L7 first-detector tube. Then adjust the first i-f transformer trimmers C-24 and C-25 so that the forward and reverse waves appearing on the Oscillograph coincide throughout their lengths and have maximum amplitude. The shape of the composite wave obtained from this operation is a true representation of the overall tuning characteristic of the i-f system. Each trimmer of the entire group should then be checked to assure that it is in correct alignment as indicated by the degree of coincidence and relative amplitude of the image on the Oscillograph screen.

R-F Trimmer Adjustments

Locations of the various antenna, detector and oscillator coil trimmers are shown by Figure 6. The test Oscillator should be removed from connection with the i-f system and its output connected to the antenna-ground terminals of the receiver. No changes are to be made in the connections of the Oscillograph at the second detector. During the following adjustments, the Oscillator output should be regulated as often as is necessary to keep the oscillographic image as low as is practically observable. Adherence to such a procedure will obviate the broadness of tuning that would result from a.v.c. action on a stronger signal. Proceed with the adjustments as follows:

Calibration

Set the receiver range switch to Band A and rotate the station selector until the tuning condenser plates are in ***full mesh*** (maximum capacitance). Then move the main dial pointer until it points exactly to the ***horizontal*** line at the low frequency end of the Band A scale.

Band A

(a) With the receiver range switch in its Band A position, tune the station selector until the dial pointer is at a reading of 1,720 kc. Adjust the test Oscillator to 1,720 kc. (modulation "On" and Frequency Modulator disconnected) and increase its output to produce a registration on the Oscillograph. Carefully align the oscillator, detector, and antenna trimmers C-20, C-10 and C-3 respectively, so that each brings about maximum amplitude of output as shown by the wave on the Oscillograph. It will be necessary to have the timing control of the Oscillograph on "Int." for this operation. After each trimmer has been peaked, the Oscillograph timing control should be set to "Ext." and the Frequency Modulator placed into operation with its connections to the Oscillator and Oscillograph made in accordance with Figure 4. Turn the modulation switch of the Oscillator to "Off" and retune the Oscillator (increase frequency) until the forward and reverse waves show on the Oscillograph and become coincident at their highest points. Adjust the trimmers C-20, C-10 and C-3 again, setting each to the point which produces the best coincidence and maximum amplitude of the wave images.

(b) Remove the Frequency Modulator cable from the Oscillator and shift the signal frequency to 600 kc. Place the modulation switch to "On". Tune the receiver to pick up this signal, disregarding the dial reading at which it is best received. Then insert the Frequency Modulator plug and retune the Oscillator (modulation "Off") until the two similar forward and reverse waves appear on the screen. For this adjustment, it is advisable to shift the Oscillator to its 200—400 kc. range and use the third harmonic of the generated signal in order to obtain the desired range of sweep. The oscillator series trimmer C-19 should then be adjusted to produce maximum amplitude of the images. No rocking will be necessary on the station selector inasmuch as the signal frequency is being "wobbled" by the Frequency Modulator to produce the same effect.

After completing this adjustment, the trimmer C-20 should be realigned as in (a) to correct for any change brought about by the adjustment of C-19.

Band X

(a) Disconnect the Frequency Modulator and tune the test Oscillator to a frequency of 400 kc. (Modulation "On"). Place the receiver range switch to its Band X position and tune the station selector until the dial pointer reads exactly 400 kc. Adjust the Oscillograph timing control to "Int." Then align each of the trimmers C-18, C-9 and C-2 to the point producing maximum output at the Oscillograph. Place the Frequency Modulator in operation and attach it to the test Oscillator by means of the shielded cable. Change the Oscillograph timing to "Ext." Increase the frequency of the Oscillator (Modulation "Off") until the two forward and reverse waves appear and become coincident at their highest point, ***approximately at* 462 kc.** These waves may be made to remain stationary on the screen by manipulation of the Oscillograph range switch (No. 2 position) and frequency control (mid-position). Readjust the three trimmers C-18, C-9 and C-2 to give maximum amplitude and complete coincidence of the waves.

(b) Change the test Oscillator so that it delivers a signal of 150 kc. with the Frequency Modulator disconnected. Tune this signal on the receiver, which should be set to the Band X setting, disregarding the dial reading at which the signal is best received. Then interconnect the Frequency Modulator with the Oscillator and retune the latter to the point at which the two similar waves appear on the screen. Adjust the trimmer C-47 for maximum amplitude of the wave images. Rocking of the tuning condenser will not be necessary for this operation as such is duplicated by the Frequency Modulator. Repeat the alignment of C-18 as in (a) to correct for any error brought about by the adjustment of C-47.

Band C

(a) Turn the range switch of the receiver to its Band C position and tune the station selector until the dial pointer reads 18,000 kc. Set the test Oscillator to 18,000 kc. (modulation "On" and Frequency Modulator disconnected) and regulate its ouput to the level required for convenient observation. Adjust the trimmer C-16 to the point producing maximum output as indicated on the Oscillograph. Check for the presence of the proper "image" signal by tuning the receiver to 17,080 kc. The 18,000 kc. signal of the Oscillator will be received at this point if the adjustment of C-16 has been properly made using the position of least capacitance which gives maximum receiver output. It may be necessary to increase the output of the Oscillator in order to get an indication of the "image". ***No adjustments should be made during this check.***

(b) Return the receiver tuning to 18,000 kc., re-align C-16 if necessary, and then adjust the detector and antenna trimmers, C-8 and C-1, for maximum signal output as evidenced by the oscillographic image. No further adjustments are to be made on this band.

OUTPUT INDICATOR ALIGNMENT

To align the receiver by means of an output indicator other than a Cathode-Ray Oscillograph will require the use of a standard test Oscillator such as that recommended above for the source of signals and means of indication for the output. The RCA Neon Output Indicator, Stock No. 4317 will be found very satisfactory for such use. It should be connected across the voice coil circuit of the loudspeaker or across the output transformer primary.

I-F Alignment

Connect the test Oscillator to the control-grid cap of the i-f tube. Advance the volume control of the receiver to its full-on position. Tune the test Oscillator to 460 kc. and align the trimmers C-29 and C-30 to give maximum receiver output. Regulate the Oscillator output during this adjustment so that the output indication is as small as can be conveniently observed. After completing the adjustments of these trimmers, reconnect the Oscillator so that it will feed into the control-grid circuit of the RCA-6L7 first detector. Then tune the first i-f transformer trimmers C-24 and C-25 for maximum receiver output.

R-F Alignment

After completing the i-f adjustments, it is advisable to correct the line-up of the circuits ahead of the first detector. The test Oscillator should be connected to the antenna-ground terminals of the receiver and the manual volume control kept at its maximum position. For each adjustment the Oscillator output should be maintained as low as possible in order to avoid broadness of tuning which would result from a.v.c. action on a stronger signal. Band A should be aligned by supplying a 1,720 kc. signal to the receiver, tuning the station selector to a dial reading of 1,720 and adjusting the trimmers C-20, C-10 and C-3 to produce maximum receiver output. The Oscillator should then be shifted to 600 kc. and the receiver tuned to resonate this signal, disregarding the reading at which it is best received. Trimmer C-19 must then be adjusted, simultaneously while rocking the station selector backward and forward through the signal until the maximum output results from the combined operations. C-20 should be rechecked to assure that its adjustment has not changed because of the trimming of C-19. Band X must be aligned at 400 kc. and 150 kc. Tune the test Oscillator to 400 kc. and turn the receiver dial to the same reading. Adjust trimmers C-18, C-9 and C-2 for maximum (peak) receiver output. Then shift the Oscillator to 150 kc. and tune the receiver to pick up this signal, disregarding the dial reading at which it is best received. Adjust trimmer C-47, simultaneously rocking the tuning condenser backward and forward through the signal, until maximum receiver output results from the combined operations. Repeat the alignment of C-18 as above to correct for any change which may have been caused by the adjustment of C-47. Change the receiver so that it is operative and the dial reads 18,000 kc. on the "C" Band. Tune the test Oscillator to 18,000 kc. Then adjust the oscillator trimmer C-16 to produce maximum (peak) output. Two positions of this trimmer will be found which conform with this requirement. The one of least capacitance is correct. Check for the presence of "image" response at 17,080 kc. by shifting the receiver tuning. If it is received at such a point, the trimmer C-16 has been correctly adjusted to the right peak. ***No adjustments are to be made during this check.*** Tune the receiver back to the 18,000 kc. dial marking, readjust C-16 if necessary, and then tune the detector and antenna capacitors C-1 and C-8 for maximum receiver output. No further adjustments are necessary.

Parts List

RCA MFG. CO., INC.

Radiotron Socket Voltages

The voltage values indicated from the Radiotron socket contacts to chassis on Figure 6 will serve to assist in the location of causes for faulty operation. Each value as specified should hold within ± 20% when the receiver is normally operative at its rated supply voltage. Variations in excess of this limit will usually be indicative of trouble in the basic circuits. The voltages given are actual operating values and do not allow for inaccuracies which may be caused by the loading effect of a voltmeter's internal resistance. This resistance should be duly considered for all readings. The amount of circuit resistance shunting the meter during measurement will determine the accuracy to be obtained, the error increasing as the meter resistance becomes comparable to or less than the circuit resistance. For the majority of readings, a meter having an internal resistance of 1,000 ohms per volt will be satisfactory when the range used for each reading is chosen as high as possible consistent with good readability.

	DRIVE ASSEMBLIES	
4362	Arm—Band indicator operating arm	.28
10194	Ball—Steel ball—Package of 20	.25
4422	Clutch—Tuning condenser drive clutch assembly—comprising drive shaft, balls, ring, spring and washers—assembled	1.00
11262	Dial—Dial scale	.60
11252	Drive—Variable tuning condenser drive assembly	1.88
4520	Indicator—Station selector indicator pointer	.18
11226	Indicator—Band indicator pointer assembly—comprising indicator pointer, arm, link and stud	.20
3993	Screw—No. 6-32-5/32" square head set-screw for band indicator operating arm—Package of 10	.25
4669	Screw—No. 8-32-5/32" set-screw for variable condenser drive assembly—Package of 10	.25
4377	Spring—Band indicator operating arm spring—Package of 5	.25
4378	Stud—Band indicator operating arm stud and nut assembly—Package of 5	.25
	REPRODUCER ASSEMBLIES	
11232	Board—Terminal board assembly with two lead wire clips	$0.18
11231	Bolt—Yoke and core assembly bolt and nut	.16
8060	Bracket—Output transformer mounting bracket	.14
11257	Clamp—Cone center suspension clamping nut and screw assembly—Package of 5	.25
11254	Coil—Field coil (L20)	2.00
11233	Coil—Neutralizing coil (L21)	.30
11235	Cone—Reproducer cone (L22)—Package of 5 (table model)	3.50
11258	Cone—Reproducer cone (L22)—Package of 5 (console model)	3.85
5119	Connector—Three-contact female connector plug for reproducer cable	.25
5118	Connector—Three-contact male connector for reproducer	.25
9618	Reproducer—Complete (table model)	6.40
9619	Reproducer—Complete (console model)	6.05
11253	Transformer—Output transformer (T2)	1.56
11230	Washer—"Binder's board" "C" washer—Used to hold field coil securely—Package of 5	.18
	MISCELLANEOUS ASSEMBLIES	
11729	Bolt—Reproducer mounting bolt assembly—Comprising one bolt, one washer, one lockwasher and one nut—Package of 2 (table model)	.20
11191	Bracket—Tuning tube mounting bracket—less clamp	.12
11319	Cable—Tuning tube cable complete with socket (table model)	1.38
11331	Cable—Tuning tube cable complete with socket (console model)	1.28
11192	Clamp—Tuning tube mounting clamp—less bracket	.12
11276	Escutcheon—Radiotron tuning tube escutcheon	.40
11337	Escutcheon—Station selector escutcheon	.70
11246	Foot—Chassis mounting foot and bracket assembly—Package of 2	.76
6614	Glass—Station selector dial glass	.30
11347	Knob—Volume control, tone control, range switch or power switch knob—Package of 5	.75
11346	Knob—Station selector knob—Package of 5	.75
11382	Resistor—1 Megohm—Carbon type—1/10 Watt—(R61)—Package of 5	.75
4578	Ring—Retaining ring for station selector dial glass—Package of 5	.34
5210	Screw—Chassis mounting screw assembly—Package of 4 (console model)	.16
11377	Screw—Chassis mounting screw assembly—Comprising one screw, one washer and one lockwasher—Package of 4 (table model)	.12
11348	Screw—No. 8-32-7/16" Headless cupped point set screw for knob, Stock No. 11346—Package of 10	.32
11381	Socket—Tuning tube socket and cover	.45
11349	Spring—Retaining spring for knob—Stock No. 11347—Package of 5	.15

1440 K.C. OSC. (C-20) ADJ. CENTER REAR OF CHASSIS.

Measured at 230 volts, 60-cycle supply

Tuned to approximately 900 kc. (Band A)—No signal being received—Volume control setting optional

For 160-volt, 60-cycle supply, 30% lower; for 230-volt d-c supply, 13% lower; for 160-volt d-c supply, 35% lower

On some instruments the following changes affecting the Schematic Circuit and Chassis Wiring Diagrams have been made.

Capacitor C42 is disconnected from the side of the power line which connects to R24 and R23 and is reconnected to the external ground terminal. The other lead of this capacitor remains connected to the side of the power line which connects to C41 and R22.

An additional capacitor (Stock No. 12480 - Capacitor - .05 Mfd. - C43 - List Price $0.30) is connected across the power line circuit. It is mounted on the power switch and connected between the dummy terminal and the lug to which the other lead of the power cord

MODEL T9-7
Circuit Data
Alignment, Parts

RCA MFG. CO., INC.

General Features

This instrument comprises a nine-tube chassis, mounted in a table type of cabinet. It uses the new metal tubes. The tuning range is from 540 to 18,000 kc. This coverage includes the important short-wave broadcast bands at 49, 31, 25, 19, and 16 meters, as well as the American broadcast band (540-1600 kc.). Chassis features include automatic volume control, cathode-ray tuning indicator ("Magic Eye"), 3-point tone control, antenna wave trap, and audio compensation. A high level of output is available from the receiver for reproduction by the 8-inch electro-dynamic speaker. The tuning dial is an illuminated semi-airplane type. Each dial scale is distinctly marked with a separate color. Positions of the range selector knob are correspondingly indexed on the control panel with sections of similar colors. The tuning control is a dual-ratio type, which permits fast tuning through a 10-to-1 drive ratio and vernier tuning through a 50-to-1 drive ratio. The latter is especially advantageous for accurate tuning of the short-wave stations.

Circuit Arrangement

The conventional superheterodyne type of circuit is used. It consists of an r-f stage, a combined first detector-oscillator stage, a single i-f stage, a diode detector-automatic volume control stage, an audio voltage amplifier stage, a push-pull audio power output stage, a tuning indicator, and a half wave rectifier power supply stage.

Tuned Circuits

The antenna coil system and the detector coil system each consist of a single primary and three series-connected secondary windings to provide the three ranges of tuning. The oscillator coil system is similarly wound on a single form. A range selector switch (S-1) is used for connecting the various sections of these three coil systems into the circuit to provide operation on the band desired. The coils are tuned by a variable three-section gang condenser having trimmer capacitors in shunt with each section. There are additional trimmer capacitors across the section of each coil used for Band "A." A series trimmer is also associated with the Band "A" oscillator coil.

The intermediate frequency amplifier system consists of an RCA-6K7 in a transformer-coupled circuit. This stage operates at a basic frequency of 460 kc. Each winding of both i-f transformers (input and output) is tuned by an adjustable trimmer capacitor.

Detector and A.V.C.

The modulated signal as obtained from the output of the i-f stage is detected by an RCA-6H6 twin-diode tube. The audio frequency secured by this process is transferred to the a-f system for amplification and final reproduction. The d-c voltage which results from detection of the signal is used for automatic volume control. This voltage, which develops across resistor R-8, is applied as automatic control-grid bias to the r-f, first-detector, and i-f tubes through a suitable resistance filter circuit. The second (auxiliary) diode of the RCA-6H6 is used to supply residual bias for the controlled tubes under conditions of little or no signal. This diode, under such conditions, draws current which flows through resistors R-8 and R-10, thereby maintaining the desired minimum operating bias on such tubes. On application of signal energy above a certain level, however, the auxiliary bias-diode ceases to draw current and the a.v.c.-diode takes over the biasing function.

Audio System

The manual volume control consists of an acoustically tapered potentiometer in the audio circuit between the output of the detector diode and the input grid of the audio-voltage-amplifier tube. This control has a tone-compensating filter connected to it, so that the correct aural balance will be obtained at different volume settings. Transformer coupling is used between the first audio stage and the push-pull power output stage. The output of the power amplifier is transformer-coupled into the dynamic loudspeaker. High-frequency tone control is effected by a capacitor across the plate circuit of one of the output tubes. Speech-music control is effected by a resistor connected to the compensated volume control circuit. Control of tone is obtained by means of the switch (S-2).

Tuning Indicator

A cathode-ray tube is used as a means of visually indicating when the receiver is accurately tuned to the incoming signal.

NOTE: On a-c and d-c circuits of 100 volts or less, the action of the "Magic Eye" will be limited.

This tube is of new design and comprises an amplifier section and a cathode-ray section built in the same glass envelope. The cathode-ray section consists of a conically shaped luminescent screen, upon which a pattern is formed by an effect of the detected signal after said effect has been amplified by the amplifier section, which is fed from the detector diode circuit. The size of the pattern is determined by the strength of the signal voltage, so that any change of tuning may be readily observed in order to facilitate tuning to exact resonance.

Rectifier

The plate, grid, and cathode voltages required for the operation of this receiver are supplied by the RCA-25Z6 rectifier operating as a half-wave rectifier. The field winding of the loudspeaker is used as a reactor in the filter circuit from which it simultaneously receives its magnetizing current.

The filaments of all nine tubes are connected in series and are fed direct from the supply line, the voltage being dropped to the required value by resistors R-19 and R-20. The correct operating voltage for the pilot lamp is developed across resistor R-20. This voltage across the pilot lamp will be slightly high when the receiver is first turned on, but will quickly drop to a normal value as soon as the tube filaments reach their operating temperature.

NOTE: (Power Supply Rating) As shipped from the factory, all instruments are connected for operation on a 200-250-volt supply line. They may be converted for operation at 140-160 volts by connecting a jumper between points shown by dotted line on resistor R-19, Figures 2 and 3.

SERVICE DATA

CAUTION: Grid caps, tuning condenser, and resistor on top of chassis may be "hot" with respect to external ground, and should be avoided when servicing, unless due precautions are taken.

The various diagrams of this bulletin contain such information as will be needed to isolate causes for defective operation when such a condition develops. Values of the resistors, capacitors, coils, etc., are indicated adjacent to the symbols signifying these parts on the diagrams. Identification titles, such as R-3, L-2, C-1, etc., are provided for reference between the diagrams and the replacement parts list. Locating of the parts in the schematic circuit is facilitated by the fact that the numerical titles increase from left to right on the diagram. The coils, reactors, and transformer windings are rated in terms of their d-c resistances only. Resistances of less than one ohm are generally omitted.

Alignment Procedure

Precise alignment is vital to the proper functioning of this receiver. There are four trimming adjustments provided in the i-f system, three in the oscillator coil system, two in the detector coil system, and two in the antenna coil system. Each of these trimmers has been accurately adjusted during manufacture and should remain properly aligned unless affected by abnormal conditions of climate, or have been altered for service purposes. Incorrect alignment is usually evidenced by loss of sensitivity, improper tone quality, and poor selectivity. These indications will generally be present together.

The correct performance of the receiver can only be obtained when the alignment is performed with adequate and reliable test apparatus. The manufacturer of this instrument has a complete assortment of such service equipment available. This equipment, illustrated and described on a separate page of this booklet, may be purchased from authorized distributors and dealers.

An oscillator (signal generator) is required as a source of the specified alignment frequencies. Visual indication of the receiver output during the adjustments is necessary to enable the serviceman to obtain an accuracy of alignment which is not possible by listening to the signal. The RCA Stock No. 9595 Full-Range Oscillator and the RCA Stock No. 4317 Neon Output Indicator are especially suitable and fulfill the above requirements.

The following procedure should be followed in adjusting the various trimmer capacitors:

I-F Trimmer Adjustments

The four trimmers of the two i-f transformers are located as shown by Figure 4. Each must be aligned to a basic frequency of 460 kc. To do this, attach the output indicator across the voice coil circuit or across the output transformer primary. Connect the output of the test oscillator through a .05 mfd. condenser to the RCA 6A8 control grid, the ground of the test oscillator being connected to the receiver ground terminal. Tune the oscillator to 460 kc. Advance the receiver volume control to its full-on position and adjust the receiver tuning control to a point within its range where no interference is encountered either from local broadcast stations or the heterodyne oscillator. Increase the output of the test oscillator until a slight indication is apparent on the output indicator. Then adjust the two trimmers, C-27 and C-28, of the second i-f transformer to produce maximum (peak) indicated receiver output. Then, adjust the two trimmers, C-24 and C-26, of the first i-f transformer for maximum (peak) receiver output as shown by the indicating device. During these adjustments, regulate the test oscillator output so that the indication is always as low as possible. By doing so, broadness of tuning due to a.v.c. action will be avoided. It is advisable to repeat the adjustment of all i-f trimmers a second time to assure that the interaction between them has not disturbed the original adjustment.

R-F Trimmer Adjustments

The seven trimmers associated with the r-f, first detector, and oscillator tuned circuits have their locations shown by Figures 3 and 4. The three trimmers which are at all times directly in shunt with the variable tuning condenser necessitates that the high-frequency range (Band C) be aligned first. The range selector switch should, therefore, be turned to its Band C position for the first adjustment. The output indicator should be left connected to the output system as for i-f alignment. Attach the output terminals of the test oscillator to the antenna and ground terminals of the receiver.

Calibrate the dial by rotating the tuning control until the variable condenser plates are in their full mesh (maximum capacity) position and adjusting the dial pointer so that its end points to the horizontal graduation (approximately 530 kc.) at the low-frequency end of the Band A scale.

Proceed further as follows:

(a) Adjust the test oscillator to 18,000 kc. and set the receiver tuning control to a dial reading of 18,000 kc.

(b) Regulate the output of the test oscillator until a slight indication is perceptible at the receiver output. Then adjust the trimmer, C-19, on the oscillator section of the variable condenser to the point at which it produces maximum indicated receiver output. Two points may be found, each of which produces such a maximum. The one of ***maximum trimmer capacitance*** is correct and should be used. (The oscillator will be 460 kc. below the signal frequency at this adjustment point.)

(c) Adjust the trimmer, C-15, of the detector section of the variable condenser, simultaneously rocking the receiver tuning control backward and forward through the 18,000 kc. input signal, until maximum receiver output results from these combined operations. Rocking of the variable condenser will prevent inaccurate adjustment, which would otherwise be caused by the interaction between the heterodyne oscillator circuit and the detector tuned circuit.

(d) With the receiver tuning control set to 18,000 kc. adjust the trimmer, C-6, on the antenna section of the variable condenser to the point which produces maximum (peak) indicated receiver output.

(e) Change the receiver range selector to its Band A position and set the receiver tuning control to a dial reading of 1,400 kc. Tune the test oscillator to 1,400 kc. and regulate its output to produce a slight indication on the receiver output indicating device.

(f) Adjust the high-frequency trimmers of the Band A oscillator, detector, and antenna coils, C-20, C-12, and C-6 respectively, to the points at which each produces maximum indicated receiver output.

(g) Shift the test oscillator frequency to 600 kc. and tune the receiver to pick up this signal, disregarding the dial reading at which it is best received.

(h) Tune the low-frequency trimmer, C-22, of the oscillator Band A coil, simultaneously rocking the tuning control of the receiver backward and forward through the signal, until maximum indicated receiver output results from these combined operations. The adjustment of C-19, C-15, and C-8 should be corrected at 18,000 kc. as in (b), (c), and (d); also C-20, C-12 and C-6 should be corrected at 1,400 kc. as in (f) to compensate for any changes caused by the adjustment of the low-frequency oscillator coil trimmer.

Phonograph Attachment

A terminal board is provided for connecting a phonograph into the audio amplifying circuit. A typical method of connection is shown on the schematic diagram (Figure 1). Correct procedure to be observed for adjustment of attachment to secure proper aural compensation is indicated.

Wave Trap Adjustment

With the receiver in operation using its normal antenna, tune station selector to the point at which the intermediate frequency interference is most intense. Then adjust the wave trap trimmer to the point which causes maximum suppression of the interference.

Radiotron Socket Voltages

The voltage values indicated from the Radiotron socket contacts, grid caps, resistors, and terminals to –B ground bracket on Figure 4 will assist in the location of causes for faulty operation. Each value as specified should hold within ± 20% when the receiver is normally operative at its rated line voltage. Variations in excess of this limit will usually be indicative of trouble in the basic circuits. These voltages were measured with set tuned to approximately 900 kc. (Band A); no signal being received, and volume control setting optional. To duplicate the conditions under which the voltages were measured requires a 1,000-ohm-per-volt d-c meter, having ranges of 10, 50, and 250 volts. Voltages below 10 read on 10-volt scale, between 10 and 50 on 50-volt scale, and between 50 and 250 on 250-volt scale. A-C voltages were measured with a corresponding a-c meter.

The prices quoted above are subject to change without notice.

NOTES

(1) Beat notes or heterodyning (whistles) may be encountered in some instances on these receivers due to excessive antenna capacitance. This condition may be corrected by reducing the size of the antenna or by inserting a 150 mmfd. capacitor in series with the antenna lead at the antenna terminal. Interference in the form of "beats" from a combination of local stations may frequently be remedied by tuning the wave trap to one of the interfering stations. The wave trap will tune from approximately 375 kc. to 700 kc.

Parts List

RCA MFG. CO., INC.

General Features

This instrument comprises a nine-tube chassis, mounted in a table type of cabinet. It uses the new metal tubes. The tuning range is from 155 to 320 kc.; from 530 to 1,500 kc.; and from 5,400 to 18,000 kc. This coverage includes the important short-wave bands at 49, 31, 25, 19 and 16 meters, the European long-wave band (150-320 kc.) and the American broadcast band (530-1,500 kc.). Chassis features include automatic volume control, cathode ray tuning indicator ("Magic Eye"), 3-point tone control, antenna wave trap, and audio compensation. A high level of output is available from the receiver for reproduction by the 8-inch electrodynamic speaker. The tuning dial is an illuminated semi-airplane type. Each dial scale is distinctly marked with a separate color. Positions of the range selector knob are correspondingly indexed on the control panel with sections of similar colors. The tuning control is a dual-ratio type, which permits fast tuning through a 10-to-1 drive ratio and vernier tuning through a 50-to-1 drive ratio. The latter is especially advantageous for accurate tuning of the short-wave stations.

Circuit Arrangement

The conventional superheterodyne type of circuit is used. It consists of an r-f stage, a combined first detector-oscillator stage, a single i-f stage, a diode detector-automatic volume control stage, an audio voltage amplifier stage, a push-pull audio power output stage, a tuning indicator, and a half-wave rectifier power supply stage.

Tuned Circuits

The antenna coil system and the detector coil system each consist of two series-connected primary windings and three series-connected secondary windings to provide the three ranges of tuning. The oscillator coil system is similarly wound on a single form. A range selector switch (S-1) is used for connecting the various sections of these three coil systems into the circuit to provide operation on the band desired. The coils are tuned by a variable three-section gang condenser having trimming capacitors in shunt with each section. There are additional trimming capacitors across the section of each Band "A" coil and each Band "X" coil. Series trimming capacitors are also associated with the Band "A" and Band "X" oscillator coils.

The intermediate frequency amplifier system consists of an RCA-6K7 in a transformer-coupled circuit. This stage operates at a basic frequency of 460 kc. Each winding of both i-f transformers (input and output) is tuned by an adjustable trimmer capacitor.

Detector and A.V.C.

The modulated signal as obtained from the output of the i-f stage is detected by an RCA-6H6 twin-diode tube. The audio frequency secured by this process is transferred to the a-f system for amplification and final reproduction. The d-c voltage which results from detection of the signal is used for automatic volume control. This voltage, which develops across resistor R-8, is applied as automatic control-grid bias to the r-f, first-detector, and i-f tubes through a suitable resistance filter circuit. The second (auxiliary) diode of the RCA-6H6 is used to supply residual bias for the controlled tubes under conditions of little or no signal. This diode, under such conditions, draws current which flows through resistors R-8 and R-10, thereby maintaining the desired minimum operating bias on such tubes. On application of signal energy above a certain level, however, the auxiliary bias-diode ceases to draw current and the a.v.c.-diode takes over the biasing function.

Audio System

The manual volume control consists of an acoustically tapered potentiometer in the audio circuit between the output of the detector diode and the input grid of the audio-voltage-amplifier tube. This control has a tone-compensating filter connected to it, so that the correct aural balance will be obtained at different volume settings. Transformer coupling is used between the first audio stage and the push-pull power output stage. The output of the power amplifier is transformer-coupled into the dynamic loudspeaker. High-frequency tone control is effected by a capacitor across the plate circuit of one of the output tubes. Speech-music control is effected by a resistor connected to the compensated volume control circuit. Control of tone is obtained by means of the switch (S-2).

Tuning Indicator

A cathode-ray tube is used as a means of visually indicating when the receiver is accurately tuned to the incoming signal.

***NOTE:** On a-c and d-c circuits of 160 volts or less, the action of the "Magic Eye" will be limited.*

This tube is of new design and comprises an amplifier section and a cathode-ray section built in the same glass envelope. The cathode-ray section consists of a conically shaped luminescent screen, upon which a pattern is formed by an effect of the detected signal after said effect has been amplified by the amplifier section, which is fed from the detector diode circuit. The size of the pattern is determined by the strength of the signal voltage, so that any change of tuning may be readily observed in order to facilitate tuning to exact resonance.

Rectifier

The plate, grid, and cathode voltages required for the operation of this receiver are supplied by the RCA-25Z6 rectifier operating as a half-wave rectifier. The field winding of the loudspeaker is used as a reactor in the filter circuit from which it simultaneously receives its magnetizing current.

The filaments of all nine tubes are connected in series and are fed direct from the supply line, the voltage being dropped to the required value by resistors R-19 and R-20. The correct operating voltage for the pilot lamp is developed across resistor R-20. This voltage across the pilot lamp will be slightly high when the receiver is first turned on, but will quickly drop to a normal value as soon as the tube filaments reach their operating temperature.

NOTE: (Power Supply Rating) As shipped from the factory, all instruments are connected for operation on a 200-250-volt supply line. They may be converted for operation at 140-160 volts by connecting a jumper between points shown by dotted line on resistor R-19, Figures 2 and 3.

SERVICE DATA

***CAUTION:** Grid caps, tuning condenser, and resistor on top of chassis may be "hot" with respect to external ground, and should be avoided when servicing, unless due precautions are taken.*

The various diagrams of this bulletin contain such information as will be needed to isolate causes for defective operation when such a condition develops. Values of the resistors, capacitors, coils, etc., are indicated adjacent to the symbols signifying these parts on the diagrams. Identification titles, such as R-3, L-2, C-1, etc., are provided for reference between the diagrams and the replacement parts list. Locating of the parts in the schematic circuit is facilitated by the fact that the numerical titles increase from left to right on the diagram. The coils, reactors, and transformer windings are rated in terms of their d-c resistances only. Resistances of less than one ohm are generally omitted.

Alignment Procedure

Precise alignment is vital to the proper functioning of this receiver. There are four trimming adjustments provided in the i-f system, five in the oscillator coil system, three in the detector coil system, and three in the antenna coil system. Each of these trimmers has been accurately adjusted during manufacture and should remain properly aligned unless affected by abnormal conditions of climate, or have been altered for service purposes. Incorrect alignment is usually evidenced by loss of sensitivity, improper tone quality, and poor selectivity. These indications will generally be present together.

The correct performance of the receiver can only be obtained when the alignment is performed with adequate and reliable test apparatus. The manufacturer of this instrument has a complete assortment of such service equipment available. This equipment may be purchased from authorized distributors and dealers.

An oscillator (signal generator) is required as a source of the specified alignment frequencies. Visual indication of the receiver output during the adjustments is necessary to enable the serviceman to obtain an accuracy of alignment which is not possible by listening to the signal. The RCA Stock No. 9595 Full-Range Oscillator and the RCA Stock No. 4317 Neon Output Indicator are especially suitable and fulfill the above requirements.

The following procedure should be followed in adjusting the various trimmer capacitors:

I-F Trimmer Adjustments

The four trimmers of the two i-f transformers are located as shown by Figure 4. Each must be aligned to a basic frequency of 460 kc. To do this, attach the output indicator across the voice coil circuit or across the output transformer primary. Connect the output of the test oscillator through a .05 mfd. condenser to the RCA-6A8 control grid, the ground of the test oscillator being connected to the receiver ground terminal. Tune the oscillator to 460 kc. Advance the receiver volume control to its full-on position and adjust the receiver tuning control to a point within its range where no interference is encountered either from local broadcast stations or the heterodyne oscillator. Increase the output of the test oscillator until a slight indication is apparent on the output indicator. Then adjust the two trimmers, C-27 and C-28, of the second i-f transformer to produce maximum (peak) indicated receiver output. Then, adjust the two trimmers, C-24 and C-26, of the first i-f transformer for maximum (peak) receiver output as shown by the indicating device. During these adjustments, regulate the test oscillator output so that the indication is always as low as possible. By doing so, broadness of tuning due to a.v.c. action will be avoided. It is advisable to repeat the adjustment of all i-f trimmers a second time to assure that the interaction between them has not disturbed the original adjustment.

R-F Trimmer Adjustments

The eleven trimmers associated with the r-f, first detector, and oscillator tuned circuits have their locations shown by Figures 3 and 4. The three trimmers which are at all times directly in shunt with the variable tuning condenser necessitate that the high-frequency range (Band C) be aligned first. The range selector switch should, therefore, be turned to its Band C position for the first adjustment. The output indicator should be left connected to the output system as for i-f alignment. Attach the output terminals of the test oscillator to the antenna and ground terminals of the receiver.

Calibrate the dial by rotating the tuning control until the variable condenser plates are in their full mesh (maximum capacity) position and adjusting the dial pointer so that its end points to the horizontal graduation (approximately 530 kc.) at the low-frequency end of the Band A scale.

Proceed further as follows:

(a) Adjust the test oscillator to 18,000 kc. and set the receiver tuning control to a dial reading of 18,000 kc.

(b) Regulate the output of the test oscillator until a slight indication is perceptible at the receiver output. Then adjust the trimmer, C-19, on the oscillator section of the variable condenser to the point at which it produces maximum indicated receiver output. Two points may be found, each of which produces such a maximum. The one of *maximum trimmer capacitance* is correct and should be used. (The oscillator will be 460 kc. below the signal frequency at this adjustment point.)

(c) Adjust the trimmer, C-15, of the detector section of the variable condenser, simultaneously rocking the receiver tuning control backward and forward through the 18,000 kc. input signal, until maximum receiver output results from these combined operations. Rocking of the variable condenser will prevent inaccurate adjustment, which would otherwise be caused by the interaction between the heterodyne oscillator circuit and the detector tuned circuit.

(d) With the receiver tuning control set to 18,000 kc. adjust the trimmer, C-8, on the antenna section of the variable condenser to the point which produces maximum (peak) indicated receiver output.

(e) Change the receiver range selector to its Band A position and set the receiver tuning control to a dial reading of 1,400 kc. Tune the test oscillator to 1,400 kc. and regulate its output to produce a slight indication on the receiver output indicating device.

(f) Adjust the high-frequency trimmers of the Band A oscillator, detector, and antenna coils, C-20, C-49, and C-6 respectively, to the points at which each produces maximum indicated receiver output.

(g) Shift the test oscillator frequency to 600 kc. and tune the receiver to pick up this signal, disregarding the dial reading at which it is best received.

(h) Tune the low-frequency trimmer, C-22, of the oscillator Band A coil, simultaneously rocking the tuning control of the receiver backward and forward through the signal, until maximum indicated receiver output results from these combined operations.

(i) Change the receiver range selector to its Band "X" position and set the receiver tuning control to a dial reading of 300 kc., set the test oscillator to 300 kc. and regulate its output to produce a slight indication on the receiver output indicating device.

(j) Adjust the high-frequency trimmers of the Band "X" oscillator, detector and antenna coils, C-50, C-48, and C-55 respectively, to the points at which each produces maximum indicated receiver output.

(k) Shift the test oscillator to 180 kc. and tune the receiver to pick up this signal, disregarding the dial reading at which it is best received.

(l) Tune the low frequency trimmer C-51 of the oscillator Band "X" coil, simultaneously rocking the tuning control of the receiver backward and forward through the signal, until maximum indicated receiver output results from these combined operations.

(m) The adjustment of C-19, C-15, and C-8 should be corrected at 18,000 kc. as in (b), (c) and (d).

(n) The adjustment of C-20, C-49 and C-6 should be corrected at 1,400 kc. as in (f) to compensate for any change caused by adjustment of the low-frequency oscillator coil trimmer.

(o) The adjustment of C-50, C-48, and C-55 should be corrected at 300 kc. as in (j) to compensate for any changes caused by the low-frequency oscillator coil trimmer.

Radiotron Socket Voltages

The voltage values indicated from the Radiotron socket contacts, grid caps, resistors, and terminals to -B ground bracket on Figure 4 will assist in the location of causes for faulty operation. Each value as specified should hold within ±20% when the receiver is normally operative at its rated line voltage. Variations in excess of this limit will usually be indicative of trouble in the basic circuits. These voltages were measured with set tuned to approximately 900 kc. (Band A); no signal being received, and volume control setting optional. To duplicate the conditions under which the voltages were measured requires a 1,000-ohm-per-volt d-c meter, having ranges of 10, 50, and 250 volts. Voltages below 10 read on 10-volt scale, between 10 and 50 on 50-volt scale, and between 50 and 250 on 250-volt scale. A-C voltages were measured with a corresponding a-c meter.

Phonograph Attachment

A terminal board is provided for connecting a phonograph into the audio amplifying circuit. A typical method of connection is shown on the schematic diagram (Figure 1). Correct procedure to be observed for adjustment of attachment to secure proper aural compensation is indicated.

Wave-Trap Adjustment

With the receiver in operation using its normal antenna, tune station selector to the point at which the intermediate frequency interference is most intense. Then adjust the wave trap trimmer to the point which causes maximum suppression of the interference.

Mechanical Specifications

Height .... 21 1/16 inches
Width .... 15 3/4 inches
Depth .... 9 1/2 inches
Weight (Net) .... 27 1/2 pounds
Weight (Shipping) .... 33 pounds
Chassis Base Dimensions ... 13 5/8 x 7 7/8 x 2 1/2 inches
Tuning Drive Ratios .... 10-to-1 and 50-to-1

RADIOTRON COMPLEMENT
(1) RCA-6K7 .... Radio-Frequency Amplifier

	REPRODUCER ASSEMBLIES	
11232	Board—Terminal board with two lead wire clips	.18
11231	Bolt—Yoke and core assembly bolt and nut	.16
[illegible]	Bracket—Output transformer mounting bracket	.14
11257	Clamp—Cone center suspension clamping nut and screw assembly—Package of 5	.18
12090	Coil—Field coil—(L22)	1.00
11233	Coil—Neutralizing coil—(L20)	.30
11235	Cone—Reproducer cone—(L21)—Package of 5	3.50
3040	Connector—4-contact female connector for reproducer cable	.25
3090	Connector—4-contact male connector for reproducer	.25
9643	Reproducer—Complete	4.50
12080	Transformer—Output transformer—(T2)	1.70
11006	Washer—Spring washer—used to hold field coil assembly—Package of 5	.50
	MISCELLANEOUS ASSEMBLIES	
11996	Clamp—Tuning tube mounting bracket and clamp assembly	.22
11376	Escutcheon—Tuning tube escutcheon	.40
11396	Escutcheon—Station selector escutcheon and crystal	.76
11382	Knob—Range switch knob—Package of 5	.50
11010	Knob—Station selector knob assembly—Comprising 1 large and 1 small knob—Package of 5	1.00
11397	Knob—Volume control or power switch knob—Package of 5	.75
11382	Resistor—1 megohm—carbon type—1/10 watt—(R18)—Package of 5	.75
11377	Screw—Chassis mounting screw assembly—Package of 4	.12
11381	Socket—Tuning tube socket and cover	.45
11380	Spring—Retaining spring for knob Stock Nos. 11397 and 11382 and small knob in No. 11010—Package of 5	.15
4982	Spring—Retaining spring for large knobs—for Stock No. 11010—Package of 10	.26

The prices quoted above are subject to change without notice.

NOTES

(1) Beat notes or heterodyning (whistles) may be encountered in some instances on these receivers due to excessive antenna capacitance. This condition may be corrected by reducing the size of the antenna or by inserting a 150 mmfd. capacitor in series with the antenna lead at the antenna terminal. Interference in the form of "beats" from a combination of local stations may frequently be remedied by tuning the wave trap to one of the interfering stations.

RCA MFG. CO., INC.

General Description

The RCA Victor Model D 9-19 combination radio receiver and manual phonograph provides excellent entertainment from either broadcast reception or record reproduction. It consists of a nine-tube, three-band radio receiver, and a manual phonograph, combined in the one cabinet. The high level of sound energy obtainable from the output of this instrument is capably handled by a new sensitive, twelve-inch, electrodynamic loudspeaker. Outstanding features of this instrument are as follows:

Magic Brain

The radio receiver includes the "Magic Brain" unit for maximum all-around efficiency. This unit is a scientifically correct co-ordination of all the parts for the r-f, oscillator, and first detector functions of a Superheterodyne Receiver. Such design of the important head end, or "Magic Brain" unit, gives greater efficiency in the short-wave ranges as all lead lengths are kept as short as possible, and all sockets and other parts are located for best possible operation.

Magic Eye

A cathode-ray tube whose fluorescent screen has the appearance of a human eye is used for visually indicating when the receiver is accurately tuned to the incoming signal. This tube is of new design. It contains two groups of elements; one group operates as an amplifier and the other group operates as a cathode-ray tube.

The cathode-ray section consists of a conically shaped luminescent screen, a cathode, and a control electrode. The detected signal from the receiver is applied through the amplifier section of the tuning tube to the control electrode of the cathode-ray section. This control electrode, in turn, affects the electron stream emitted by the cathode in such a manner as to cause a triangular shadow on the luminescent screen. The size of the shadow caused by the control electrode is determined by the strength of the incoming signal, so that a change-of-tuning is readily exhibited on the cathode-ray screen, and therefore tuning to exact resonance can be definitely obtained.

RCA All-Metal Tubes

The new metal tubes are used in the radio receiver for amplifying and detecting purposes. These tubes make possible a greater range of stable amplification not previously attainable with corresponding glass types. Their metal envelopes form a perfect electrostatic and electromagnetic shield, precluding the former necessity for elaborate shielding by means of cans. The metal tubes are especially adaptable to the modern, extended-range receivers because of their efficient shielding and their favorable internal characteristics.

Phonograph Mechanism

An improved manually operated phonograph mechanism is used in this model. The 12-inch turntable will accommodate either the 10-inch or the 12-inch phonograph records. The turntable rotates at a speed of 78 r.p.m. A speed regulator is provided for accurate adjustment of this speed. The instrument may be purchased with any one of three ratings as specified under Electrical Specifications. *It is important that a machine of any particular rating be operated at the frequency and voltage for which it is rated.* Attempts to operate at ratings other than specified for the particular instrument may result in damage to both the phonograph motor and the radio receiver. An automatic switch is provided to turn "off" the phonograph motor at the completion of record play when the eccentric-type inside groove record is used.

Colorband Dial

An open face airplane-type of dial is used. Each scale has a band of color adjacent to its graduations and three short strips of corresponding colors at the lower part of the dial for index purposes. An index pointer, which moves as the band switch is rotated, points to one of these colors to identify the band in use. The drive mechanism is variable, there being either a 50-to-1 or 10-to-1 ratio available between the tuning knob and condenser drive shaft. The new shock-proof condenser mounting reduces microphonic tendencies to a minimum.

CIRCUIT FEATURES

The circuit is based upon the Superheterodyne principle. The three ranges of tuning are covered by three sets of coils. A single r-f stage provides the desired selectivity and gain ahead of the hexode first-detector tube. The oscillator stage operates separately from the first detector. A single stage i-f system is employed. Its basic frequency is 460 kc. Diode detection is performed by a double diode RCA-6H6 Radiotron. Automatic volume control is provided by this same tube. The audio system consists of two stages, the driver, an RCA-6F5, and the output, an RCA-6F6. High voltages for plate, screen, and bias supplies are obtained from an RCA-5Z3 full-wave rectifier through an efficient filter. The field of the loudspeaker acts as a reactor in the filter circuit. Further details of the circuit are as follows:

Oscillator

The oscillator circuit has extreme stability of frequency and good uniformity of output over the tuning ranges. These qualities assure that the tuning of the receiver will not drift as the line voltage varies. The action of the circuit is such that when the cathode emission tends to change with line voltage or because of other reasons, the variation of voltage drop in the plate and screen resistor restores the operating characteristics of the tube to normal and thus maintains constancy of the generated signal.

First Detector

This stage has unusually good high frequency mixing efficiency. The tube used, an RCA-6L7, is a new hexode type. The signal is supplied to the first control-grid and the oscillator voltage is fed in on a second control-grid, a screen-grid separating the two. The arrangement of the grids prevents degenerative difficulties, particularly at the higher frequencies. The second grid is direct-connected to the cathode of the oscillator and has no d-c bias.

Compensated Volume Control

The variation in response of the human ear with different degrees of volume is compensated for by a resistor and condenser network in the manual volume control circuit. The volume control itself is an acoustically tapered potentiometer which provides equal changes of sound intensity for the listener per degree of rotation.

Range Switch

The band-change switch has several functions. It exchanges the antenna, detector, and oscillator coils in order to select the range desired. At the same time, it shorts out the unused coils so as to eliminate their absorptive effects. It also varies the fidelity by shorting a coupling condenser in the audio system to provide the desired reproduction for short-wave as well as long-wave reception.

Tone Control

Provision is included for variable reduction of high frequencies. This consists of a resistor and condenser combination across the primary winding of the output transformer, the resistor being the variable element. As it is decreased, the high-frequency response limit is lowered.

Power System

The power transformer has its primary winding capacitively shielded from its secondary windings to eliminate transfer of line disturbances into the receiver and to stop any tendency for the circuit to radiate into the line. Rectification is performed in the usual manner by a full-wave tube.

Detection and A.V.C.

The modulated signal as obtained from the output of the i-f system is detected by an RCA-6H6 twin diode tube. The audio frequency secured by this process is passed on to the a-f system for amplification and final reproduction. The d-c voltage which results from detection of the signal is used for automatic volume control. This voltage, which develops across resistor R-8, is applied as automatic control-grid bias to the r-f, first-detector, and i-f tubes through suitable resistance-capacitance filter circuits. The second diode of the RCA-6H6 is used to supply residual bias for these controlled tubes under conditions of little or no signal. This diode, under such conditions, draws current, which flows through R-9 and R-8, thereby maintaining the desired minimum operating bias on such tubes. On application of signal energy above a certain level, however, the auxiliary bias diode ceases to draw current and the a.v.c. diode takes over the biasing function.

SERVICE DATA

The various diagrams of this booklet contain such information as will be needed for servicing the receiver. The ratings of all resistors, capacitors, coils, etc., are indicated adjacent to the symbols signifying these parts on the diagrams. The coils, reactors, and transformer windings are rated in terms of their d-c resistances only. Ratings of less than one ohm are generally omitted. Identification titles such as R-3, L-2, C-1, etc., are provided for reference between the illustrations and replacement parts.

Alignment Procedure

The extensive frequency range of this receiver necessitates a more or less involved method of alignment. However, if the following directions are carefully applied, the normal performance of the instrument will be obtained.

Correct performance of the receiver can only be obtained when the trimmer adjustments have been made by a skilled service man with the use of adequate and reliable test equipment. Such apparatus as may be required for this particular instrument is illustrated and described on a separate page of this booklet.

Two methods of alignment are applicable. One utilizes a Cathode-Ray Oscillograph as a means of output indication and the other follows former procedure where a glow type indicator or meter is used. The oscillographic method is much to be preferred, since greater accuracy is possible from the type of indication afforded. There are no approximations necessary as with the meter or aural method, but each adjustment can be made with excellent precision. Both methods are hereinafter outlined so that alignment operations may be made according to the equipment available.

It is wise to determine the necessity for alignment as well as the direction of misalignment before making adjustments. The RCA Tuning Wand is an instrument designed particularly for such a purpose.

The Tuning Wand consists of a bakelite rod having a small brass cylinder at one end and a core of finely divided iron at the other. It may be inserted into a tuned coil while a signal of the normal resonant frequency is being supplied to such coil to obtain an indication of the tuning. Holes are provided at the top of the r-f shield cans for entrance of the Wand. The presence of either end of the Wand will cause a change in tuning which will be indicated at the receiver output as an increase or decrease in signal level. If there is a decrease of output when either end is inserted, the tuning is correct and will require no adjustment. However, should there be an increase of output due to the iron core and decrease with the brass cylinder, an increase in inductance or capacitance is indicated as necessary to bring the circuit into line. The trimmer involved should therefore be increased accordingly. If the brass cylinder end causes an increase in output while the iron end causes a decrease, reduction of inductance will be necessary to place the circuit in alignment. This is equivalent to decreasing the trimmer concerned. The following tabulation gives the various changes and the adjustments required:

WAND	SIGNAL	TRIMMER
Brass	Decrease	None
Iron	Decrease	
Brass	Increase	Decrease
Iron	Decrease	
Brass	Decrease	Increase
Iron	Increase	

Radiotron Socket Voltages

The voltage values indicated from the Radiotron socket contacts to chassis on Figure 5 will serve to assist in the location of causes for faulty operation. Each value as specified should hold within ± 20% when the receiver is normally operative at its rated supply voltage. Variations in excess of this limit will usually be indicative of trouble in the basic circuits. The voltages given are actual operating values and do not allow for inaccuracies which may be caused by the loading effect of a voltmeter's internal resistance. This resistance should be duly considered for all readings. The amount of circuit resistance shunting the meter during measurement will determine the accuracy to be obtained, the error increasing as the meter resistance becomes comparable to or less than the circuit resistance. For the majority of readings, a meter having an internal resistance of 1,000-ohms-per-volt will be satisfactory when the range used for each reading is chosen as high as possible consistent with good readability.

CATHODE-RAY ALIGNMENT

Equipment

A standard source of the specified alignment frequencies is required. Such a source should consist of an RCA Full Range Oscillator, Stock No. 9595. Output indication should be by means of an RCA Stock No. 9545 Cathode-Ray Oscillograph. An RCA Stock No. 9558 Frequency Modulator will be needed to sweep the generated signal and synchronize it with the Oscillograph in order to make possible the visual representation of the resonant characteristic of the circuit being tuned on the cathode-ray fluorescent screen.

I-F Trimmer Adjustments

The four trimmers of the two i-f transformers are located as shown by Figure 5. Each must be aligned to a basic frequency of 460 kc. The last transformer must be aligned firstly and the first transformer aligned secondly. For such a process, it is necessary to feed the output of the Full-Range Oscillator to the stages in their order of alignment, adjusting the trimmers of each transformer and observing the effect at the second detector output on the Cathode-Ray Oscillograph. The proper point of connection of the Oscillograph is with its vertical "high" input terminal attached to the junction of R-7, R8 and R9 as illustrated in Figure 5, and with the "0" or ground terminal to the chassis. The "Ext. Sync." terminals of the Oscillograph should be connected to the Frequency Modulator as shown by Figure 4. A .001 mfd. capacitor installed in series with the Oscillator "Ant." lead will prevent the voltages of the stage under alignment from becoming upset. The vertical "A" amplifier should be "On" for the ensuing adjustments and the gain control kept at its maximum position. For each adjustment, the Oscillator output need be regulated so that the image obtained on the Oscillograph screen will be of sufficient size as to be accurately observable. Proceed further as follows:

(a) Place the receiver, Oscillograph and test Oscillator in operation. Set the receiver range switch to Band "A" and tune the station selector to a point where no interference will be picked up, shorting the antenna and ground terminals if necessary. Set the Oscillograph horizontal "B" amplifier to "Timing" and control its gain so that the luminescent spot sweeps a straight line trace completely across the screen. Place the timing control to "Int." Adjust the intensity and focusing controls of the Oscillograph to produce the correct size and strength of the spot.

(b) Attach the output of the test Oscillator between the control grid cap of the RCA-6K7 i-f tube and chassis ground as shown typically by Figure 4. Tune the Oscillator to 460 kc. and set its modulation switch to "On". Regulate its output until the signal produces a wave pattern on the Oscillograph screen, adjusting the Oscillograph controls to give the desired number of cycles. Cause the image to stand still on the screen by manipulation of the frequency and synchronizing controls. Then carefully tune the two trimmers C-29 and C-30 of the second i-f transformer to produce maximum amplitude (vertical deflection) of the oscillographic image. Under this condition the transformer will be sharply resonated to 460 kc.

(c) The Frequency Modulator should then be placed in operation and interconnected with the Full-Range Oscillator by means of the special shielded patch cord. Figure 4 shows the proper arrangement. Set the Frequency Modulator sweep range switch to its "Lo" position and turn the Oscillator modulation switch to "Off". Change the timing control of the Oscillograph to "Ext." and place the range switch to its No. 2 position. Then carefully shift the tuning of the Oscillator so as to increase its frequency, until two distinct and similar waves appear on the Oscillograph screen and become exactly coincident at their highest points. These curves will be found to occur at an Oscillator setting of *approximately 540 kc.* They will be identical in shape but appearing in reversed positions. Adjust the frequency control of the Oscillograph in order to cause the waves to conform with the above requirements and to make them remain motionless on the screen. This will require a setting of approximately ½ clockwise rotation of the frequency control. The trimmers C-29 and C-30 should then be re-adjusted so that the two curves move together and become exactly coincident throughout their lengths, maintaining the maximum amplitude at which this condition can be brought about.

(d) Leaving the equipment connected and adjusted as in (c), change the Oscillator output to the control-grid cap of the RCA-6L7 first-detector tube. Then adjust the first i-f transformer trimmers C-24 and C-25 so that the forward and reverse waves appearing on the Oscillograph coincide throughout their lengths and have maximum amplitude. The shape of the composite wave obtained from this operation is a true representation of the overall tuning characteristic of the i-f system. Each trimmer of the entire group should then be checked to assure that it is in correct alignment as indicated by the degree of coincidence and relative amplitude of the image on the Oscillograph screen.

R-F Trimmer Adjustments

Locations of the various antenna, detector and oscillator coil trimmers are shown by Figure 5. The test Oscillator should be removed from connection with the i-f system and its output connected to the antenna-ground terminals of the receiver. No changes are to be made in the connections of the Oscillograph at the second detector. During the following adjustments, the Oscillator output should be regulated as often as is necessary to keep the oscillographic image as low as is practically observable. Adherence to such a procedure will obviate the broadness of tuning that would result from a.v.c. action on a stronger signal. Proceed with the adjustments as follows:

Calibration

Set the receiver range switch to Band A and rotate the station selector until the tuning condenser plates are in *full mesh* (maximum capacitance). Then move the main dial pointer until it points exactly to the *horizontal* line at the low frequency end of the Band A scale.

Band A

(a) With the receiver range switch in its Band A position, tune the station selector until the dial pointer is at a reading of 1,720 kc. Adjust the test Oscillator to 1,720 kc. (modulation "On" and Frequency Modulator disconnected) and increase its output to produce a registration on the Oscillograph. Carefully align the oscillator, detector, and antenna trimmers C-20, C-10 and C-3 respectively, so that each brings about maximum amplitude of output as shown by the wave on the Oscillograph. It will be necessary to have the timing control of the Oscillograph on "Int." for this operation. After each trimmer has been peaked, the Oscillograph timing control should be set to "Ext." and the Frequency Modulator placed into operation with its connections to the Oscillator and Oscillograph made in accordance with Figure 4. Turn the modulation switch of the Oscillator to "Off" and retune the Oscillator (increase frequency) until the forward and reverse waves show on the Oscillograph and become coincident at their highest points. Adjust the trimmers C-20, C-10 and C-3 again, setting each to the point which produces the best coincidence and maximum amplitude of the wave images.

(b) Remove the Frequency Modulator cable from the Oscillator and shift the signal frequency to 600 kc. Place the modulation switch to "On". Tune the receiver to pick up this signal, disregarding the dial reading at which it is best received. Then insert the Frequency Modulator plug and retune the Oscillator (modulation "Off") until the two similar forward and reverse waves appear on the screen. For this adjustment, it is advisable to shift the Oscillator to its 200—400 kc. range and use the third harmonic of the generated signal in order to obtain the desired range of sweep. The oscillator series trimmer C-19 should then be adjusted to produce maximum amplitude of the images. No rocking will be necessary on the station selector inasmuch as the signal frequency is being "wobbled" by the Frequency Modulator to produce the same effect.

After completing this adjustment, the trimmer C-20 should be realigned as in (a) to correct for any change brought about by the adjustment of C-19.

Band X

(a) Disconnect the Frequency Modulator and tune the test Oscillator to a frequency of 400 kc. (Modulation "On"). Place the receiver range switch to its Band X position and tune the station selector until the dial pointer reads exactly 400 kc. Adjust the Oscillograph timing control to "Int." Then align each of the trimmers C-18, C-9 and C-2 to the point producing maximum output at the Oscillograph. Place the Frequency Modulator in operation and attach it to the test Oscillator by means of the shielded cable. Change the Oscillograph timing to "Ext." Increase the frequency of the Oscillator (Modulation "Off") until the two forward and reverse waves appear and become coincident at their highest point, *approximately at 461 kc.* These waves may be made to remain stationary on the screen by manipulation of the Oscillograph range switch (No. 2 position) and frequency control (mid-position). Readjust the three trimmers C-18, C-9 and C-2 to give maximum amplitude and complete coincidence of the waves.

(b) Change the test Oscillator so that it delivers a signal of 150 kc. with the Frequency Modulator disconnected. Tune this signal on the receiver, which should be set to the Band X setting, disregarding the dial reading at which the signal is best received. Then interconnect the Frequency Modulator with the Oscillator and retune the latter to the point at which the two similar waves appear on the screen. Adjust the trimmer C-47 for maximum amplitude of the wave images. Rocking of the tuning condenser will not be necessary for this operation as such is duplicated by the Frequency Modulator. Repeat the alignment of C-18 as in (a) to correct for any error brought about by the adjustment of C-47.

Band C

(a) Turn the range switch of the receiver to its Band C position and tune the station selector until the dial pointer reads 18,000 kc. Set the test Oscillator to 18,000 kc. (modulation "On" and Frequency Modulator disconnected) and regulate its ouput to the level required for convenient observation. Adjust the trimmer C-16 to the point producing maximum output as indicated on the Oscillograph. Check for the presence of the proper "image" signal by tuning the receiver to 17,080 kc. The 18,000 kc. signal of the Oscillator will be received at this point if the adjustment of C-16 has been properly made using the position of least capacitance which gives maximum receiver output. It may be necessary to increase the output of the Oscillator in order to get an indication of the "image". *No adjustments should be made during this check.*

(b) Return the receiver tuning to 18,000 kc., re-align C-16 if necessary, and then adjust the detector and antenna trimmers, C-8 and C-1, for maximum signal output as evidenced by the oscillographic image. No further adjustments are to be made on this band.

OUTPUT INDICATOR ALIGNMENT

To align the receiver by means of an output indicator other than a Cathode-Ray Oscillograph will require the use of a standard test Oscillator such as that recommended above for the source of signals and means of indication for the output. The RCA Neon Output Indicator, Stock No. 4317 will be found very satisfactory for such use. It should be connected across the voice coil circuit of the loudspeaker or across the output transformer primary.

I-F Alignment

Connect the test Oscillator to the control-grid cap of the i-f tube. Advance the volume control of the receiver to its full-on position. Tune the test Oscillator to 460 kc. and align the trimmers C-29 and C-30 to give maximum receiver output. Regulate the Oscillator output during this adjustment so that the output indication is as small as can be conveniently observed. After completing the adjustments of these trimmers, reconnect the Oscillator so that it will feed into the control-grid circuit of the RCA-6L7 first detector. Then tune the first i-f transformer trimmers C-24 and C-25 for maximum receiver output.

R-F Alignment

After completing the i-f adjustments, it is advisable to correct the line-up of the circuits ahead of the first detector. The test Oscillator should be connected to the antenna-ground terminals of the receiver and the manual volume control kept at its maximum position. For each adjustment the Oscillator output should be maintained as low as possible in order to avoid broadness of tuning which would result from a.v.c. action on a stronger signal. Band A should be aligned by supplying a 1,720 kc. signal to the receiver, tuning the station selector to a dial reading of 1,720 and adjusting the trimmers C-20, C-10 and C-3 to produce maximum receiver output. The Oscillator should then be shifted to 600 kc. and the receiver tuned to resonate this signal, disregarding the reading at which it is best received. Trimmer C-19 must then be adjusted, simultaneously while rocking the station selector backward and forward through the signal until the maximum output results from the combined operations. C-20 should be rechecked to assure that its adjustment has not changed because of the trimming of C-19. Band X must be aligned at 400 kc. and 150 kc. Tune the test Oscillator to 400 kc. and turn the receiver dial to the same reading. Adjust trimmers C-18, C-9 and C-2 for maximum (peak) receiver output. Then shift the Oscillator to 150 kc. and tune the receiver to pick up this signal, disregarding the dial reading at which it is best received. Adjust trimmer C-47, simultaneously rocking the tuning condenser backward and forward through the signal, until maximum receiver output results from the combined operations. Repeat the alignment of C-18 as above to correct for any change which may have been caused by the adjustment of C-47. Change the receiver so that it is operative and the dial reads 18,000 kc. on the "C" Band. Tune the test Oscillator to 18,000 kc. Then adjust the oscillator trimmer C-16 to produce maximum (peak) output. Two positions of this trimmer will be found which conform with this requirement. The one of least capacitance is correct. Check for the presence of "image" response at 17,080 kc. by shifting the receiver tuning. If it is received at such a point, the trimmer C-16 has been correctly adjusted to the right peak. ***No adjustments are to be made during this check.*** Tune the receiver back to the 18,000 kc. dial marking, readjust C-16 if necessary, and then tune the detector and antenna capacitors C-1 and C-8 for maximum receiver output. No further adjustments are necessary.

Centering Armature

Refer to Figure 10 showing the pickup inner structure. The armature is shown in its proper relation to the magnet pole pieces, i. e., exactly centered. Whenever this centering adjustment has been disturbed, the screws A, B, and C should be loosened and the armature clamp adjusted to the point where the vertical axis of the armature is at right angles to the horizontal axis of the pole pieces, and centered between them. This centering operation may be facilitated by inserting a small rod or nail into the armature needle hole, using it as a lever to test the angular movement of the armature. The limitation of the movement in each direction will be caused by the armature striking the pole pieces. The proper adjustment is obtained when there is equal angular displacement of the armature and adjustment rod or nail to each side of the vertical axis of the magnet and coil assembly. The screws A and B should then be secured, observing care not to disturb the adjustment of the armature clamp. Then place the pickup in a vise and secure the centering spring-clamp by means of the screw C, allowing the centering spring to remain in the position at which the armature is exactly centered between the pole pieces. With a little practice, the correct adjustment of the armature may be readily obtained. The air gap between the pole pieces and the armature should be kept free from dust, filings, and other such foreign materials which would obstruct the movement of the pickup armature.

Damping Block

The viscoloid block which is attached to the back end of the armature shank serves as a mechanical filter to eliminate undesirable resonances and to cause the frequency response to be uniform. Should it be necessary to replace this damping block, it may be done by removing screw D and the cover support bracket from the mechanism and taking off the old viscoloid block. The surface of the armature which is in contact with the viscoloid should be thoroughly cleaned with fine emery cloth. Then insert the new block so that it occupies the same position as it did originally. Make certain that the block is in correct vertical alignment with the armature. The hole in the new viscoloid block is somewhat smaller than the diameter of the armature in order to permit a snug fit. With the viscoloid aligned on the armature, screw D and the cover support bracket should then be replaced. Heat should be applied to the armature (viscoloid side) so that the viscoloid block will fuse at the point of contact and become rigidly attached to the armature. A special-tip soldering iron constructed as shown in Figure 11 will be found very useful in performing this operation. The iron should be applied only long enough to slightly melt the block and cause a small bulge on both sides.

Replacing Coil

Whenever there is defective operation due to an open or shorted pickup coil, this coil should be replaced. The method of replacement will be obvious upon inspection of the pickup assembly and by study of the cut-a-way illustrations. Make sure that the new coil is properly centered with the hole in the support strip and glued securely in that position. It is important to readjust the armature as previously explained after reassembly of the mechanism. Only rosin core solder should be used for soldering the coil leads in the pickup. This same type of solder should be used when necessary for soldering the centering spring to the armature.

Magnetizing

Loss of magnetization will not usually occur when the pickup has received normal care due to the fact that the magnet and pole pieces are one unit and the magnetic circuit remains closed at all times. When the pickup has been mishandled, subjected to a strong a-c field, jolted, or dropped, there may be an appreciable loss of magnetic strength, in which case it will be necessary to remagnetize the entire structure. This should be done by first removing the cover and then placing the pickup assembly on the poles of a standard pickup magnetizer such as the RCA Stock No. 9549 Pickup Magnetizer and charging the pickup in accordance with the instructions accompanying the magnetizer. It is recommended that the pickup be magnetized while the armature assembly is in place. This will necessitate that one of the poles of the magnetizer be rotated 180 degrees. This will provide proper clearance for the armature clamp assembly. It is preferable to check the polarity of the pickup magnet and to remagnetize it so that the same polarity is maintained.

MODEL D9-19
Parts List

RCA MFG. CO., INC.

REPLACEMENT PARTS

Insist on genuine factory tested parts, which are readily identified and may be purchased from authorized dealers

Stock No.	DESCRIPTION	List Price
	RECEIVER ASSEMBLIES	
11698	Board—Three-terminal phonograph terminal board	$0.22
4427	Bracket—Volume control or high-frequency tone control mounting bracket	.18
5237	Bushing—Variable tuning condenser mounting bushing assembly—Package of 3	.43
11350	Cap—Contact cap—Package of 5	.20
11223	Capacitor—Adjustable capacitor (C19)	.46
11256	Capacitor—Adjustable capacitor (C-47)	.48
11292	Capacitor—22 MMfd. (C7)	.24
11321	Capacitor—33 MMfd. (C33)	.26
11289	Capacitor—50 MMfd. (C11)	.26
11291	Capacitor—115 MMfd. (C21)	.24
5116	Capacitor—175 MMfd. (C35)	.18
11290	Capacitor—400 MMfd. (C48)	.25
11269	Capacitor—800 MMfd. (C46)	.30
4409	Capacitor—1120 MMfd. (C38)	.35
11287	Capacitor—4500 MMfd. (C15)	.30
4868	Capacitor—.005 Mfd. (C34)	.20
4838	Capacitor—.005 Mfd. (C44)	.20

5170	Capacitor—0.25 Mfd. (C23, C28, C36)	.25
11248	Capacitor—4 Mfd. (C41)	1.06
11240	Capacitor—10 Mfd. (C39)	1.08
5212	Capacitor—18 Mfd. (C40)	1.16
11272	Clamp—Antenna cable clamp—Located near antenna terminal	.10
4748	Clamp—Capacitor mounting clamp assembly—for Stock No. 11248	.15
5215	Coil—Antenna coil (A and C Bands)—(L1, L2, L5, L6, C1, C3)	2.32
11325	Coil—Antenna coil (X Band)—(L3, L4, C2)	1.56
5216	Coil—Detector coil (A and C Bands)—(L7, L8, L11, L12, C8, C10)	2.34
11326	Coil—Detector coil (X Band)—(L9, L10, C9)	1.80
5217	Coil—Oscillator coil (A and C Bands)—(L13, L15, C16, C20)	2.20
11327	Coil—Oscillator coil (X Band)—(L14, L23, C18)	1.44
11214	Condenser—Three-gang variable tuning condenser (C5, C14, C22)	4.28
11697	Cover—Phonograph terminal board cover	.12
4840	Lamp—Dial lamp—Package of 5	.66
8041	Plate—R.F. or I.F. coil shield locking plate—Package of 2	.12
11244	Resistor—Voltage divider resistor, comprising one 7500-ohm and one 9200-ohm sections (R18, R19)	1.06
11245	Resistor—Voltage divider resistor, comprising one 148-ohm, one 32-ohm, and one 110-ohm section (R15, R16, R17)	.62
5112	Resistor—1000 Ohm—Carbon type—¼ Watt—(R2)—Package of 5	1.00
5114	Resistor—15,000 Ohm—Carbon type—1 Watt—(R5)	.22
11300	Resistor—33,000 Ohm—Carbon type—1/10 Watt—(R4)—Package of 5	.75
11322	Resistor—39,000 Ohm—Carbon type—¼ Watt—(R10)—Package of 5	1.00
5029	Resistor—56,000 Ohm—Carbon type—¼ Watt—(R13)—Package of 5	1.00
3118	Resistor—100,000 Ohm—Carbon type—¼ Watt—(R1, R3, R6)—Package of 5	1.00
11323	Resistor—270,000 Ohm—Carbon type—¼ Watt—(R12)—Package of 5	1.00
11172	Resistor—470,000 Ohm—Carbon type—¼ Watt—(R14)—Package of 5	1.00
11151	Resistor—2.2 Megohms—Carbon type—¼ Watt—(R9, R60, R67)—Package of 5	1.00
5249	Shield—Antenna, detector, or oscillator coil shield	.20
5250	Shield—I.F. transformer shield	.22
11273	Shield—Rectifier Radiotron shield	.25
11222	Socket—Dial lamp socket	.18
4794	Socket—Four-contact rectifier Radiotron socket	.15
11313	Socket—Five-contact Radiotron socket	.18
11198	Socket—Seven-contact Radiotron socket	.15
11236	Switch—Band switch (S1, S2, S3, S4, S5, S6, S7, S8, S9, S10, S11)	2.44
11133	Switch—Power switch (S12)	.62
5238	Terminal—Antenna terminal clip assembly	.14
11238	Tone Control—High-frequency tone control (R20)	.96
11216	Transformer—First intermediate frequency transformer (L16, L17, C24, C25)	2.15
11239	Transformer—Second intermediate frequency transformer (L18, L19, C29, C30, C31, R7, R8)	2.72
11242	Transformer—Power transformer—105-125 Volts—25-60 Cycles	6.52
11243	Transformer—Power transformer—100-130, 140-160, 195-250 Volts—40-60 Cycles—(T1)	4.64
11237	Volume control (R11)	1.20
	DRIVE ASSEMBLIES	
4382	Arm—Band indicator operating arm	.28
10194	Ball—Steel ball—Package of 20	.25
4422	Clutch—Tuning condenser drive clutch assembly—comprising drive shaft, balls, ring, spring and washers—assembled	1.00
11262	Dial—Dial scale	.60
11252	Drive—Variable tuning condenser drive assembly	1.88
4520	Indicator—Station selector indicator pointer	.18
11226	Indicator—Band indicator pointer assembly—comprising indicator pointer, arm, link and stud	20
3993	Screw—No. 6-32-5/32" square set-screw for band indicator operating arm—Package of 10	.25
4669	Screw—No. 8-32-5/32" set-screw for variable condenser drive assembly—Package of 10	.25
4377	Spring—Band indicator operating arm spring—Package of 5	.25
4378	Stud—Band indicator operating arm stud and nut assembly—Package of 5	.25
	MOTOR ASSEMBLIES	
11703	Governor—Governor complete for phonograph motor—Stock No. 11701 or No. 11702	3.05
11701	Motor—Phonograph turntable motor—110 Volts—50 to 60 Cycles—(M1)	21.20
11702	Motor—Phonograph turntable motor—110 Volts—25 Cycles	33.35
	MOTOR BOARD ASSEMBLIES	
4594	Box—Used needle box (cup)	.30
7084	Cover—Turntable cover	.40
11704	Damper—Turntable rubber damper and damper plate	
4596	Escutcheon—Speed regulator escutcheon plate	.36
4597	Screw—Motor mounting screw assembly—comprising four screws, four lockwashers, four spacers, and four nuts	.22
11696	Turntable—Complete	2.48
11695	Volume Control—Phonograph volume control (R65, S14)	1.60
	ECCENTRIC AUTOMATIC BRAKE SWITCH ASSEMBLIES	
3994	Cover—Eccentric automatic switch cover and screw	.26
10174	Springs—Automatic brake springs—comprising one each of four springs—Package of 2	.50
6806	Switch—Eccentric automatic brake and switch assembly—less switch cover	2.50
3322	Switch—Eccentric automatic switch only—less cover (S13)	.75
	PICKUP AND ARM ASSEMBLIES	
11705	Arm—Pickup arm complete—less escutcheon and pickup unit	4.50
11707	Armature—Pickup armature	.28
6346	Back—Pickup housing back	.45
11709	Coil—Pickup coil (L50)	.58
3521	Cover—Pickup back cover	.18
11708	Cover—Pickup front cover	.15
3737	Damper—Pickup damper—Package of 5	.65
3390	Escutcheon—Pickup arm escutcheon	.46
11706	Pickup Unit—Complete (L50)	4.80
3389	Rod—Eccentric automatic brake trip rod—Package of 5	.40
3387	Screw Assembly—Pickup mounting screw assembly—comprising one screw, one lockwasher and one nut—Package of 10	.40
11549	Screw—Pickup front cover screw—Package of 10	.42
11547	Screw—Pickup needle holding screw—Package of 10	.42
	CABLE ASSEMBLIES	
11700	Cable—Five-conductor shielded cable—approximately 24" long—Connects phonograph volume control to compensator pack and chassis terminal strip	.88
11699	Cable—Radiotron tuning tube cable complete with socket and cover—approximately 25" long	1.32
4573	Plug—Female section of two-contact plug—Used on power cable to motor	.30
4577	Plug—Male section of two-contact plug—Used on motor leads	.30
11382	Resistor—1 Megohm—Carbon type—1/10 Watt—Located in tuning tube socket—(R61)—Package of 5	.75
11381	Socket—Radiotron tuning tube socket and cover	.45
	REPRODUCER ASSEMBLIES	
11232	Board—Terminal board assembly with two lead wire clips	.18
11231	Bolt—Yoke and core assembly bolt and nut	.16
8060	Bracket—Output transformer mounting bracket	.14
11257	Clamp—Cone center suspension clamping nut and screw assembly—Package of 5	.25
11254	Coil—Field coil (L20)	2.00
11233	Coil—Hum neutralizing coil (L21)	.30
11258	Cone—Reproducer cone (L22)—Package of 5	3.85
5118	Connector—Three-contact male connector for reproducer	.25
5119	Connector—Three-contact female connector plug for reproducer cable	.25
9619	Reproducer—Complete	6.05
11253	Transformr—Output transformer (T2)	1.56
11250	Washer—"Binder's board" "C" washers—Used to hold field coil assembly	.18
	MISCELLANEOUS ASSEMBLIES	
11191	Bracket—Tuning tube mounting bracket—less clamp	.12
11192	Clamp—Tuning tube mounting clamp—less bracket	.12
11694	Compensator—Phonograph input compensator pack—comprising one 150-ohm, one 220-ohm, and one 1000-ohm resistor, one 0.1 Mfd. and one 2 Mfd. capacitor, and one 0.25 H reactor—(R62, R63, R64, C60, C61, L51)	3.88
11337	Escutcheon—Station selector escutcheon	.70
11276	Escutcheon—Radiotron tuning tube escutcheon	.40
11246	Foot—Chassis mounting foot and bracket assembly—Package of 2	.76
6614	Glass—Station selector dial glass	.30
11346	Knob—Station selector knob—Package of 5	.75
11347	Knob—Phonograph volume control, radio volume control, tone control, power switch or range switch knob—Package of 5	.75
4678	Ring—Retaining ring for station selector dial glass—Package of 5	.34
11210	Screw—Chassis mounting screw assembly—Package of 4	.28
11348	Screw—No. 8-32-7/16" set-screw for knob—Stock No. 11346—Package of 10	.32
3391	Spring—Motor board mounting spring assembly—comprising one bolt, one "C" washer, two cup washers, one bottom spring, one lockwasher, and one cap nut	.50
11349	Spring—Retaining spring for knob—Stock No. 11347—Package of 5	.15

Selector Dial

Figure 11 illustrates the relation of the various parts of the dial mechanism when in its "Standard broadcast" position with the range switch likewise turned to its "Standard broadcast" position. In re-assembling the dial after repairs, see that the gears are meshed in accordance with the diagram, at the same time noting that the range switch is in its "Standard broadcast" position and the lever attached to the range-switch shaft placed in the position shown.

To adjust the dial mechanism, set the range switch to its "Standard broadcast" position. Place a straight-edge across the center of the dial so that its edge is even with the lower (end) marking at both the low-frequency and high-frequency ends of the dial. Under such conditions the straight-edge should be parallel with the top of the chassis base. If the straight-edge is not parallel with the top of the chassis base, loosen the nut on the rear of the roller link pivot stud and move the stud up or down until the link roller moves the dial to the desired position so that the end calibration marks obtain the position mentioned above. Tighten the nut on the roller link pivot stud.

Set the gang tuning condenser to its maximum capacity position. Adjust the dial pointer to the low-frequency (end) mark on "Standard broadcast" scale. This is a friction adjustment.

With the gang tuning condenser plates still in full mesh, loosen the two set screws on the vernier-dial hub. Rotate the vernier dial until the "0" marking is in a vertical plane above the center of the shaft. Tighten set screws.

Antenna and Ground Terminals

These receivers are equipped with an antenna-ground terminal board having three terminals. These terminals are marked "A2," "A1," and "G," the latter being the ground terminal and should always be connected to a good external ground. The transmission-line leads of the RCA RK-40A antenna system should be connected to terminals "A2" and "A1." The receiver coupling units of the RCA RK-40 and the RCA Spider-Web antenna systems should be connected to terminals "A1" and "G." Connect a single-wire antenna to terminal "A1."

General Description

These receivers represent the result of thorough development, design, and substantial manufacture. Noteworthy technical improvements have been applied in achieving marked advantages of operation, and efficiency of performance.

Model 10T is a ten-tube, table-type, "Magic Brain" superheterodyne receiver with an eight-inch electrodynamic loudspeaker. Model 10K employs an identical radio chassis, is of the console-type, has a twelve-inch electrodynamic loudspeaker, and incorporates the newly developed "Magic Voice." Design features incorporated in these receivers include built-in doublet antenna coupler, "Magic Brain", improved plunger-type air-dielectric adjustable trimming capacitors in the antenna, detector, and oscillator coil circuits; tuned r-f amplifier, high-efficiency first detector (converter) with separate oscillator, two-stage i-f amplifier, beam-type power amplifier, magnetite core adjusted i-f transformers, low-frequency oscillator tracking, and wave-trap, range-selector sensitivity control; fidelity control; two-point aural compensated volume control, music-speech switch; automatic volume control, phonograph terminal board, new selector dial; and a dust-proof electrodynamic loudspeaker.

Service convenience has been a controlling factor in the layout of the chassis parts and wiring. The assembly of these various elements is such that the number of conductors is minimized, with all important connections being readily accessible. Trimming adjustments are located at accessible points. A double tuning-knob arrangement permits the choice of either a twenty-to-one or a hundred-to-one dial drive ratio. The latter permits ease of tuning, especially in the "Medium wave", "Short wave", and "Ultra short wave" bands.

Circuit Arrangement

The conventional type of superheterodyne circuit is used. It consists of an r-f amplifier stage, first-detector (converter) stage, separate oscillator stage, two i-f amplifier stages, a diode-detector—automatic-volume-control stage, an audio voltage-amplifier stage, a beam-type power-amplifier stage, a tuning indicator "Magic Eye", and a full-wave rectifier.

"Magic Brain"

The new "Magic Brain" is constructed as a separate, self-contained, completely shielded, five-band, oscillator-detector-antenna-tuning unit which plugs into the main chassis.

A single-wire antenna, or a doublet antenna, when connected to the proper input terminals of the receiver, is coupled to the control grid of the RCA-6K7 r-f amplifier tube through the tuned r-f transformer consisting of L6, L5, L4, L3, and L2 (except when range selector is in "Ultra short wave" position). The primary coil L13 of the "Ultra short wave" (D) band tuned r-f transformer remains in the antenna circuit at all times. A unique method of switching is used. In the "Long wave" (X) band, L6 becomes the primary with L5, L4, L3, and L2 as secondary. In the "Standard broadcast" (A) band, L5 becomes the primary with L4, L3, and L2 as secondary (L6 shorted out). In the "Medium wave" (B) band, L4 becomes the primary with L3 and L2 as secondary (L6 and L5 shorted out). In the "Short wave" (C) band, L3 becomes the primary with L2 as secondary (L6, L5, L4, and tap on L4 shorted out). The tap on L4 is provided to prevent interaction with L3 and L2 when operating receiver in "Short wave" band. In the "Ultra short wave" (D) band, L6, L5, L4, and L3 are shorted out and grounded, and secondary L14 is placed in shunt with L2. The latter connection prevents undesirable interaction of L2 with L14. This method of switching reduces the total number of coils and leads, and results in having a low-loss primary and secondary winding for each band with high efficiency of operation.

The band switching of the detector circuits is similar to that of the antenna circuits. Coils L15, L21, and L20 are always connected in series with the plate circuit of the RCA-6K7 r-f amplifier tube. In the "Long wave" (X) band, L19, [illegible], L17, and L16 are connected in series as the secondary circuit. The ground of the coil system is at the low end of L19. L20 acts as the primary which transfers energy to the secondary L19. Capacitor C33 resonates primary L20 at the proper frequency. In the "Standard broadcast" (A) band, L18, L17, and L16 are connected in series as the secondary circuit. The ground of the coil system is now between L18 and L19. L19 is used as the primary and is resonated at the proper frequency by capacitors C34 and C35 which are in shunt with this coil. Capacitor C33 is connected to transfer energy to the primary coil L19. In the "Medium wave" (B) band, L17 and L16 are connected in series as the secondary. The ground of the coil system is now between L17 and L18. L18 is used as the primary and is resonated at the proper frequency by capacitor C34 which is in shunt with this coil. L19 is shorted by the range selector. Capacitor C33 transfers the r-f energy from the plate circuit to the primary L18. In the "Short wave" (C) band, L16 is the secondary. The ground of the coil system is now between L16 and L17. L17 is used as the primary and is resonated to the proper frequency by capacitor C34. In addition, L15 acts as a high-frequency primary which resonates above 20 mc and improves the gain at the high-frequency end of the "Short wave" band. Coils L19 and L18 are shorted by the range selector. L21 is effectively r-f bypassed in this position by capacitor C32. In the "Ultra short wave" (D) band, L22 is the secondary, or grid coil, and consists of approximately a single turn of silver plated strap around a 7/8 inch coil form. The primary coils, L21 and L15 are in series on this band, with L21 acting as a low-frequency primary and L15 as a high-frequency primary. L16 is shunted by L22 instead of being shorted directly by the range selector. Any inductive effect of L16 is thus eliminated. L19, L18, and L17 are shorted directly by the range selector.

Separate windings, with the exception of L23, are employed in the oscillator stage for each position of the range selector. L23 (inductively coupled to L11 and L12) is placed in the oscillator plate circuit to provide additional feed-back when operating receiver on the "Ultra short wave" (D) band. This coil is effectively r-f bypassed by capacitor C12, when range selector is in the "Short wave" (C) position, to prevent undesirable reactions. Its effect on the remaining bands is negligible. The inherent stability of the oscillator circuit provides minimum frequency drift which is especially advantageous for high-frequency reception. The locally-generated signal is capacitance coupled to grid No. 3 of the RCA-6L7 first detector.

The output of the "Magic Brain" is fed to the i-f amplifier through the plug-in cable. This cable also supplies all power required by the "Magic Brain" unit.

I-F Amplifier

The intermediate-frequency amplifier consists of two RCA-6K7 tubes in a two-stage, transformer-coupled circuit. The windings of all three i-f transformers are resonated by fixed capacitors, and are adjusted by molded magnetite cores (both primary and secondary) to tune to 460 kc. A third winding L26, in the first i-f transformer, is placed in series with the main secondary L25 when the fidelity control switch S5 is thrown to "broad" position (see figure 2), thereby increasing the coupling between the primary and secondary circuits with consequent broadening of the band width of the i-f amplifier. The increased band width of the i-f amplifier therefore causes less attenuation of the higher audio modulation side-band frequencies, permitting higher fidelity reception.

Detector and A.V.C.

The modulated signal, as obtained from the output of the last i-f stage, is detected by an RCA-6H6 twin-diode tube (No. 2 diode). The audio frequency secured by this process is transferred to the a-f system for amplification and final reproduction. The d-c voltage which results from detection of the signal is used for automatic volume control. This voltage, which develops across resistors R17 and R19, is applied as automatic control grid bias to the r-f, first-detector, and i-f tubes. The No. 1 diode of the RCA-6H6 is used to supply residual bias to the controlled tubes under conditions of little or no signal. This diode, under such conditions, draws current which flows through resistors R18, R17, and R19, thereby maintaining the desired operating bias on such tubes. On application of signal energy above a certain level, however, the auxiliary bias diode ceases to draw current and the a-v-c diode takes over the biasing function. The sensitivity of the receiver is increased in the "Ultra short wave" (D), "Short wave" (C), and "Medium wave" (B) bands by reducing the residual bias on the above mentioned controlled tubes with switch S7 which is operated by the range selector control.

Audio System

The manual volume control consists of an acoustically tapered potentiometer in the audio circuit between the output of the detector-diode and the input grid of the RCA-6F5 audio voltage-amplifier tube. This control has a two-point tone-compensating filter connected to it so that the correct aural balance will be obtained at different volume settings. Phonograph terminals are provided to feed the output of an external phonograph pickup to the control grid of the audio amplifier through this aurally compensated volume control.

The output of the voltage amplifier is resistance-capacitance coupled to the control grid of the RCA-6L6 power-output tube. The output of this stage is transformer coupled to the voice coil of the electrodynamic speaker.

The "Music-speech" control consists of a switch S6 which, in the "Speech" position, places an additional capacitor C66 and resistor R26 in shunt with the capacitor C61 in one of the tone compensating filters. This reduces the low-frequency response of the amplifier and provides maximum intelligibility of the voice frequencies.

Fidelity Control

The fidelity control consists essentially of the combination of a conventional high audio-frequency tone control, including capacitor C70 and variable resistor R29 in shunt with the plate circuit of the output tube, and means for changing the band width of the i-f amplifier. It performs in the following manner:

When the fidelity control is in its extreme counter-clockwise position, the resistance of R29 is a minimum, and winding L26 is disconnected from the i-f circuit (S5 in sharp position, see figure 2). Capacitor C70 is most effective at this point causing maximum attenuation of the higher audio frequencies. As the control is turned clockwise, placing more resistance in series with capacitor C70, the capacitor becomes less and less effective, and the upper frequency range of the audio amplifier is extended. When the fidelity control nears its extreme clockwise position, resistor R29 is disconnected and switch S5, operated by fidelity control shaft, places winding L26 (first i-f transformer) in series with L25 (S5 in broad position).

"Magic Eye"

An RCA-6E5 cathode-ray tuning tube is used as a means of visually indicating when the receiver is accurately tuned to the incoming signal. This tube consists of an amplifier section and a cathode-ray section built in the same glass envelope. A portion of the signal voltage developed across resistor R19 is used to actuate the grid of the amplifier section. Maximum voltage is applied to this grid when the receiver is tuned to resonance with an incoming carrier. This condition is evidenced by the minimum width of the dark sector on the fluorescent screen.

"Magic Voice" (Model 10K)

Model 10K is designed with a cabinet incorporating the "Magic Voice." This is accomplished by having the rear of the speaker compartment completely enclosed by a tight-fitting back.

Five metal open-end pipes of equal diameter but of three different lengths are inserted in holes in the cabinet base and extend upward in the speaker compartment. The effect is to cause the lower-frequency waves, reaching the front of the cabinet through the pipes, to arrive approximately in-phase giving extended low-frequency response without boominess, or cabinet resonance.

SERVICE DATA

The various diagrams in this booklet contain such information as will be needed to locate causes for defective operation if such develops. The values of the various resistors, capacitors, coils, etc., are indicated adjacent to the symbols signifying these parts on the diagram. Identification titles, such as C1, L2, R1, etc., are provided for reference between the illustrations and the Replacement Parts List. The coils, reactors, and transformer windings are rated in terms of their d-c resistance only. Resistance values of less than one ohm are generally omitted.

Alignment Procedure

There are seventeen adjustments required for the alignment of the oscillator, first-detector, and antenna-tuned circuits; one adjustment for the wave-trap, and six adjustments for the i-f system. Fifteen of these adjustments are made with plunger-type air trimming capacitors and require the use of an RCA Stock No. 12636 Adjusting Tool. Each of these capacitors has a lock nut for securing the plunger in place after adjustment. The remaining nine adjustments are made by means of screws attached to molded magnetite cores. These cores change the inductance of the particular coils in which they are inserted to provide exact alignment. All of these adjustments are accurately made during manufacture and should remain in proper alignment unless affected by abnormal conditions of climate or purported alterations for servicing, or unless altered by other means. Loss of sensitivity, improper tone quality, and poor selectivity are the usual indications of improper alignment. Such conditions will usually exist simultaneously. Correct performance of this receiver can only be obtained when these adjustments have been made by a skilled service engineer with the use of adequate and reliable test equipment. The manufacturer of this receiver has such test equipment available for sale through its distributors and dealers.

The extensive frequency range of these receivers necessitates a more or less involved method of alignment. However, if the following directions are carefully applied in the sequence given, normal performance of the instruments will be obtained.

The plunger-type air trimming capacitors have their approximate plunger settings tabulated on figure 6. If the plungers have been disturbed from their original adjustments, they may be roughly set to the specified dimensions prior to alignment.

In performing services on the "Magic Brain", the leads should be restored to their original positions, since the lead-dress is important for proper operation and dial calibration.

Precautionary Dressing of Leads for "Magic Brain" Alignment
(Refer to Figure 4)

Band "X"

1. Keep blue lead A of S1 to antenna coil L4-5 dressed away from chassis, and from yellow lead X of S1 to antenna coil L5-6.
2. Bus lead from C10 to S1 should be as short as possible.
3. Keep blue lead A of S2 to detector coil L18-19 clear of chassis, coil shield, coil, and other leads.
4. Keep spaghetti lead C6 to X of S1 apart from spaghetti lead C5 to A of S1, and from chassis.

Band "A"

1. Keep green lead terminal S1 to antenna coil tap L4 away from chassis, coil shield, and coil.
2. Keep spaghetti lead C5 to A of S1 apart from spaghetti lead C6 to X of S1 and from chassis.

Band "C"

Lead from C19 to oscillator coil L7 should be maintained as short and straight as possible.

For alignment, the test-oscillator frequency should be quite accurate. A convenient and reliable means of accurately checking the frequency of test oscillators, receivers, etc., is the RCA Stock No. 9572 Crystal Calibrator.

If the test-oscillator signal cannot be heard as the receiver (heterodyne) oscillator air-trimmer plunger is changed from its minimum-capacity to maximum-capacity position (receiver dial and test oscillator set to the specified frequencies, and the correct oscillator air-trimmer used) it may be an indication that the test-oscillator frequency is outside the range covered by the air-trimmer. Under such conditions, when a more accurate setting of the test oscillator cannot be determined, set the oscillator air-trimmer plungers to the approximate settings given on figure 6. Tune the test oscillator until the signal is heard in the speaker. Each of two test-oscillator settings (the fundamentals or the harmonics of which are 920 kc apart) produce a signal. The lower-frequency test-oscillator setting should be used as this places the test-oscillator (signal) frequency 460 kc below the frequency of the receiver heterodyne oscillator.

Holes are provided in the top of the r-f and antenna coil cans on some models to enable a tuning check with the RCA Stock No. 6679 Tuning Wand. The hole in the top of the detector coil can has a cinch button which must be removed before insertion of the tuning wand. When the brass end of the wand is inserted in the coil, the inductance of the coil is decreased. If this results in an increase of output, the respective air-trimmer capacitance should be decreased (plunger pulled out). If inserting the iron end of the tuning wand causes an increase in output, resulting from an increase of inductance of the coil, the respective air-trimmer capacitance should be increased (plunger pushed in). If the range of the air trimmer is not sufficient to give the desired results, the lead-dress may be changed in the particular circuit being aligned, so as to cause the circuit to resonate within the range of the trimmer. An increase in the capacity-to-ground of the circuit will be required if the iron end of the tuning wand causes an increase of signal output when the air-trimmer plunger is full-in, while a decrease in the capacity-to-ground will be required if the brass end of the tuning wand causes an increase in signal output when the air-trimmer plunger is full-out.

Two methods of alignment are applicable—one requires use of the cathode-ray oscillograph, and the other requires a voltmeter or glow-type indicator. The cathode-ray alignment method is advantageous in that the indication provided is in the form of a wave-image which represents the resonance characteristics of the circuit being tuned. This method is preferred because of the i-f characteristics of these receivers. This type of alignment is possible through use of apparatus such as the RCA Stock No. 9558 Frequency Modulator and the RCA Stock No. 9545 Cathode-Ray Oscillograph. If this equipment is not available, an approximate alignment may be performed by the output-indicator method with an instrument such as the RCA Stock No. 4317 Neon Glow Indicator attached across the loudspeaker voice coil. Alignment by this method is similar to the cathode-ray method outlined below except that the receiver volume control should be at maximum, the trimmers adjusted to peak response and the test-oscillator sweeping operations omitted. Either of these methods require the use of a reliable test oscillator such as the RCA Stock No. 9595.

Cathode-Ray Alignment

Make alignment apparatus connections shown on figure 5. Remove the plug of the frequency-modulator cable from the test-oscillator jack. Connect the receiver chassis to a good external ground. Connect oscillograph "Vertical" input terminals as indicated on figure 3. Set oscillograph power switch to "On" and adjust "Intensity" and "Focus" controls to give a clearly defined spot, or line, on the screen. Set oscillograph "Ampl. A" switch to "On," "Vertical gain" control full-clockwise, "Ampl. B" switch to "Timing," "Range" switch to No. 2 position, and "Timing" switch to "Int." Place the "Sync." control, "Freq." control, and "Horizontal gain" control to about their mid-positions. For each of the following adjustments, the test-oscillator output must be regulated so that the image obtained on the oscillograph screen will be of the minimum size for accurate observation. The receiver volume-control setting is optional.

I-F Adjustments

(a) Set fidelity control to counter-clockwise position. Connect the "Ant." output of the test oscillator to the grid cap of RCA-6K7 second i-f tube (with grid lead in place) through a .001-mfd. capacitor, with "Gnd." to receiver chassis. Tune the test oscillator to 460 kc and place its modulation switch to "On" and its output switch to "Hi."

(b) Turn on the receiver and test oscillator. Increase the output of the test oscillator until a deflection is noticeable on the oscillograph screen. The figures obtained represent several waves of the detected signal, the amplitude of which may be observed as an indication of output. Cause the wave-image formed (400-cycle waves) to be spread completely across the screen by adjusting the "Horizontal gain" control. The image should be synchronized and made to remain motionless by adjusting the "Sync." and "Freq." controls.

(c) Adjust the two magnetite core screws L30 and L29 (see figures 1 and 8) of the third i-f transformer (one on top and one on bottom) to produce maximum vertical deflection of the oscillographic image. This adjustment places the transformer in exact resonance with the 460-kc signal.

(d) The sweeping operation should follow using the frequency modulator. Shift the oscillograph "Timing" switch to "Ext." Insert plug of frequency-modulator cable in test-oscillator jack. Turn the test-oscillator modulation switch to "Off." Turn on the frequency modulator and place its sweep-range switch to "Hi."

(e) Increase the frequency of the test oscillator by slowly turning its tuning control until two separate, distinct, and similar waves appear on the screen. If only one wave appears, increase the "Freq." control on the oscillograph to obtain two waves. These waves will be identical in shape, totally disconnected, and appear in reversed positions. They will have a common base line, which is discontinuous. Adjust the "Freq." and "Sync." controls of the oscillograph to make them remain motionless on the screen. Continue increasing the test-oscillator frequency until these forward and reverse curves move together and overlap, with their highest points exactly coincident. This condition will be obtained at a test-oscillator setting of approximately 575 kc.

(f) With the images established as in (e), re-adjust the two magnetite core screws L30 and L29 on the third i-f transformer so that they cause the curves on the oscillograph screen to become exactly coincident throughout their lengths and have maximum amplitude.

(g) Without altering the adjustments of the apparatus, shift the "Ant." output of the test oscillator to the grid cap of the RCA-6K7 first i-f tube (with grid lead in place), through a .001-mfd. capacitor. Regulate the test-oscillator output so that the amplitude of the oscillographic image is approximately the same as used for adjustment (f) above.

(h) The two second i-f transformer magnetite core screws L28 and L27 (one on top and one on bottom) should then be adjusted so that they cause the forward and reverse curves to become coincident throughout their lengths and have maximum amplitude.

(i) Without altering the adjustments of the apparatus, shift the "Ant." output of the test oscillator to the input of the i-f system, i.e., to the grid cap of the RCA-6L7 first-detector, (with grid lead in place) through a .001-mfd. capacitor. Regulate the test-oscillator output so the amplitude of the oscillographic image is approximately the same as used for adjustment (h) above.

(j) The two first i-f transformer magnetite core screws L23 and L24 (one on top and one on bottom) should then be adjusted so that they cause the forward and reverse waves to become coincident throughout their lengths and have maximum amplitude.

(k) Note width of oscillographic image at a point which is 50% of maximum amplitude. Turn receiver fidelity control to extreme clockwise position. Note width of oscillographic image at a point which is 50% of maximum amplitude. Under normal conditions the latter measurement should be approximately 60% greater in width than the former measurement. The image should also appear slightly double humped. These conditions indicate proper broadening of the band width of the i-f amplifier. Turn range selector to "Medium wave" (B) band and note increase of amplitude. The amplitude should increase several times. It may be necessary to decrease output of test oscillator to keep image on screen. Turn receiver fidelity control to extreme counter-clockwise position and proceed to "R-F Adjustments."

R-F Adjustments

Make receiver dial adjustments as outlined by "Selector dial," figure 11. Alignment must be made in sequence of "Wave-trap," "Ultra short wave" band, "Short wave" band, "Medium wave" band, "Standard broadcast" band, and "Long wave" band.

"Wave-Trap" Adjustment

(a) Connect the "Ant." output of the test oscillator to the antenna terminal "A1" through a 200-mmfd. (important) capacitor. Remove the plug of the frequency-modulator cable from the test-oscillator jack. Turn test-oscillator modulation switch to "On." Shift the oscillograph "Timing" switch to "Int." Place receiver range selector in "Standard broadcast" position. Set the receiver dial to a position of no extraneous signals near 600 kc. Tune the test oscillator to 460 kc. Adjust the wave-trap magnetite core screw L1 to the

MODELS 10T,10K
Alignment,Part 2
Parts List

RCA MFG. CO., INC.

point which causes minimum amplitude of output (maximum suppression of signal) as shown by the waves on the oscillograph. An increase of the test-oscillator output may be necessary before this point of minimum amplitude, obtained by correct adjustment of wave-trap screw, becomes apparent on oscillograph screen.

"Ultra Short Wave" Band

(b) Connect the "Ant." output of the test oscillator to the antenna terminal "A1" of the receiver through a 300-ohm resistor. Set the receiver range selector to its "Ultra short wave" position and its dial pointer to 57,000 kc. Adjust the test oscillator to 19,000 kc. The third harmonic of 19,000 kc is used for this adjustment. If the indication on the oscillograph screen is not sufficient for the following adjustments at 57,000 kc, the vertical-input terminals of the cathode-ray oscillograph may be connected thus: "Hi" to the plate contact of the RCA-6L6 power-output tube socket with the "0" terminal to chassis-ground. The receiver should be turned off while making this connection since the plate potential is impressed across the oscillograph input and a severe shock will result if contact is made between these two points. If this connection is made, advance the receiver volume control to its maximum position.

Adjust oscillator air-trimmer C23 for maximum (peak) output. Two positions, each producing maximum output, may be found. The position of minimum capacitance (plunger near out) should be used. This places the receiver heterodyne oscillator 460 kc higher in frequency than the incoming signal. Tighten lock nut. Adjust the detector air-trimmer C39, while slightly rocking the gang tuning condenser back and forth through the signal, for maximum (peak) output. Two peaks may be found on this trimmer. The peak of maximum capacitance (plunger near in) should be used. Tighten lock nut. Adjust the antenna air-trimmer C10 for maximum (peak) output while slightly rocking the gang tuning condenser back and forth through the signal. Two peaks may be found on this trimmer which produce maximum output. The peak with maximum capacitance (plunger near in) should be used. Tighten lock nut. Check the image frequency by changing the receiver dial setting to 56,080 kc. If the image signal is received at this position, the adjustment of the oscillator air-trimmer C23 has been correctly made. No adjustments should be made while checking for the image signal.

(c) Re-tune receiver for maximum response to 57,000 kc (not image response) without disturbing test-oscillator adjustments. Change test oscillator to 6,800—14,000 kc range. Tune test oscillator until signal is heard in speaker (should occur at approximately 14,250 kc, fourth harmonic of test oscillator used). Two test-oscillator settings (230 kc apart) will produce a signal at this point. The lower frequency test-oscillator setting should be used, as this places the test oscillator harmonic 460 kc below the frequency of the receiver heterodyne oscillator. Tune receiver for maximum response at a dial setting of approximately 28,500 kc (image should tune in at a dial setting approximately 27,580 kc) without altering test-oscillator adjustment. Test-oscillator second harmonic of 14,250 kc is used for the following check. Check calibration of receiver dial. A receiver-dial reading of less than 28,500 kc indicates that the inductance of the oscillator secondary coil L11 is too low and should be increased. If the receiver dial reading is greater than 28,500 kc, the inductance of L11 is too high and should be decreased. If it is necessary to change the inductance of L11, first remove bottom cover of "Magic Brain" and then set receiver dial pointer to 28,500 kc. To decrease inductance, move the grounded ends (straps) of L11 and L12 (see figure 4) nearer chassis. Do not allow straps to touch chassis except where connected. To increase inductance, move the straps farther away from chassis. Adjust position of straps until maximum (peak) output results. The alignment of the detector tuned circuit should next be checked at 28,500 kc without changing either the receiver or test oscillator adjustments. An increase of output when the brass end of a tuning wand is brought near L22 indicates that L22 is too high in inductance, while an increase when the iron end is brought near the coil indicates that the inductance is too low. The inductance of L22 may be varied by changing the spacing between the grounded end (strap) of L22 and the strap connected from C41 to contact on S2 (figure 4). An increase of spacing will increase the inductance, while a decrease of spacing will decrease the inductance. Adjust the spacing until maximum (peak) output results. Replace "Magic Brain" bottom cover and repeat adjustments in (b) prior to those of "Short wave" band.

"Short Wave" Band

(d) Set the receiver range selector to its "Short wave" position and its dial pointer to 20,000 kc. Adjust the test oscillator to 20,000 kc. If the vertical input cathode-ray connections were changed for adjustment (b) above, they should be restored to their original position as shown on figure 3. Adjust oscillator air-trimmer C13 until maximum (peak) output is reached. Two peaks may be found with this circuit. The peak with minimum capacitance (plunger near out) should be used. Tighten lock nut. Adjust detector air-trimmer C35 until maximum (peak) output is reached, while slightly rocking the gang tuning condenser back and forth through the circuit. The peak with maximum capacitance (plunger near in) should be used. Tighten lock nut. Adjust antenna air-trimmer C3 until maximum (peak) output is reached while slightly rocking the gang tuning condenser back and forth through the signal. Two peaks may be found with this circuit. The peak with maximum capacitance (plunger near in) should be used. Tighten lock nut. Check the image frequency by changing the receiver dial setting to 19,080 kc. The image signal should be received at this position indicating that the adjustment of C13 has been correctly made. No adjustments should be made while checking for the image signal.

"Medium Wave" Band

(e) Place receiver range selector to its "Medium wave" position with its dial pointer set to 6,000 kc. Tune the test oscillator to 6,000 kc. Adjust oscillator air-trimmer C14 to produce maximum (peak) output as shown by the waves on the oscillograph. Two peaks may be found with this circuit. The peak with minimum capacitance (plunger near out) should be used. Tighten lock nut. Adjust the detector air-trimmer C36 for maximum (peak) output while slightly rocking the gang tuning condenser back and forth through the signal. Two peaks may be found with this circuit. The peak with maximum capacitance (plunger near in) should be used. Tighten lock nut. Adjust antenna air-trimmer C4 to produce maximum (peak) output. Tighten lock nut.

"Standard Broadcast" Band

(f) Remove the 300-ohm resistor from between the test-oscillator "Ant." post and receiver antenna terminal "A1" and insert a 200-mmfd. capacitor in its place. Place receiver range selector to "Standard broadcast" position with receiver dial pointer set to 600 kc. Tune the test oscillator to 600 kc. Adjust oscillator magnetite core screw L9 (top of large oscillator coil can) for maximum (peak) output as shown by the waves on the oscillograph screen.

(g) Set receiver dial pointer to 1,500 kc. Tune test oscillator to 1,500 kc (1,500–3,100-kc range) and increase its output to produce a registration on the oscillograph screen. Carefully adjust the oscillator, detector, and antenna air-trimmers C16, C37, and C5, respectively, to produce maximum (peak) output as shown by the waves on the oscillograph screen. Shift the oscillograph "Timing" switch to "Ext." Place the frequency modulator sweep-range switch to its "Lo" position and insert plug of the frequency-modulator cable in test-oscillator jack. Turn test-oscillator modulation switch to "Off." Re-tune the test oscillator (increase frequency) until the forward and reverse waves show on the oscillograph screen and become coincident at their highest points. This will occur at a test-oscillator setting of approximately 1,680 kc. Adjust trimmers C16, C37, and C5 again, setting each to the point which produces the best coincidence and maximum amplitude of the images.

(h) Remove the plug of the frequency-modulator cable from the test-oscillator jack. Turn test-oscillator modulation switch to "On." Set oscillograph "Timing" switch to "Int." Tune test oscillator to 200 kc (200–400-kc range). Tune receiver for maximum response to this signal at a dial reading of approximately 600 kc. The third harmonic of the 200-kc signal is used for this adjustment. Shift oscillograph "Timing" switch to "Ext." Insert the plug of the frequency modulator cable in test-oscillator jack. Turn test-oscillator modulation switch to "Off." Re-tune the test oscillator (increased frequency) until the forward and reverse waves show on the oscillograph screen. This will occur at a test-oscillator setting of approximately 230 kc. Disregarding the fact that the two images may or may not come together, adjust the oscillator magnetite core screw L9 (top of large oscillator coil can) to produce maximum (peak) amplitude of the images. Shift the oscillograph "Timing" switch to "Int." Remove the plug of the frequency-modulator cable from the test-oscillator jack. Turn the test-oscillator modulation switch to "On." Repeat adjustments in (g) above to compensate for any changes caused by the adjustment of L9 core, tightening lock nuts on C16, C37, and C5, respectively, after each is adjusted.

"Long Wave" Band

(i) Shift the oscillograph "Timing" switch to "Int." Remove the plug of the frequency-modulator cable from the test-oscillator jack. Turn the test-oscillator modulation switch to "On." Place receiver range selector to its "Long wave" position. Set the receiver dial pointer to 175 kc. Tune the test oscillator to 175 kc and increase its output until a deflection is noticeable on the oscillograph screen. Adjust oscillator magnetite core screw L10 (located on top of small oscillator coil can) so that maximum (peak) amplitude of output is shown on the oscillograph screen.

(j) Set receiver dial pointer to 350 kc. Tune test oscillator to 350 kc. Adjust the oscillator, detector, and antenna air-trimmers C18, C38, and C6 to produce maximum (peak) output as shown by the waves on the oscillograph screen. Without disturbing the connections, shift the oscillograph "Timing" switch to "Ext." Place the frequency-modulator sweep-range switch to its "Hi" position and insert plug of frequency-modulator cable in test-oscillator jack. Turn test-oscillator modulation switch to "Off." Re-tune the test oscillator (decrease frequency) until the forward and reverse waves show on the oscillograph screen and become coincident at their highest points. This will occur at a test-oscillator setting of approximately 198 kc. This setting places the test-oscillator frequency to 175 kc. The second harmonic is now used for the 350 kc adjustment. Adjust air-trimmers C18, C38, and C6, again, to produce maximum amplitude of the images and best coincident throughout their lengths.

(k) Re-tune the receiver to approximately 175 kc so that the forward and reverse waves appear on the oscillograph screen. Adjust the oscillator magnetite core screw L10 to produce maximum (peak) amplitude of the waves, disregarding the fact that the two images may or may not come together.

(l) Shift the receiver dial setting to 350 kc without altering any other adjustments (frequency modulator still in operation). Adjust air-trimmers C18, C38, and C6, respectively, to produce maximum amplitude and best coincidence of the waves. These adjustments compensate for any changes caused by the adjustment of the magnetite core screw L10. Tighten lock nuts on C18, C38, and C6, respectively, after each is adjusted.

Loudspeaker

Centering of the loudspeaker voice coil is made in the usual manner with three narrow paper feelers after first removing the front paper dust cover. This may be removed by softening its cement with a very light application of acetone using care not to allow the acetone to flow down into the air gap. The dust cover may be cemented back in place with ambroid upon completion of adjustment.

Phonograph Terminal Board

A terminal board is provided for connecting a phonograph into the audio amplifying circuit. Typical methods of connecting a low-impedance pickup, or the RCA Victor Models R-93, R-93-2, and R-93-S Record Players are shown on the Schematic Diagram (figure 2).

Stock No.	Description	List Price
	RECEIVER ASSEMBLIES	
12863	Board—Phonograph input terminal board.	$0.25
4427	Bracket—Volume control mounting bracket	.18
12987	Bracket—Band changeover switch bracket.	.15
12985	Cable—Tuning lamp cable and socket....	1.70
12991	Cable—3-conductor shielded fidelity control cable, approximately 7¼ inches long	.50
12511	Cap—Grid contact cap—Package of 5....	.15
12948	Capacitor—33 Mmfd. (C62)...........	.30
12629	Capacitor—56 Mmfd. (C60)...........	.20
12404	Capacitor—120 Mmfd. (C56, C59)......	.26
13734	Capacitor—120 Mmfd. (C67)...........	.28
13022	Capacitor—390 Mmfd. (C45, C47, C51, C53)	.25
5148	Capacitor—.007 Mfd. (C69)...........	.30
4858	Capacitor—.01 Mfd. (C46, C48, C50, C54, C55, C58, C68)	.25
4624	Capacitor—.01 Mfd. (C59)...........	.34
11313	Capacitor—.015 Mfd. (C71)...........	.20
4886	Capacitor—.05 Mfd. (C70)...........	.20
4836	Capacitor—.05 Mfd. (C61)...........	.30
4841	Capacitor—0.1 Mfd. (C52)...........	.22
5190	Capacitor—0.25 Mfd. (C49)...........	.25
4840	Capacitor—0.25 Mfd. (C63)...........	.30
12741	Capacitor—0.5 Mfd. (C74)...........	.30
5212	Capacitor—18 Mfd. (C78)...........	1.16
12872	Capacitor—20 Mfd.—Used in 40-cycle model only (C76)	.90
12467	Capacitor—30 Mfd. (C73, C75).......	1.40
12873	Capacitor Pack—Comprising one 20-Mfd. and one 3-Mfd. capacitor, 25-cycle model only (C76, C77)...........	1.20
12978	Compensator Pack—Comprising one .015-Mfd., one .033-Mfd., and one 0.1-Mfd. capacitor and one 3,900-ohm, one 8,200-ohm and one 27,000-ohm resistor (C64, C65, C66, R23, R24, R26)...........	1.35
12006	Core—Core and stud assembly for intermediate frequency transformer........	.22
12866	Foot—Chassis foot assembly—Package of 2	.75
5226	Lamp—Pilot lamp—Package of 5.......	.70
12868	Link—Link mechanism on band indicator operating arm...........	.45
12871	Reactor—Filter reactor (L33)........	1.50
4669	Screw—Set screw for flexible coupling or gear, Stock Nos. 12905 and 12906—Package of 10...........	.25
12901	Shaft—Direct drive shaft and pinion gear for planetary drive...........	.75
12900	Shaft—Vernier drive shaft for planetary drive...........	.25
12903	Spring—Tension spring for planetary drive bearing—Package of 10........	.30
12907	Spring—Tension spring for gear, Stock No. 12906—Package of 10...........	.20
8051	Spring—Tension spring for link, Stock No. 8051—Package of 5...........	.32
	REPRODUCER ASSEMBLIES	
12914	Board—Reproducer terminal board......	.25
12640	Bracket—Output transformer mounting bracket and clamp...........	.18
12913	Coil—Reproducer field coil (L33)....	1.70
13290	Cone—Reproducer cone and dust cap (L31) (Model 10T)...........	1.55
13291	Cone—Reproducer cone and dust cap (L31) (Model 10K)...........	2.55
5118	Connector—3-contact male connector for speaker leads...........	.25
9757	Reproducer, complete (Model 10T).....	8.70
11222	Socket—Upper right or lower left hand dial lamp socket...........	.18
11381	Socket—Tuning tube socket and cover...	.45
11196	Socket—Voltage supply or 6F5 Radiotron socket	.15
12007	Spring—Retaining spring for core in I.F. transformer—Package of 10.......	.36
12986	Stud—Band indicator operating arm stud—Package of 5...........	.65
12860	Switch—Low frequency tone and power switch (S4, S6)...........	1.50
12988	Switch—Band changeover switch (S1, S2, S3)...........	.65
12979	Tone Control—High frequency tone and fidelity control (R39, S5)...........	1.60
12981	Transformer—First intermediate frequency transformer (L24, L25, L26, C45, C47)	2.15
12990	Transformer—Second intermediate frequency transformer (L27, L28, C51, C53)...........	1.85
12982	Transformer—Third intermediate frequency transformer (L29, L30, C56, C57, C60, R17, R19)...........	2.25
12856	Transformer—Power transformer, 105-125 volts, 50/60 cycles (T1)...........	5.35
12857	Transformer—Power transformer, 105-125 volts, 25/60 cycles...........	7.10
12858	Transformer—Power transformer, 110-125-150-210-240 volts, 40/60 cycles.......	8.75
12861	Volume Control (R22)...........	1.00
	MAGIC BRAIN UNIT ASSEMBLIES	
12806	Board—3-contact antenna and ground terminal board...........	.25
5237	Bushing—Variable condenser mounting bushing assembly—Package of 3......	.45
12886	Cable—Shielded power cable, approximately 4 inches long, complete with 8-contact male plug...........	1.50
12511	Cap—Grid contact cap—Package of 5....	.15
12714	Capacitor—Adjustable trimmer capacitor (C3, C4, C5, C6, C14, C16)........	.38
12884	Capacitor—Adjustable trimmer capacitor (C10, C18, C23, C38, C39)........	.40

12890	Capacitor—1,500 Mmfd. (C12)........	.20
12729	Capacitor—1,550 Mmfd. (C20)........	.26
12728	Capacitor—4,300 Mmfd. (C19)........	.36
12897	Capacitor—4,700 Mmfd. (C43)........	.40
4858	Capacitor—.01 Mfd. (C8, C30, C31, C32)	.25
12879	Coil—Antenna coil and shield, XABC bands (L2, L3, L4, L5, L6)...........	1.90
12888	Coil—Antenna coil, "D" band (L13, L14)	.60
12880	Coil—Detector coil and shield, XABC bands (L15, L16, L17, L18, L19, L20)	2.05
12980	Resistor—Voltage divider resistor—Comprising one 250-ohm, one 37-ohm, one 21-ohm and one 38-ohm sections (R31, R32, R33, R35)...........	.55
12311	Resistor—1,000 ohms—insulated, ½ watt (R11, R16)—Package of 5...........	1.00
11935	Resistor—1,000 ohms—carbon type, 1/10 watt (R14)—Package of 5...........	.75
13097	Resistor—10,000 ohms—insulated, 1 watt (R30)...........	.22
12876	Resistor—10,000 ohms—wire wound (R10)...........	.35
12864	Resistor—17,000 ohms—wire wound resistor (R34)...........	.70
11383	Resistor—56,000 ohms—carbon type, 1/10 watt (R37)—Package of 5...........	.75
12875	Resistor—56,000 ohms—carbon type, 1 watt (R13)—Package of 5...........	1.10
11365	Resistor—82,000 ohms—carbon type, ¼ watt (R15)—Package of 5...........	1.00
8064	Resistor—82,000 ohms—carbon type, ½ watt (R37)—Package of 5...........	1.00
11281	Resistor—100,000 ohms—carbon type, 1/10 watt (R12)—Package of 5......	.75
11398	Resistor—220,000 ohms—carbon type, 1/10 watt (R19)—Package of 5.......	.75
11323	Resistor—270,000 ohms—carbon type, ¼ watt (R27)—Package of 5...........	1.00
11172	Resistor—470,000 ohms—carbon type, ¼ watt (R25, R28)—Package of 5......	1.00
12013	Resistor—1.0 megohm—carbon type, 1/10 watt—Located in tuning tube socket (R11)—Package of 5...........	.75
11626	Resistor—2.2 megohm—carbon type, ¼ watt (R18)—Package of 5...........	1.00
12874	Resistor—3.3 megohm—carbon type, ¼ watt (R20, R21)—Package of 5......	1.00
12870	Scale—Vernier dial scale...........	.65
12008	Shield—Intermediate frequency transformer shield...........	.28
12607	Shield—1st or 2nd I.F. transformer shield top...........	.30
12581	Shield—3rd I.F. transformer shield top...	.36
11195	Socket—5-contact 5Z4 Radiotron socket.	.15
11198	Socket—7-contact 6K7, 6L6 or 6H6 Radiotron socket...........	.15
13095	Socket—Upper left or lower right hand dial lamp socket...........	.25
9758	Reproducer, complete (Model 10K).....	9.40
13289	Transformer—Output transformer (T2).	2.90
11886	Washer—Spring washer to hold field coil securely—Package of 5...........	.20
	MISCELLANEOUS ASSEMBLIES	
11996	Bracket—Tuning lamp bracket and clamp	.22
12915	Escutcheon—Station selector escutcheon and crystal...........	1.30
12742	Escutcheon—Tuning lamp escutcheon...	.22
12699	Knob—Large station selector knob—Package of 5...........	.68
12700	Knob—Small (vernier) station selector knob—Package of 5...........	.58

11349	Spring—Retaining spring for knob, Stock Nos. 12700 and 11347—Package of 5.	.15
12709	Coil—Oscillator coil and shield, ABC bands (L7, L8, L9)...........	2.02
12881	Coil—Oscillator coil and shield, X band only (L10)...........	.80
12890	Coil—Oscillator coil, "D" band (L11, L12, L23)...........	.70
12889	Coil—R.F. coil, "D" band (L21, L22)...	.65
12877	Condenser—3-gang variable tuning condenser (C9, C27, C41)...........	5.10
12887	Connector—8-contact male connector and cover for power cable, Stock No. 12886	.40
12664	Core—Adjustable core and stud for Stock No. 12654...........	.22
12800	Core—Adjustable core and stud for Stock No. 12709...........	.20
12882	Core—Adjustable core and stud for Stock No. 12881...........	.20
11314	Resistor—560 ohms—carbon type, ¼ watt (R2)—Package of 5...........	1.00
5112	Resistor—1,000 ohms—carbon type, ¼ watt (R3)—Package of 5...........	1.00
11298	Resistor—5,600 ohms—carbon type, 1 watt (R6)...........	.22
3998	Resistor—15,000 ohms—carbon type, ¼ watt (R5)—Package of 5...........	1.00
11282	Resistor—56,000 ohms—carbon type, 1/10 watt (R4, R9)—Package of 5........	.75
8064	Resistor—82,000 ohms—carbon type, ½ watt (R8)—Package of 5...........	1.00
11397	Resistor—560,000 ohms—carbon type, 1/10 watt (R1, R7)—Package of 5...	.75
12651	Shield—Coil shield for Stock Nos. 12879, 12880...........	.22
12710	Shield—Coil shield for Stock No. 12709.	.38
12883	Shield—Coil shield for Stock No. 12881.	.20
11198	Socket—7-contact 6K7 Radiotron socket.	.15
11279	Socket—7-contact 6L7 Radiotron socket..	.30
12885	Socket—8-contact 6J7 Radiotron socket.	.20
12007	Spring—Retaining spring for core, Stock Nos. 12664, 12800, 12882—Package of 10...........	.36
12878	Switch—Range switch and mounting nut (S1, S2, S3)...........	3.60
12654	Trap—Wave-trap, complete (L1).......	.75
	DRIVE ASSEMBLIES	
10705	Ball—5/32-inch diameter steel ball for planetary drive—Package of 20.......	.25
10941	Ball—⅛-inch diameter steel ball for planetary drive bearing—Package of 20	.25
12904	Bushing—Plate and bushing assembly for planetary drive mounting...........	.30
12905	Coupling—Flexible coupling and shaft assembly, complete...........	.30
12909	Dial—Band indicating dial and cam assembly...........	1.05
12899	Drive—Variable tuning condenser drive, complete, including mounting bracket drive, dial scale and indicator, less vernier dial, Stock No. 12870 and link, Stock No. 12868...........	4.40
12906	Gear—Anti-lash drive gear, complete....	.75
12910	Gear—Sector gear and link assembly for band selector...........	.28
12908	Indicator—Station selector indicator pointer	.28
8051	Link—Link and roller assembly, complete with spring...........	.30
12911	Screen—Dial lamp screen and light diffuser...........	.30

General Description

The RCA Victor Model D 11-2 combination radio receiver and automatic phonograph provides excellent entertainment from either broadcast reception or record reproduction. It consists of an eleven-tube, three-band radio receiver, and an automatic phonograph, combined in the one cabinet. The high level of sound energy obtainable from the output of this instrument is capably handled by a new Super-Sensitive, twelve-inch, electrodynamic loudspeaker. Outstanding features of this instrument are as follows:

Magic Brain

The radio receiver includes the "Magic Brain" unit for maximum all-around efficiency. This unit is a scientifically correct co-ordination of all the parts for the r-f, oscillator, and first detector functions of a Superheterodyne Receiver. Such design of the important head end, or "Magic Brain" unit, gives greater efficiency in the short-wave ranges as all lead lengths are kept as short as possible, and all sockets and other parts are located for best possible operation.

Magic Eye

A cathode-ray tube whose fluorescent screen has the appearance of a human eye, is used for visually indicating when the receiver is accurately tuned to the incoming signal. This tube is of new design. It contains two groups of elements; one group operates as an amplifier and the other group operates as a cathode-ray tube.

The cathode-ray section consists of a conically shaped luminescent screen, a cathode, and a control electrode. The detected signal from the receiver is applied through the amplifier section of the tuning tube to the control electrode of the cathode-ray section. This control electrode, in turn, affects the electron stream emitted by the cathode in such a manner as to cause a triangular shadow on the luminescent screen. The size of the shadow caused by the control electrode is determined by the strength of the incoming signal, so that a change-of-tuning is readily exhibited on the cathode-ray screen, and therefore, tuning to exact resonance can be definitely obtained.

RCA All-Metal Tubes

The new metal tubes are used in the radio receiver for amplifying and detecting purposes. These tubes make possible a greater range of stable amplification not previously attainable with corresponding glass types. Their metal envelopes form a perfect electrostatic and electromagnetic shield, precluding the former necessity for elaborate shielding by means of cans. The metal tubes are especially adaptable to the modern, extended-range receivers because of their efficient shielding and their favorable internal characteristics.

Automatic Record Changer

An improved automatic mechanism is used in this model. It is of the record ejector type, having a record capacity of seven for the ten-inch type, and a capacity of six for the twelve-inch type. The turntable speed is fixed at 78 r.p.m. by the design of the drive motor and the intermediate gear mechanism. *This speed is invariable and does not vary as long as the supply line frequency remains constant.* The instrument may be purchased with any one of seven ratings as specified under Electrical Specifications. *It is very important that a machine of any particular rating be operated at the frequency for which it is designed and rated.* Attempts to operate at other frequencies will result in improper reproduction from the phonograph system. The ejecting mechanism is arranged so that it will trip on various types of records. This is obtained by having a trip mechanism which is actuated by the rate of needle acceleration toward the center of the record.

Selector Dial

The dial drive and station indicator system are of unique design. There are three individual dial scales, each with full 180 degree band spread, one for use on each of the three tuning bands. These scales are eccentrically arranged on a rotary disc which operates in conjunction with the range selector switch, so that as the switch is shifted to a particular band, the corresponding dial scale rotates into position, leaving the remaining scales concealed. The driving mechanism for the dial pointer and the variable gang condenser has tuning ratios of 10-to-1 and 50-to-1. Control may be interchanged between these two ratios by a push-pull operation of a positive-action clutch which is actuated by the tuning control knob. A vernier dial with an auxiliary pointer (band-spreader) is provided for the accurate tuning required for short-wave reception. The vernier pointer is geared to the main dial-shaft through a mechanism which causes it to rotate ten times to a 180 degree rotation of the main dial-pointer. The dial-drive mechanism connects to the variable gang condenser by means of a flexible coupling. This coupling arrangement together with the new shock-proof condenser mounting makes possible the rigid attachment of the drive mechanism to the receiver-chassis base without causing serious microphonic coupling between the base and the tuning condenser.

CIRCUIT ARRANGEMENT

The Superheterodyne principle of operation forms the basis of the circuit design. A single, tuned r-f stage is used ahead of the first detector. The functions of oscillator and detector are performed by two separate tubes. One i-f stage is employed and designed to operate at 460 kc. The combined second detector and a.v.c. stage uses an RCA-6H6 double diode. The audio system consists of two single amplifier stages working in cascade with a push-pull power output stage. The loudspeaker is an electrodynamic type, receiving its field supply from the rectifier and filter system and simultaneously acting as a filter reactor. Full wave rectification is performed in the RCA-5Z3 tube. The outstanding features of electrical design are concerned with the following:

Tuned Circuits

A total of seven circuits are tuned to provide gain and selectivity to the incoming signal. The variable gang condenser resonates the antenna transformer secondary, the detector transformer secondary and the oscillator coil. Alignment trimmers are included for each of these same circuits. Additional trimmers are used on the i-f transformers, tuning both the secondaries and primaries to 460 kc. There are separate groups of antenna, detector and oscillator coils for each of the tuning ranges. They are placed into operation by means of a rugged rotary switch.

First Detector

This stage has unusually good high frequency mixing efficiency. The tube used, an RCA-6L7, is a new hexode type. The signal is supplied to the first control grid and the oscillator is fed in on a second control grid, a screen grid separating the two. The arrangement of the grids prevents degenerative difficulties, particularly at the higher frequencies. The second grid is direct-connected to the cathode of the oscillator tube and has no d-c bias.

Oscillator

The oscillator circuit is worthy of careful study inasmuch as it is different from the type ordinarily employed. It has self-stabilizing properties which are very advantageous for short wave operation. The generated frequency remains substantially constant, the circuit being unaffected by variation of line voltage and other similar influences. Output also remains uniform over the individual tuning ranges. The switching of the tuning coils is arranged so as to short those not in use in order to prevent absorption or any reactive effects in the particular band being tuned.

Detector and A.V.C.

The modulated signal as obtained from the output of the i-f system is detected by an RCA-6H6 double diode tube. The audio frequency secured by this process is passed on to the a-f system for amplification and final reproduction. The d-c voltage which results from detection of the signal, is used for automatic volume control. This voltage, which develops across resistors R-7 and R-8, is applied as automatic control grid bias to the r-f, first detector and i-f tubes through suitable resistance-capacitance filter circuits. The second diode of the RCA-6H6 is used to supply residual bias for these controlled tubes under conditions of little or no signal. This diode, under such conditions, draws current, which flows through resistors R-7, R-8 and R-9, thereby maintaining the desired minimum operating bias on such tubes. On application of signal energy above a certain level, however, the auxiliary bias diode ceases to draw current and the a.v.c. diode takes over the biasing function. The cathode and anode of the signal-a.v.c. diode have positive potential in respect to chassis-ground and cathodes of the a.v.c. controlled tubes when no signal is being received.

Audio System

Manual volume control of the detected signal is effected by an acoustically tapered potentiometer in the grid circuit of the first a-f stage. This control has tone compensating filters connected to two points thereon. These filters effect the correct aural balance at different volume settings. A music-speech switch (low frequency tone control) is associated with one of the compensation filters. The purpose of this control is to make speech reproduction more intelligible and to reduce hum obtained from stray modulation on a carrier. The driver stage of the audio system uses an RCA-6C5 which is resistance coupled to the first a-f tube and transformer coupled into the push-pull power output stage.

SERVICE DATA

The various diagrams of this booklet contain such information as will be needed to isolate causes for defective operation when such develops. The ratings of the resistors, capacitors, coils, etc., are indicated adjacent to the symbols signifying these parts on the diagrams. Identification titles such as R-3, L-2, C-1, etc., are provided for reference between the illustrations and the Replacement Parts List. The coils, reactors, and transformer windings are rated in terms of their d-c resistances only. Ratings of less than one ohm are generally omitted.

Alignment Procedure

Eleven alignment trimmers are provided in the r-f, first detector and oscillator tuning system and four are used in the i-f system. All of these are accurately adjusted during manufacture and should remain in proper alignment unless affected by abnormal conditions of climate or have been altered by other means. Loss of sensitivity, improper tone quality and poor selectivity are the usual indications of improper alignment.

Correct performance of the receiver can only be obtained when the trimmer adjustments have been made by a skilled service man with the use of adequate and reliable test equipment. Such apparatus as may be required for alignment of this particular instrument is illustrated and described on a separate page of this booklet.

Two methods of alignment are applicable. One utilizes a Cathode-Ray Oscillograph as a means of output indication and the other follows former procedure where a glow type indicator or meter is used.

The oscillographic method is much to be preferred, since greater accuracy is possible from the type of indication afforded. There are no approximations necessary as with the meter or aural method, but each adjustment can be made with definite precision. Both methods are hereinafter outlined so that alignment operations may be made according to the equipment available.

It is wise to determine the necessity for alignment as well as the direction of misalignment before making adjustments. The RCA Tuning Wand is an instrument designed particularly for such a purpose.

The Tuning Wand consists of a bakelite rod having a small brass cylinder at one end and a core of finely divided iron at the other. It may be inserted into a tuned coil while a signal of the normal resonant frequency is being supplied to such coil to obtain an indication of the tuning. Holes are provided at the top of the r-f shield cans for entrance of the Wand. The presence of either end of the Wand will cause a change in tuning which will be indicated at the receiver output as an increase or decrease in signal level. If there is a decrease of output when either end is inserted, the tuning is correct and will require no adjustment. However should there be an increase of output due to the iron core and decrease with the brass cylinder, an increase in inductance or capacitance is indicated as necessary to bring the circuit into line. The trimmer involved should therefore be increased accordingly. If the brass cylinder end causes an increase in output while the iron end causes a decrease, reduction of inductance will be necessary to place the circuit in alignment.

This is equivalent to decreasing the trimmer concerned. The following tabulation gives the various changes and the adjustments required:

Wand	Signal	Trimmer
Brass	Decrease	None
Iron	Decrease	
Brass	Increase	Decrease
Iron	Decrease	
Brass	Decrease	Increase
Iron	Increase	

Dial Adjustment

Figure 10 illustrates the relations of the various parts of the dial mechanism when it is in its A—Broadcast position and the range switch is likewise turned to its Band A setting. In re-assembling the dial after repairs, see that the gears are meshed in accordance with the diagram, at the same time noting that the lever which is attached to the range-switch shaft is in the position as shown

Radiotron Socket Voltages

The voltage values indicated from the Radiotron socket contacts to chassis on Figure 5 will serve to assist in the location of causes for faulty operation. Each value as specified should hold within ± 20% when the receiver is normally operative at its rated supply voltage. Variations in excess of this limit will usually be indicative of trouble in the basic circuits. The voltages given are actual operating values and do not allow for inaccuracies which may be caused by the loading effect of a voltmeter's internal resistance. This resistance should be duly considered for all readings. The amount of circuit resistance shunting the meter during measurement will determine the accuracy to be obtained, the error increasing as the meter resistance becomes comparable to or less than the circuit resistance. For the majority of readings, a meter having an internal resistance of 1000 ohms per volt will be satisfactory when the range used for each reading is chosen as high as possible consistent with good readability.

Automatic Record Ejector

The record changing mechanism is designed to be simple and fool-proof. Under normal operating conditions, service difficulties should be negligible. Occasionally, however, certain adjustments may be required. These adjustments are illustrated and explained in Figure 9.

It is important when servicing the automatic mechanism, to have it placed on a level support. It is also important to refrain from forcing the mechanism if there is a tendency to bind or jam, since bent levers and possibly broken parts may result.

The tip of the record ejector is adjustable in relation to the turntable spindle, the two being exactly coaxial when properly adjusted. To align the tip, remove the rubber silencer of the ejector assembly, loosen ejector tip retaining nut and slide the tip assembly to the position where it is in true-line with the axis of the turntable spindle. This adjustment may be simplified by placing several records on the turntable, depressing the spindle through the top record hole and lining up the ejector tip in the spindle hole of the record.

To insure that the ejector tip rotates freely, apply a slight amount of oil to the shank of the tip at the point where it is in contact with the ball bearing.

Magnetic Pickup

The pickup used in the phonograph unit is of an improved design, having several variations from the usual type of pickup. The horseshoe magnet is solidly welded to the pole pieces and is irremovable. There is a centering spring attached to the armature to maintain proper adjustment and provides a damping effect on the movement of the armature. The frequency response is uniform over a wide range.

Service operations which may be necessary on the pickup are as follows:

MODEL D11-2
Alignment

RCA MFG. CO., INC.

CATHODE-RAY ALIGNMENT

Equipment

A standard source of alignment frequencies is required. Such a source should consist of an RCA Full Range Oscillator, Stock No. 9595. Output indication should be by means of an RCA Stock No. 9545 Cathode-Ray Oscillograph. An RCA Stock No. 9558 Frequency Modulator will be needed to sweep the generated signal and synchronize it with the Oscillograph in order to obtain visual representation of the resonant characteristic of the circuit being tuned on the cathode-ray fluorescent screen.

I-F Trimmer Adjustments

The four trimmers of the two i-f transformers are located as shown by Figure 1. Each must be aligned to a basic frequency of 460 kc. The last transformer must be aligned firstly and the first transformer aligned secondly. For such a process, it is necessary to feed the output of the Full Range Oscillator to the stages in their order of alignment, adjusting the trimmers of each transformer and observing the effect at the second detector output on the Cathode-Ray Oscillograph. The proper point of connection of the Oscillograph is with its vertical "high" input terminal attached to the juncture of R-7 and R-8, as illustrated in Figure 5, and with the "G" or ground terminal to the chassis. The "Ext. Sync" terminals of the Oscillograph should be connected to the Frequency Modulator as shown by Figure 4. A .001 mfd capacitor installed in series with the Oscillator "Ant." lead will prevent the voltages of the stage under alignment from becoming upset. The vertical "A" amplifier should be "On" for the ensuing adjustments and its gain control kept at maximum. For each adjustment, the Oscillator output must be regulated so that the image obtained on the Oscillograph screen will be of the minimum size convenient for accurate observation. Proceed further as follows.

(a) Place the receiver, Oscillograph and test Oscillator in operation. Set the receiver range switch to Band "A" and tune the station selector to a point where no interference will be encountered from signal pickup or from the RCA-6J7 oscillator, removing the tube if necessary. Set the Oscillograph horizontal "B" amplifier to "Timing" and control its gain so that the luminescent spot sweeps a straight line trace completely across the screen. Place the timing control to "Int." Adjust the intensity and focusing controls of the Oscillograph to produce the correct size and strength of spot.

(b) Attach the output of the test Oscillator between the control grid cap of the RCA-6K7 i-f tube and chassis ground as shown typically by Figure 4. Tune the Oscillator to 460 kc. and set its modulation switch to "On." Regulate its output until the signal produces a wave pattern on the Oscillograph screen, adjusting the Oscillograph controls to give a shape which is convenient for peak indications. Cause the image to stand still on the screen by manipulation of the frequency and synchronizing controls. Then carefully tune the two trimmers C-20 and C-21 of the second i-f transformer to produce maximum amplitude (vertical deflection) of the oscillographic image. Under this condition the transformer will be sharply resonated to 460 kc.

(c) The Frequency Modulator should then be placed in operation and interconnected with the Full Range Oscillator by means of the special shielded patch cord. Figure 4 shows the proper arrangement. Set the Frequency Modulator sweep range switch to its "Lo" position and turn the Oscillator modulation switch to "Off." Change the timing control of the Oscillograph to "Ext." and place the range switch to its No. 2 position. Then carefully shift the tuning of the Oscillator so as to increase its frequency, until two distinct and similar waves appear on the Oscillograph screen and become exactly co-incident at their highest points. This condition will be found to occur at an Oscillator setting of *approximately* 540 kc. The curves will be identical in shape but appearing in reversed positions. Adjust the frequency control of the Oscillograph in order to cause the waves to conform with the above requirement and to make them remain motionless on the screen. This will require a setting of approximately ½ clockwise rotation of the frequency control. The trimmers C-20 and C-21 should then be re-adjusted so that the two curves move together and become exactly coincident throughout their lengths, maintaining the maximum amplitude at which this condition can be brought about.

(d) Leaving the equipment connected and adjusted as in (c), change the Oscillator output to the control grid cap of the RCA-6L7 first detector tube. Then adjust the first i-f transformer trimmers C-16 and C-17 so that the forward and reverse waves appearing on the Oscillograph coincide throughout their lengths and have maximum amplitude. The shape of the composite wave obtained from this operation is a true representation of the overall tuning characteristic of the i-f system.

R-F Trimmer Adjustments

For Bands A and X, adjustments must be made at the high and low frequency ends of the range. On Band C, alignment is required only at the high frequency end.

Locations of the various antenna, detector and oscillator coil trimmers are shown by Figure 5. The test Oscillator should be removed from connection with the i-f system and its output connected to the antenna-ground terminals of the receiver. No changes are to be made in the connections of the Oscillograph at the second detector. During the following adjustments, the Oscillator output should be regulated as often as is necessary to keep the oscillographic image as low as is practically observable. Adherence to this procedure will obviate the broadness of tuning that would result from a.v.c. action on a stronger signal. Proceed with the adjustments as follows:

CALIBRATION

Set the receiver range switch to Band A and rotate the station selector until the tuning condenser plates are in full mesh (maximum capacitance). Then move the main dial pointer until it points exactly to the horizontal line at the low frequency end of the Band A scale. Correct the setting of the vernier second hand pointer to read zero.

BAND A

(a) With the receiver range switch in its Band A position, tune the station selector until the dial pointer is at a reading of 1720 kc. Adjust the test Oscillator to 1720 kc. (modulation "On" and Frequency Modulator disconnected) and increase its output to produce a registration on the Oscillograph. Carefully align the oscillator, detector and antenna trimmers, C-47, C-12 and C-3 respectively, so that each brings about maximum amplitude of output as shown by the wave on the Oscillograph. It will be necessary to have the timing control of the Oscillograph on "Int." for this operation. After each trimmer has been peaked, the Oscillograph timing control should be set to "Ext." and the Frequency Modulator placed into operation with its connections to the Oscillator and Oscillograph made in accordance with Figure 4. Turn the modulation switch of the Oscillator to "Off" and retune the Oscillator (increase frequency) until the forward and reverse waves show on the Oscillograph and become coincident at their highest points. Adjust the trimmers C-47, C-12 and C-3 again, setting each to the point which produces the best coincidence and maximum amplitude of the wave images.

(b) Remove the Frequency Modulator cable from the Oscillator and shift the signal frequency to 600 kc. Place the modulation switch to "On". Tune the receiver to pick up this signal, disregarding the dial reading at which it is best received. Then insert the Frequency Modulator plug and retune the Oscillator (modulation "Off") until the two similar forward and reverse waves appear on the screen. For this adjustment, it is advisable to shift the Oscillator to its 200-400 kc. range using the third harmonic of the generated signal in order to obtain the desired range of sweep. The oscillator series trimmer, C-46, should then be adjusted to produce maximum amplitude of the images. No rocking will be necessary on the station selector inasmuch as the signal frequency is being "wobbled" by the Frequency Modulator to produce the same effect. After completing this adjustment, the trimmer C-47 should be re-aligned as in (a) to correct for any change brought about by the adjustment of C-46.

BAND X

(a) Disconnect the Frequency Modulator and tune the test Oscillator to a frequency of 400 kc. (Modulation "On"). Place the receiver range switch in its Band X position and turn the station selector until the dial pointer reads 400 kc. Adjust the Oscillograph timing control to "Int." Then align each of the trimmers C-45, C-11 and C-2 to the point producing maximum output at the Oscillograph. Place the Frequency Modulator in operation and attach it to the Oscillator in the normal manner. Change the Oscillograph timing to "Ext." Increase the frequency of the Oscillator (modulation "Off") until the two waves appear and become coincident at their highest points, *approximately at 462 kc.* They may be made to remain stationary on the screen by manipulation of the Oscillograph range switch and frequency control. Readjust the three trimmers C-45, C-11 and C-2 to give maximum amplitude and complete coincidence of the waves.

(b) Change the test Oscillator so that it delivers a signal of 150 kc. with the Frequency Modulator disconnected. Tune this signal on the receiver which has previously been set to Band X, disregarding the dial reading at which the signal is best received. Then interconnect the Frequency Modulator with the Oscillator and retune the latter to the point at which the two similar waves appear on the screen. Adjust trimmer C-61, for maximum amplitude of the wave images. Rocking of the tuning condenser will not be necessary as the Frequency Modulator duplicates such an operation. Repeat the alignment of C-45 as outlined in (a) to correct for any reflective error brought about by the adjustment of C-61.

BAND C

(a) Turn the range switch of the receiver to its Band C position and tune the station selector until the dial pointer reads 18,000 kc. Set the test Oscillator to the same frequency (modulation "On" and Frequency Modulator disconnected) and regulate its output to the level required for convenient observation. Adjust the trimmer C-43 to the point producing maximum output as indicated on the Oscillograph. Check for the presence of the proper "image" signal by tuning the receiver to 17,080 kc. The 18,000 kc. signal of the Oscillator will be received at this point if the adjustment of C-43 has been properly made by using the position of least capacitance which gives maximum receiver output. It may be necessary to increase the output of the Oscillator in order to get an indication of the "image". *No adjustments should be made during this check.*

(b) Return the receiver tuning to 18,000 kc., re-align C-43 if necessary, and then adjust the detector and antenna trimmers, C-10 and C-1, for maximum signal output as evidenced by the oscillographic image. No further adjustments are to be made on this band.

OUTPUT INDICATOR ALIGNMENT

To align the receiver by means of an output indicator other than a Cathode-Ray Oscillograph will require the use of a standard test Oscillator, such as that recommended above, for the source of signals and means of indication for the output. The RCA Neon Output Indicator, Stock No. 4317, will be found very satisfactory for such use. It should be connected across the voice coil circuit of the loud-speaker or across the output transformer primary.

I-F Alignment

Connect the test Oscillator to the control grid cap of the i-f tube. Advance the volume control of the receiver to its full-on position. Tune the test Oscillator accurately to 460 kc. and align the trimmers C-20 and C-21 to give maximum receiver output. Regulate the Oscillator output during this adjustment so that the output indication is as small as can be conveniently observed. After completing the adjustments of these trimmers, re-connect the Oscillator so that it will feed into the control-grid circuit of the RCA-6L7 first detector. Then tune the first i-f transformer trimmers C-16 and C-17 for maximum receiver output.

R-F Alignment

After completing the i-f adjustments, it is advisable to correct the line-up of the circuits ahead of the first detector. The test Oscillator should be connected to the antenna-ground terminals of the receiver and the manual volume control turned to its maximum position. For each adjustment, the Oscillator output should be maintained as low as possible in order to avoid broadness of tuning which would result from a.v.c. action on a stronger signal.

Band A—This band should be aligned by supplying a 1720 kc. signal to the receiver, tuning the station selector to a dial reading of 1720 and adjusting the trimmers C-47, C-12 and C-3 to produce maximum receiver output. The Oscillator should then be shifted to 600 kc. and the receiver tuned to resonate this signal, disregarding the reading at which it is best received. Trimmer C-46 must then be adjusted, simultaneously while rocking the station selector backward and forward through the signal until the maximum output results from the combined operations. C-47 should be rechecked to assure that its adjustment has not changed because of the trimming of C-46.

Band X—Change the range switch to its Band "X" position. Tune the receiver to read 400 kc. and set the Oscillator to 400 kc. Adjust trimmers C-45, C-11 and C-2 to produce maximum receiver output. Then shift the Oscillator frequency to 150 kc. and tune the receiver to pick up this signal, disregarding the dial reading at which it is best received. Then tune the oscillator series trimmer, C-61, simultaneously rocking the tuning control (receiver) backward and forward through the signal, until maximum output results from the combined operations. Repeat the alignment of C-45 as in (a) to correct for any change caused by the adjustment of C-61.

Band C—Change the receiver so that it is operative and the dial reads 18,000 kc. on the "C" Band. Tune the test Oscillator to this same frequency. Then adjust the oscillator trimmer C-43 to produce maximum (peak) output. Two positions of this trimmer will be found which conform with this requirement. The one of least capacitance is correct. Check for the presence of "image" response at 17,080 kc. by shifting the receiver tuning. If it is received at such a point, the trimmer C-43 has been correctly adjusted to the right peak. *No adjustments are to be made during this check.* Tune the receiver back to the 18,000 kc. dial marking, readjust C-43 if necessary, and then tune the detector and antenna capacitors C-10 and C-1 for maximum receiver output. No further adjustments are necessary.

Standard Transformer

The transformer used on some models of this instrument is adaptable for voltages and frequencies as given under Ratings A and B of Electrical Specifications. Its schematic and wiring are shown by Figure 7.

CENTERING ARMATURE

Refer to Figure 11 showing the pickup inner structure. The armature is shown in its proper relation to the magnet pole pieces, i. e., exactly centered. Whenever this centering adjustment has been disturbed, the screws A, B, and C should be loosened and the armature clamp adjusted to the point where the vertical axis of the armature is at right angles to the horizontal axis of the pole pieces, and centered between them. This centering operation may be facilitated by inserting a small rod or nail into the armature needle hole, using it as a lever to test the angular movement of the armature. The limitations of the movement in each direction will be caused by the armature striking the pole pieces. The proper adjustment is obtained when there is equal angular displacement of the armature and adjustment rod or nail to each side of the vertical axis of the magnet and coil assembly. The screws A and B should then be secured, observing care not to disturb the adjustment of the armature clamp. Then place the pickup in a vise and secure the centering spring-clamp by means of the screw C, allowing the centering spring to remain in the position at which the armature is exactly centered between the pole pieces. With a little practice, the correct adjustment of the armature may be readily obtained. The air gap between the pole pieces and the armature should be kept free from dust, filings, and other such foreign materials which would obstruct the movement of the pickup armature.

DAMPING BLOCK

The viscoloid block which is attached to the back end of the armature shank serves as a mechanical filter to eliminate undesirable resonances and to cause the frequency response to be uniform. Should it be necessary to replace this damping block, it may be done by removing screw D and the cover support bracket from the mechanism and taking off the old viscoloid block. The surface of the armature which is in contact with the viscoloid should be thoroughly cleaned with fine emery cloth. Then insert the new block so that it occupies the same position as it did originally. Make certain that the block is in correct vertical alignment with the armature. The hole in the new viscoloid block is somewhat smaller than the diameter of the armature in order to permit a snug fit. With the viscoloid aligned on the armature, screw D and the cover support bracket should then be replaced. Heat should be applied to the armature (viscoloid side) so that the viscoloid block will fuse at the point of contact and become rigidly attached to the armature. A special tip soldering iron constructed as shown in Figure 12 will be found very useful in performing this operation. The iron should be applied only long enough to slightly melt the block and cause a small bulge on both sides.

REPLACING COIL

Whenever there is defective operation due to an open or shorted pickup coil, this coil should be replaced. The method of replacement will be obvious upon inspection of the pickup assembly and by study of the cut-a-way illustrations. Make sure that the new coil is properly centered with the hole in the support strip and glued securely in that position. It is important to readjust the armature as previously explained after re-assembly of the mechanism. Only rosin core solder should be used for soldering the coil leads in the pickup. This same type of solder should be used when necessary for soldering the centering spring to the armature.

MAGNETIZING

Loss of magnetization will not usually occur when the pickup has received normal care, due to the fact that the magnet and pole pieces are one unit and the magnetic circuit remains closed at all times. When the pickup has been mishandled, subjected to a strong a-c field, jolted, or dropped, there may be an appreciable loss of magnetic strength, in which case it will be necessary to re-magnetize the entire structure. This should be done by first removing the pickup cover and then placing the pickup assembly on the poles of a standard pickup magnetizer such as the RCA Pickup Magnetizer, Stock No. 9549, and charging the pickup in accordance with the instructions accompanying the magnetizer. It is recommended that the pickup be magnetized with the armature in place. This will require that one pole piece on the pickup magnetizer be rotated 180 degrees. This gives the desired clearance for the armature clamp assembly. It is preferable to check the polarity of the pickup magnet and to re-magnetize it so that the same polarity is maintained

RCA MFG. CO., INC.

MODEL D11-2
Parts List

REPLACEMENT PARTS

Stock No.	Description	List Price
	RECEIVER ASSEMBLIES	
4427	Bracket—High or low frequency tone control or volume control mounting bracket	$0.18
5237	Bushing—Variable condenser mounting bushing assembly. Package of 3	.43
11524	Cable—Two conductor cable with two prong male sections of connector plug	.36
11712	Cable—Shielded three conductor cable from volume control (R14) to "C" of No. 4 socket, "G" of No. 6 socket and input transformer	1.24
11713	Cable—Shielded two conductor volume control cable	.80
11223	Capacitor—Adjustable capacitor (C46)	.46
5241	Capacitor—Adjustable capacitor (C61)	.40
11292	Capacitor—22 MMfd. (C9)	.24
11289	Capacitor—50 MMfd. (C8)	.26
11291	Capacitor—115 MMfd. (C50)	.24
11290	Capacitor—400 MMfd. (C60)	.25
11317	Capacitor—600 MMfd. (C34)	.30
11269	Capacitor—800 MMfd. (C59)	.30
3784	Capacitor—900 MMfd. (C31)	.30
11316	Capacitor—1225 MMfd. (C36)	.40
11287	Capacitor—4300 MMfd. (C58)	.30
5107	Capacitor—.0025 Mfd. (C62, C63)	.16
4838	Capacitor—0.005 Mfd. (C40, C41)	.20
4868	Capacitor—0.005 Mfd. (C33)	.20
4624	Capacitor—0.01 Mfd. (C30)	.54
4937	Capacitor—0.01 Mfd. (C39)	.25
4858	Capacitor—.01 Mfd. (C24*)	.25
11315	Capacitor 0.015 Mfd. (C38)	.20
5196	Capacitor—.035 Mfd. (C57)	.18
4886	Capacitor—0.05 Mfd. (C24*)	.20
4836	Capacitor—0.05 Mfd. (C4, C13, C18, C23)	.30
4835	Capacitor—0.1 Mfd. (C64)	.28
4885	Capacitor 0.1 Mfd. (C7, C19, C27, C52)	.28
4841	Capacitor—0.1 Mfd. (C6)	.22
5170	Capacitor—0.25 Mfd. (C32)	.25
11203	Capacitor—10 Mfd. (C53)	1.18
5212	Capacitor—18 Mfd. (C54)	1.16
11215	Capacitor pack—Comprising one 16 Mfd., two 10 Mfd., and two 8 Mfd. capacitors (C29, C35, C36, C55, C56)	3.85
11201	Clamp—Cable clamp—located near variable tuning condenser—Package of 5	.20
11272	Clamp—Cable clamp—located above antenna terminal	.10
4691	Clamp—Electrolytic capacitor clamp—for stock No. 11215	.15
5215	Coil—Antenna coil—A and C bands (L1, L2, L5, L6, C1, C3)	2.32
11325	Coil—Antenna coil—X band (L3, L4, C2)	1.56
5216	Coil—Detector coil—A and C bands (L7, L8, L11, L12, C10, C12)	2.34
11326	Coil—Detector coil—X band (L9, L10, C11)	1.60
5217	Coil—Oscillator coil—A and C bands (L13, L15, C43, C47)	2.20
11327	Coil—Oscillator coil—X band (L14, L23, C45)	1.44
11320	Coil—Choke coil (L20)	1.00
11318	Capacitor Pack—Comprising one 0.015 Mfd., one .05 Mfd. capacitor, one 27,000 ohm and one 10,000 ohm resistor—(C25, C28, R12, R13)	1.30
5214	Condenser—Three gang variable tuning condenser (C5, C14, C48)	4.42
11205	Volume Control (R14)	1.30
11219	Tone Control—High frequency tone control (R22)	.90
4151	Connector—Four contact female connector for cables, stock Nos. 11712 and 11713	.48
11710	Lead—Shielded antenna lead	.40
8041	Plate—I. F. or R. F. coil shield locking plate with screw—Package of 2	.12
11220	Resistor—Voltage divider resistor—Comprising one 3900 ohm and one 4200 ohm section (R31, R32)	.84
11221	Resistor—Voltage divider resistor—Comprising one 50 ohm, one 28 ohm and one 195 ohm section (R28, R29, R30)	.48
5112	Resistor—1000 ohm—Carbon type—¼ watt (R2)—Package of 5	1.00
3706	Resistor—1800 ohm—Carbon type—¼ watt (R15)—Package of 5	1.00
5159	Resistor—2200 ohm—Carbon type—¼ watt (R20)—Package of 5	1.00
5175	Resistor—5600 ohm—Carbon type—½ watt (R21)—Package of 5	1.00
2731	Resistor—10,000 ohm—Carbon type—1 watt (R25)—Package of 5	1.10
11305	Resistor—22,000 ohm—Carbon type—¼ watt (R16, R17)—Package of 5	1.00
11300	Resistor—33,000 ohm—Carbon type—1/10 watt (R24)—Package of 5	.75
5033	Resistor—33,000 ohm—Carbon type—1 watt (R23)—Package of 5	1.10
3118	Resistor—100,000 ohm—Carbon type—¼ watt (R1, R3, R5, R6)—Package of 5	1.00
5027	Resistor—150,000 ohm—Carbon type—¼ watt (R19)—Package of 5	1.00
11151	Resistor—2.2 megohms—Carbon type—¼ watt (R9, R10, R11)—Package of 5	1.00
5249	Shield—R. F. coil shield	.20
11273	Shield—Radiotron shield	.25
5250	Shield—I. F. transformer shield	.22
11199	Socket—Dial lamp socket	.14
4794	Socket—4-contact Radiotron socket	.15
11197	Socket—6-contact Radiotron socket	.14
11198	Socket—7-contact Radiotron socket	.15
5224	Switch—Low frequency tone control switch and power switch (S11, S13)	1.00
11236	Switch—Range switch (S1, S2, S3, S4, S5, S6, S7, S8, S9, S10, S12)	2.44
5238	Terminal—Antenna terminal assembly	.14
11218	Transformer—Audio driver transformer (T2)	2.58
11216	Transformer—First intermediate frequency transformer (L16, L17, C16, C17)	3.15
11217	Transformer—Second intermediate frequency transformer (L18, L19, C20, C21, C22, R7, R8)	3.10
11213	Transformer—Power transformer—105-125-150-210-250 volts—40-60 cycles (T1)	5.10
11212	Transformer—Power transformer—105-125 volts—25-60 cycles	7.18
	DRIVE ASSEMBLIES	
5243	Arm—Band indicator operating arm	.42
10194	Ball—Steel ball for drive assembly—Package of 20	.25
8054	Cam—Five position cam for station selector drive assembly	.28
4422	Clutch—Tuning condenser drive clutch assembly—Comprising shaft, balls, ring, spring and washers, assembled	1.00
8048	Coupling—Flexible coupling for variable capacitor (includes indicator shaft)	.70
11693	Dial—Station selector dial and cam assembly	1.00
8045	Disc—Drive disc and gear assembly	.46
11692	Drive—Tuning condenser drive assembly, complete	6.45
8044	Escutcheon—Dial escutcheon with vernier scale	1.08
8046	Gear—Indicator shaft drive gear and vernier idler with one spring	.72
8050	Gear—Gear sector and band indicator operating link (link connects to arm on band switch)	.15
8053	Indicator Station selector indicator pointer	.12
8051	Link—Complete with roller and spring	.30
8049	Pinion—Vernier pointer drive pinion and shaft	.55
4669	Screw—Square head No. 8-32x5/32 set screw—Package of 10	.25
9047	Spring—Coil spring for indicator shaft drive gear and vernier idler (stock No. 8046)	.12
8052	Spring—Coil spring for link—Package of 5	.32
8042	Stud—Band indicator operating arm stud—Package of 5	.25
	EJECT ARM ASSEMBLIES	
11541	Arm—Eject arm, complete	.82
11533	Ball—¼-inch diameter steel ball—Package of 10	.20
10129	Ball—⅛-inch diameter steel ball—Package of 20	.25
11529	Bearing—Ejector tip bearing and nut	.32
11538	Bracket—Eject arm bracket	1.72
11537	Collar—Eject arm shaft collar and set screw	.24
11540	Cover—Eject arm cover	1.52
11536	Cushion—Counter balance roller cushion—Located inside of eject arm	.14
4055	Post—Vertical adjustment post—Located on eject arm bracket	.30
3729	Roller—Eject arm counter balance roller—Located inside of eject arm	.45
4580	Screw—No. 6—32—⅛-inch square head set screw for eject arm collar—Package of 10	.25
11534	Screw—No. 8—36—⅛-inch special screw for eject arm tip center adjustment—Package of 10	.14
11535	Shaft and Collar—Eject arm vertical action shaft and collar assembly	.15
11528	Silencer—Ejector tip silencer	.14
4067	Spring—Eject arm bracket spring—Package of 10	.38
11531	Spring—Ejector tip spring—Package of 10	.42
11530	Tip—Ejector tip with tip center, adjusting screw and cap	.32
11539	Yoke—Eject arm yoke assembly	.94
	PICKUP AND ARM ASSEMBLIES	
11720	Arm—Pickup arm, complete—less escutcheon and pickup unit	4.65
11724	Armature—Pickup armature	.38
11548	Back—Pickup back	.32
11722	Coil—Pickup coil (L24)	.52
11545	Cover—Pickup front cover	.22
11546	Cover—Pickup back cover with mounting screws	.14
3737	Damper—Pickup damper—Package of 5	.65
3516	Damper—Damper assembly for pickup arm base—Comprising one upper and one lower damper—one upper bushing and one lower bearing	.14
11723	Escutcheon—Pickup arm escutcheon	.62
11721	Pickup—Pickup unit, complete	4.75
11549	Screw—Pickup front cover screw—Package of 10	.42
3387	Screw, nut and washer for mounting pickup to arm—Package of 10	.40
11547	Screw—Pickup needle screw—Package of 10	.42
	OPERATING MECHANISM	
5502	Cam—Cam and gear assembly	1.18
6806	Clutch—Trip lever friction clutch	.30
11558	Cover—Metal cover for trip lever and friction finger assembly	.36
6809	Finger—Manual index lever finger assembly	.25
3670	Finger—Friction finger assembly	.32
11554	Lever—Manual index lever—less pin	.62
11556	Lever—Main lever and link assembly	1.10
11557	Lever—Main spring lever	.42
3677	Lever—Pickup arm cable lever assembly—Comprising lever with cable screw, spring and nut	.40
11555	Lever—Trip lever and friction clutch assembly	.94
6503	Pawl—Trip pawl assembly	.40
4124	Plate—Eject arm actuating plate assembly	.30
4563	Screw—Cable lever screw and nut—Package of 10	.60
4564	Screw—Manual index lever finger set screw—Package of 10	.20
4039	Screw—Trip lever clutch tension adjustment screw—Package of 10	.22
4566	Screw—Special screw used to fasten main lever and link assembly bushing—Package of 10	.30
11559	Spacer—Pickup arm mounting spacer	.28
4127	Spring—Actuating spring—Package of 10	.24
3666	Spring—Cable lever tension spring—Package of 10	.44
4565	Spring—Manual index lever finger tension spring—Package of 10	.30
4061	Spring—Main spring lever tension spring—Package of 10	.38
2895	Spring—Trip lever latch plate tension spring—Package of 10	.30
3917	Washer—Spring washer, "U" type—Package of 10	.25
	MOTOR ASSEMBLIES	
9012	Motor—105-125 volts—25 cycles (M1)	24.16
9014	Motor—105-125 volts—50 cycles (M1)	19.72
9011	Motor—105-125 volts—60 cycles (M1)	19.72
4562	Suspension Spring—Motor mounting spring, washer, and stud assembly—Comprising six springs, six cup washers, three spring washers and three studs	.58
	AUTOMATIC SWITCH ASSEMBLIES	
3994	Cover—Motor switch cover	.26
10184	Plate—Automatic brake latch plate—Package of 5	.40
10174	Springs—Automatic brake springs—Package of 2	.50
6805	Switch Assembly—Automatic switch, complete	1.90
3322	Switch—Motor switch (S15)	.75
	MOTOR BOARD ASSEMBLIES	
11553	Escutcheon Index escutcheon engraved Manual—12-10	.44
3764	Nut—Cap nut for motor board suspension assembly—Package of 4	.40
3672	Pin—Manual index pin	.43
11551	Rest—Pickup rest	.14
3654	Roller—Pickup arm cable guide roller—Comprising bracket roller and guide pin	.34
3763	Suspension Spring—Suspension spring, washer and bolt assembly for motor board—Comprising one bolt, two cup washers, two springs, two "C" washers and one cap nut	.42
4671	Switch—Operating switch—toggle type (S14)	.72
11542	Cover—Turntable cover	.88
11599	Turntable, complete	2.90
11348	Screw—No. 8-32—⅛-in. headless cupped point set screw for knob (Stock No. 11346)—Package of 10	.32
11381	Socket—Tuning lamp socket and cover	.45
11349	Spring—Retaining spring for knob (Stock No. 11347)—Package of 5	.15
11714	Transformer—Phonograph input transformer—Comprising 1 transformer, 1 choke coil, 3 resistors and 3 capacitors (T4, L25, C65, C66, C67, R33, R34, R36)	3.96
11715	Volume Control—Phonograph volume control (S16, S17, R35)	1.55
	REPRODUCER ASSEMBLIES	
8059	Board—Reproducer terminal board (2 terminals)	.14
8060	Bracket—Output transformer mounting bracket	.14
11304	Cable—Reproducer cable—Complete with female connector	.80
8058	Clamp—Cone rim clamp—Package of 4	.44
11189	Coil—Field coil, magnet and cone housing (L22)	10.60
8056	Cone—Reproducer cone (L21)	1.38
5039	Connector—4 prong male connector plug for reproducer	.25
5040	Connector—4 contact female connector socket for reproducer cable	.25
9620	Reproducer, complete	16.32
8057	Transformer—Output transformer (T3, C42)	3.22
	MISCELLANEOUS ASSEMBLIES	
11881	Base—Phonograph compartment lamp base	.55
4391	Box—Needle box	.70
11191	Bracket—Radiotron tuning lamp mounting bracket—less clamp (Stock No. 11192)	.12
11319	Cable—Radiotron tuning lamp cable and plug—approximately 25-in. long	1.38
11716	Cable—Two conductor shielded cable—Volume control "H-J and F" to chassis cable (Stock No. 11712)	.64
11717	Cable—Five conductor shielded cable from volume control "A-B-C-D-G-K" to input transformer terminals No. 4 and No. 7.	1.14
11192	Clamp Radiotron tuning lamp mounting clamp—less bracket (Stock No. 11191)	.12
6123	Connector—Four contact male connector plug for cable (Stock No. 11717)	.30
11570	Connector—Four contact male connector for cable (Stock No. 11716)	.32
11276	Escutcheon—Radiotron tuning lamp escutcheon	.40
11379	Escutcheon—Station selector escutcheon and crystal	1.08
11346	Knob—Station selector knob—Package of 5	.75
11347	Knob—Volume control, tone control, power switch or range switch knob—Package of 5	.75
11383	Resistor—1 megohm—Carbon type—1/10 watt (R27)—Package of 5	.75
11711	Shade—Phonograph compartment lamp shade	.16

RCA MFG. CO., INC.

GENERAL FEATURES

This instrument comprises an eleven-tube chassis mounted in a table type of cabinet. Its tuning ranges cover the long wave, standard broadcast, short wave broadcast, amateur and aviation bands. The following points of design are of particular importance:

Metal Radiotrons

The new metal tubes are used in the radio receiver for amplifying and detecting purposes. These tubes make possible a greater range of stable amplification not previously attainable with corresponding glass types. Their metal envelopes form a perfect electrostatic and electromagnetic shield, precluding the former necessity for elaborate shielding by means of cans. The metal tubes are especially adaptable to the modern, extended-range receivers because of their efficient shielding and their favorable internal characteristics.

Tuning Condenser

The variable tuning condenser is supported by a new design of shock-proof mount which has been developed by our engineers to prevent chassis vibration from producing audio frequency howl.

Chassis

Servicing convenience has been a governing factor in the layout of the chassis parts and the associated wiring. Each part has been situated so that a minimum of wiring is necessary. Adjustments provided by means of substantial trimmers are mounted where they may be easily reached. Holes are included in the shield cans of the r-f coil system for testing the tuning with a Tuning Wand.

Loudspeaker

An eight-inch, electrodynamic reproducer unit is used to handle the high level output of the receiver. The speaker is designed to operate in such manner with the acoustics of the cabinet that the best quality of reproduction is obtained. Connections from the chassis to speaker are made through a plug and connector, which permits either unit to be removed quickly for service.

Color Band Dial

The station indicating dial is neatly designed with each scale identified by a different color. As the range switch is changed from one band to another, an index pointer moves so as to point to a short strip of color at the lower part of the dial to indicate the band being used. A push-in clutch arrangement gives a 10-to-1 or 50-to-1 drive ratio. The vernier pointer has a ratio of 20-to-1 with respect to the main pointer.

CIRCUIT ARRANGEMENT

The Superheterodyne principle of operation forms the basis of the circuit design. A single, tuned r-f stage is used ahead of the first detector. The functions of oscillator and detector are performed by two separate tubes. One i-f stage is employed and designed to operate at 460 kc. The combined second detector and a.v.c. stage uses an RCA-6H6 double diode. The audio system consists of two single amplifier stages working in cascade with a push-pull power output stage. The loudspeaker is an electrodynamic type, receiving its field supply from the rectifier and filter system and simultaneously acting as a filter reactor. Full wave rectification is performed in the RCA-5Z3 tube. The outstanding features of electrical design are concerned with the following:

Tuned Circuits

A total of seven circuits are tuned to provide gain and selectivity to the incoming signal. The variable gang condenser resonates the antenna transformer secondary, the detector transformer secondary and the oscillator coil. Alignment trimmers are included for each of these same circuits. Additional trimmers are used on the i-f transformers, tuning both the secondaries and primaries to 460 kc. There are separate groups of antenna, detector and oscillator coils for each of the tuning ranges. They are placed into operation by means of a rugged rotary switch.

First Detector

This stage has unusually good high frequency mixing efficiency. The tube used, an RCA-6L7, is a new hexode type. The signal is supplied to the first control grid and the oscillator is fed in on a second control grid, a screen grid separating the two. The arrangement of the grids prevents degenerative difficulties, particularly at the higher frequencies. The second grid is direct-connected to the cathode of the oscillator tube and has no d-c bias.

Oscillator

The oscillator circuit is worthy of careful study inasmuch as it is different from the type ordinarily employed. It has self-stabilizing properties which are very advantageous for short wave operation. The generated frequency remains substantially constant, the circuit being unaffected by variation of line voltage and other similar influences. Output also remains uniform over the individual tuning ranges. The switching of the tuning coils is arranged so as to short those not in use in order to prevent absorption or any reactive effects in the particular band being tuned.

Detector and A.V.C.

The modulated signal as obtained from the output of the i-f system is detected by an RCA-6H6 double diode tube. The audio frequency secured by this process is passed on to the a-f system for amplification and final reproduction. The d-c voltage which results from detection of the signal, is used for automatic volume control. This voltage, which develops across resistors R-7 and R-8, is applied as automatic control grid bias to the r-f, first detector and i-f tubes through suitable resistance-capacitance filter circuits. The second diode of the RCA-6H6 is used to supply residual bias for these controlled tubes under conditions of little or no signal. This diode, under such conditions, draws current, which flows through resistors R-7, R-8 and R-9, thereby maintaining the desired minimum operating bias on such tubes. On application of signal energy above a certain level, however, the auxiliary bias diode ceases to draw current and the a.v.c. diode takes over the biasing function. The cathode and anode of the signal-a.v.c. diode have positive potential in respect to chassis-ground and cathodes of the a.v.c. controlled tubes when no signal is being received.

Audio System

Manual volume control of the detected signal is effected by an acoustically tapered potentiometer in the grid circuit of the first a-f stage. This control has tone compensating filters connected to two points thereon. These filters effect the correct aural balance at different volume settings. A music-speech switch (low frequency tone control) is associated with one of the compensation filters. The purpose of this control is to make speech reproduction more intelligible and to reduce hum obtained from stray modulation on a carrier. The driver stage of the audio system uses an RCA-6C5 which is resistance coupled to the first a-f tube and transformer coupled into the push-pull power output stage.

Tuning Indicator

A cathode-ray tube is used as a means of visually indicating when the receiver is accurately tuned to the incoming signal. This tube is of new design and comprises an amplifier section and a cathode-ray section built in the same glass envelope. The cathode-ray section consists of a conically shaped luminescent screen, upon which a pattern is formed by an effect of the detected signal after said effect has been amplified by the amplifier section which is fed from the detector diode circuit. The size of the pattern is determined by the strength of the signal voltage, so that any change of tuning may be readily observed in order to facilitate tuning to exact resonance.

SERVICE DATA

The various diagrams of this booklet contain such information as will be needed to isolate causes for defective operation when such develops. The ratings of the resistors, capacitors, coils, etc., are indicated adjacent to the symbols signifying these parts on the diagrams. Identification titles such as R-3, L-2, C-1, etc., are provided for reference between the illustrations and the Replacement Parts List. The coils, reactors, and transformer windings are rated in terms of their d-c resistances only. Ratings of less than one ohm are generally omitted.

Alignment Procedure

Eleven alignment trimmers are provided in the r-f, first detector and oscillator tuning system and four are used in the i-f system. All of these are accurately adjusted during manufacture and should remain in proper alignment unless affected by abnormal conditions of climate or have been altered by other means. Loss of sensitivity, improper tone quality and poor selectivity are the usual indications of improper alignment.

Correct performance of the receiver can only be obtained when the trimmer adjustments have been made by a skilled service man with the use of adequate and reliable test equipment. Such apparatus as may be required for alignment of this particular instrument is illustrated and described on a separate page of this booklet.

Two methods of alignment are applicable. One utilizes a Cathode-Ray Oscillograph as a means of output indication and the other follows former procedure where a glow type indicator or meter is used. The oscillographic method is much to be preferred, since greater accuracy is possible from the type of indication afforded. There are no approximations necessary as with the meter or aural method, but each adjustment can be made with definite precision. Both methods are hereinafter outlined so that alignment operations may be made according to the equipment available.

It is wise to determine the necessity for alignment as well as the direction of misalignment before making adjustments. The RCA Tuning Wand is an instrument designed particularly for such a purpose.

The Tuning Wand consists of a bakelite rod having a small brass cylinder at one end and a core of finely divided iron at the other. It may be inserted into a tuned coil while a signal of the normal resonant frequency is being supplied to each coil to obtain an indication of the tuning. Holes are provided at the top of the r-f shield cans for entrance of the Wand. The presence of either end of the Wand will cause a change in tuning which will be indicated at the receiver output as an increase or decrease in signal level. If there is a decrease of output when either end is inserted, the tuning is correct and will require no adjustment. However should there be an increase of output due to the iron core and decrease with the brass cylinder, an increase in inductance or capacitance is indicated as necessary to bring the circuit into line. The trimmer involved should therefore be increased accordingly. If the brass cylinder end causes an increase in output while the iron end causes a decrease, reduction of inductance will be necessary to place the circuit in alignment. This is equivalent to decreasing the trimmer concerned. The following tabulation gives the various changes and the adjustments required:

WAND	SIGNAL	TRIMMER
Brass	Decrease	None
Iron	Decrease	
Brass	Increase	Decrease
Iron	Decrease	
Brass	Decrease	Increase
Iron	Increase	

CATHODE-RAY ALIGNMENT

Equipment

A standard source of alignment frequencies is required. Such a source should consist of an RCA Full Range Oscillator, Stock No. 9595. Output indication should be by means of an RCA Stock No. 9545 Cathode-Ray Oscillograph. An RCA Stock No. 9558 Frequency Modulator will be needed to sweep the generated signal and synchronize it with the Oscillograph in order to obtain visual representation of the resonant characteristic of the circuit being tuned on the cathode-ray fluorescent screen.

I-F Trimmer Adjustments

The four trimmers of the two i-f transformers are located as shown by Figure 6. Each must be aligned to a basic frequency of 460 kc. The last transformer must be aligned firstly and the first transformer aligned secondly. For such a process, it is necessary to feed the output of the Full Range Oscillator to the stages in their order of alignment, adjusting the trimmers of each transformer and observing the effect at the second detector output on the Cathode-Ray Oscillograph. The proper point of connection of the Oscillograph is with its vertical "high" input terminal attached to the juncture of R-7 and R-8, as illustrated in Figure 6, and with the "0" or ground terminal to the chassis. The "Ext. Sync." terminals of the Oscillograph should be connected to the Frequency Modulator as shown by Figure 5. A .001 mfd. capacitor installed in series with the Oscillator "Ant." lead will prevent the voltages of the stage under alignment from becoming upset. The vertical "A" amplifier should be "On" for the ensuing adjustments and its gain control kept at maximum. For each adjustment, the Oscillator output must be regulated so that the image obtained on the Oscillograph screen will be of the minimum size convenient for accurate observation. Proceed further as follows:

(a) Place the receiver, Oscillograph and test Oscillator in operation. Set the receiver range switch to Band "A" and tune the station selector to a point where no interference will be encountered from signal pickup or from the RCA-6J7 oscillator, removing the tube if necessary. Set the Oscillograph horizontal "B" amplifier to "Timing" and control its gain so that the luminescent spot sweeps a straight line trace completely across the screen. Place the timing control to "Int." Adjust the intensity and focusing controls of the Oscillograph to produce the correct size and strength of spot.

(b) Attach the output of the test Oscillator between the control grid cap of the RCA-6K7 i-f tube and chassis ground as shown typically by Figure 5. Tune the Oscillator to 460 kc. and set its modulation switch to "On." Regulate its output until the signal produces a wave pattern on the Oscillograph screen, adjusting the Oscillograph controls to give a shape which is convenient for peak indications. Cause the image to stand still on the screen by manipulation of the frequency and synchronizing controls. Then carefully tune the two trimmers C-20 and C-21 of the second i-f transformer to produce maximum amplitude (vertical deflection) of the oscillographic image. Under this condition the transformer will be sharply resonated to 460 kc.

(c) The Frequency Modulator should then be placed in operation and interconnected with the Full Range Oscillator by means of the special shielded patch cord. Figure 5 shows the proper arrangement. Set the Frequency Modulator sweep range switch to its "Lo" position and turn the Oscillator modulation switch to "Off." Change the timing control of the Oscillograph to "Ext." and place the range switch to its No. 2 position. Then carefully shift the tuning of the Oscillator so as to increase its frequency, until two distinct and similar waves appear on the Oscillograph screen and become exactly co-incident at their highest points. This condition will be found to occur at an Oscillator setting of approximately 840 kc. The curves will be identical in shape but appearing in reversed positions. Adjust the frequency control of the Oscillograph in order to cause the waves to conform with the above requirement and to make them remain motionless on the screen. This will require a setting of approximately ½ clockwise rotation of the frequency control. The trimmers C-20 and C-21 should then be re-adjusted so that the two curves move together and become exactly coincident throughout their lengths, maintaining the maximum amplitude at which this condition can be brought about.

(d) Leaving the equipment connected and adjusted as in (c), change the Oscillator output to the control grid cap of the RCA-6L7 first detector tube. Then adjust the first i-f transformer trimmers C-16 and C-17 so that the forward and reverse waves appearing on the Oscillograph coincide throughout their lengths and have maximum amplitude. The shape of the composite wave obtained from this operation is a true representation of the overall tuning characteristic of the i-f system.

R-F Trimmer Adjustments

For Bands A and X, adjustments must be made at the high and low frequency ends of the range. On Band C, alignment is required only at the high frequency end.

Locations of the various antenna, detector and oscillator coil trimmers are shown by Figure 6. The test Oscillator should be removed from connection with the i-f system and its output connected to the antenna-ground terminals of the receiver. No changes are to be made in the connections of the Oscillograph at the second detector. During the following adjustments, the Oscillator output should be regulated as often as is necessary to keep the oscillographic image as low as is practically observable. Adherence to this procedure will obviate the broadness of tuning that would result from a.v.c. action on a stronger signal. Proceed with the adjustments as follows:

CALIBRATION

Set the receiver range switch to Band A and rotate the station selector until the tuning condenser plates are in full mesh (maximum capacitance). Then move the main dial pointer until it points exactly to the horizontal line at the low frequency end of the Band A scale. Correct the setting of the vernier second hand pointer to read zero.

BAND A

(a) With the receiver range switch in its Band A position, tune the station selector until the dial pointer is at a reading of 1720 kc. Adjust the test Oscillator to 1720 kc. (modulation "On" and Frequency Modulator disconnected) and increase its output to produce a registration on the Oscillograph. Carefully align the oscillator, detector and antenna trimmers, C-47, C-12 and C-3 respectively, so that each brings about maximum amplitude of output as shown by the wave on the Oscillograph. It will be necessary to have the timing control of the Oscillograph on "Int." for this operation. After each trimmer has been peaked, the Oscillograph timing control should be set to "Ext." and the Frequency Modulator placed into operation with its connections to the Oscillator and Oscillograph made in accordance with Figure 5. Turn the modulation switch of the Oscillator to "Off" and retune the Oscillator (increase frequency) until the forward and reverse waves show on the Oscillograph and become coincident at their highest points. Adjust the trimmers C-47, C-12 and C-3 again, setting each to the point which produces the best coincidence and maximum amplitude of the wave images.

(b) Remove the Frequency Modulator cable from the Oscillator and shift the signal frequency to 600 kc. Place the modulation switch to "On". Tune the receiver to pick up this signal, disregarding the dial reading at which it is best received. Then insert the Frequency Modulator plug and retune the Oscillator (modulation "Off") until the two similar forward and reverse waves appear on the screen. For this adjustment, it is advisable to shift the Oscillator to its 200-400 kc. range using the third harmonic of the generated signal in order to obtain the desired range of sweep. The oscillator series trimmer, C-46, should then be adjusted to produce maximum amplitude of the images. No rocking will be necessary on the station selector inasmuch as the signal frequency is being "wobbled" by the Frequency Modulator to produce the same effect. After completing this adjustment, the trimmer C-47 should be re-aligned as in (a) to correct for any change brought about by the adjustment of C-46.

BAND X

(a) Disconnect the Frequency Modulator and tune the test Oscillator to a frequency of 400 kc. (Modulation "On"). Place the receiver range switch in its Band X position and turn the station selector until the dial pointer reads 400 kc. Adjust the Oscillograph timing control to "Int." Then align each of the trimmers C-45, C-11 and C-2 to the point producing maximum output at the Oscillograph. Place the Frequency Modulator in operation and attach it to the Oscillator in the normal manner. Change the Oscillograph timing to "Ext." Increase the frequency of the Oscillator (modulation "Off") until the two waves appear and become coincident at their highest points, approximately at 462 kc. They may be made to remain stationary on the screen by manipulation of the Oscillograph range switch and frequency control. Readjust the three trimmers C-45, C-11 and C-2 to give maximum amplitude and complete coincidence of the waves.

(b) Change the test Oscillator so that it delivers a signal of 150 kc. with the Frequency Modulator disconnected. Tune this signal on the receiver which has previously been set to Band X, disregarding the dial reading at which the signal is best received. Then interconnect the Frequency Modulator with the Oscillator and retune the latter to the point at which the two similar waves appear on the screen. Adjust trimmer C-44 for maximum amplitude of the wave images. Rocking of the tuning condenser will not be necessary as the Frequency Modulator supplies such an operation. Repeat the alignment of C-45 as outlined in (a) to correct for any influence error brought about by the adjustment of C-44.

BAND C

(a) [illegible] 18,000 kc. signal of the Oscillator will be received at this point if the adjustment of C-43 has been properly made by using the position of least capacitance which gives maximum receiver output. It may be necessary to increase the output of the Oscillator in order to get an indication of the "image". *No adjustments should be made during this check.*

(b) Return the receiver tuning to 18,000 kc., realign C-43 if necessary, and then adjust the detector and antenna trimmers, C-10 and C-1, for maximum signal output as evidenced by the oscillographic image. No further adjustments are to be made on this band.

OUTPUT INDICATOR ALIGNMENT

To align the receiver by means of an output indicator other than a Cathode-Ray Oscillograph will require the use of a standard test Oscillator, such as that recommended above, for the source of signals and means of indication for the output. The RCA Neon Output Indicator, Stock No. 4317, will be found very satisfactory for such use. It should be connected across the voice coil circuit of the loudspeaker or across the output transformer primary.

I-F Alignment

Connect the test Oscillator to the control grid cap of the i-f tube. Advance the volume control of the receiver to its full on position. Tune the test Oscillator accurately to 460 kc. and align the trimmers C-20 and C-21 to give maximum receiver output. Regulate the Oscillator output during this adjustment so that the output indication is as small as can be conveniently observed. After completing the adjustments of these trimmers, re-connect the Oscillator so that it will feed into the control grid circuit of the RCA-6L7 first detector. Then tune the first i-f transformer trimmers C-16 and C-17 for maximum receiver output.

R-F Alignment

After completing the i-f adjustments, it is advisable to correct the line-up of the circuits ahead of the first detector. The test Oscillator should be connected to the antenna-ground terminals of the receiver and the manual volume control turned to its maximum position. For each adjustment, the Oscillator output should be maintained as low as possible in order to avoid broadness of tuning which would result from a.v.c. action on a stronger signal.

MODEL T11-8
Alignment, Part 2
Parts List

RCA MFG. CO., INC.

Band A—This band should be aligned by supplying a **1720 kc.** signal to the receiver, tuning the station selector to a dial reading of **1720** and adjusting the trimmers C-47, C-12 and C-3 to produce maximum receiver output. The Oscillator should then be shifted to **600 kc.** and the receiver tuned to resonate this signal, disregarding the reading at which it is best received. Trimmer C-46 must then be adjusted, simultaneously while rocking the station selector backward and forward through the signal until the maximum output results from the combined operations. C-47 should be rechecked to assure that its adjustment has not changed because of the trimming of C-46.

Band X—Change the range switch to its Band "X" position. Tune the receiver to read **400 kc.** and set the Oscillator to **400 kc.** Adjust trimmers C-45, C-11 and C-2 to produce maximum receiver output. Then shift the Oscillator frequency to **150 kc.** and tune the receiver to pick up this signal, disregarding the dial reading at which it is best received. Then tune the oscillator series trimmer, C-61, simultaneously rocking the tuning control (receiver) backward and forward through the signal, until maximum output results from the combined operations. Repeat the alignment of C-45 as in (a) to correct for any change caused by the adjustment of C-61.

Band C—Change the receiver so that it is operative and the dial reads **18,000 kc.** on the "C" Band. Tune the test Oscillator to this same frequency. Then adjust the oscillator trimmer C-43 to produce maximum (peak) output. Two positions of this trimmer will be found which conform with this requirement. The one of least capacitance is correct. Check for the presence of "image" response at **17,080 kc.** by shifting the receiver tuning. If it is received at such a point, the trimmer C-43 has been correctly adjusted to the right peak. *No adjustments are to be made during this check.* Tune the receiver back to the **18,000 kc.** dial marking, readjust C-43 if necessary, and then tune the detector and antenna capacitors C-10 and C-1 for maximum receiver output. No further adjustments are necessary.

Radiotron Socket Voltages

The voltage values indicated from the Radiotron socket contacts to chassis on Figure 6 will serve to assist in the location of causes for faulty operation. Each value as specified should hold within ± 20% when the receiver is normally operative at its rated supply voltage. Variations in excess of this limit will usually be indicative of trouble in the basic circuits. The voltages given are actual operating values and do not allow for inaccuracies which may be caused by the loading effect of a voltmeter's internal resistance.

Standard Transformer

The transformer used on some models of this instrument is adaptable for voltages and frequencies as given under Ratings A and B of Electrical Specifications. Its schematic and wiring are shown by Figure 7.

Phonograph Attachment

A terminal board is provided for connecting a phonograph attachment into the audio amplifying circuit. Two typical methods of connection are shown on the schematic diagram Figure 1. The radio volume control must be set to minimum when using phonograph.

Radiotron Complement

(1) RCA-6K7..........Radio-Frequency Amplifier
(2) RCA-6L7..........First Detector
(3) RCA-6J7..........Heterodyne Oscillator
(4) RCA-6K7..........Intermediate Amplifier
(5) RCA-6H6..........Second Detector and A.V.C.
(6) RCA-6C5..........First Audio Amplifier
(7) RCA-6C5..........Audio Driver Amplifier
(8) RCA-6F6..........Power Output Amplifier
(9) RCA-6F6..........Power Output Amplifier
(10) RCA-5Z3..........Full-Wave Rectifier
(11) RCA-6E5..........Tuning Indicator

REPLACEMENT PARTS

Insist on genuine factory tested parts, which are readily identified and may be purchased from authorized dealers

5212	Capacitor—18 Mfd. (C54)	1.16
11215	Capacitor pack—Comprising one 16 Mfd., two 10 Mfd., and two 8 Mfd. capacitors (C29, C35, C36, C55, C56)	3.85
4693	Clamp—Electrolytic condenser mounting clamp—for stock No. 11215	.15
11325	Coil—Antenna coil—X band (L3, L4, C2)	1.56
11326	Coil—Detector coil—X band (L9, L10, C11)	1.60
11327	Coil—Oscillator coil—X band (L14, L23, C45)	1.44
5215	Coil—Antenna coil—A and C bands (L1, L2, L5, L6, C1, C3)	2.32
5216	Coil—Detector coil—A and C bands (L7, L8, L11, L12, C10, C12)	2.34
5217	Coil—Oscillator coil—A and C bands (L13, L15, C43, C47)	2.20
11277	Compensating Pack—Comprising one 8200 ohm and one 27,000 ohm resistors, one .015 Mfd., one .035 Mfd. capacitors (C25, C28, R12, R13)	.92
11214	Condenser—Three-gang variable tuning condenser (C5, C14, C48)	4.20
11697	Cover—Terminal board cover	.12
11202	Foot—Chassis foot and bracket assembly—Package of 2	.78
11710	Lead—Shielded lead—connects antenna terminal to range switch	.40
11303	Indicator—Station selector vernier indicator pointer	.22
11226	Indicator—Band indicator pointer assembly—comprising indicator, arm, link and stud	.20
4475	Indicator—Station selector indicator	.18
4340	Lamp—Dial lamp—Package of 5	.60
3993	Screw—No. 6-32-5/32-in. set screw for band indicator operating arm—Package of 10	.25
4669	Screw—No. 8-32-5/32-in. square head set screw—for tuning condenser shaft—Package of 10	.25
4377	Spring—Band indicator operating arm spring—Package of 5	.25
4378	Stud—Band indicator operating arm stud assembly—Package of 5	.25
	REPRODUCER ASSEMBLIES	
11232	Board—Terminal board with two lead wire clips	.18
11231	Bolt—Yoke and core assembly bolt and nut	.16
8060	Bracket—Mounting bracket for output transformer and connector	.14
11304	Cable—Reproducer cable—Complete with female connector	.80
11257	Clamp—Cone center suspension clamping nut and screw assembly—Package of 5	.25
11234	Coil—Field coil (L-22)	2.15
11233	Coil—Neutralizing coil	.30
11235	Cone—Reproducer cone (L21)—Package of 5	3.50
5040	Connector—4 contact female connector socket for reproducer cable	.25
5039	Connector—4 prong male connector plug for reproducer	.25
9617	Reproducer—Complete	6.60
11229	Transformer—Output transformer (T3)	1.66
11230	Washer—Binders board "C" washer—used to hold field coil securely—Package of 5	.18
	MISCELLANEOUS ASSEMBLIES	
11729	Bolt—Reproducer mounting bolt assembly—Comprising one bolt, one washer, one lockwasher and one nut—Package of 2	.20
11191	Bracket—Tuning lamp mounting bracket—less clamp	.12
11319	Cable—Tuning tube cable—complete with socket	1.38
11192	Clamp—Tuning lamp mounting clamp—less bracket	.12
11276	Escutcheon—Tuning lamp escutcheon	.40
11337	Escutcheon—Station selector escutcheon	.70
6614	Glass—Station selector dial glass	.30
11347	Knob—Volume control, tone control, range switch or power switch knob—Package of 5	.75
11346	Knob—Station selector knob—Package of 5	.75
11382	Resistor—1 megohm—Carbon type—1/10 watt (R27)—Package of 5	.75
4678	Ring—Spring retaining ring for station selector dial glass—Package of 5	.34
11377	Screw—Chassis mounting screw assembly—Comprising one screw, one washer and one lockwasher—Package of 4	.12
11348	Screw—No. 8-32—1/16-in. headless cupped point set screw for knob (Stock No. 11346)—Package of 10	.32
11381	Socket—Tuning tube socket and cover	.45
11349	Spring—Retaining spring for knob (Stock No. 11347)—Package of 5	.15

The prices quoted above are subject to change without notice.

MODEL 15K
Circuit Data
Alignment, Part 1

RCA MFG. CO., INC.

General Description

This receiver represents the result of thorough development, design, and substantial manufacture. Noteworthy technical improvements have been applied in achieving marked advantages of operation, and efficiency of performance.

Model 15K is a fifteen-tube, console-type, "Magic Brain" superheterodyne receiver with a twelve-inch electro-dynamic loudspeaker, and the newly developed "Magic Voice." Design features incorporated in this receiver include built-in doublet antenna coupler; "Magic Brain"; improved plunger-type air-dielectric adjustable trimming capacitors in the antenna, detector, and oscillator coil circuits; tuned r-f amplifier; high-efficiency first detector (converter) with separate oscillator; two-stage i-f amplifier; selective "Magic Eye"; push-pull beam-type power amplifier; magnetite core adjusted i-f transformers, low-frequency oscillator tracking, and wave-trap; range-selector sensitivity control; fidelity control; "Magic Voice"; three-point aural compensated volume control; music-speech switch; automatic volume control; phonograph terminal board; new selector dial; and a dust-proof aluminum voice-coil, electrodynamic loudspeaker.

Service convenience has been a controlling factor in the layout of the chassis parts and wiring. The assembly of these various elements is such that the number of conductors is minimized, with all important connections being readily accessible. Trimming adjustments are located at accessible points. A double tuning-knob arrangement permits the choice of either a twenty-to-one or a hundred-to-one dial drive ratio. The latter permits ease of tuning, especially in the "Medium wave", "Short wave", and "Ultra short wave" bands.

Circuit Arrangement

The conventional type of superheterodyne circuit is used. It consists of an r-f amplifier stage, first detector (converter) stage, separate oscillator stage, two signal i-f amplifier stages, tuning tube i-f amplifier and rectifier stages, a diode-detector—automatic volume-control stage, an audio voltage-amplifier stage, an audio driver-amplifier stage, a push-pull beam-type power-amplifier stage, a tuning indicator "Magic Eye", and a full-wave rectifier.

"Magic Brain"

The new "Magic Brain" is constructed as a separate, self-contained, completely shielded, five-band, oscillator-detector-antenna-tuning unit which plugs into the main chassis.

A single-wire antenna, or a doublet antenna, when connected to the proper input terminals of the receiver, is coupled to the control grid of the RCA-6K7 r-f amplifier tube through the tuned r-f transformer consisting of L6, L5, L4, L3, and L2 (except when range selector is in "Ultra short wave" position). The primary coil L13 of the "Ultra short wave" (D) band tuned r-f transformer remains in the antenna circuit at all times. A unique method of switching is used. In the "Long wave" (X) band, L6 becomes the primary with L5, L4, L3, and L2 as secondary. In the "Standard broadcast" (A) band, L5 becomes the primary with L4, L3, and L2 as secondary (L6 shorted out). In the "Medium wave" (B) band, L4 becomes the primary with L3 and L2 as secondary (L6 and L5 shorted out). In the "Short wave" (C) band, L3 becomes the primary with L2 as secondary (L6, L5, L4, and tap on L4 shorted out). The tap on L4 is provided to prevent interaction with L3 and L2 when operating receiver in "Short wave" band. In the "Ultra short wave" (D) band, L6, L5, L4, and L3 are shorted out and grounded, and secondary L14 is placed in shunt with L2. The latter connection prevents undesirable interaction of L2 with L14. This method of switching reduces the total number of coils and leads, and results in having a low-loss primary and secondary winding for each band with high efficiency of operation.

The band switching of the detector circuits is similar to that of the antenna circuits. Coils L15, L21, and L20 are always connected in series with the plate circuit of the RCA-6K7 r-f amplifier tube. In the "Long wave" (X) band, L19, L18, L17, and L16 are connected in series as the secondary circuit. The ground of the coil system is at the low end of L19. L20 acts as the primary which transfers energy to the secondary L19. Capacitor C33 resonates primary L20 at the proper frequency. In the "Standard broadcast" (A) band, L18, L17, and L16 are connected in series as the secondary circuit. The ground of the coil system is now between L18 and L19. L19 is used as the primary and is resonated at the proper frequency by capacitors C34 and C33 which are in shunt with this coil. Capacitor C33 is connected to transfer energy to the primary coil L19. In the "Medium wave" (B) band, L17 and L16 are connected in series as the secondary. The ground of the coil system is now between L17 and L18. L18 is used as the primary and is resonated at the proper frequency by capacitor C34 which is in shunt with this coil. L19 is shorted by the range selector. Capacitor C33 transfers the r-f energy from the plate circuit to the primary L18. In the "Short wave" (C) band, L16 is the secondary. The ground of the coil system is now between L16 and L17. L17 is used as the primary and is resonated to the proper frequency by capacitor C34. In addition, L15 acts as a high-frequency primary which resonates above 20 mc and improves the gain at the high-frequency end of the "Short wave" band. Coils L19 and L18 are shorted by the range selector. L21 is effectively r-f bypassed in this position by capacitor C32. In the "Ultra short wave" (D) band, L22 is the secondary, or grid coil, and consists of approximately a single turn of silver plated strap around a 7/8-inch coil form. The primary coils, L21 and L15 are in series on this band, with L21 acting as a low-frequency primary and L15 as a high-frequency primary. L16 is shunted by L22 instead of being shorted directly by the range selector. Any inductive effect of L16 is thus eliminated. L19, L18, and L17 are shorted directly by the range selector.

Separate windings, with the exception of L23, are employed in the oscillator stage for each position of the range selector. L23 (inductively coupled to L11 and L12) is placed in the oscillator plate circuit to provide additional feed-back when operating receiver on the "Ultra short wave" (D) band. This coil is effectively r-f bypassed by capacitor C12, when range selector is in the "Short wave" (C) position, to prevent undesirable reactions. Its effect on the remaining bands is negligible. The inherent stability of the oscillator circuit provides minimum frequency drift which is especially advantageous for high-frequency reception. The locally generated signal is capacitance coupled to grid No. 3 of the RCA-6L7 first detector.

The output of the "Magic Brain" is fed to the i-f amplifier through a plug-in cable. This cable also supplies all power required by the "Magic Brain" unit.

I-F Amplifier (Signal)

The intermediate-frequency amplifier consists of two RCA-6K7 tubes in a two-stage, transformer-coupled circuit. The windings of all three i-f transformers are resonated by fixed capacitors, and are adjusted by molded magnetite cores (both primary and secondary) to tune to 460 kc. A third winding L26, in the first i-f transformer, is placed in series with the main secondary L25 when the fidelity control switch S4 is thrown to "broad" position (see figure 2), thereby increasing the coupling between the primary and secondary circuits with consequent broadening of the band width of the i-f amplifier. The increased band width of the i-f amplifier therefore causes less attenuation of the higher audio modulation side-band frequencies, permitting higher fidelity reception. A third winding L31 in the third i-f transformer supplies signal input to the tuning tube i-f amplifier.

Tuning Tube I-F Amplifier

The i-f signal voltage developed in L31 (third i-f transformer) is applied to the control grid of the RCA-6K7 tuning tube i-f amplifier. The output of this tube is coupled through a sharply tuned transformer to the RCA-6H6 tuning tube rectifier. All or a portion of the voltage which develops across resistor R27 (adjustable from back of chassis, see figure 1) is transferred from the movable arm to the grid of the RCA-6E5 cathode-ray tuning tube through a suitable resistance-capacitance filter. The sharpness of this amplifier permits the receiver to be accurately tuned to the incoming carrier with the tuning tube "Magic Eye" while operating receiver with the fidelity control in extreme clockwise (broad) position.

Detector and A.V.C.

The modulated signal, as obtained from the output of the last i-f stage, is detected by an RCA-6H6 twin-diode tube (No. 2 diode). The audio frequency secured by this process is transferred to the a-f system for amplification and final reproduction. The d-c voltage which results from detection of the signal is used for automatic volume control. This voltage, which develops across resistors R21 and R23, is applied, as automatic control-grid bias to the r-f, first-detector, and i-f tubes. The No. 1 diode of the RCA-6H6 is used to supply residual bias to the controlled tubes under conditions of little or no signal. This diode, under such conditions, draws current which flows through resistors R33, R37, and R35, thereby maintaining the desired operating bias on such tubes. [illegible] The sensitivity of the receiver is increased in the "Ultra short wave" (D), "Short wave" (C), and "Medium wave" (B) bands by [illegible] range selector control.

Audio System

The manual volume control consists of an acoustically tapered potentiometer in the audio circuit between the output of the detector-diode and the input grid of the RCA-6C5 audio voltage-amplifier tube. This control has a three-point tone-compensating filter connected to it so that the correct aural balance will be obtained at different volume settings. Phonograph terminals are provided to feed the output of an external phonograph pickup to the control grid of the audio amplifier through this aurally compensated volume control.

The output of the voltage amplifier is resistance-capacitance coupled to the control grid of the RCA-6C5 driver tube. The output of this stage is transformer coupled to the control grids of the RCA-6L6 push-pull power output tubes. The output of this stage is transformer coupled to the voice coil of the electro-dynamic speaker.

The "Music-speech" control consists of a switch S7 which is connected to two of the tone compensating filters. When this control is turned to its No. 1 (Music) position, maximum low audio-frequency response is obtained. When the control is moved to its No. 2 position, resistor R20 is placed in shunt with capacitor C63, giving greater attenuation of the lower frequencies. This position is a compromise between the "Music" and the "Speech" positions. In the No. 3 (Speech) position, operation is the same as No. 2 position except that capacitor C61 is shorted, giving additional low-frequency attenuation (minimum lows).

Fidelity Control

The fidelity control consists essentially of the combination of a conventional high audio-frequency tone control, including the combinations of capacitor C77 and a variable resistor R34, capacitor C78 and switch S6 in shunt with the secondary winding of transformer T2, and means for changing the band width of the i-f amplifier. It performs in the following manner:

When the fidelity control is in its extreme counter-clockwise (sharp) position, the resistance of R34 is minimum, capacitor C78 shunts the secondary of T2, and winding L26 is disconnected from the i-f circuit (S6 and S4 in sharp position, see figure 2). Capacitor C77 is most effective at this point causing maximum attenuation of the higher audio frequencies. As this control is turned clockwise, placing more resistance in series with capacitor C77, the capacitor becomes less and less effective, and the upper frequency range of the audio amplifier is extended. When the fidelity control nears its extreme clockwise position, resistor R34 is disconnected and switches S6 and S4 (operated by fidelity control shaft) respectively disconnect capacitor C78 from the audio circuit and place winding L26 (first i-f transformer) in series with L25 (S6 and S4 in broad position) thereby increasing the higher audio-frequency range of the audio amplifier and broadening the i-f amplifier simultaneously.

Selective "Magic Eye"

An RCA-6E5 cathode-ray tuning tube is used as a means of visually indicating when the receiver is accurately tuned to the incoming signal. This tube consists of an amplifier section and a cathode-ray section built in the same glass envelope. The adjustable arm of R27 selects the voltage used to actuate the grid of the amplifier section. Maximum voltage is applied to this grid when the receiver is tuned to resonance with an incoming carrier. This condition is evidenced by minimum width of the dark sector on the fluorescent screen.

"Magic Voice"

This receiver is designed with a cabinet incorporating the "Magic Voice." This is accomplished by having the rear of the speaker compartment completely enclosed by a tight-fitting back.

Five metal open-end pipes of equal diameter but of three different lengths are inserted in holes in the cabinet base and extend upward in the speaker compartment. The effect is to cause the lower-frequency waves, reaching the front of the cabinet through the pipes, to arrive approximately in-phase with the sound waves emitted from the front of the speaker giving extended low-frequency response without boominess, or cabinet resonance.

SERVICE DATA

The various diagrams in this booklet contain such information as will be needed to locate causes for defective operation if such develops. The values of the various resistors, capacitors, coils, etc., are indicated adjacent to the symbols signifying these parts on the diagram. Identification titles, such as C1, L2, R1, etc., are provided for reference between the illustrations and the Replacement Parts List. The coils, reactors, and transformer windings are rated in terms of their d-c resistance only. Resistance values of less than one ohm are generally omitted.

Alignment Procedure

There are seventeen adjustments required for the alignment of the oscillator, first-detector, and antenna-tuned circuits; one adjustment for the wave-trap; and eight adjustments for the i-f system. Fifteen of these adjustments are made with plunger-type air trimming capacitors and require the use of an RCA Stock No. 12636 Adjusting Tool. Each of these capacitors has a lock nut for securing the plunger in place after adjustment. The remaining eleven adjustments are made by means of screws attached to molded magnetite cores. These cores change the inductance of the particular coils in which they are inserted to provide exact alignment. All of these adjustments are accurately made during manufacture and should remain in proper alignment unless affected by abnormal conditions of climate or purported alterations for servicing, or unless altered by other means. Loss of sensitivity, improper tone quality, and poor selectivity are the usual indications of improper alignment. Such conditions will usually exist simultaneously. Correct performance of this receiver can only be obtained when these adjustments have been made by a skilled service engineer with the use of adequate and reliable test equipment. The manufacturer of this receiver has such test equipment available for sale through its distributors and dealers.

The extensive frequency range of this receiver necessitates a more or less involved method of alignment. However, if the following directions are carefully applied in the sequence given, normal performance of the instrument will be obtained.

The plunger-type air trimming capacitors have their approximate plunger settings tabulated on figure 7. If the plungers have been disturbed from their original adjustments, they may be roughly set to the specified dimensions prior to alignment.

In performing services on the "Magic Brain", the leads should be restored to their original positions, since the lead-dress is important for proper operation and dial calibration.

Precautionary Dressing of Leads for "Magic Brain" Alignment

(Refer to Figure 4)

Band "X"

1. Keep blue lead A of S1 to antenna coil L4-5 dressed away from chassis, and from yellow lead X of S1 to Antenna coil L5-6.
2. Bus lead from C10 to S1 should be as short as possible.
3. Keep blue lead A of S3 to detector coil L18-19 clear of chassis, coil shield, coil, and other leads.
4. Keep spaghetti lead C6 to X of S1 apart from spaghetti lead of C5 to A of S1, and from chassis.

Band "A"

1. Keep green lead terminal S1 to antenna coil tap L4 away from chassis, coil shield, and coil.
2. Keep spaghetti lead C5 to A of S1 apart from spaghetti lead C6 to X of S1 and from chassis.

Band "C"

Lead from C19 to oscillator coil L7 should be maintained as short and straight as possible.

For alignment, the test-oscillator frequency should be quite accurate. A convenient and reliable means of accurately checking the frequency of test oscillators, receivers, etc., is the RCA Stock No. 9972 Crystal Calibrator.

If the test-oscillator signal cannot be heard as the receiver (heterodyne) oscillator air-trimmer plunger is changed from its minimum-capacity to maximum-capacity position (receiver dial and test oscillator set to the specified frequencies, and the correct oscillator air-trimmer used) it may be an indication that the test-oscillator frequency is outside the range covered by the air-trimmer. Under such conditions, when a more accurate setting of the test oscillator cannot be determined, set the oscillator air-trimmer plungers to the approximate settings given on figure 7. Tune the test oscillator until the signal is heard in the speaker. Each of two test-oscillator settings (the fundamentals or the harmonics of which are 920 kc apart) produce a signal. The lower-frequency test-oscillator setting should be used as this places the test-oscillator (signal) frequency 460 kc below the frequency of the receiver heterodyne oscillator.

Holes are provided in the top of the r-f and antenna coil cans on some models to enable a tuning check with the RCA Stock No. 6679 Tuning Wand. The hole in the top of the detector coil can has a cinch button which must be removed before insertion of the tuning wand. When the brass end of the wand is inserted in the coil, the inductance of the coil is decreased. If this results in an increase of output, the respective air-trimmer capacitance should be decreased (plunger pulled out). If inserting the iron end of the tuning wand causes an increase in output, resulting from an increase of inductance of the coil, the respective air-trimmer capacitance should be increased (plunger pushed in). If the range of the air trimmer is not sufficient to give the desired results, the lead-dress may be changed in the particular circuit being aligned, so as to cause the circuit to resonate within the range of the trimmer. An increase in the capacity-to-ground of the circuit will be required if the iron end of the tuning wand causes an increase of signal output when the air-trimmer plunger is full-in, while a decrease in the capacity-to-ground will be required if the brass end of the tuning wand causes an increase in signal output when the air-trimmer plunger is full-out.

Two methods of alignment are applicable—one requires use of the cathode-ray oscillograph, and the other requires a voltmeter or glow-type indicator. The cathode-ray alignment method is advantageous in that the indication provided is in the form of a wave-image which represents the resonance characteristics of the circuit being tuned. This method is preferred because of the i-f characteristics of this receiver. This type of alignment is possible through use of apparatus such as the RCA Stock No. 9550 Frequency Modulator and the RCA Stock No. 9545 Cathode-Ray Oscillograph. If this equipment is not available, an approximate alignment may be performed by the output-indicator method with an instrument such as the RCA Stock No. 4317 Neon Glow Indicator attached across the loudspeaker voice coil. Alignment by this method is similar to the cathode-ray method outlined below except that the receiver volume control should be at maximum, the trimmers adjusted to peak response (with the exception of the wave-trap) and the test-oscillator sweeping operations omitted. Either of these methods require the use of a reliable test oscillator such as the RCA Stock No. 9595.

Cathode-Ray Alignment

Make alignment apparatus connections shown on figure 5. Remove the plug of the frequency-modulator cable from the test-oscillator jack. Connect the receiver chassis to a good external ground. Connect oscillograph "Vertical" input terminals as indicated on figure 5. Set oscillograph power switch to "On" and adjust "Intensity" and "Focus" controls to give a clearly defined spot, or line, on the screen. Set oscillograph "Ampl. A" switch to "On," "Vertical gain" control full-clockwise, "Ampl. B" switch to "Timing," "Range" switch to No. 2 position, and "Timing" switch to "Int." Place the "Sync." control, "Freq." control, and "Horizontal gain" control in about their mid-positions. For each of the following adjustments, the test-oscillator output must be regulated so that the image obtained on the oscillograph screen will be of the minimum size for accurate observation. The receiver volume-control setting is optional.

I-F Adjustments

(a) Turn range selector to its "Standard broadcast" (A) position and tune receiver to a position of no extraneous signals near 600 kc. Set fidelity control to counter-clockwise position. Connect the "Ant." output of the test oscillator to the grid cap of RCA-6K7 second i-f tube (with grid lead in place) through a .001-mfd. capacitor, with "Gnd." to receiver chassis. Tune the test oscillator to 460 kc and place its modulation switch to "On" and its output switch to "Hi."

(b) Turn on the receiver and test oscillator. Increase the output of the test oscillator until a deflection is noticeable on the oscillograph screen. The figures obtained represent several waves of the detected signal, the amplitude of which may be observed as an indication of output. Cause the wave-image formed (400-cycle waves) to be spread completely across the screen by adjusting the "Horizontal gain" control. The image should be synchronized and made to remain motionless by adjusting the "Sync." and "Freq." controls.

(c) Adjust the two magnetite core screws L30 and L29 (see figures 1 and 10) of the third i-f transformer (one on top and one on bottom) to produce maximum vertical deflection of the oscillographic image. This adjustment places the transformer in exact resonance with the 460 kc signal.

(d) Turn tuning tube adjustment screw R27 (see figure 1) to extreme clockwise position. Adjust output of test oscillator until the width of the dark sector on the fluorescent screen in the RCA-6E5 tuning tube is very narrow ("Magic Eye" almost closed). Adjust the two magnetite core screws L33 and L32 (one on top and one on bottom, see figures 1 and 10) of the tuning tube i-f transformer until minimum width of the dark sector on the fluorescent screen is observed. A decrease of the test-oscillator output may be necessary before the point of minimum width of the dark sector becomes apparent.

(e) The sweeping operation should follow using the frequency modulator. Shift the oscillograph "Timing" switch to "Ext." Insert plug of frequency-modulator cable in test-oscillator jack. Turn the test-oscillator modulation switch to "Off." Turn on the frequency modulator and place its sweep-range switch to "Hi."

(f) Increase the frequency of the test oscillator by slowly turning its tuning control until two separate, distinct, and similar waves appear on the screen. If only one wave appears, increase the "Freq." control on the oscillograph to obtain two waves. These waves will be identical in shape, totally disconnected, and appear in reversed positions. They will have a common base line which is discontinuous. Adjust the "Freq." and "Sync." controls of the oscillograph to make them remain motionless on the screen. Continue increasing the test-oscillator frequency until these forward and reverse curves move together and overlap, with their highest points exactly coincident. This condition will be obtained at a test-oscillator setting of approximately 575 kc.

(g) With the images established as in (f), re-adjust the two magnetite core screws L30 and L29 on the third i-f transformer so that they cause the curves on the oscillograph screen to become

RCA MFG. CO., INC.

MODEL 15K
Alignment, Part 2
Parts List

exactly coincident throughout their lengths and have maximum amplitude.

(h) Without altering the adjustments of the apparatus, shift the "Ant." output of the test oscillator to the grid cap of the RCA-6K7 first i-f tube (with grid lead in place), through a .001-mfd. capacitor. Regulate the test-oscillator output so that the amplitude of the oscillographic image is approximately the same as used for adjustment (g) above.

(i) The two second i-f transformer magnetic core screws L26 and L27 (one on top and one on bottom) should then be adjusted so that they cause the forward and reverse curves to become coincident throughout their lengths and have maximum amplitude.

(j) Without altering the adjustments of the apparatus, shift the "Ant." output of the test oscillator to the input of the i-f system, i.e., to the grid cap of the RCA-6L7 first-detector, (with grid lead in place) through a .001-mfd. capacitor. Regulate the test-oscillator output to the amplitude of the oscillographic image is approximately the same as used for adjustment (i) above.

(k) The two first i-f transformer magnetic core screws L25 and L24 (one on top and one on bottom) should then be adjusted so that they cause the forward and reverse waves to become coincident throughout their lengths and have maximum amplitude.

(l) Note width of oscillographic image at a point which is 50% of maximum amplitude. Turn receiver fidelity control to extreme clockwise position. Note width of oscillographic image at a point which is 50% of maximum amplitude. Under normal conditions the latter measurement should be approximately 60% greater in width than the former measurement. The image should also appear slightly double humped. These conditions indicate proper broadening of the band width of the i-f amplifier. Turn range selector to "Medium wave" (B) band and note increase of amplitude. The amplitude should increase several times. It may be necessary to decrease output of test oscillator to keep image on screen. Turn receiver fidelity control to extreme counter-clockwise position and proceed to "R-F Adjustments."

R-F Adjustments

Make receiver dial adjustments as outlined by "Selector dial," figure 12. Alignment must be made in sequence of "Wave-trap," "Ultra short wave" band, "Short wave" band, "Medium wave" band, "Standard broadcast" band, and "Long wave" band.

"Wave-Trap" Adjustment

(a) Connect the "Ant." output of the test oscillator to the antenna terminal "A1" through a 200-mmfd. (important) capacitor. Remove the plug of the frequency-modulator cable from the test-oscillator jack. Turn test-oscillator modulation switch to "On." Shift the oscillograph "Timing" switch to "Int." Place receiver range selector in "Standard broadcast" position. Set the receiver dial to a position of no extraneous signals near 600 kc. Tune the test oscillator to 460 kc. Adjust the wave-trap magnetic core screw L1 to the point which causes minimum amplitude of output (maximum suppression of signal) as shown by the waves on the oscillograph. An increase of the test-oscillator output may be necessary before this point of minimum amplitude, obtained by correct adjustment of wave-trap screw, becomes apparent on oscillograph screen.

"Ultra Short Wave" Band

(b) Connect the "Ant." output of the test oscillator to the antenna terminal "A1" of the receiver through a 300-ohm resistor. Set the receiver range selector to its "Ultra short wave" position and its dial pointer to 57,000 kc. Adjust the test oscillator to 19,000 kc. The third harmonic of 19,000 kc is used for this adjustment.

Adjust oscillator air-trimmer C21 for maximum (peak) output. Two positions, each producing maximum output, may be found. The position of minimum capacitance (plunger near out) should be used. This places the receiver heterodyne oscillator 460 kc higher in frequency than the incoming signal. Tighten lock nut. Adjust the detector air-trimmer C39 while slightly rocking the gang tuning condenser back and forth through the signal, for maximum (peak) output. Two peaks may be found on this trimmer. The peak of maximum capacitance (plunger near in) should be used. Tighten lock nut. Adjust the antenna air-trimmer C10 for maximum (peak) output while slightly rocking the gang tuning condenser back and forth through the signal. Two peaks may be found on this trimmer which produce maximum output. The peak with maximum capacitance (plunger near in) should be used. Tighten lock nut. Check the image frequency by changing the receiver dial setting to 56,080 kc. If the image signal is received at this position, the adjustment of the oscillator air-trimmer C21 has been correctly made. No adjustments should be made while checking for the image signal.

(c) Re-tune receiver for maximum response to the 57,000 kc input signal (not image response) without disturbing test-oscillator adjustments. Change test oscillator to 6,000—14,000 kc range. Tune test oscillator until signal is heard in speaker (should occur at approximately 14,250 kc, fourth harmonic of test oscillator used). Two test-oscillator settings (230 kc apart) will produce a signal at this point. The lower frequency test-oscillator setting should be used as this places the test-oscillator harmonic 460 kc below the frequency of the receiver heterodyne oscillator. Tune receiver for maximum response at a dial setting of approximately 28,500 kc (image should tune in at a dial setting approximately 27,580 kc) without altering test-oscillator adjustment. Test oscillator second harmonic of 14,250 kc is used for the following check. Check calibration of receiver-dial. A receiver-dial reading of less than 28,500 kc indicates that the inductance of the oscillator secondary coil L11 is too low and should be increased. If the receiver dial reading is greater than 28,500 kc, the inductance of L11 is too high and should be decreased. If it is necessary to change the inductance of L11, first remove bottom cover of "Magic Brain" and then set receiver dial pointer to 28,500 kc. To decrease inductance, move the grounded ends (straps) of L11 and L12 (see figure 4) nearer chassis. Do not allow straps to touch chassis except where connected. To increase inductance, move the straps farther away from chassis. Adjust position of straps until maximum (peak) output results. The alignment of the detector tuned circuit should next be checked at 28,500 kc without changing either the receiver or test-oscillator adjustments. An increase of output when the brass end of a tuning wand is brought near L22 indicates that L22 is too high in inductance, while an increase when the iron end is brought near the coil indicates that the inductance is too low. The inductance of L22 may be varied by changing the spacing between the grounded end (strap) of L22 and the strap connected from C41 to contact on S2 (figure 4). An increase of spacing will increase the inductance, while a decrease of spacing will decrease the inductance. Adjust the spacing until maximum (peak) output results. Replace "Magic Brain" bottom cover and repeat adjustments in (b) prior to those of "Short wave" band.

"Short Wave" Band

(d) Set the receiver range selector to its "Short wave" position and its dial pointer to 20,000 kc. Adjust the test oscillator to 20,000 kc. Adjust oscillator air-trimmer C15 until maximum (peak) output is reached. Two peaks may be found with this circuit. The peak with minimum capacitance (plunger near out) should be used. Tighten lock nut. Adjust detector air-trimmer C35 until maximum (peak) output is reached, while slightly rocking the gang tuning condenser back and forth through the signal. Two peaks may be found with this circuit. The peak with maximum capacitance (plunger near in) should be used. Tighten lock nut. Adjust antenna air-trimmer C3 until maximum (peak) output is reached while slightly rocking the gang tuning condenser back and forth through the signal. Two peaks may be found with this circuit. The peak with maximum capacitance (plunger near in) should be used. Tighten lock nut. Check the image frequency by changing the receiver dial setting to 19,080 kc. The image signal should be received at this position indicating that the adjustment of C15 has been correctly made. No adjustments should be made while checking for the image signal.

"Medium Wave Band"

(e) Place receiver range selector to its "Medium wave" position with its dial pointer set to 6,000 kc. Tune the test oscillator to 6,000 kc. Adjust oscillator air-trimmer C14 to produce maximum (peak) output as shown by the waves on the oscillograph. Two peaks may be found with this circuit. The peak with minimum capacitance (plunger near out) should be used. Tighten lock nut. Adjust the detector air-trimmer C36 for maximum (peak) output while slightly rocking the gang tuning condenser back and forth through the signal. Two peaks may be found with this circuit. The peak with maximum capacitance (plunger near in) should be used. Tighten lock nut. Adjust antenna air-trimmer C4 to produce maximum (peak) output. Tighten lock nut.

"Standard Broadcast" Band

(f) Remove the 300-ohm resistor from beneath the test-oscillator "Ant." post and receiver antenna terminal "A1" and insert a 200-mmfd. capacitor in its place. Place receiver range selector to "Standard broadcast" position with receiver dial pointer set to 600 kc. Tune the test oscillator to 600 kc. Adjust oscillator magnetic core screw L8 (top of large oscillator coil can) for maximum (peak) output as shown by the waves on the oscillograph screen.

(g) Set receiver dial pointer to 1,500 kc. Tune test oscillator to 1,500 kc (1,500—3,200-kc range) and increase its output to produce a registration on the oscillograph screen. Carefully adjust the oscillator, detector, and antenna air-trimmers C16, C37, and C5, respectively, to produce maximum (peak) output as shown by the waves on the oscillograph screen. Shift the oscillograph "Timing" switch to "Ext." Place the frequency modulator sweep-range switch to its "Lo" position and insert plug of the frequency-modulator cable in test-oscillator jack. Turn test-oscillator modulation switch to "Off." Re-tune the test oscillator (increase frequency) until the forward and reverse waves show on the oscillograph screen and become coincident at their highest points. This will occur at a test-oscillator setting of approximately 1,600 kc. Adjust air-trimmers C16, C37, and C5 again, setting each to the point which produces the best coincidence and maximum amplitude of the images.

(h) Remove the plug of the frequency-modulator cable from the test-oscillator jack. Turn test-oscillator modulation switch to "On." Set oscillograph "Timing" switch to "Int." Tune test oscillator to 200 kc (200—400-kc range). Tune receiver for maximum response to this signal at a dial reading of approximately 600 kc. The third harmonic of the 200-kc signal is used for this adjustment. Shift oscillograph "Timing" switch to "Ext." Insert the plug of the frequency modulator cable in test-oscillator jack. Turn test-oscillator modulation switch to "Off." Re-tune the test oscillator (increase frequency) until the forward and reverse waves show on the oscillograph screen. This will occur at a test-oscillator setting of approximately 230 kc. Disregarding the fact that the two images may or may not come together, adjust the oscillator magnetic core screw L9 (top of large oscillator coil can) to produce maximum (peak) amplitude of the images. Shift the oscillograph "Timing" switch to "Int." Remove the plug of the frequency-modulator cable from the test-oscillator jack. Turn the test-oscillator modulation switch to "On." Repeat adjustments in (g) above to compensate for any changes caused by the adjustment of L9 core, tightening lock nuts on C16, C37, and C5, respectively, after each is adjusted.

"Long Wave" Band

(i) Shift the oscillograph "Timing" switch to "Int." Remove the plug of the frequency-modulator cable from the test-oscillator jack. Turn the test-oscillator modulation switch to "On." Place receiver range selector to its "Long wave" position. Set the receiver dial pointer to 175 kc. Tune the test oscillator to 175 kc and increase its output until a deflection is noticeable on the oscillograph screen. Adjust oscillator magnetic core screw L10 (located on top of small oscillator coil can) so that maximum (peak) amplitude of output is shown on the oscillograph screen.

(j) Set receiver dial pointer to 350 kc. Tune test oscillator to 350 kc. Adjust the oscillator, detector, and antenna air-trimmers C18, C38, and C6 to produce maximum (peak) output as shown by the waves on the oscillograph screen. Without disturbing the connections, shift the oscillograph "Timing" switch to "Ext." Place the frequency-modulator sweep-range switch to its "Hi" position and insert plug of frequency-modulator cable in test-oscillator jack. Turn test-oscillator modulation switch to "Off." Re-tune the test oscillator (decrease frequency) until the forward and reverse waves show on the oscillograph screen and become coincident at their highest points. This will occur at a test-oscillator setting of approximately 190 kc. This setting places the test-oscillator frequency to 175 kc. The second harmonic is now used for the 350 kc adjustment. Adjust air-trimmers C18, C38, and C6, again, to produce maximum amplitude of the images where they best coincide throughout their lengths.

(k) Re-tune the receiver to approximately 175 kc so that the forward and reverse waves appear on the oscillograph screen. Adjust the oscillator magnetic core screw L10 to produce maximum (peak) amplitude of the waves, disregarding the fact that the two images may or may not come together.

(l) Shift the receiver dial setting to 350 kc without altering any other adjustments (frequency modulator still in operation). Adjust air-trimmers C18, C38, and C6, respectively, to produce maximum amplitude and best coincidence of the waves. These adjustments compensate for any changes caused by the adjustment of the magnetic core screw L10. Tighten lock nuts on C18, C38, and C6, respectively, after each is adjusted.

Tuning Tube Adjustment

An adjustment, R27, is provided on the rear apron of chassis (see figure 1) for regulating the sensitivity of the tuning tube ("Magic Eye"). Adjustment may be performed by first tuning in the strongest local station and then turning adjusting screw until the width of the dark sector on the fluorescent screen of the RCA-6E5 tuning tube is very narrow ("Magic Eye" almost closed). No other adjustment is necessary.

Phonograph Terminal Board

A terminal board is provided for connecting a phonograph into the audio amplifying circuit. Typical methods of connecting a low-impedance pickup, or the RCA Victor Models R-93, R-93-2, and R-93-3 Record Players are shown on the Schematic Diagram (figure 2).

Loudspeaker

Centering of the loudspeaker voice coil is made in the usual manner with three narrow paper feelers after first removing the front paper dust cover. This may be removed by softening its cement with a very light application of acetone using care not to allow the acetone to flow down into the air gap. The dust cover may be cemented back in place with ambroid upon completion of adjustment.

Antenna and Ground Terminals

These receivers are equipped with an antenna-ground terminal board having three terminals. These terminals are marked "A2," "A1," and "G," the latter being the ground terminal and should always be connected to a good external ground. The transmission-line leads of the RCA RK-40A antenna system should be connected to terminals "A2" and "A1." The receiver coupling units of the RCA RK-40 and the RCA Spider-Web antenna systems should be connected to terminals "A1" and "G." Connect a single-wire antenna to terminal "A1."

Selector Dial

Figure 12 illustrates the relation of the various parts of the dial mechanism when in its "Standard broadcast" position with the range switch likewise turned to its "Standard broadcast" position. In re-assembling the dial after repairs, see that the gears are meshed in accordance with the diagram, at the same time noting that the range switch is in its "Standard broadcast" position and the lever attached to the range-switch shaft placed in the position shown.

To adjust the dial mechanism, set the range switch to its "Standard broadcast" position. Place a straight-edge across the center of the dial so that its edge is even with the lower (end) marking at both the low-frequency and high-frequency ends of the dial. Under such conditions the straight-edge should be parallel with the top of the chassis base. If the straight-edge is not parallel with the top of the chassis base, loosen the nut on the rear of the roller link pivot stud and move the stud up or down until the link roller moves the dial to the desired position so that the end calibration marks obtain the position mentioned above. Tighten the nut on the roller link pivot stud.

Set the gang tuning condenser to its maximum capacity position. Adjust the dial pointer to the low-frequency (end) mark on "Standard broadcast" scale. This is a friction adjustment.

With the gang tuning condenser plates still in full mesh, loosen the two set screws on the vernier-dial hub. Rotate the vernier dial until the "0" marking is in a vertical plane above the center of the shaft. Tighten set screws.

REPLACEMENT PARTS

Stock No.	Description	List Price
	RECEIVER ASSEMBLIES	
[illegible]	Board—Phonograph terminal board	$0.25
[illegible]	Bracket—Mounting bracket for [illegible] switch	.15

RCA VICTOR MODELS C11-3, C13-3, AND C15-4
AND SUPPLEMENT TO
RCA VICTOR MODELS C11-1, C13-2, AND C15-3
TECHNICAL INFORMATION AND SERVICE DATA

With the exception of the cabinets, Models C11-3, C13-3, and C15-4 are respectfully identical to Models C11-1, C13-2, and C15-3 (with metal rectifiers). Schematic and Wiring Diagrams for metal rectifier socket are shown by Figures 1 and 2. Other information is as follows:

Models C11-1 and C11-3 (with metal rectifier).
Service Data for Model C11-1 are directly applicable to these instruments, except the parts listed below as Substitute and Additional Replacement Parts. Replacement Part changes applying to all Models C11-1 and C11-3 are:
(1) Change description of Stock No. 8053 to read:
Indicator—Station selector vernier indicator pointer.
(2) Capacitor C24 should be replaced with Stock No. 4886 instead of Stock No. 4858.
(3) Add Stock Nos. 4886, 11710, and 11793 as listed below.

Models C13-2 and C13-3 (with metal rectifier).
Service Data for Model C13-2 are directly applicable to these instruments, except the parts listed below as Substitute and Additional Replacement Parts. Replacement Part changes applying to all Models C13-2 and C13-3 are:
(1) Change description of Stock No. 8053 to read:
Indicator—Station selector vernier indicator pointer.
(2) Capacitor C60 should be replaced with Stock No. 4886 instead of Stock No. 4883.
(3) Add Stock Nos. 4886, 11710, and 11793 as listed below.

Models C15-3 and C15-4 (with metal rectifier).
Service Data for Model C15-3 are directly applicable to these instruments, except the parts listed below as Substitute and Additional Replacement Parts. Replacement Part changes applying to all Models C15-3 and C15-4 are:
(1) Change description of Stock No. 8053 to read:
Indicator—Station selector vernier indicator pointer.
(2) Capacitor C47 should be replaced with Stock No. 4870 instead of Stock No. 4858.
(3) Add Stock Nos. 4870, 11710, and 11793 as listed below.

MODEL R-93
Connection Data
Pickup Data,Parts

RCA MFG. CO., INC.

General Description

This phonograph turntable and pickup assembly is designed to provide record reproduction to the owner of a modern radio receiver by utilizing the audio amplifier system and loudspeaker of the radio receiver in such a way as to provide quality of reproduction equal to or better than that obtained from radio stations. A switch is provided for changing from radio to record reproduction, or vice versa. Simplicity, compact size, and ease of connections are outstanding features of this instrument.

Electrically, the instrument consists of a magnetic pickup for transforming the mechanical variations of the record grooves to voltage variations, a combined power switch and volume control for turning power on and off and adjusting the output voltage to any desired level, and a radio-record switch for shifting the connections to the receiver so that either radio or record reproduction may be obtained as desired by the user.

Figure 1 shows a typical layout of an ideal installation. Figure 3 shows the schematic and wiring diagrams. The wiring diagram indicates the proper connections to be made between the pickup unit, the switch assembly, and the end of the cable connecting to the switch.

Connecting Phonograph to the Radio Receiver

When connecting a phonograph unit to a radio receiver, a few fundamental facts should be considered. First, the output of the pickup must be connected to the receiver at a point where sufficient audio gain between it and the speaker is available to give normal sound output. Second, when doing this, some attention should be given to the possibilities of introducing hum and undesired noise, both in the audio and in the radio circuits.

In general, it will be found that the grid or cathode circuits of the second detector of a superheterodyne receiver are suitable for phonograph input. However, on receivers using the type 6H6 as a second detector, the grid of the first audio amplifier should be used. On tuned r-f receivers, either the detector cathode or the first audio transformer primary circuit may be employed, depending upon the amount of audio gain and the type of detector used.

On receivers employing a volume control in the audio circuit between the first and second audio stages, it is advisable to set the phonograph volume control to maximum and use the radio receiver volume control for adjusting the phonograph output. In circuits of this type which are aurally compensated, advantage is taken of the compensation feature when the radio receiver volume control is used.

On receivers employing a volume control between the second detector and first audio, or in the antenna, r-f, or i-f circuits, and with the phonograph input connected to the first a-f stage, it will be necessary to control the phonograph output by using the phonograph volume control. The receiver volume control may then be set to minimum to "kill" radio reception.

Investigation of a large number of receivers has shown that six general types of connections (five of which may be made without removing the chassis from the cabinet) cover practically every type of receiver. These connections are as follows:

(1) Receivers having phonograph input jacks and Radio-Record Switches. With these receivers, the cable and switch supplied with the R-93 are not used. The phonograph output is connected direct to the phonograph input jack and the Radio-Record Switch on the receiver is used for changing from Record to Radio reproduction.

(2) Receivers having phonograph terminal board connections. Such connections should be made in accordance with the instructions pertaining to that particular instrument.

(3) Receivers using the type 2B7 or 6B7 second detectors. With receivers of this type, the yellow and green leads are connected in series with the grid cap connection of this tube, the green lead connected to the grid cap itself.

(4) Receivers using the type 6F5 as a first audio tube. On receivers of this type, the yellow and green leads are connected in series with the grid cap connection of this tube, the green lead connected to the grid cap itself.

(5) Receivers not having any of the foregoing features. On receivers of this type, a split cathode connection is necessary. Stock No. 4611 five-prong adapter, or Stock No. 4612 six-prong adapter, may be used which is placed under the tube used in the second detector socket of the receiver. Stock No. 11957 eight-prong "octal" adapter may be placed under the first audio tube, such as the type 6C5. In the above cases, the yellow and green leads are connected in series with the cathode, the green lead connected to the tube cathode and yellow lead to the cathode socket contact.

(6) Under Chassis Connections. The above connections (3), (4), and (5), are recommended when it is desired to connect the R-93 without removing the chassis and making changes in its wiring. Better results may often be obtained by making permanent connections underneath the chassis. Additional parts (such as a cathode bias resistor and its by-pass capacitor) may be added to supply the necessary bias for phonograph operation when the stage is signal biased. A typical example of such an arrangement as recommended for Model C 15-3 is shown by Figure 2. (Note the additional jumpers added to the switch for killing radio.) All leads should be kept as short as possible and properly shielded. Also, care should be taken in the placement of leads in regard to a-c heater wiring, power transformer, etc., to prevent hum pickup. Receivers using a multi-purpose tube for i-f and second detector (such as Model T 4-8), the yellow and green leads should be connected in series with the detector grid; the connection being made in series with the ground side of the i-f transformer secondary to avoid detuning due to capacity effects.

It will be noted that red and blue leads are brought out from the switch for "killing" the radio circuit during record reproduction. On early receivers, these may be connected in series with the antenna lead to open the antenna circuit during phonograph operation. In the event of unsatisfactory radio suppression with this connection, better results may be obtained by re-connecting the red and blue leads to the adjacent respective lugs on the Radio-Phono Switch and attaching the outer ends to the Ant.-Gnd. terminals of the receiver so as to short-circuit these terminals during phonograph operation. CAUTION: This scheme of connection should be avoided on AC-DC receivers unless a small capacitor (.05 mfd.) is used in series with either switch lead.

For most positive radio suppression, a split cathode adapter should be used in an i-f socket and the red and blue leads connected (standard connection at Radio-Phono Switch) in series with the cathode so that this circuit will be open for phonograph operation.

If the receiver is of the "All-Wave" type, it is recommended that a split cathode adapter always be used in an i-f socket. CAUTION: If a "Doublet" antenna is used, do not place the switch in series with either side of the transmission line as the operation of the antenna system may be affected.

On the preceding page, a list of numerous receivers and their proper connections are given.

RK-24 Phonograph Oscillator

In addition to the above recommended connections of the R-93 to radio receivers, the RCA Stock No. 9554 RK-24 Phonograph Oscillator provides a convenient and reliable means for connection and operation of the R-93 with a radio receiver of any type of manufacture. Its proper connections are shown in the RCA Victor RK-24 Service Notes.

Phonograph Motor Service Data

NOTE: The motor used in the Second Production R-93 turntables is somewhat different from that used in the First Production. They are hereinafter designated as (1) First Production and (2) Second Production. Changes denoting the difference between the two types are indicated in Figure 5 (First Production) and Figure 6 (Second Production). Replacement Parts are likewise tabulated separately for each type.

The synchronous motor used in this instrument is designed to be simple and foolproof. Among its many features are constancy of speed, low power consumption, single moving part, ease of starting, viscoloid damper and long life. The main parts of the motor and the points that may require attention are shown by Figure 5 (First Production) and Figure 6 (Second Production). The motor is started by turning "On" the power switch and giving the turntable a clockwise spin with the hand. If the motor is difficult to start it may be due to the stator failing to rotate on the outer bearing. This may be corrected by applying a slight amount of oil to the bearing surfaces. It is very important that the ball bearing be at the bottom of the main bearing assembly.

Excessive Hum and Vibration

A small amount of hum when starting, decreasing to a negligible amount while running, is normal. If excessive vibration occurs either at starting or running, it may be due to one of the following:

(1) Insufficient lubrication in outer bearing or any other failure that will cause the stator to bind.
(2) Metal washer not above the leather washer at the bottom of the main bearing.
(3) Leather washer not oiled. When replacing the leather washer, make sure that it is thoroughly soaked in oil.
(4) Motor not properly supported from motor board. Unless the motor is properly supported from the motor board, normal vibration will be excessive.
(5) Burrs on salient poles of rotor or stator. They should be removed with fine emery cloth.

Removing Rotor from Stator

The rotor which includes the turntable may be removed as follows:

(1) First Production. Loosen the screw shown in Figure 5 until it clears the rotor. Then lift the turntable, being careful not to lose the steel ball of the end-bearing. After replacing the rotor, tighten the retaining screw securely.
(2) Second Production. Loosen the nut shown in (5) of Figure 6, pushing the stop out of the slot and rotating 180 degrees. Then lift the turntable, being careful not to lose the ball end-bearing. After replacing the rotor, return the stop to its normal position and tighten the nut securely.

PICKUP UNIT SERVICE DATA

The magnetic pickup and tone arm assembly of this instrument is of new design and unique construction. Service work will consist of centering the armature and replacing the spacer cushions, damping block, and replacing the magnet coil.

Dissembling the Pickup

The pickup may be dissembled in the following manner.

(a) Unsolder the two cable connections to the terminal strip.
(b) Remove the needle screw and screws "A" and "B."
(c) Remove the pickup assembly from the arm and housing.
(d) Unsolder the two magnet coil leads attached to the terminals and then remove screw E. This will allow the removal of the terminal board.
(e) If centering the pickup armature is the only adjustment required, such centering can be done without removing the terminal board indicated in (d). The armature is centered by loosening screw F, accessible through the hole shown, and holding the armature with the finger in proper position while screw F is tightened. "Feeling" the armature while deflecting it between its two extremes is the best manner of ascertaining proper centering. When centering, after work has been done or the magnet removed, it is important that the magnet be remagnetized while in place.
(f) If the coil or spacer cushions are to be replaced, the pickup must be further disassembled. This is done by removing the magnet and then removing screws C and D. The pole piece may now be removed and the old coil and sleeve disassembled. Acetone will be found helpful for dissolving the old cement that holds the coil in place. The new coil, with its sleeve, may now be replaced and cemented in a similar position to that occupied by the old coil. Duco household or Ambroid cement may be used to hold the coil in place. Be careful to center the coil with its paper sleeve before cementing. Only rosin core solder should be used for soldering the coil leads in the pickup.
(g) The spacer cushions are replaced by loosening the armature adjusting screw F and removing screw G, clamp H and washer I and removing the armature from its bracket. Damping block J must be removed from the armature. After putting the new spacer cushions in place, a new damping block should be fastened to the armature as outlined in instructions on replacing the damping block. The cushions can then be removed by slipping them from each end of the pivot shaft.

Replacing the Damping Block

If it is desired to replace the damping block, it may be done in the following manner:

(a) Disassemble the pickup as described under the preceding section.
(b) Remove the damping block from the armature and clean the armature shaft with emery paper.
(c) Insert the armature through the new block so that it occupies the same position as that of the old. Also ascertain that the block is in correct vertical alignment with the armature. It will be noted that the hole in the damping block is somewhat smaller than the shaft diameter. This is done so that a snug fit will be obtained.
(d) After properly locating the damping block, a soldering iron should be applied to the armature so that the block will melt slightly at its point of contact with the armature. A special tip, constructed as shown in Figure 8, will prove desirable for fusing the block in place. The iron should be applied only long enough to melt the block sufficiently to cause a small bulge on each side, and must be removed before any bubbling occurs. The pickup should then be reassembled.

It is important to remember that in all operations after reassembling but before placing in the tone arm, the pickup should be magnetized and the armature centered after remagnetizing. Magnetizing should be done by placing the pickup magnet on the magnetizer and sliding it onto the pole pieces, after magnetizing being careful not to break the magnetic circuit.

10194	Ball—Steel ball bearing—Package of 20	$0.15
7657	Base—Motor base and bearing assembly—50-60 cycle—105-115/200-250 volt operation	1.20
9523	Base—Motor base and bearing assembly—25 cycle operation	1.20
9519	Coil—Stator assembly—Comprising coil and laminations—105-125 volt, 60 cycle operation	2.50
9511	Coil—Stator assembly—Comprising coil and laminations—105-125 volt, 50 cycle operation	2.35
9514	Coil—Stator assembly—Comprising coil and laminations—105-125 volt, 25 cycle operation	2.35
9529	Coil—Stator coil assembly—Comprising coil and laminations—50 cycle, 200-250 volt operation	2.50
9515	Motor—105-125 volts—60 cycle motor	8.80
9516	Motor—105-125 volts—50 cycle motor	8.42
9517	Motor—105-125 volts—25 cycle motor	9.00
9528	Motor—200-250 volts—50 cycle motor	9.60
4456	Motor accessories—Comprising 3 nuts, 1 shield and 1 screw	.10
3813	Motor suspension assembly—Comprising one screw, one metal bushing, two rubber bushings, one flat washer, one lockwasher and one nut—Package of 5	.56
4457	Spring, screw and washer assembly—Used to mount rotor laminations to turntable—Comprising 3 springs, 3 screws and 9 washers	.15
9520	Turntable—Turntable assembly complete with rotor laminations—60 cycle operation	4.45
9525	Turntable—Turntable assembly complete with rotor laminations—25 cycle operation	4.85
9522	Turntable—Turntable assembly complete with rotor laminations—105-125/200-250 volt—50 cycle operation	4.15
4083	Washer—Leather washer—Package of 10	.20
4084	Washer—Metal washer—Package of 10	.26
	MOTOR ASSEMBLIES SECOND PRODUCTION	
10194	Ball—Steel ball bearing—Package of 20	.15
11740	Base—Motor base and bearing assembly	1.45
11733	Coil—Stator assembly—Comprising coil and laminations—105-125 volt, 60 cycle operation	2.96
11734	Coil—Stator assembly—Comprising coil and laminations—105-125 volt, 50 cycle operation	3.08
11748	Damper—Motor damper assembly—Comprising one damper, one damper plate, one screw, two rubber washers, and one "C" washer	.20
11873	Motor—105-125 volts—60 cycle motor	9.95
11874	Motor—105-125 volts—50 cycle motor	9.95
4456	Motor accessories—Comprising 3 nuts, 1 shield and 1 screw	.10
11876	Turntable—Turntable assembly complete with rotor laminations—60 cycle operation	4.35
11875	Turntable—Turntable assembly complete with rotor laminations—50 cycle operation	4.35
4083	Washer—Leather washer—Package of 10	.20
4084	Washer—Metal washer—Package of 10	.26
	PICKUP AND ARM ASSEMBLIES	
3812	Armature—Pickup armature	.32
4462	Cable—Pickup cable	.20
3810	Coil—Pickup coil	.32
3091	Cushion—Pickup armature spacer cushion—Package of 10	.50
4543	Damper—Damper block complete with damper clamp, washer	.10
4503	Pickup and arm assembly complete	4.95
3811	Screw—Needle holding screw—Package of 10	.46
	CABINET ASSEMBLIES	
X-249	Bottom—Lower section of wood cabinet	2.95
X-248	Cover—Top half of wood cabinet	3.00
	MISCELLANEOUS ASSEMBLIES	
4611	Adaptor—Five-prong split cathode adaptor	1.00
4612	Adaptor—Six-prong split cathode adaptor	1.00
11957	Adaptor—Eight-prong "octal" split cathode adaptor with ground lug	1.00
4461	Cable—5-conductor—Radio-Record switch cable	.28
4459	Bracket—Volume control mounting bracket	.10
4463	Foot—Felt foot for bottom cover—Package of 10	.20
3829	Knob—Radio-Record switch knob—Package of 5	1.10
3961	Knob—Volume control knob—Package of 5	.60
4458	Post—Binding post—Package of 10	2.50
4507	Rest—Pickup rest—Package of 5	.60
4119	Screw—No. 8-32-1/4-inch headless set screw for knob—Package of 20	.18
4480	Switch—Radio-Record switch	.40
4502	Volume control (R1)	1.14

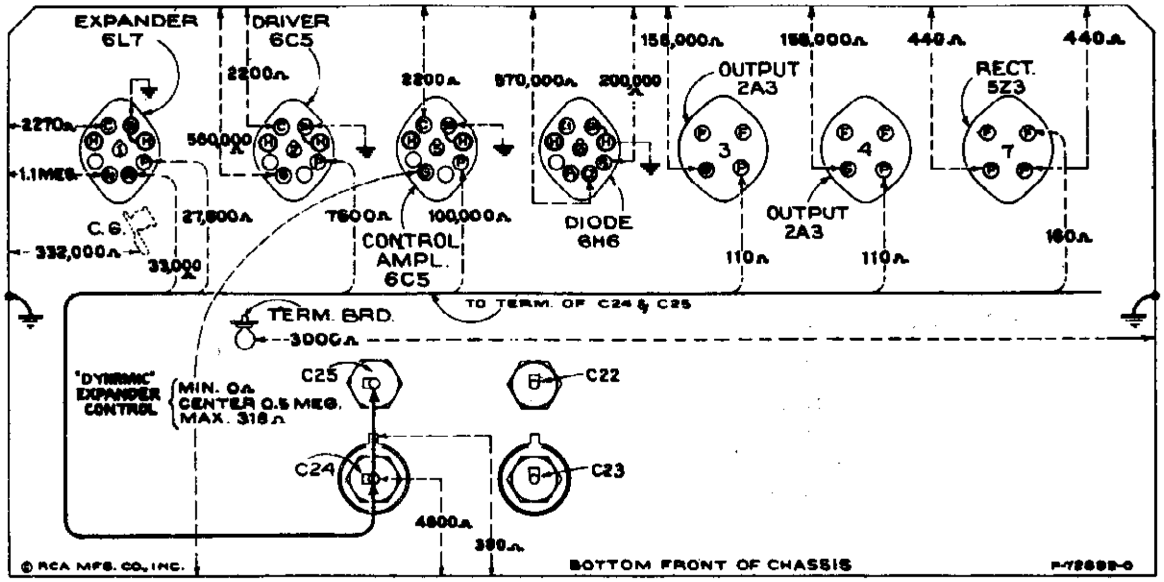

Figure 5—Resistance Diagram

Power supply disconnected—Radiotrons in sockets

The resistance values shown between Radiotron socket contacts, grid caps, resistors, terminals, and amplifier chassis ground, on figure 5, have been carefully selected so as to facilitate a rapid continuity check of the circuits. The use of this diagram in conjunction with the Schematic Circuit Diagram, figure 1, and Chassis Wiring Diagram, figure 2, will permit the location of certain troubles which might otherwise be difficult to ascertain. Each value as specified should hold within ±20%. Variations in excess of this limit will usually be indicative of trouble in circuit under test. When measuring the resistance between points of the circuit and ground, it will be necessary to connect the negative terminal of the resistance meter to chassis-ground. If the polarity of the resistance meter is not known, it may be readily ascertained by connecting a d-c voltmeter of indicated polarity across the terminals of the device.

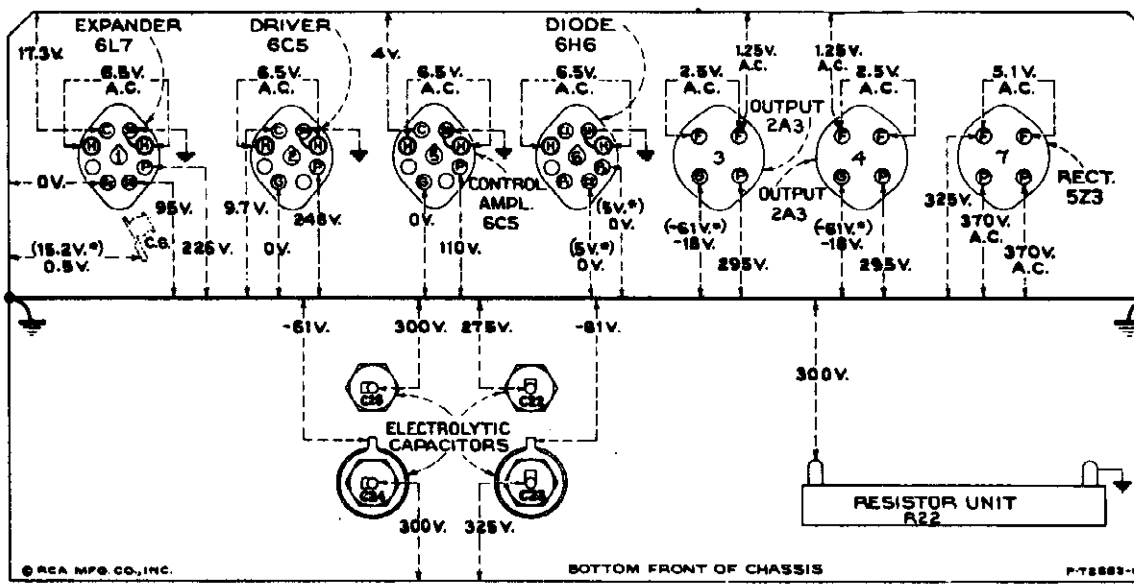

Figure 7—Radiotron Socket Voltages

Measured at 120 volts on 120-volt tap, rated frequency—Volume control minimum—
Expander "Dynamic" control minimum—Dynamic amplifier adjusted as per text—No signal

***Note:** Two voltage values are shown for some readings. The higher value shown in parenthesis with asterisk (*) indicates operating conditions without voltmeter loading. The lower value is the actual measured voltage and differs from the higher value because of the additional loading of the voltmeter through the high series circuit resistance.*

The voltage values indicated from the Radiotron socket contacts, grid caps, resistors, and terminals to amplifier chassis ground on figure 7 will assist in locating cause for faulty operation. Each value as specified should hold within ±20% when the amplifier is normally operative at its rated line voltage. Variations in excess of this limit will usually be indicative of trouble in the basic circuits. To duplicate the conditions under which the voltages were measured requires a 1,000-ohm-per-volt d-c meter, having ranges of 10, 50, 250, 500, and 1,000 volts. Use the nearest range above the voltage to be measured. A-c voltages were measured with a corresponding a-c meter.

General Description

The RCA Victor Model R-99 High-Fidelity Electrola comprises the ultimate in present-day record reproduction. It consists of the revolutionary dynamic expander; a high-quality, high-power output, power amplifier; a 12-inch, aluminum voice-coil, electrodynamic loudspeaker with a high-frequency tone diffuser; a light weight, high-fidelity pickup; an acoustically tapered volume control; a spring-balanced tone arm; a powerful synchronous motor; and a high audio-frequency tone control. The instrument will play either 10- or 12-inch records.

Dynamic Amplifier

Limitations imposed by present methods of disc recording necessitate a constricted range of sound intensity which may be recorded. The minimum intensity of sound which may be recorded is determined by unavoidable record surface-noise which masks the recorded sound when such sound approaches the intensity of the noise. The maximum sound intensity which may be recorded is determined by the thickness of the record groove wall into which the record cutting stylus makes an impression of the original sound. The amplitude of the lateral cutting is, therefore, regulated so that the stylus will not break over into the adjacent groove. It is because of these upper and lower limits that the volume range of sound reproduction cannot be identical to the original sound which is produced in the recording studio. In order to keep the recorded sound within the limits of the record, the recording control engineer regulates the recording amplifiers accordingly.

The dynamic amplifier of this reproducing instrument is designed to compensate for the above-mentioned recording limitations of volume range. It serves to restore the original intensity relations of the recorded sound by varying the amplification of the reproducing amplifier in direct accordance with the average intensity value of the sound. Thus, when there is a prevailing rise in the intensity of the recorded sound, the dynamic amplifier increases in gain accordingly, producing a further increase in volume, and conversely when there is a prevailing tendency toward a decrease of the recorded sound the dynamic amplifier decreases in gain, and produces a further decrease in volume. The functions of the dynamic amplifier are particularly advantageous in the reproduction of symphonic and certain other types of music where very great ranges of sound intensity are encountered. The dynamic amplifier causes the very loud or fortissimo, and the very soft or pianissimo passages to be reproduced in their natural relations, although they may have been somewhat modified in the actual recording on the record.

Power Amplifier

In order that the dynamic amplifier may bring about its designed purpose, the amplifier and reproducing system into which it works must have an undistorted range of amplification consistent with the degree of volume expansion provided in the dynamic amplifier. The power amplifier is, therefore, designed to have a maximum output of 15 watts.

Loudspeaker

The 12-inch dust-proof electrodynamic loudspeaker provided with this unit is of massive design. It is constructed with an aluminum voice coil, which permits the weight of the moving unit to be greatly reduced, with consequent increase of the frequency range. A high-frequency tone diffuser is provided in front of the cone of the loudspeaker unit to disperse the higher frequency sound waves over a wide acoustic angle instead of being emitted in a concentrated beam directly in front of the unit.

Pickup

The magnetic pickup and tone arm assembly is of an improved design. It is constructed with a short and very light armature for the most delicate response. The tone arm is spring-balanced, allowing the effective weight of the pickup on the record to be materially reduced.

Electrical Circuits

The circuits consist of a phonograph pickup with compensating filters, dynamic expander stage, expander amplifier stage, expander diode-rectifier stage, audio driver stage, push-pull power output stage, and a full-wave rectifier.

The electrical impulses, generated in the pickup coil L1, are boosted in the input transformer T2 before they are fed to the dynamic amplifier. A compensation filter is placed in shunt with the output of T2 to correct the frequency response of the reproducing system so as to compensate for the recording characteristic.

Dynamic Amplifier

The signal from the input transformer T2 is applied to control grid No. 1 of the RCA-6L7 (expander) through the acoustically tapered volume control R4, and is simultaneously applied through the expander control R14 to the control grid of the first RCA-6C5 (expander amplifier). The signal applied to this latter tube is first amplified and then fed to the RCA-6H6 (expander diode-rectifier) tube where it is rectified. The output of the RCA-6H6 is of the nature of a pulsating direct current, the amount varying in direct relation with the average value of intensity of the audio signal. This pulsating voltage appears across resistor R18 and is applied to the second control grid of the RCA-6L7 (expander) through a delay filter (R7 and C7). The value of the bias on this control grid determines the amplification of the RCA-6L7 expander stage. The gain of the dynamic amplifier is, therefore, automatically regulated by the average intensity of the audio signal.

Audio Driver

The audio output of the RCA-6L7 is resistance-capacitance coupled to the control grid of RCA-6C5 audio driver. The output of this tube is shunt fed to the primary of the interstage transformer T3 by means of the reactance L3 and blocking capacitor C21. This arrangement prevents the plate current of the RCA-6C5 from flowing through the primary of T3, emitting increased fidelity.

Power Amplifier

The audio signal developed across the secondary of T3 is applied to the control grids (push-pull) of the RCA-2A3 tubes for final power amplification. The bias for these control grids is developed across the loudspeaker field winding L8 and is applied through a suitable resistance-capacitance filter. The output of the power-amplifier stage is transformer-coupled to the voice coil of the electrodynamic loudspeaker.

Power Supply

The power-supply system consists of an RCA-5Z3 rectifier tube, which is supplied from an efficiently designed power transformer, and which works into a suitable filter. The potentials required for the plate, screen, control grid, and cathode circuits are obtained from this filter. The electrodynamic loudspeaker field coil is used as a filter reactor.

SERVICE DATA

The various diagrams in the booklet contain such information as will be needed to locate causes for defective operation if such develops. The values of various resistors, capacitors, coils, etc., are indicated adjacent to the symbols signifying these parts on the diagrams. Identification titles, such as L1, C2, R1, etc., are provided for reference between the illustrations, and the Replacement Parts List. The coils, reactors, and transformer windings are rated in terms of their d-c resistance only. Resistance values of less than one ohm are generally omitted.

Dynamic Amplifier Adjustments

It is essential that correct voltages and currents exist at the RCA-6L7 audio expander stage in order that the expanding function may take place in the proper manner. A screw-driver adjustment is accordingly provided to regulate the RCA-6L7 control grid No. 2 bias to the correct operating value. Two methods of adjustment are applicable. Either method requires a normal voltage of 300 volts across the filter output (resistor R32, see figure 7). The one to be preferred (a) requires the use of the RCA Stock No. 9633 Beat Frequency Oscillator or the equivalent, a 100-ohm resistor, a 200-ohm resistor, and a 1,000-ohm-per-volt a-c voltmeter (rectifier-type) having a "low" range of 1.0 volt and a "high" range of 250 volts or greater. The less accurate method (b) requires the use of the RCA Stock No. 12333 Split Plate Adapter (supplied with instrument), and a suitable d-c milliammeter. Both of these procedures are outlined below. CAUTION: Before using either method, be sure that power-supply fuse is in proper position for the line voltage.

(a) Preferred Method.

Turn power switch (left front) off. Connect the 200-ohm and the 100-ohm resistors in series between the beat-frequency oscillator terminals (upper "250" and "CT") with the 100-ohm resistor connected to "CT." Calibrate the beat-frequency oscillator, adjust it to 1,000 cycles, and reduce its output. Connect the 1,000-ohm-per-volt a-c voltmeter (1-volt range) to the beat frequency oscillator terminals (upper "250" and "CT"). Remove the "M" plug from the "F" receptacle on the shielded cable running between the input transformer T2 and the compensator pack "Comp." (see figure 9). Connect beat-frequency oscillator terminal "CT" to the large pin on the "M" plug. Connect the junction of the 200-ohm and the 100-ohm resistors to the small pin on the "M" plug.

Adjust beat-frequency oscillator output until the voltmeter reads exactly 1.0 volt. Remove the voltmeter leads from beat-frequency oscillator terminals without disturbing any of the oscillator adjustments. Place the voltmeter to its 250-volt or greater range and connect it between the plate prongs of the two RCA-2A3 power-output tubes. Connections to the tube prongs may be made by stripping approximately ½ inch of insulation from the ends of two short leads of rubber-covered wire, wrapping one bare end around each plate prong (being careful not to allow the bare ends to short on the chassis when the tubes are placed in their sockets), and connecting the voltmeter to these leads. CAUTION: Do not touch these plate connections after the power is turned on since the potential at these points is rather high and carelessness might result in a serious shock.

Set the expander "Dynamic" control (center front) to its extreme counter-clockwise position. Set the phonograph volume control (right front) to its extreme clockwise position. Turn on power switch (left front) and rotate this control to its extreme clockwise position, allowing it to remain in this position for all adjustments. Allow a few minutes for the instrument to become stabilized. Adjust the expander bias control R20, on rear apron of amplifier (see figure 9), until the voltmeter reads 195 volts. Turn phonograph volume control to extreme counter-clockwise position. Transfer lead from the junction of the 200-ohm and the 100-ohm resistors to the beat-frequency oscillator (upper "250") terminal without disturbing any of the oscillator adjustments. Adjust phonograph volume control (right front) until the voltmeter reads 10 volts. Turn the expander "Dynamic" control (center front) to its extreme clockwise position allowing maximum expansion to take place. The voltmeter reading should now read not less than 150 volts if the expander circuit is operating correctly. Failure to do so indicates a defect in the system and the usual service procedure should be followed.

(b) Alternate Method.

Turn power switch (left front) off. Place RCA Stock No. 12333 Split Plate Adapter under the RCA-6L7. Connect a suitable d-c milliammeter to the adapter. Turn both the phonograph volume control (right front) and the expander "Dynamic" control (center front) to their extreme counter-clockwise positions. Turn on power switch (left front) and allow a few minutes for the instrument to become stabilized. Adjust expander bias control R20, on rear apron of amplifier (see figure 9), to give 1.0 milliampere of plate current with no signal input to the dynamic amplifier.

Magnetic Pickup

The pickup used in the phonograph unit is of an improved design. The horseshoe magnet is rigidly welded to the pole pieces and is irremovable. There is a centering spring attached to the armature to maintain proper adjustment and to provide a limiting effect on the movement of the armature. The frequency response is substantially uniform over a wide range. Service operations which may be necessary on the pickup are as follows:

Centering Armature

Refer to figure 4 showing the pickup inner structure. The armature is shown in its proper relation to the magnet pole pieces, i.e., exactly centered. Whenever this centering adjustment has been disturbed, the screws A, B, and C should be loosened and the armature clamp adjusted to the point where the vertical axis of the armature is at right angles to the horizontal axis of the pole pieces, and centered between them. This centering operation may be facilitated by inserting a small rod or nail into the armature needle hole, using it as a lever to test the angular movement of the armature. The limitations of the movement in each direction will be caused by the armature striking the pole pieces. The proper adjustment is obtained when there is equal angular displacement of the armature and adjustment rod or nail to each side of the vertical axis of the magnet and coil assembly. The screws A and B should then be secured, observing care not to disturb the adjustment of the armature clamp. Then place the pickup in a vise and secure the centering spring-clamp by means of the screw C, allowing the centering spring to remain in the position at which the armature is exactly centered between the pole pieces. With a little practice, the correct adjustment of the armature may be readily obtained. The air gap between the pole pieces and the armature should be kept free from dust, filings, and other such foreign materials which would obstruct the movement of the pickup armature.

Damping Block

The viscoloid block which is attached to the back end of the armature shank serves as a mechanical filter to eliminate undesirable resonances and to cause the frequency response to be uniform. Should it be necessary to replace this damping block, it may be done by removing screw D and the cover support bracket from the mechanism and taking off the old viscoloid block. The surface of the armature which is in contact with the viscoloid should be thoroughly cleaned with fine emery cloth. Then insert the new block so that it occupies the same position as it did originally. Make certain that the block is in correct vertical alignment with the armature. The hole in the new viscoloid block is somewhat smaller than the diameter of the armature in order to permit a snug fit. With the viscoloid aligned on the armature, screw D and the cover support bracket should then be replaced. Heat should be applied to the armature (viscoloid side) so that the viscoloid block will fuse at the point of contact and become rigidly attached to the armature. A special-tip soldering iron constructed as shown in figure 6 will be found very useful in performing this operation. The iron should be applied only long enough to slightly melt the block and cause a small bulge on both sides.

Replacing Coil

Whenever there is defective operation due to an open or shorted pickup coil, this coil should be replaced. The method of replacement will be obvious upon inspection of the pickup assembly and by study of the cut-a-way illustrations. Make sure that the new coil is properly centered with the hole in the support strip and glued securely in that position. It is important to re-adjust the armature as previously explained after re-assembly of the mechanism. Only rosin core solder should be used for soldering the coil leads in the pickup. This same type of solder should be used when necessary for soldering the centering spring to the armature.

Magnetizing

Loss of magnetization will not usually occur when the pickup has received normal care because the magnet and pole pieces are one unit and the magnetic circuit remains practically closed at all times. When the pickup has been mishandled, subjected to a strong a-c field, jolted, or dropped, there may be an appreciable loss of magnetic strength, in which case it will be necessary to re-magnetize the entire structure. To do this, it will be necessary to first remove the pickup mechanism from the tone arm, and then remove the magnet assembly. Place the magnet assembly on the poles of a standard pickup magnetizer such as the RCA Stock No. 9549 Pickup Magnetizer and charging the magnet in accordance with the instructions accompanying the magnetizer. It is preferable to check the polarity of the pickup magnet and to re-magnetize it so that the same polarity is maintained.

Phonograph Mechanism

The phonograph motor is of the synchronous type and is designed to be simple and foolproof. Under normal operating conditions, service difficulties should be negligible. Occasionally, however, certain adjustments may be required. These adjustments are illustrated and explained in figure 8.

Loudspeaker

Centering of the loudspeaker voice coil is made in the usual manner with three narrow paper feelers after first removing the front paper dust cover. This may be removed by softening its cement with a very light application of acetone using care not to allow the acetone to flow down into the air gap. The dust cover should be cemented back in place with ambroid upon completion of adjustment.

REPLACEMENT PARTS

Stock No.	Description	List Price
12332	Resistor—27,000 ohms, carbon type, 1 watt (R9)—Package of 3	1.10
12487	Resistor—33,000 ohms, carbon type, 1 watt (R8)	.35
12286	Resistor—56,000 ohms, insulated, ¼ watt (R15)—Package of 5	1.50
12263	Resistor—100,000 ohms, insulated, ¼ watt (R13, R16, R17, R19)—Package of 5	1.00
12452	Resistor—150,000 ohms, insulated, ¼ watt (R5)—Package of 5	1.00
12283	Resistor—470,000 ohms, insulated, ¼ watt (R18)—Package of 5	1.00
12486	Resistor—560,000 ohms, insulated, ¼ watt (R7, R10)—Package of 5	1.00
4794	Socket—4-contact 5Z3 or 2A3 Radiotron socket	.35
11197	Socket—6 contact 6C5 Radiotron socket	.14
11198	Socket—7-contact 6H6 or 6L7 Radiotron socket	.35
12464	Transformer—Interstage transformer (T3, L5)	3.95
12482	Transformer—Power transformer, 110-120 volt, 50-60 cycle (T1)	8.58
	MISCELLANEOUS CABLES AND PLUGS	
12547	Cable—2-conductor shielded pickup cable, 35 inches long, complete less female connector, Stock No. 11488	.44
12480	Cable—Power cable, approximately 30 inches long, complete with two female connectors	.50
12363	Cable—Shielded input cable, approximately 9 inches long, complete with 4-contact male connector	.26
12364	Cable—Shielded tone control cable, approximately 10½ inches long, with 4-contact male connector	.34
12490	Cable—Shielded tone control cable, approximately 14 inches long, complete with female connector	.36
12362	Cable—Shielded volume control cable, approximately 28 inches long, complete with 2 male connectors	.38
12491	Cable—Shielded volume control cable, approximately 17 inches long, complete with 2 female connectors	.60
12492	Cable—Speaker cable, approximately 40 inches long, complete with female connectors	.44
4674	Connector—2-contact male connector for volume control cable, input transformer cable, compensator cable, motor leads, tone control switch leads and indicator lamp cable (socket end)	.25
11488	Connector—2-contact female connector for pickup cable, Stock No. 12547, or indicator lamp cable (chassis end)	.14
4577	Connector—2-contact male connector for motorboard power leads	.30
12565	Connector—4-contact male tone control and input cable connector	.30

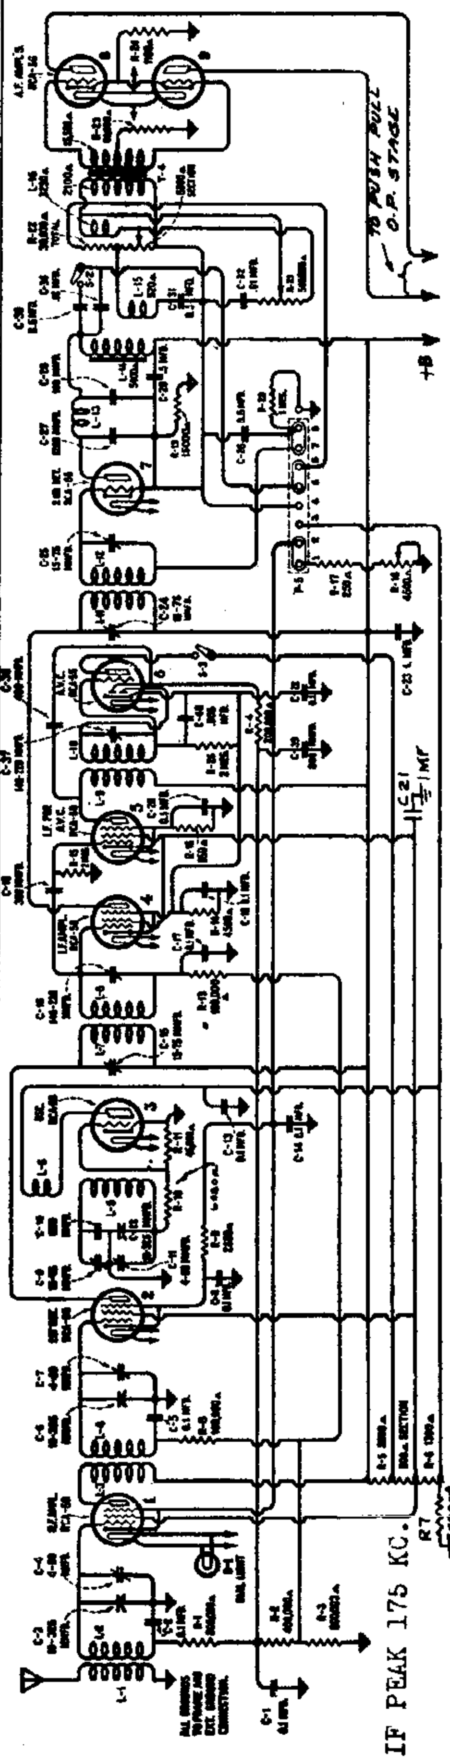
MODEL R-78 with
Noise Suppressor

RCA MFG. CO., INC.

Schematic, Voltage
Alignment, Notes



RCA R-78 with Noise Suppressor

The schematic diagram, showing the inclusion of noise suppression to the early Model R-78, is shown in the accompanying illustration. If you will compare the schematic diagram of the R-78 that is shown on *RCA page 3-38 of Rider's Volume III and on page 1910 of the Rider-Combination Manual*, with the one given herewith, it will be seen that the 56 AVC tube in the early model has been replaced with a 55 tube and the values of several resistors have been changed. The power pack and output stage is the same in each case.

The untuned i-f. transformer used in the older model has been changed to a natural period plate coil, L-9, and a sharply tuned secondary coil, L-10. Coil L-9 supplies the voltage to operate the AVC circuit and L-10 supplies that used to operate the suppressor circuits. An examination of this circuit will show that with no signal voltage impressed on coil L-10, no current is rectified in the diode plate and hence the grid of the 55 tube operates at zero bias. The plate current is then at maximum—about 10 ma.—and since the cathodes of the 55 tube and the signal channel i-f. tube are common, the i-f. tube is biased to cutoff. This prevents signal voltage from reaching the second detector.

When the set is tuned to a signal, the signal voltage is amplified in the AVC amplifier and impressed on L-9 and L-10. On the positive half of the signal voltage, the signal is rectified in the suppressor circuit which generates a negative potential on the grid of the 55 tube. The plate current is thereby reduced to nearly zero, which releases the high bias potential on the signal channel i-f. amplifier. Signal voltage will then be impressed on the second detector.

AVC bias for the r-f., first detector, and i-f. tubes will be generated when the i-f. voltage on the AVC diode overcomes and exceeds the positive potential on the cathode of the 55. This bias is about 10 volts when the set is tuned to a signal.

The sensitivity control is in the cathode circuit of the r-f. and first detector tubes and is indicated as R-18 on the diagram. The sensitivity of the set is reduced by increasing the residual bias on these two tubes, i.e. the first two 58's in the set. One end of the sensitivity control has a switch, S-3, which is provided so that the noise suppressor circuit may be cut out, then the full sensitivity of the set is obtained.

Alignment:

Remove the oscillator tube and ground the chassis. Couple the output of the test oscillator, set to 175 kc., the i-f. peak of the set, from the control grid of the first detector to ground. With the receiver volume control at maximum, the noise suppressor control at its extreme counter clockwise position, and the noise suppressor switch open, adjust the oscillator output until a deflection is obtained in the output indicator.

Adjust the secondary and primary of the second and then the first i-f. transformer, until a maximum deflection is obtained. Check the adjustments.

Then close the noise suppression control switch by advancing slightly clockwise, but do not advance the control beyond the snapping of the switch. The single noise suppressor circuit should then be adjusted for maximum output. Keep the input signal as low as possible so that every change can be followed in the output indicator.

For other adjustment data and notes that apply to this model see *pages 3-39 and 3-41 in Rider's Volume III and pages 1911 and 1913 in the Rider-Combination Manual.*

Voltage Data:

Below will be found the voltage data for the R-78 with noise suppression. Note that the line voltage is 120. The antenna is shorted to ground and no signal.

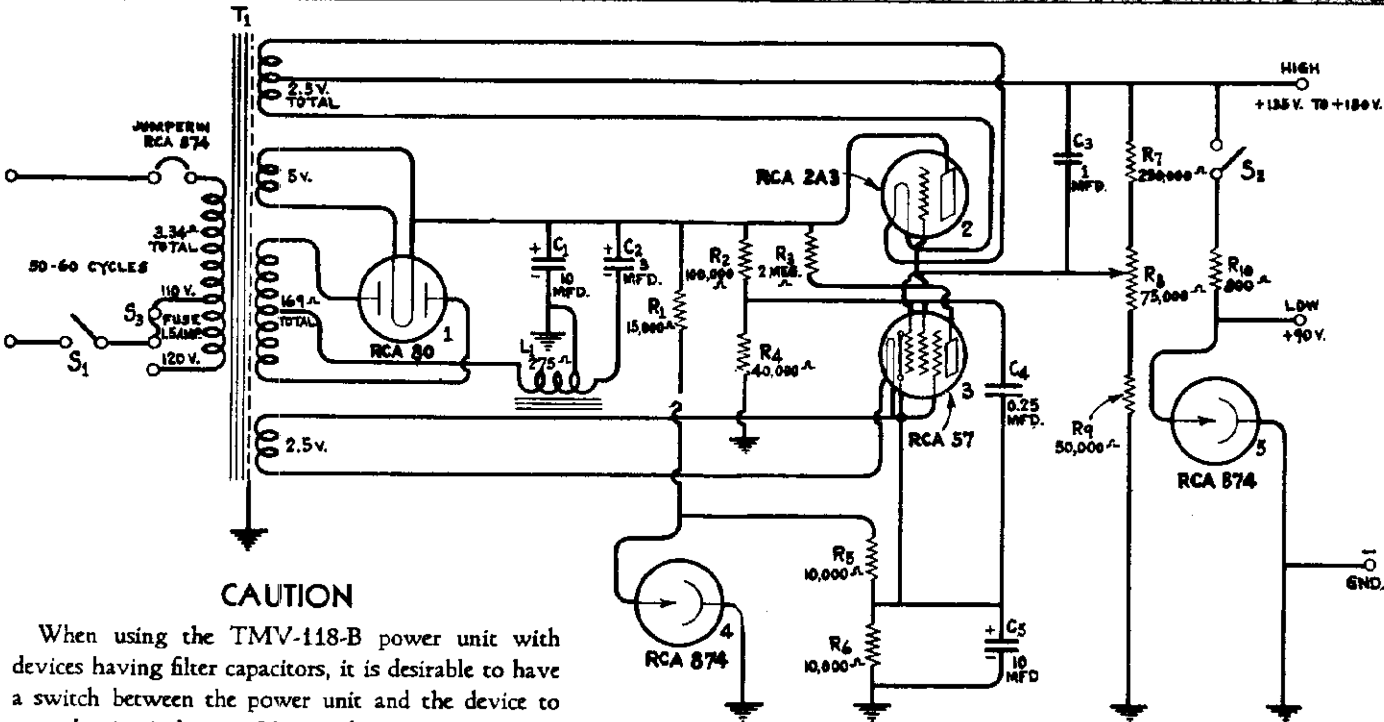
All D. C. voltages are to ground except heaters—Voltages are with 180-volt, 50 M. A. load, 90-volt switch "off"—Input voltage 115 volts, 60 cycles—transformer on 110-volt tap.

Voltages at Radiotron Sockets



CAUTION

When using the TMV-118-B power unit with devices having filter capacitors, it is desirable to have a switch between the power unit and the device to open the circuit during a 30-second warming-up period. During this warming-up period, the output voltages may be high and unless the filter or by-pass capacitors are conservatively rated, premature failure may result.

(1) EXCESSIVE HUM

Excessive hum may be caused by operating the TMV-118-B beyond the limits of its capacity. A reference to the curves shown in Figure 4 shows the safe limits and regulation to be expected for such operation. A good test for maximum load is maximum permissible hum. Excessive hum with the equipment in normal condition is an indication of excessive load.

Excessive hum accompanied by high voltage is caused by a defective Radiotron RCA-57.

Excessive hum accompanied by normal voltage is an indication of a defective capacitor C-3.

(2) LOW VOLTAGE

Low voltage may be caused by a low emission Radiotron RCA-80 or RCA-2A3.

(3) HIGH VOLTAGE

High voltage may be caused by a defective Radiotron UX-874 or, if accompanied by hum, a defective RCA-57.

(4) VOLTAGE READINGS

The voltages shown on Figure 4 are those at which the various tubes operate. When taking readings, suitable allowance must be made for the load of the meter.

(5) VOLTAGE REGULATION

Figures 6 to 11, inclusive, show the voltage regulation of the TMV-118-B over a wide range of line voltages, load current and output voltage conditions. A reference to the charts should be made to ascertain the regulation for any given condition, prior to placing the unit in operation.

Transformer, Data
Regulating Circuits

RCA MFG. CO., INC.

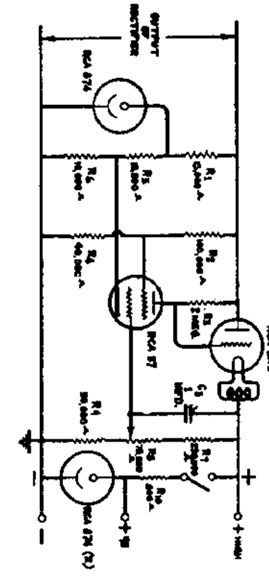

Figure 3—Voltage Regulating Circuits

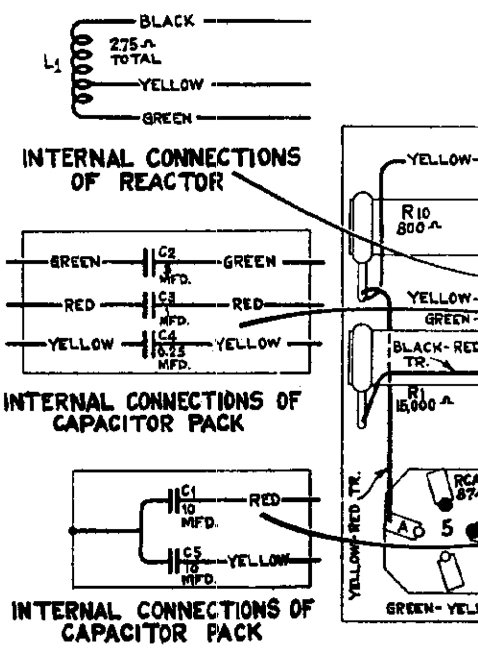
The RCA Regulated Power Unit, Type TMV-118-B, is a device for converting the usual alternating current line power into direct current suitable for use with devices normally requiring "B" batteries. The voltage regulation is better than that obtained from a set of heavy-duty batteries while the hum is negligible. A special regulating circuit maintains constant output voltages independently of line or load variations over a wide range. A general view of the external appearance of the TMV-118-B Power Unit is shown in Figure 1.

The RCA-874 is a gaseous tube of two elements, using either Neon or Argon. The tube functions to maintain a fairly constant voltage (90 volts) across a circuit, independently of load due to the fact that its resistance varies with the voltage across its terminals. The tube requires 125 volts for starting and maintains an approximately constant D. C. voltage across its terminal for any current from 10 to 50 milliamperes. A link circuit is provided by having two of the tube prongs tied together so that the power circuit may be wired through this link. This prevents power from being applied to the unit without the RCA-874 in place. Excessive voltage might otherwise occur if such a condition existed due to absence of the load of the regulator tube.

A. C. Input Voltage Rating 90–130 Volts
Frequency Rating..........50–60 Cycles
Power Consumption...........70 Watts



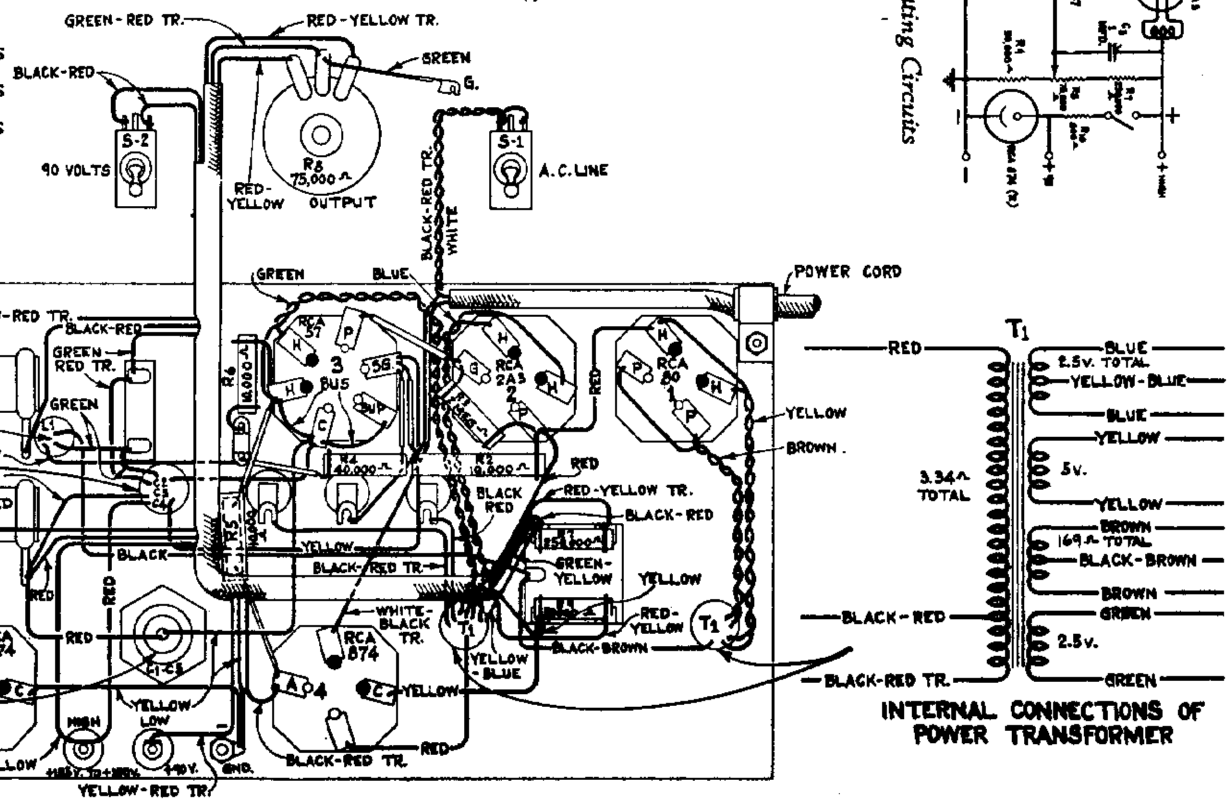


Figure 5—Wiring Diagram

RCA MFG. CO., INC.

INTRODUCTION

The Type TMV-128-A Frequency Modulator is a levice for use with a test oscillator (such as the TMV-97-C or similar) to "sweep" the oscillator frequency and at the same time provide a voltage for synchronizing the timing axis of a cathode-ray oscillograph (such as the TMV-122-B) with the position of the sweep condenser. It consists of a driving motor coupled to a sweep condenser and an impulse generator. Two ranges of sweep capacity are provided, as listed below, and a cable fitted with plugs at each end is furnished for connection to the test oscillator. The unit operates entirely from a 110/120 volt, 50/60 cycle a-c supply.

INSTALLATION

Figure 1 shows the interconnections of the Frequency Modulator with the TMV-97-C Test Oscillator and Cathode-Ray Oscillograph, Type TMV-122-B. This arrangement is commonly used for making r-f and i-f alignment of a radio receiver. For other applications, this set up may be modified according to the requirements of the particular case.

OPERATION

When the units are properly interconnected, select the "Hi" or "Lo" position of the range switch according to the percentage sweep desired (see the curve on the back of this sheet), and turn the motor "On." When through operating, turn the motor switch to the "Off" position.

MAINTENANCE AND SERVICE

Specifications

Power Supply Voltage and Freq.	110/120 Volts, 50/60 Cycles
Power Consumption	25 Watts
Drive Motor	Shaded Pole-Induction; 1/200 HP.
Drive Motor Speed	1550 R.P.M.
Sweep Condenser Capacitance	High Range—25 to 70 Mmfd. Low Range—15 to 37 Mmfd.
Connection Cable Capacitance	40 Mmfd.
Impulse Generator Output	1.5 Volts
Over All Dimensions	Height, 8½ Inches Width, 9¾ Inches Depth, 4½ Inches
Weight	5¼ Pounds

Bearing Lubrication

The small induction drive motor has oil holes at each of its waste-packed bearings. Light engine oil should be used at these points. A ball-bearing support is used at the impulse generator. It is packed with "vaseline," which should be replenished after every 100 hours of operation.

Sweep Condenser

This element of the assembly consists of two conventional type rotary condensers, each having a single rotor plate attached to a revolving shaft. The stators are wired so that one remains connected at all times and a switch is used to parallel the two in order to increase the range of sweep.

The rotor plates should be exactly centered between the stator plates when the mechanism is operating at its normal speed (1550 r.p.m.). If the plates change their relation, they should be re-centered by adjusting the drive shaft in the coupling, or shifting the rotor plates on the shaft. The line-up of the rotor plates in respect to the armature of the impulse generator is important in that it governs the synchronization of the system. The proper adjustment is obtained when the two rotor plates are either at maximum or minimum capacitance, and the armature sets horizontal (air gap minimum). A slight shift may be necessary to center the resonance curve on the screen of the TMV-122-B.

Impulse Generator

A small induction generator is used to furnish means of controlling the frequency of the "Saw Tooth Oscillator" of the Oscillograph. It is necessary to maintain a definite polarity on the output connections of this generator. The horse-shoe magnet should therefore be replaced as originally installed, if it has been removed for repair or service. It is also important to retain the original relation of the coils. Correct polarity exists when a positive swing is obtained on a 200 microampere d-c meter with its plus terminal connected to "high," and the mechanism rotated by hand in such a direction as to cause a decrease in air gap.

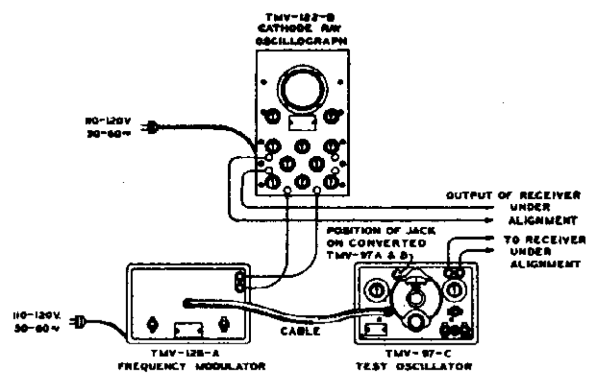

Figure 1

Mechanical Alignment

The drive motor, sweep condenser and impulse generator must be in correct physical relations to each other, inasmuch as they all rotate on the same shaft. The motor mounting screws are arranged to permit small lateral adjustments of the motor position. Both the stator and rotor plates of the sweep condenser may be adjusted to obtain the correct centering alignment. End-play of the shaft should be kept at a minimum without affecting the freedom of rotation.

Brush Connection

The point of contact between the revolving shaft and the brush of the sweep condenser circuit should be kept clean at all times. No oil or dirt should be allowed to accumulate. Poor contact is evidenced by ragged wave form on the oscillographic image.

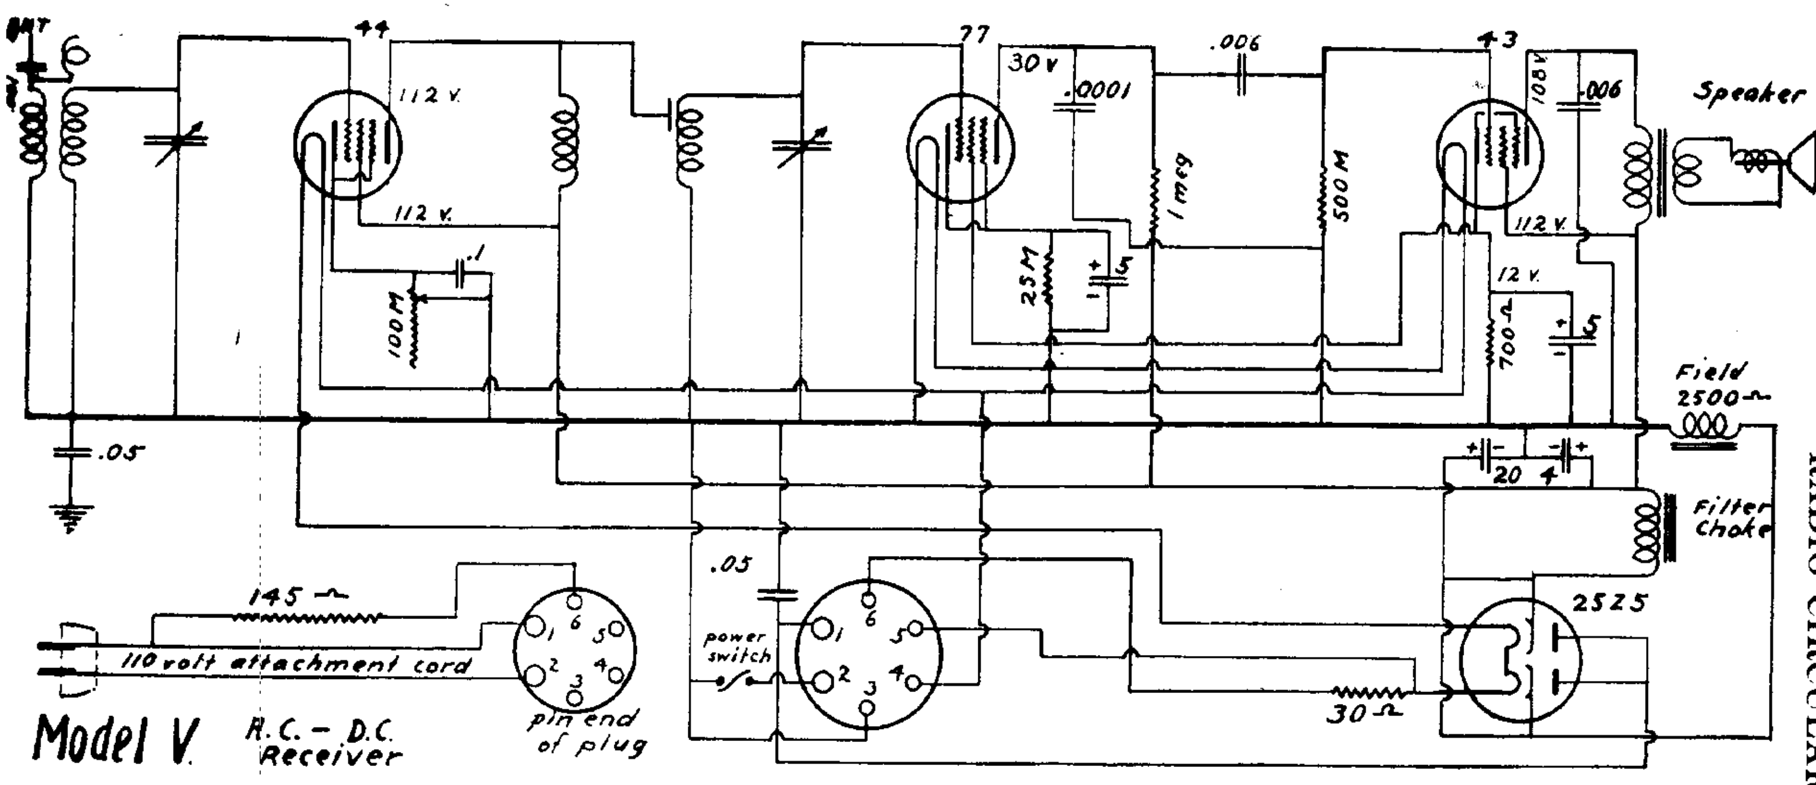
7906	Post—Binding post engraved "High"—"Low"	.45
7900	Switch—Toggle switch (S1, S2)—Off-On, High-Low—Less escutcheon	.75

RADIO CIRCULAR



CAUTION:

This instrument is equipped for operation on 110 volts D. C. or A. C., any frequency from 25 to 133 cycles per second. Before attempting to operate on any other voltage be sure that the proper adaptors are connected and the instructions accompanying them are understood. Special adaptors can be secured from the factory at a slight extra cost, for operating this receiver on automobiles, 32 volt farm light plants and 200 volt A. C. or D. C. ALWAYS plug cord into back of set before plugging into power supply. Cord for 110 volt or 220 volt heats moderately, as the cord contains resistance necessary for operation at these voltages. The 20 ft. aerial wire extending from the back of the set should be unwound, laid out along the floor or hung outside a window and is ordinarily all the aerial required. No ground connection should be used. Sometimes results are better if the tip of the antenna wire is connected to a radiator or other ground connection or to an outside aerial.

PHONOGRAPH:

Connect pick-up leads to single pole toggle switch, which may be mounted in large hole in rear flange of set. Unsolder black wire and 5 mfd condenser from ground lug of coil on under side of chassis and resolder to one side of toggle switch. Solder other side of switch to ground lug of coil.

SERVICE NOTES:

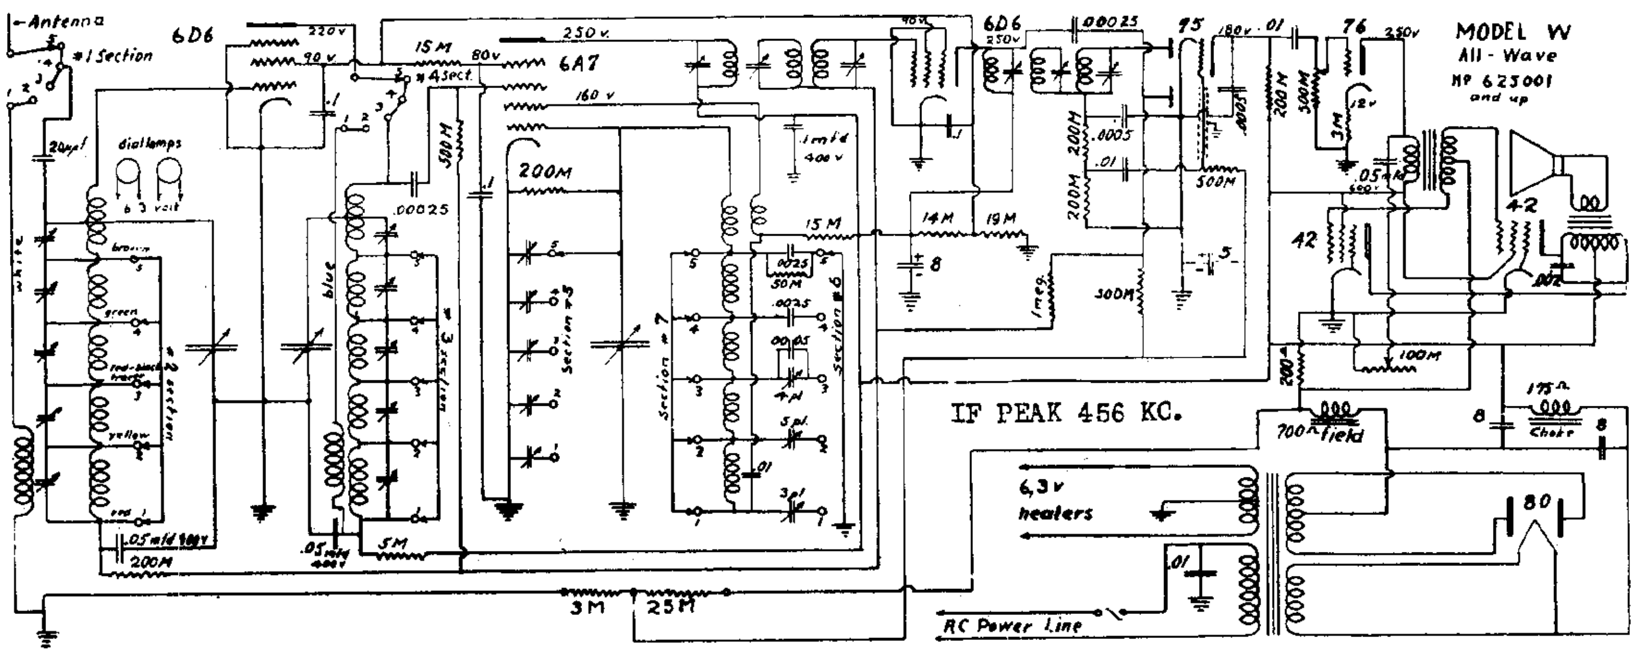
To remove set from cabinet, disconnect from power supply, remove knobs, remove back if compact model, and unscrew the four felt headed screws on bottom of cabinet.

To balance set remove from cabinet, turn tuning condenser plates completely out, attach a test oscillator delivering 1712 K. C. to antenna of set and adjust trimmers on tuning condenser to loudest signal. Change test oscillator signal to 1400 K. C., turn tuning condenser until signal is tuned in and check trimmers again without moving tuning condenser.

If used in automobiles antenna stage should be trimmed to the car antenna at time of installation.

MODEL W, Worldwide
Schematic, Notes
Voltage, Alignment

RADIO CIRCULAR



MODEL W WORLDWIDE

CAUTION—Do not attempt to operate on current other than that noted on the instrument.

INSTALLATION—A good aerial, 25 to 50 feet long, well away from surrounding metal structures and power lines, is essential for best results. Power noise interferes especially with short-wave reception. If the set is located where power noise is prevalent it may be necessary to install an aerial high above the street and use a "transposition" lead-in to the set. A good ground connection (water pipe or equivalent) will also contribute to quieter reception.

CONTROL KNOBS—The left hand knob is, initially, the power switch and thereafter, tone control. The second knob from the left is band selector switch. The third knob from the left is tuning control. The right hand knob is volume control.

OPERATION—After the set has been properly installed by the attachment of suitable aerial and ground connection and the power cord plugged into an outlet of the proper voltage, the left hand knob is turned to the right and a few seconds allowed for the tubes to reach operating temperature. The second knob has five positions, each corresponding to one of the numbers as shown on the dial. The volume control knob is turned full to the right and then the tuning knob turned slowly until the desired station is heard. Note that each frequency band is indicated on the dial by a number corresponding to the various positions of the band selector switch, and also that in connection with each band, there is shown on the dial the type of station that may be tuned in.

SERVICE NOTES—If the radio fails to operate when unpacked, or stops working after a few days, proceed as follows: (1) Have the tubes checked. (2) Remove the chassis from the cabinet and check for loose connections. (3) Have a competent "Radio Service Man" check over entirely. Do not return unless you have made the above tests. This set left the factory carefully inspected.

The intermediate stages are carefully phased to 456KC at the factory. Should rephasing be necessary attach the output lead from a 456 KC test oscillator to the grid cap of the 6A7 tube, keep the signal to a very low audible value and carefully adjust the three trimmer screws, two in the top and one in the bottom of each of the two tall cans, to loudest volume. If an output meter is available it should be used across the two outside black leads at the speaker transformer. An all-wave oscillator having a range from 150 KC to 20 MC will be necessary to rephase the frequency bands. The oscillator output is attached to the aerial lead of the set and the oscillator output kept always at a low audible level. The R. F. coil trimmers are reached through a series of five (5) holes in the side of the R. F. shield cans and correspond to frequency band Nos. 1, 2, 3, 4, and 5, from top down. The oscillator parallel trimmers are seen on the under side of the set when the front of it is raised and are located alongside of the band switch, No. 1 being the one nearest the back of chassis and No. 5 nearest the front. The dual porcelain trimmers at back of chassis are series padders, the left hand for band No. 2 and the right hand one for band No. 1. The series padder for band No. 3 is the single trimmer at the center of the chassis. Each band is trimmed first at the minimum end of its range, band No. 5 being first, No. 4 second, then No. 3, etc. Bands 3, 2, and 1 are also tracked near their maximum ranges, or with the tuning condenser turned well in, by adjusting that series padder belonging to the particular band being used, location of which is given above.

NOTE—Should it be necessary to write to the factory for parts or information, always give the serial number of the set as stamped on the back of the chassis.

PHONOGRAPH—Install a single pole double throw toggle switch in rear flange of chassis near right-hand end. Disconnect .01 mfd condenser from volume control and connect to one side of switch, connect volume control to center terminal of switch, connect one side of phonograph pickup to other side of switch and remaining pickup terminal to remaining outside volume control terminal.

SHORT WAVE TIPS—In listening for short-wave broadcast DON'T forget to consider the difference in time between the location of the broadcaster and the receiver. DON'T expect to hear a station because it is on the air, as many things govern short-wave reception. DON'T get discouraged if reception is poor one night; it may be fine the next. DON'T expect stations to tune broadly; most stations tune sharply. DON'T tune below 10,000 kilocycles (above 30 meters) for distant stations in daylight. DON'T expect to find stations on all parts of the dial. Short-wave stations are widely separated, except in a few instances. DON'T skim over the dial. It requires some knowledge of tuning to get good results. Tune very slowly. DON'T pass up any weak signal, as it may often be brought in stronger by careful tuning.

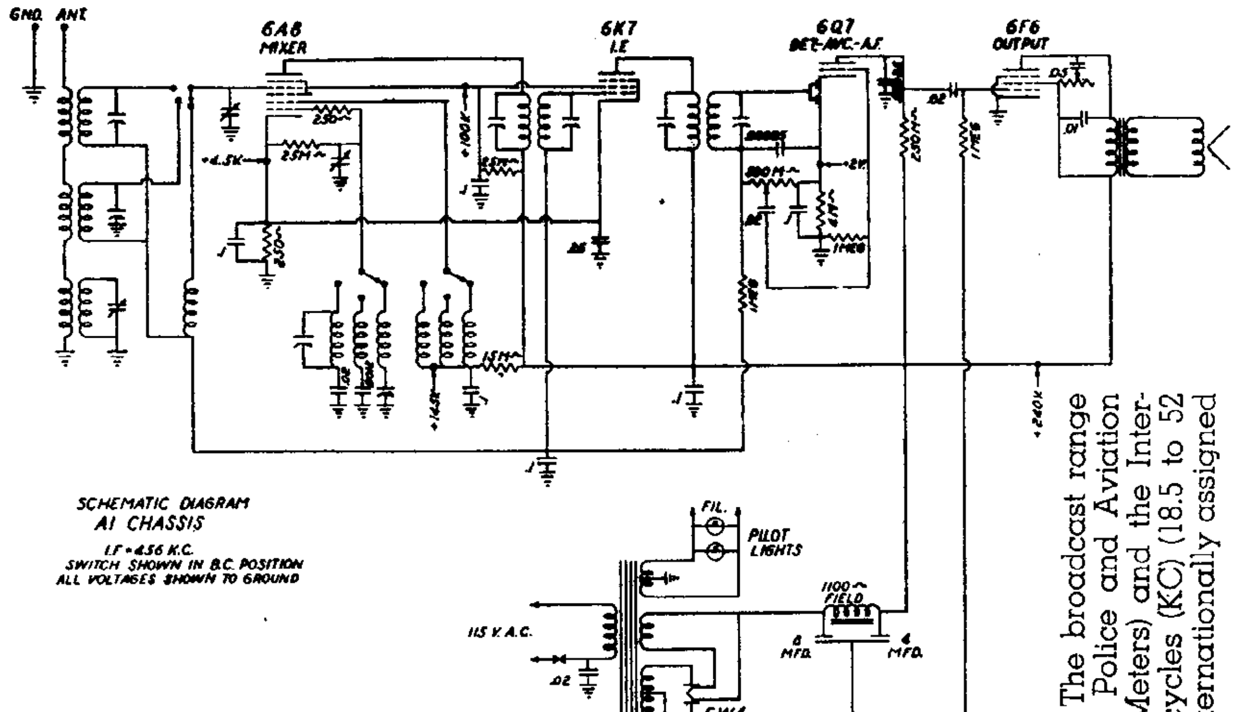
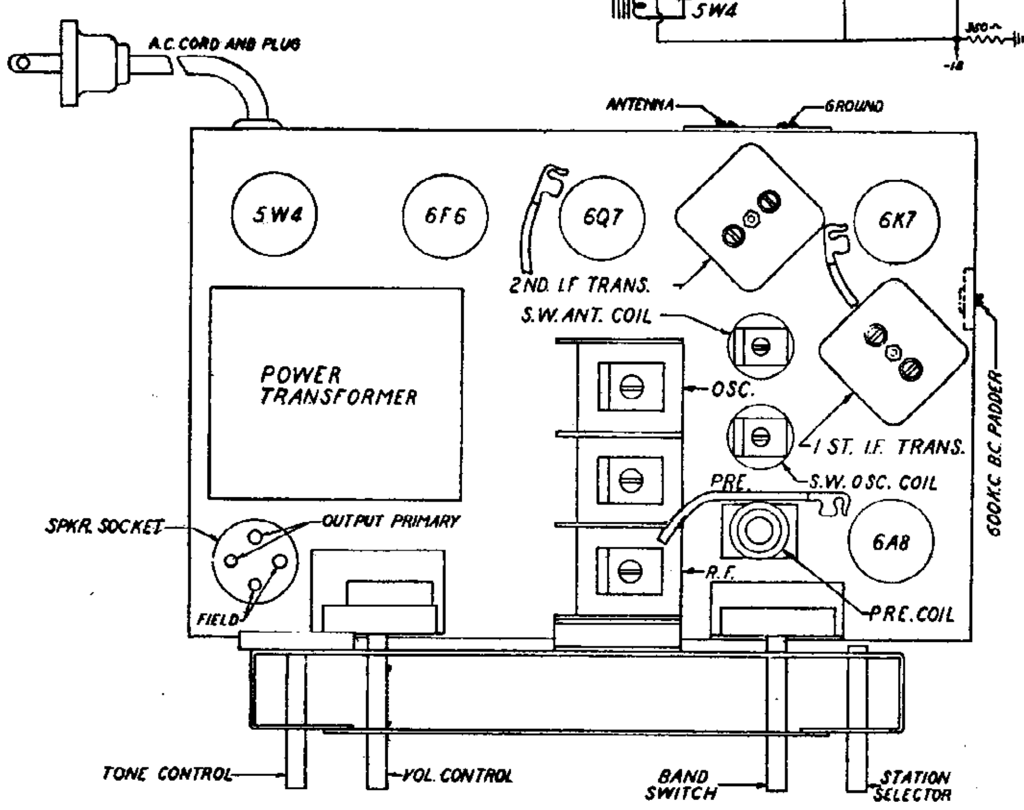
MODEL 5-Tube AC Super
Chassis A-1
Schematic, Voltage





Five Tube A.C. Superheterodyne
A1 Chassis

This receiver is designed to operate over three tuning ranges. The broadcast range which extends from 545 to 1715 Kilocycles (KC) (175 to 550 meters), Police and Aviation Band which extends from 1715 to 5350 Kilocycles (KC) (56 to 175 Meters) and the International Short Wave Band which extends from 5760 to 16200 Kilocycles (KC) (18.5 to 52 meters). This short wave range is the one which includes the four internationally assigned bands—the 19, 25, 31 and 49 meter bands.

MODEL 5-Tube AC Super
Chassis A-1
Alignment,Parts List

RADIO PRODUCTS CORP.

ALIGNMENT DATA AND SERVICING

GENERAL DATA The alignment of this receiver requires the use of a test oscillator that will cover the frequencies of 456, 600, 1400, 1800, 4000, 6000, and 14,000 KC and an output meter to be connected across the primary or secondary of the output transformers. If possible, all alignments should be made with the volume control on maximum and the test oscillator ouput as low as possible, to prevent the AVC from operating and giving false readings.

CORRECT ALIGNMENT PROCEDURE The intermediate frequency (I.F.) stage should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the Broadcast Band should always be the next procedure; after which, either or both of the Short Wave Bands may be aligned.

I.F. ALIGNMENT Adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tubes (6A7) through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the chassis ground. Align all four I.F. trimmers to peak or maximum reading on the output meter.

BROADCAST BAND ALIGNMENT Adjust the oscillator to 1400 KC and connect the output to the antenna post marked "A" through a .0001 mfd. mica condenser to give the equivalent of an antenna about 60 feet. Set the receiver pointer to 1400 KC and adjust the rear gang condenser trimmer (oscillator circuit) to peak. After this has been carefully done, the next step is to adjust the center and front trimmers of the gang condenser to peak. The front gang section tunes the R.F. or grid coil of the 6A8 tube and the center condenser section tunes the pre-selector stage circuit.

Next, re-set the dial pointer on the receiver and the test oscillator to 600 KC. Slowly increase or decrease the oscillator padding condenser and at the same time continuously tune back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment seems a little complicated but is the easiest way to adjust the oscillator to the pre-selector or R.F. section. The padding condenser is located on the right hand end of the chassis near the 6K7 tube.

Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 600 KC.

This completes the correct sequence of operations in properly aligning the receiver for the Broadcast Band, and **must always be done before** attempting to align the Short Wave Bands.

FOREIGN BAND The Foreign Band of 18 to 49 meters can be adjusted by the two trimmers on the short wave coil located on the top of the chassis. Set the test oscillator to 14,000 KC. The oscillator coil is located nearest the front of the chassis and the antenna or R.F. coil is located directly in back of the Short Wave oscillator coil. These two trimmers should be adjusted for peak at 14,000 KC and as the inherent design of the circuit has been expressly designed for simplicity in servicing, no other adjustments are necessary for aligning this band. **Note:** Always start this procedure by having the oscillator coil trimmer loose (cut all the way), and the antenna coil trimmer fairly tight (in all the way); otherwise it is possible to make a false alignment on the image frequency.

Important: Do not attempt any adjustment of the gang condenser trimmers in aligning the Foreign Band as this will throw the Broadcast Band out of alignment.

POLICE BAND There is only one adjustment to be made in the alignment of the Police Band. Due to the circuit design and correct matching of the coils, no oscillator adjustment is necessary.

Set the dial pointer to 4000 KC (also the test oscillator) and adjust the antenna coil trimmer to resonance. The two police band coils are under the chassis, but the antenna coil trimmer for this band is on top of the chassis and is located at the right front corner along side of wave band switch.

Important: This is the only adjustment necessary for the Police Band. Do not attempt any adjustment of the gang condenser trimmers in aligning the Police Band, otherwise the Broadcast Band will be thrown out of alignment.

49 METER BAND The popular 49 meter band is the area adjacent to the 6 megacycle calibration and offers the most consistent reception from Italy, Germany, Africa and Java. This area also affords the most popular reception of North and South American Short Wave Broadcasts and many other Foreign Countries. (Best evening reception all year round.)

31 METER BAND The 31 meter band is the area extending from 9 to 10 megacycles and lists Spain, Italy, Portugal and Australia as the most favorable of the Foreign Countries in this range. (Late afternoon and early evening.)

25 METER BAND The 25 meter band is the area adjacent to the twelve megacycle calibration and associates itself with the listing of Russia, France, England and Holland. (Late afternoon and early evening. This band is unusually free from static during the summer months when maximum static is prevalent on the Standard Broadcast Band.)

19 METER BAND The 19 meter band is the area extending from the 15 megacycle calibration and lists France, Holland, England and Amateur phones. This band offers the least possibilities for satisfactory reception due to the unreliable character of this particular frequency.

STANDARD BROADCAST BAND (White Scale) (175 to 550 Meters)—The upper white scale is calibrated from 55 to 170 (Standard Broadcast). This scale, by adding mentally an "0," gives a correct accurate calibration reading from 550 to 1700 kilocycles (KC).

This band covers all Standard Broadcast frequencies of the United States, Canada, Mexico, Cuba and many Central and South American Countries; also the popular 1712 kilocycle (KC) Police Band.

POLICE BAND (Red Scale) (56 to 175 Meters)—The scale is graduated from 450 to 170, which also reads directly in kilocycles (KC) by adding an "0" mentally. This scale covers reception of Short Wave Police Bands, Airplanes, Amateurs, and Ships at Sea.

FOREIGN AND AMERICAN SHORT WAVE BAND (Green Scale) (18.5 to 52 Meters)—The entire lower half of the scale is devoted to this band which covers the most popular Foreign and American Short Wave Broadcasts. This scale is numerically graduated from 6 to 15 megacycles. Mentally adding three "0s" converts megacycles to kilocycles (KC): i.e., 6 megacycles equals 6,000 kilocycles (KC) and 15 megacycles is equivalent to 15,000 kilocycles (KC).

ANTENNA

An antenna post is provided for the use of a regular antenna. Any of the doublet or transmission line types may be used.

DOUBLET OR TRANSPOSED LEAD-IN TYPE **Without matching transformer** — Connect two transposed lead-in wires to two posts marked "A" and "G" respectively.

TRANSMISSION LINE TYPE **With line matching transformers** — Connect leads from matching transformer to antenna posts marked "A" and "G." The use of a good ground on the ground post may be necessary in some cases.

TUNING IN STATIONS

RIGHT HAND KNOB **(Manual Volume Control and "On-Off" Switch)**—Turn the right hand knob to the extreme right. The switch will click and the dial will become illuminated, with volume wide open. Wait about a minute for the tubes to become heated.

RIGHT HAND KNOB **(Two Position Wave Band Selecting Switch)**—Turned to the right, it is set for Standard Broadcast Band; turned to the extreme left, it is set for Foreign and American Short Wave Reception, Police, Aviation, Amateurs, and Ships at Sea.

CENTER KNOB **(Station Selector)** — Rotate the indicator needle slowly over a narrow range of the dial at a point where the desired station is located, until the station is received with maximum volume; then readjust the volume control to the proper level. **Never** use the station selector to adjust volume as this practice results in distorted tone quality and deficient bass response. The Volume Control **only** is to be used for this purpose. The indicator needle should be adjusted to the center of the area covered by the station being received.

ALIGNMENT DATA AND SERVICING

GENERAL DATA The alignment of this receiver requires the use of a test oscillator that will cover the frequencies of 456, 600, 1400, and 6000 KC and an output meter to be connected across the primary or secondary of the output transformers. If possible, all alignments should be made with the volume control on maximum and the test oscillator output as low as possible, to prevent the AVC from operating and giving false readings.

CORRECT ALIGNMENT PROCEDURE The intermediate frequency (I.F.) stage should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the Broadcast Band should always be the next procedure; after which, the Short Wave Band may be aligned.

I.F. ALIGNMENT Adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tubes (6A7) through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the chassis ground. Align all four I.F. trimmers to peak or maximum reading on the ouput meter.

BROADCAST BAND ALIGNMENT Adjust the oscillator to 1400 KC and connect the output to the antenna lead (Blue) through a .0001 mfd. mica condenser to give the equivalent of an antenna about 60 feet. Set the receiver pointer to 1400 KC and adjust the rear gang condenser trimmer (oscillator circuit) to peak. After this has been carefully done, the next step is to adjust the front trimmer of the gang condenser to peak.

Next, re-set the dial pointer on the receiver and the test oscillator to 600 KC. Slowly increase or decrease the oscillator padding condenser and at the same time continuously tune back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment seems a little complicated but is the easiest way to adjust the oscillator to the pre-selector or R.F. section. The padding condenser is located on the right hand end of the chassis near the 6A7 tube.

Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 600 KC.

This completes the correct sequence of operations in properly aligning the receiver for the Broadcast Band, and **must always be done before** attempting to align the Short Wave Band.

SHORT WAVE BAND There is only one adjustment to be made in the alignment of the Short Wave Band. Due to the circuit design and correct matching of the coils, no oscillator adjustment is necessary.
Set the dial pointer to 600 KC (also the test oscillator) and adjust the antenna and antenna trimmer to resonance. The short wave band coils are under the chassis and are located at the right front corner along side of wave band switch.

IMPORTANT: This is the only adjustment necessary for the Short Wave Band. Do not attempt any adjustment of the gang condenser trimmers in aligning the Short Wave Band, otherwise the Broadcast Band will be thrown out of alignment.

Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 6000 KC.

This completes the correct sequence of operations in properly aligning the receiver for the Broadcast Band, and MUST ALWAYS BE DONE BEFORE attempting to align the Short Wave Band.

ALIGNMENT DATA AND SERVICING

GENERAL DATA The alignment of this receiver requires the use of a test oscillator that will cover the frequencies of 456, 600, 1400, 1800, 4000, 6000, and 14,000 KC and an output meter to be connected across the primary or secondary of the output transformers. If possible, all alignments should be made with the volume control on maximum and the test oscillator ouput as low as possible, to prevent the AVC from operating and giving false readings.

CORRECT ALIGNMENT PROCEDURE The intermediate frequency (I.F.) stage should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the Broadcast Band should always be the next procedure; after which, either or both of the Short Wave Bands may be aligned.

I.F. ALIGNMENT Adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tubes (6A7) through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the chassis ground. Align all four I.F. trimmers to peak or maximum reading on the output meter.

BROADCAST BAND ALIGNMENT Adjust the oscillator to 1400 KC and connect the output to the antenna post marked "A" through a .0001 mfd. mica condenser to give the equivalent of an antenna about 60 feet. Set the receiver pointer to 1400 KC and adjust the rear gang condenser trimmer (oscillator circuit) to peak. After this has been carefully done, the next step is to adjust the center and front trimmers of the gang condenser to peak. The front gang section tunes the R.F. or grid coil of the 6A8 tube and the center condenser section tunes the pre-selector stage circuit.

Next, re-set the dial pointer on the receiver and the test oscillator to 600 KC. Slowly increase or decrease the oscillator padding condenser and at the same time continuously tune back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment seems a little complicated but is the easiest way to adjust the oscillator to the pre-selector or R.F. section. The padding condenser is located on the right hand end of the chassis near the 6K7 tube.

Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 600 KC.

This completes the correct sequence of operations in properly aligning the receiver for the Broadcast Band, and **must always be done before** attempting to align the Short Wave Bands.

FOREIGN BAND The Foreign Band of 19 to 49 meters can be adjusted by the two trimmers on the short wave coil located on the top of the chassis. Set the test oscillator to 14,000 KC. The oscillator coil is located near the 1st I.F. Transformer and the antenna or R.F. coil is located directly in front of the Short Wave oscillator coil and about midway between the 1st I.F. Transformer and the 6A7 tube. These two trimmers should be adjusted for peak at 14,000 KC and as the inherent design of the circuit has been expressly designed for simplicity in servicing, no other adjustments are necessary for aligning this band. **Note:** Always start this procedure by having the oscillator coil trimmer loose (out all the way), and the antenna coil trimmer fairly tight (in all the way); otherwise it is possible to make a false alignment on the image frequency.

Important: Do not attempt any adjustment of the gang condenser trimmers in aligning the Foreign Band as this will throw the Broadcast Band out of alignment.

POLICE BAND There is only one adjustment to be made in the alignment of the Police Band. Due to the circuit design and correct matching of the coils, no oscillator adjustment is necessary.

Set the dial pointer to 4000 KC (also the test oscillator) and adjust the antenna coil trimmer to resonance. In preparing the test oscillator for alignment of this band, connect a 400 ohm carbon resistor in series with the .0001 mfd. condenser on the output lead of the test oscillator. This resistor is used with the test oscillator only on the Short Wave Bands and should not be used for Broadcast Band alignment. The two police band coils are under the chassis and the antenna coil trimmer is mounted on the end of the antenna coil.

Important: This is the only adjustment necessary for the Police Band. Do not attempt any adjustment of the gang condenser trimmers in aligning the Police Band, otherwise the Broadcast Band will be thrown out of alignment.

This receiver is designed to operate over three tuning ranges. The broadcast range which extends from 545 to 1715 Kilocycles (KC) (175 to 550 meters), Police and Aviation Band which extends from 1715 to 5350 Kilocycles (KC) (56 to 175 Meters) and the International Short Wave Band which extends from 5760 to 16200 Kilocycles (KC) (18.5 to 52 meters). This short wave range is the one which includes the four internationally assigned bands—the 19, 25, 31 and 49 meter bands. PRICES ARE SUBJECT TO CHANGE WITHOUT NOTICE

ALIGNMENT DATA AND SERVICING

GENERAL DATA The alignment of this receiver requires the use of a test oscillator which will cover the frequencies of 456, 600, 1400, 1800, 4000, 6000 and 14,000 KC and an output meter which is to be connected across the primary or secondary of the output transformer. If possible, all alignments should be made with the volume control on maximum and the test oscillator output as low as possible, to prevent the AVC from operating and giving false readings.

CORRECT ALIGNMENT PROCEDURE The intermediate frequency (I.F.) stage should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the Broadcast Band should always be the next procedure; after which, either or both of the Short Wave Bands may be aligned.

I.F. ALIGNMENT Adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tube (1C6) through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the chassis ground. Align all four I.F. trimmers to peak or maximum reading on the output meter.

BROADCAST BAND ALIGNMENT Adjust the oscillator to 1400 KC and connect the output to the antenna post marked "A" through a .0001 mfd. mica condenser to give the equivalent of an antenna about 60 feet. Set the receiver pointer to 1400 KC and adjust the rear gang condenser trimmer (oscillator circuit) to peak. After this has been carefully done, the next step is to adjust the front trimmer of the gang condenser to peak. The front condenser section tunes the RF or grid circuit of the 1C6 tube. Next, re-set the dial pointer or the receiver and the test oscillator to 600 KC. Slowly increase or decrease the oscillator padding condenser and at the same time continuously tune back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment may seem a little complicated but is the easiest way to adjust the oscillator to the R.F. section. The padding condenser is located on the left hand side of the chassis, directly to the left of the 1C6 tube and in front of the first I.F. transformer. Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 600 KC.

This completes the correct sequence of operations in properly aligning the receiver for the Broadcast Band, and must always be done before attempting to align the Short Wave Bands.

FOREIGN BAND ALIGNMENT The Foreign Band of 19 to 49 meters can be adjusted by the two trimmers on the short wave coils located on the top of the chassis. Set the test oscillator to 14,000 KC. In preparing the test oscillator for alignment of this band, connect a 400 ohm carbon resistor in series with the .0001 mfd. condenser on the output lead of the test oscillator. The oscillator coil is located near the 1st I.F. Transformer and the antenna or R.F. coil is located directly in front of the Short Wave oscillator coil and alongside the front section of the gang condenser. These two trimmers should be adjusted for peak at 14,000 KC and as the inherent design of the circuit has been expressly developed for simplicity in servicing, no other adjustments are necessary for aligning this band. **Note:** Always start this procedure by having the oscillator coil trimmer loose (out all the way), and the antenna coil trimmer fairly tight (in all the way); otherwise it is possible to make a false alignment on the image frequency. In order to prevent alignment on the image frequency, it is suggested that the following check be made: Readjust the pointer to 13,100 KC where the image frequency should be found. If properly aligned, the image frequency will be found to be weaker. If, however, the signal at 13,100 KC is found to be stronger than the signal at 14,000 KC, it signifies that alignment was incorrectly made on the image frequency.

IMPORTANT: Do not attempt any adjustment of the gang condenser trimmers in aligning the Foreign Band as this will throw the Broadcast Band out of alignment.

POLICE BAND ALIGNMENT There is only one adjustment to be made in the alignment of the Police Band. Due to the circuit design and correct matching of the coils, no oscillator adjustment is necessary. Set the dial pointer to 4000 KC (also the test oscillator) and adjust the antenna coil trimmer to resonance. In preparing the test oscillator for alignment of this band, connect a 400 ohm carbon resistor in series with the .0001 mfd. condenser on the output lead of the test oscillator. This resistor is used with the test oscillator only on the Short Wave Bands and should not be used for Broadcast Band alignment. The two police band coils are under the chassis and the antenna coil trimmer is mounted on the end of the antenna coil. **Important:** This is the only adjustment necessary for the Police Band. Do not attempt any adjustment of the gang condenser trimmers in aligning the Police Band, otherwise the Broadcast Band will be thrown out of alignment.

SERVICE DATA FOR ALL BANDS

If it is suspected that the oscillator has stopped but is doubtful due to the presence of the usual amount of noise level, it is suggested that the oscillator plate voltage be checked. To ascertain whether the tube is oscillating, ground the oscillator grid of the 1C6 (short stator and rotor plates of oscillator section on gang condenser). If oscillating properly, grounding the grid will cause an appreciable drop in oscillator voltage.

BATTERY SELECTION This receiver is designed to operate entirely from a 6 volt storage battery. It requires no other batteries. It will operate from any storage battery having a capacity ranging from 90 to 175 ampere hours. It is suggested, for the sake of greatest economy, that the largest possible capacity battery be used. The following is a schedule giving the number of hours of service on a single charge from batteries of standard capacities. A fully charged battery will provide satisfactory power for the periods specified before requiring additional charge.

90 Ampere Hour Capacity provides	60 hours use.
100 Ampere Hour Capacity provides	66 hours use.
110 Ampere Hour Capacity provides	73 hours use.
120 Ampere Hour Capacity provides	80 hours use.
150 Ampere Hour Capacity provides	100 hours use.
170 Ampere Hour Capacity provides	113 hours use.

Note: The above tabulation is rated very conservatively and in most cases, with new or correctly rated batteries in good condition, many additional hours of service can be obtained from each charge. If, for any reason, the proper hours of service are not obtained, it will be due to the use of an old battery whose condition and rating are no longer up to standard. If a brand new battery fails to give the required hours of service, it is due to the battery being wrongly rated.

BATTERY CONNECTIONS At the rear of the receiver there will be found extending from the left end of the chassis, the battery connecting cable. Observation will show that 5 wires are brought out from the braided cable. The **red** and **red with black tracer** wires are joined together and should **both** be securely fastened to the positive (+) terminal of the 6 volt storage battery. The other 3 wires which are **brown, black with green tracer** and **Metallic shield lead** are also joined together and should be securely connected to the negative (—) post of the battery.

Note: It is extremely important that only the best possible means of obtaining a secure connection to the battery terminals be employed. If a battery with automobile terminal posts is used, the **large** post is the positive (+) post; the **smaller post** is the **negative** (—) terminal. It is suggested, when using a battery with auto type posts that large heavy lead covered battery clips be used in making connections. Make sure that **all wires** are firmly connected to clips (solder if possible). Also see that the jaw teeth of the clips are clean, and firmly bite into the post. It is very important that the battery posts and battery clip teeth be cleaned at frequent intervals to assure maintaining good connections. Corrosion may be readily removed by cleaning with a solution of 3 tablespoons of bicarbonate of soda (baking soda) and one cup of water. This solution neutralizes the acid coating that causes the corrosion and leaves a protective condition that retards further corrosion. It is important that this solution does not in any way enter the interior of the battery.

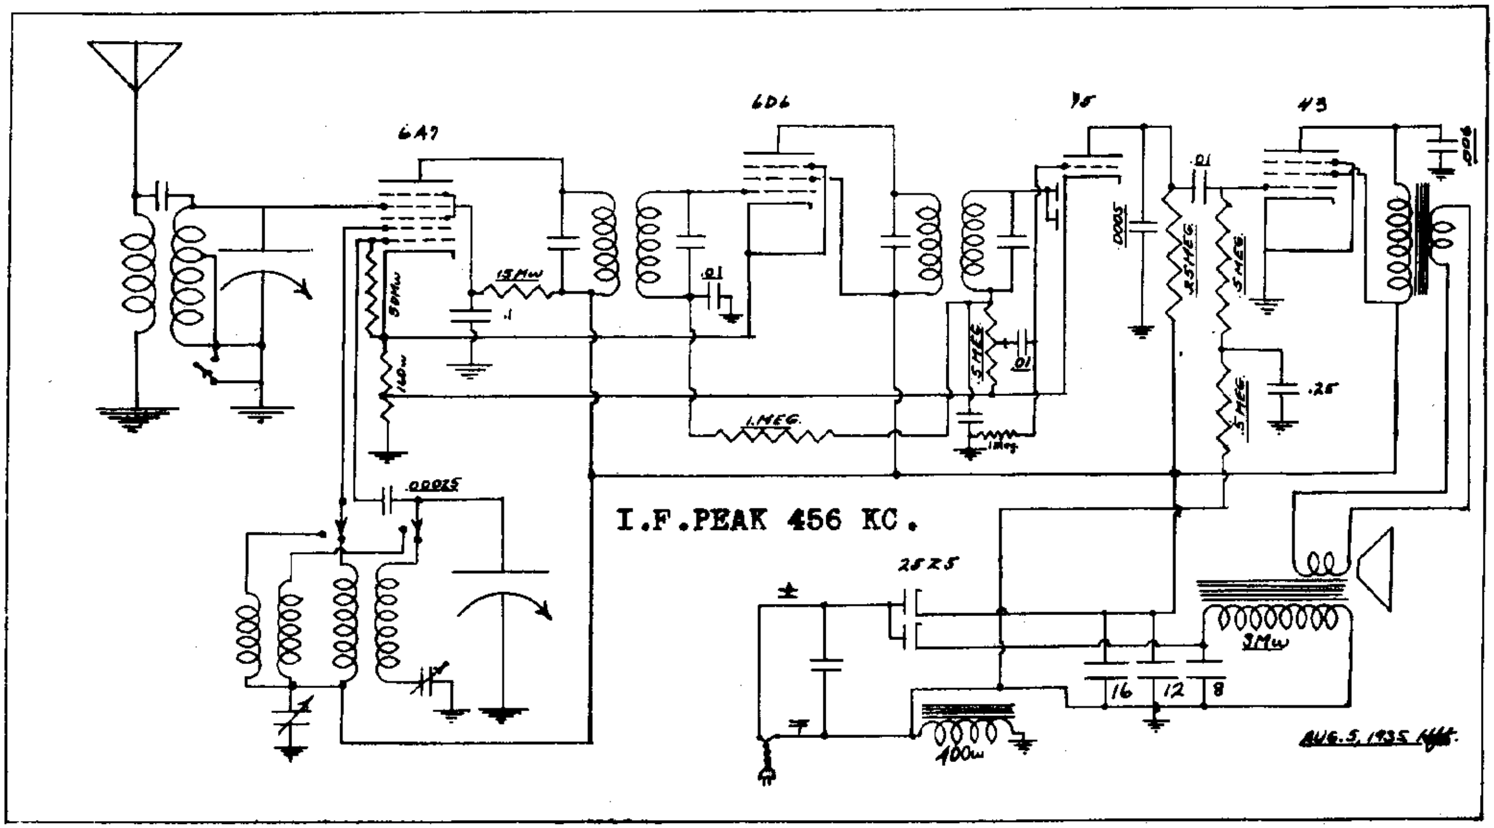
RADOLEK CO.



This receiver is a five-tube superheterodyne type which operates on EITHER AC OR DC CURRENT at a frequency of 25 to 60 cycles and at 110 volts. It has two bands, covering the standard broadcast from 1500 to 540 kilocycles, and the police band from 4500 to 1650 kilocycles. Refer to tube layout on bottom of cabinet for position of tubes.

ANTENNA

A 20-foot coil of antenna wire is supplied connected to the receiver. This is usually sufficient for most locations if it is unrolled and laid on the floor or thrown out of window. However, in some buildings of steel construction it may be necessary to use an outside antenna to obtain satisfactory results. Connect it to end of the antenna supplied.

GROUND

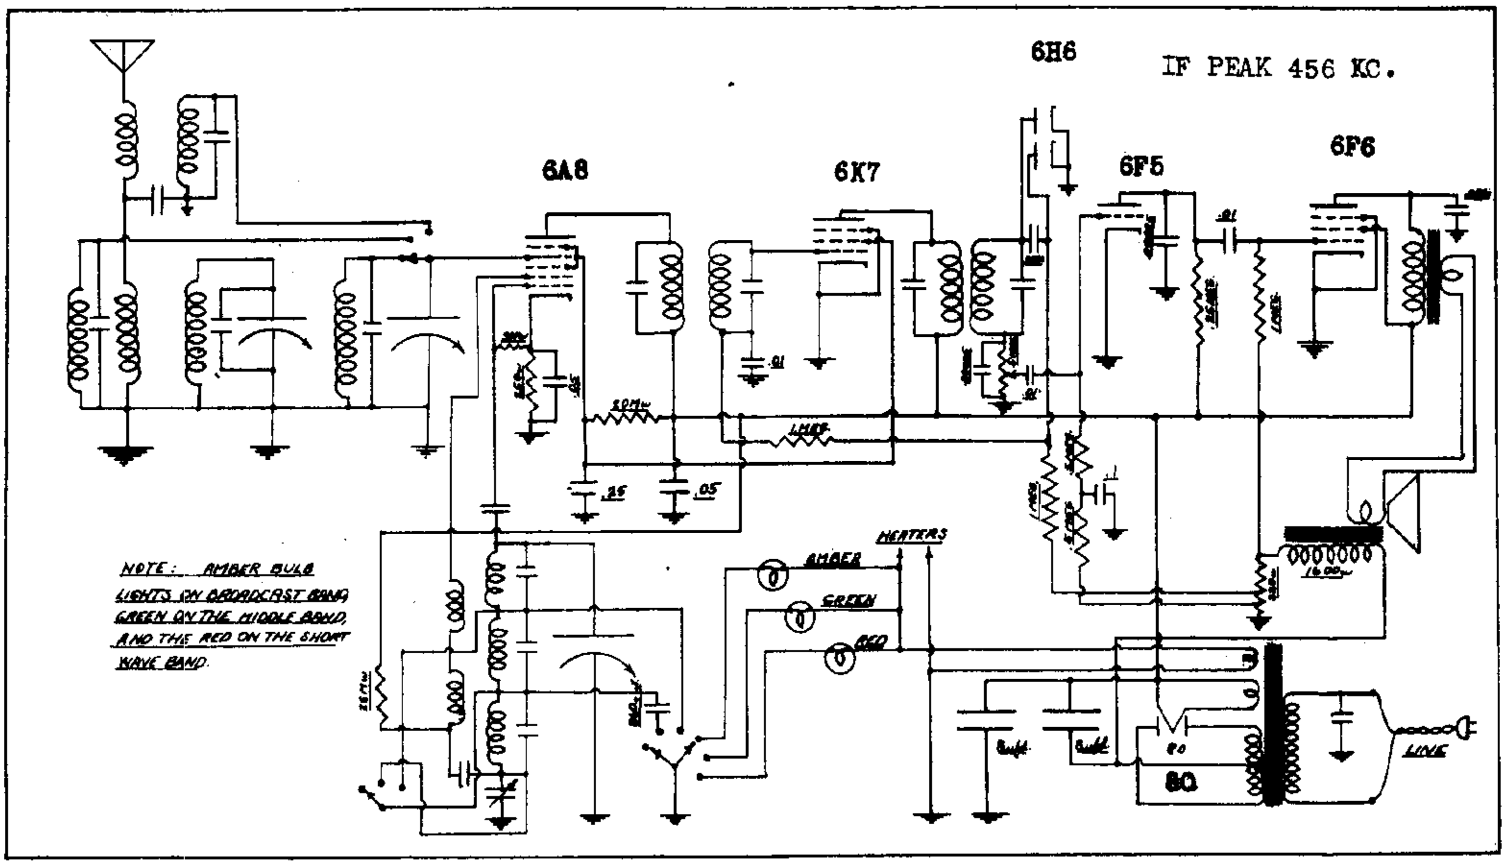
No ground connection is necessary. There is no provision made for its use on this set.

OPERATION OF SET

The set is turned on with the left hand knob; when turned to the right, it switches on the set, illuminating the dial, and when turned further acts as the volume control. The right hand knob is the station selector with which the stations are tuned in. A knob at the rear of the set switches on the short wave band. Best reception on the short wave can only be expected with the attachment of the antenna lead to an outside aerial. This will help to bring in more distant stations and will eliminate background noise. The wall plug may have to be reversed in its socket if set does not play, as on DC current, it will play only in one position, but on AC current, will play in either position....Do not become alarmed at warmth of cord, as it is asbestos lined, and is the means of escape of the heat generated in the radio.

MODEL 10927
Schematic
Notes

RADOLEK CO.



This radio is a six-tube Superheterodyne type which operates ON AC CURRENT ONLY at a frequency of 60 cycles and at 110 volts.
It covers three wave bands, as follows:

Standard Broadcast band - 540-1750 kc - AMBER light
Police and Amateur band - 1650-5000 kc - GREEN light
Short wave, American & Foreign - 18-5.7 meg.-RED light

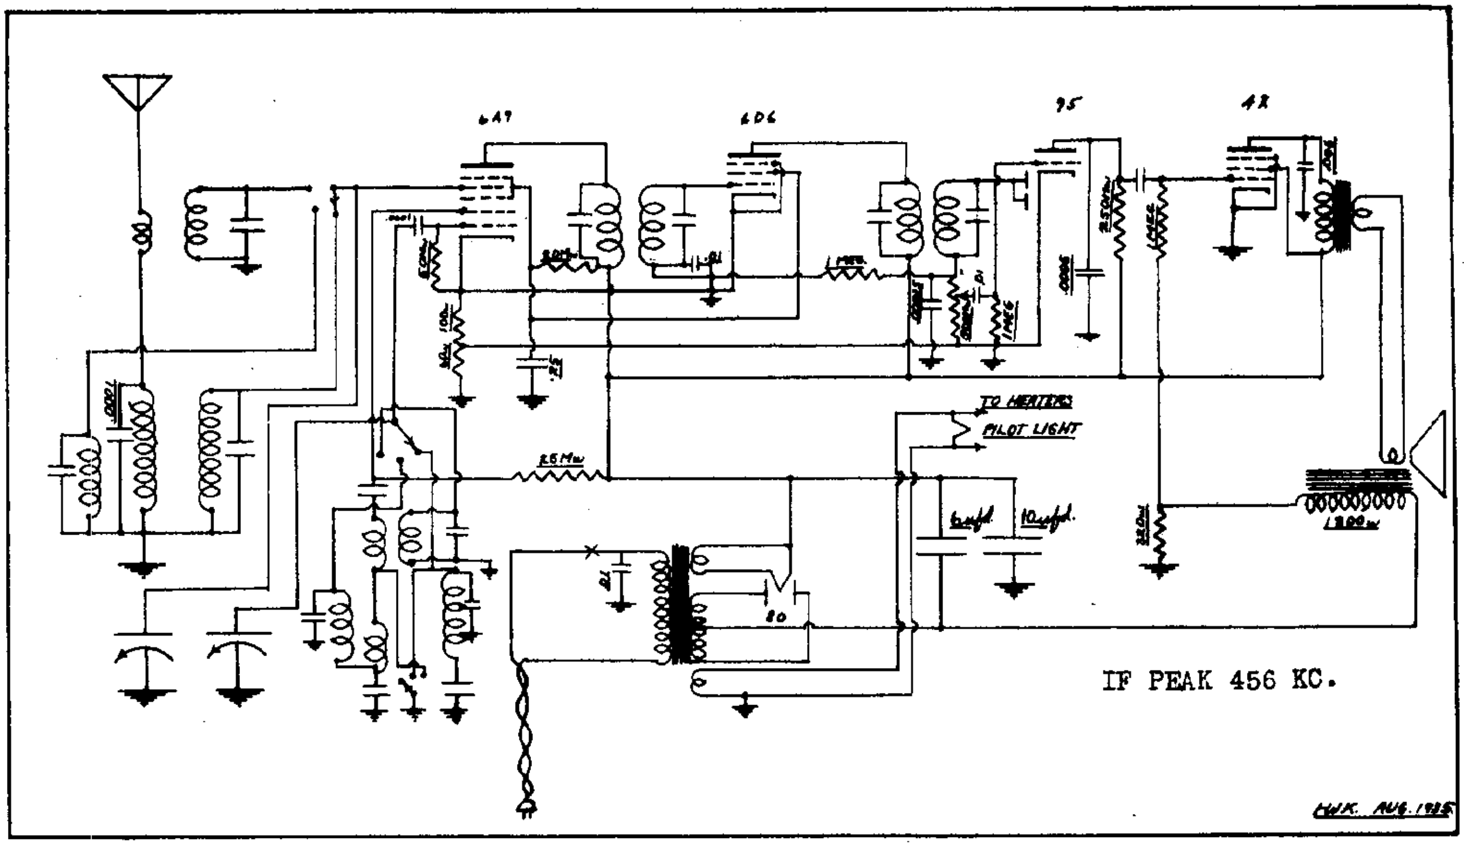
Antenna and Ground

An outside antenna is desirable with this radio in order to obtain the maximum in performance. With an efficient outside antenna, foreign reception is guaranteed. The short red wire in the rear should be connected to the antenna. It is desirable to have this antenna clear of surrounding objects and as high as possible from the ground. The black wire is the grounding terminal. If the lighting circuit is not already grounded, reception will be improved by connecting this black wire to the cold water pipe or radiator; otherwise the ground wire can be left free.

Operation of Set

The right hand knob switches on the set, and thereafter acts as the volume control. The upper middle knob is the station selector with which the stations are tuned in. The lower middle knob is the variable tone control, allowing you to control the tone for base or sharp timbre. The left hand knob controls the three wave bands of the set. When turned to the extreme left, the broadcast band is on, showing an AMBER light; switched to the center, the police and amateur band is on, showing a GREEN light; the extreme right brings in the short wave, showing a RED light. Success with short wave requires more careful tuning than with the broadcast band and necessitates study of a chart to ascertain location of the principal short wave broadcasting stations. Air conditions are not always favorable to short wave reception, under which conditions nothing can be done, but with reasonable atmospheric clearance, good foreign reception may be had.

RADOLEK CO.



This radio is a five-tubes Superheterodyne type which operates on AC CURRENT ONLY at a frequency of 60 cycles and at 110 volts. It covers three wave bands, as follows:

.Standard broadcast band -- 540-1750 kc - No. 1 on left-hand knob
Police & Amateur band -- 1650-5000 kc - No. 2 on left-hand knob
Short wave, American & Foreign - 18-5.7 meg. No. 3 on left-hand knob

Antenna and Ground

An outside antenna is desirable with this radio in order to obtain the maximum in performance. With an efficient outside antenna, foreign reception is guaranteed. The short red wire in the rear should be connected to the antenna. It is desirable to have this antenna clear of surrounding objects and as high as possible from the ground. The black wire is the grounding terminal. If the lighting circuit is not already grounded, reception will be improved by connecting this black wire to the cold water pipe or radiator; otherwise the ground wire can be left free.

Operation of Set

The right hand knob switches on the set, and thereafter acts as the volume control. The center knob is the station selector with which the stations are tuned in. The left hand knob controls the three wave bands. The line on the knob properly aligned with the numbers 1, 2, or 3 shown on the face of the cabinet will bring in the respective bands shown above. Success with short wave requires more careful tuning than with the broadcast band, and necessitates study of a chart to ascertain location of the principal short wave broadcasting stations. Air conditions are not always favorable to short wave reception, but with reasonable atmospheric clearance, good foreign reception is guaranteed.

SUPPLY VOLTAGE

This receiver operates from any 110 volt light socket of any frequency AC or straight DC. When operating on a DC socket, the plug may have to be reversed in the socket to obtain the correct polarity, as it will work only in one position on DC current, but in either position on AC current.

ANTENNA

A 20 foot coil of antenna wire is supplied connected to the receiver. This is usually sufficient for most locations if it is unrolled and laid on the floor or thrown out of window. However, in some buildings of steel construction it may be necessary to use an outside antenna to obtain satisfactory results. Connect it to end of the antenna supplied.

TUBE LOCATIONS

R. F. ALIGNMENT:

With the wave-change switch in broadcast position, set oscillator to 1500 kilocycles and connect in series with a .00025 mfd. condenser to Antenna of receiver. Rotate variable condenser to the 1500 setting on the dial and adjust trimmer condenser of oscillator section to resonance.

The oscillator section is the rear section of variable condenser. Re-set oscillator to 1400 kilocycle dial setting. Now adjust antenna section trimmer (front section) to resonance. Set oscillator to 600 and 1000 kilocycles and check alignment at these frequencies. If necessary, bend plates of antenna section for low frequency alignment. Do not bend plates of oscillator section. No adjustment should be necessary for the police band. However, set test oscillator to 1.6 and 4.0 megacycles and check alignment at these frequencies.

I. F. ALIGNMENT:

Connect an output meter to the screen and plate terminals of the 42 tube. Rotate gang condenser to maximum capacity and turn volume control on full. Now connect a test oscillator in series with a .00025 mfd. condenser to the grid of the 6D6 tube. Set the test oscillator to 456 kilocycles. Tune the second I.F. transformer to 456 kc. by adjusting the trimmer across the secondary of the I.F. transformer. This trimmer is located under the chassis. Then connect the oscillator to the grid of the 6A7 tube and adjust the first I.F. trimmers to resonance.

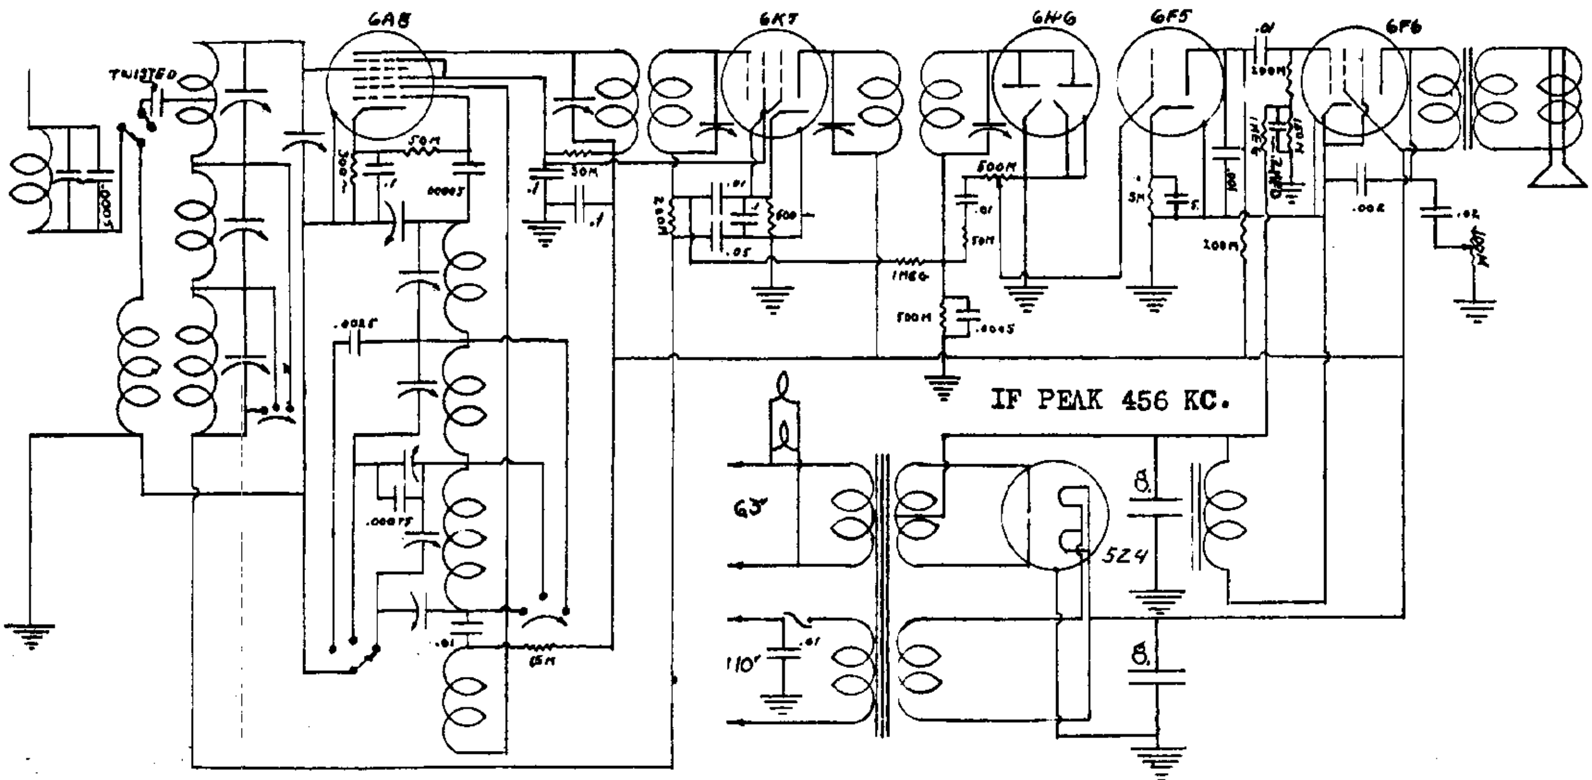
Alignment

RADOLEK CO.



SERVICE NOTES: If the radio fails to operate when unpacked, or stops working after a few days, proceed as follows: (1) Have the tubes checked. (2) Remove the chassis from the cabinet and check for loose connections. (3) Have a competent "Radio Service Man" check over entirely. This set left the factory carefully inspected. Should rephasing be necessary, attach the output lead from a 456 KC test oscillator to the grid cap of the converter tube, keep the signal to a very low audible value and carefully adjust the two trimmer screws in the top of I. F. coils to loudest volume. If an output meter is available it should be used across the voice coil leads at the speaker transformer. An oscillator covering a frequency from 550 KC to 16 megacycles should be used to rephase the R. F. The test oscillator output is attached to the aerial lead of the set. At all times keep the oscillator signal turned down to a low point of audibility. Trim the short-wave band first, next the intermediate band, and then the broadcast band, to a frequency near the high frequency end of the dial in each case. Looking at underside of chassis with controls toward front the trimmers on oscillator coil from right to left are short-wave, intermediate and broadcast, respectively. The trimmers for the R. F. are in can on topside of chassis and are in the same order with short-wave closest to base. The porcelain base trimmer in the center of chassis is the intermediate band padding condenser, and the porcelain base trimmer closest to front is for broadcast. These are adjusted to set the low frequency ends of the intermediate and broadcast bands to correct location on the dial.

NOTE: On E Models (European) the three-plate bakelite trimmer connected from porcelain trimmer to band switch is the long wave trimmer. The trimmer on the left of oscillator coil is turned tight and should not need adjustment. The porcelain trimmer in center of chassis is long wave, and the one closest to front is broadcast. These two padding condensers are adjusted to set the low frequency ends of the broadcast and long wave bands to correct location on the dial.

PHONOGRAPH: Install a single pole double-throw toggle switch near the 75 tube, disconnect the .01 mfd. condenser from the volume control and connect to one side of switch, connect the volume control to center terminal of the switch, connect one side of the phonograph pickup to remaining side of the switch and the other side of the pickup to "B" minus.

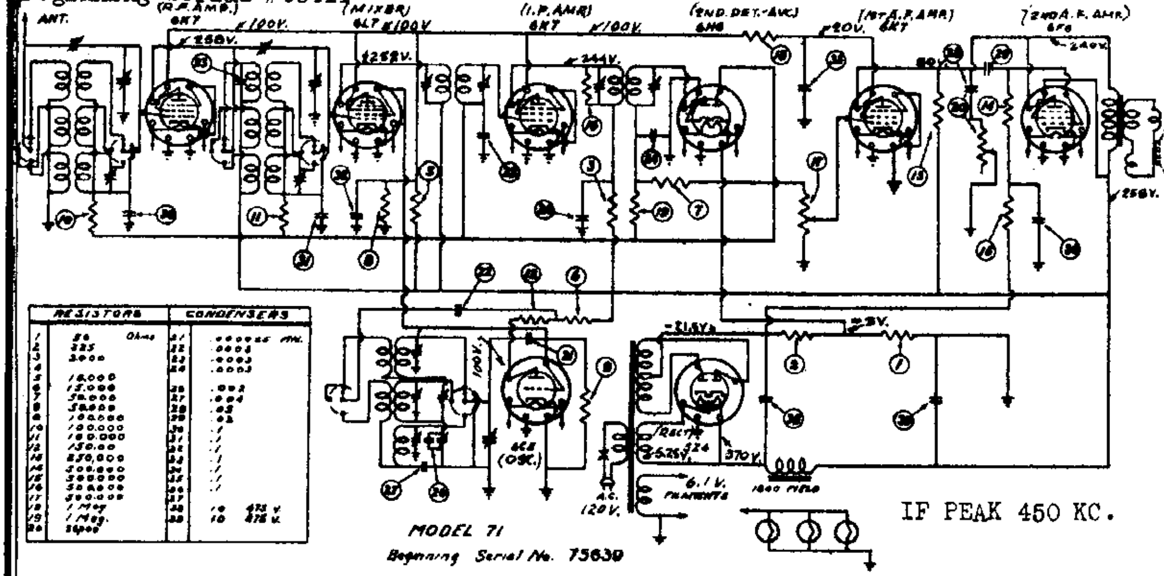
Schematics, Voltage, Data



The R.F. Mixer and oscillator coils are located in the square shields on the right end of the chassis. Trimmers for these circuits are mounted along the end of the chassis in the following order from front to rear:- R.F. short wave, mixer short wave, oscillator short wave, oscillator medium wave, oscillator broadcast. The R.F. broadcast and the mixer broadcast trimmers are mounted on the S.W. switch assembly.

Oscillator pads are located on the back of the chassis. The broadcast pad is nearest the end of the chassis and the medium wave next.

Model 40 (late)

The first I.F. transformer is in the aluminum shield at the back of the variable condenser. The mixer coil is trimmed by the back section trimmer and is located over the variable condenser. The oscillator coil is within the chassis and is trimmed by the front section trimmer on the variable condenser. The second I.F. transformer is also located within the chassis and may be trimmed by the condensers mounted thereon. The intermediate frequency used is 450 kilocycles.

Model 41

The antenna and mixer coils are located over the variable condenser, while the oscillator coils are at the rear of the condenser. The trimmer for the short-wave section of the mixer coil is located at the end of the form. The oscillator series padding condenser for the broadcast range is mounted at the right end of the chassis. The I.F. transformers are located within the chassis. In moving the chassis from the cabinet, pry off the knobs with a wooden screwdriver and pull off the pointer from the condenser shaft.

D.C. VOLTAGES: (No signal; volume control full on)

The antenna and R.F. coils are in the shielding can nearest the front of the chassis and the mixer coil is in the shield within the chassis. The first I.F. transformer is mounted in the shield between the 6A7 and 6D6 tubes; while the second I.F. transformer is located between the 6D6 and 75 tubes. The oscillator coil is within the set and is trimmed by the trimming condenser mounted adjacent to the coil.

Trimmers for the short wave position are located at the top of the R.F. coil and on the right end of the chassis within the coil shields. No trimmer is provided for the oscillator short wave position. The oscillator padding condenser for the broadcast position is located at the right end of the chassis.

D.C. VOLTAGES (No signal):

Readings taken with 1000-Ohm per volt meter.

The R.F. stage coils are located in the shield at the back of the variable condenser and the mixer coils in the shield between the 6K7 R.F. amplifier tube and the first I.F. stage. The oscillator coils are within the shield nearest the front of the chassis. Trimmers for the oscillator coils are mounted at the bottom of the coil and are accessible from within the chassis. The B.C. trimmer is nearest the front of the chassis, with the M.W. and S.W. sections next in order from front to rear. The trimmers for the S.W., R.F. and mixer coils are located in the tops of the respective coil shields. The trimmer nearest the back of the gang switch trims the M.W. R.F. coil, while the trimmer between the first and second switch sections is a coupling condenser from the R.F. to mixer stages.

Poor performance on the low frequency portion of the S.W. range may be traced to a weak 6A8 tube. Excessive hum may be due to a defective 6J7 or 5Z4 tube.

Model 60

The antenna and mixer coils are located adjacent to the variable condenser while the oscillator coil is located under the condenser. The short-wave coils are mounted near the broadcast oscillator coil. Trimmers for the oscillator and mixer circuits are on the variable condenser. The first I.F. transformer is in the shield at the rear of the chassis while the second I.F. transformer is below the chassis. The I.F. frequency is 450 K.C.

The antenna and mixer coils are located adjacent to the variable condenser, while the oscillator coils are mounted below the chassis floor. The trimmer for the short-wave section of the mixer coil is located on top of the coil form. The oscillator series padding condenser for the broadcast range is mounted at the right end of the chassis. The I.F. transformers are located within the two shield cans; trimmers for adjusting these are located in the tops of the shield cans. In removing the chassis from the cabinet, pry off the knobs with a wooden screwdriver where set screw knobs are not used.

The location of the antenna coil is near the variable condenser. The oscillator coil is mounted under the chassis with the short wave coil adjacent. Trimmers for the broadcast band are located on the side of the variable condenser. The I. F. transformers are within the square shields on the top of the chassis with trimmers adjustable thru holes in the tops of the shields. The I. F. frequency is 450 K. C.

89 - Output	150	155	165	170	*	*	15.5	18	3	3
80 - Rectifier	Max. d. c. = 295 v.						Plate current = 22 m.a. per plate			

* - High series resistance, (a) - Too low to read, Watts = 80, Speaker field voltage = 110v.

Control grid readings taken on 150 volt scale of 1000 ohms per voltmeter; others on 750 volt scale. Readings taken with antenna and ground shorted together and no signal received. These are average values. Ordinarily, deviations up to 20% are permissable and do not necessarily indicate a fault. Where series grid resistors prevent grid voltage readings, proper plate current at the rated plate voltage will serve as an indication of proper grid bias and normal functioning of the tube. Care must be used when readings are taken with an analyzer since the capacity of the cable may cause the circuit to oscillate and give erratic readings. Usually, touching a finger to the grid or plate will stop oscillation. These readings were taken with the speaker field hot. Readings taken when the field is cold will be higher because of the lowered field resistance.

ALIGNMENT PROCEDURE

If it becomes necessary to align the oscillator-translator and R. F. stages, it should be done at about 1250 kc and then "touched up" at about 1600 kc. Trouble may be experienced if an attempt is made to secure alignment at 1600 kc without having obtained approximate alignment at 1250 kc. At 1600 kc the capacity of the oscillator-translator trimmer may be sufficient to tune the oscillator-translator stage to the same frequency as the R. F. stage, resulting in feedback and violent oscillation.

SERVICE NOTE

The 2500 ohm speaker field is used as the filter choke. It carries the plate and screen current of all the tubes as well as the bleeder current flowing through the screen supply resistors to ground. Should the output transformer, plug, or voice coil be replaced, it is important that it be reconnected with polarity correct as shown in the service illustration. Otherwise the hum due to the field will be in phase with that in the hum bucking coil, intensifying instead of eliminating the speaker hum.

S.R. MODEL 7157 & 1869X

ALIGNMENT PROCEDURE

I.F. Transformers:

1. Connect the feeder from the oscillator to the grid of the 77 autodyne tube. Remove the grid connection and connect a 500 M ohm resistor from grid of the tube to ground. Rotate the variable condenser to full open position.

2. Set the oscillator to 456 K.C. and adjust the I.F. and diode feeder trimmers to obtain maximum reading on the output meter.

Variable Condensers.

1. Set the service oscillator to 1540 K.C. and connect it to the antenna lead of the set.

2. Rotate the condenser all the way out and adjust the trimmer on the oscillator section for greatest output.

3. Set the service oscillator to 1400 K.C. and tune the signal in on one set.

4. Adjust the antenna trimmer for maximum gain.

5. Set the service oscillator to 600 K.C. Tune the set to the signal and adjust the padder for maximum gain while tuning the variable back and forth across the signal.

January 4, 1935

ALIGNMENT PROCEDURE

The IF Stages:

1. Connect the low scale of the output meter across the loud speaker voice coil.

2. Connect the ground lead of the test oscillator to the receiver chassis.

3. Connect the other lead of the test oscillator, through a .1 mfd. condenser, to the control grid of the 58 second IF tube. The grid clip should be left attached to the cap.

4. Set the test oscillator to 445 kc and tune the IF output transformer. The locations of its tuning adjustments are shown in the Service Illustration.

5. Change the test oscillator connection to the control grid cap of the 58 first IF tube and tune the IF interstage transformer.

6. Change the test oscillator connection to the control grid cap of the 58 translator tube and tune the IF input transformer.

In all of these adjustments the tone control should be in the brilliant position, the volume control on full, and the test oscillator adjusted to give the lowest possible output consistent with a readable deflection of the output meter. After all three IF transformers have been peaked, it is advisable to repeat the operations, starting with the IF output transformer, to secure greater accuracy.

RF Alignment; Broadcast:

1. Set the test oscillator to 1750 kc.

2. Loosely couple the output of the test oscillator to the antenna lead of the set, with the antenna connected. Leave the output meter connected to the loud speaker voice coil as for IF alignment. The tone control and volume control also should be left full "on" as for RF alignment.

3. Turn the variable condenser plates all the way. Then adjust the oscillator trimmer for maximum output. The locations of the trimmers are indicated in the Service Illustrations.

4. Set the test oscillator to 1400 kc and adjust the trimmers on the antenna and translator sections of the variable condenser.

5. Set the test oscillator to 600 kc and tune in its signal. Then slowly rotate the variable condenser back and forth a degree or two and, at the same time, adjust the broadcast oscillator padder for maximum output.

6. Repeat the 1750 kc and 1400 kc adjustments to secure greater accuracy. Always use the lowest possible output from the test oscillator.

RF Alignment; Short Wave:

1. Set the test oscillator to 15 megacycles, leaving it coupled to the set's antenna lead as for broadcast alignment.

2. Turn the wave band switch to the short wave position and tune in the test oscillator signal. Then adjust the trimmer on the short wave translator coil for maximum output.

The lead from the wave switch to the center condenser section should be kept as far away as possible from the short wave oscillator coil.

ALIGNMENT PROCEDURE

The IF Stages:

1. Connect the low scale of the output meter across the loud speaker terminals.

2. Connect the ground lead of the test oscillator to the chassis.

3. Connect the other lead of the test oscillator, in series of .1 mfd. condenser, to the grid of the second IF tube. Leave the grid clip attached to the cap.

4. Set the test oscillator to 175 kc and tune the IF output transformer. The locations of the tuning adjustments are shown in the Service Illustrations.

5. Change the test oscillator connection to the grid of the first IF tube and peak the IF interstage circuit. This circuit contains a single tuning adjustment.

6. Change the test oscillator connection to the grid of the translator tube and tune the IF input transformer.

7. Repeat all of the adjustments to secure greater accuracy. Start with the IF output transformer.

Always use as low an output as possible from the test oscillator in order to render the AVC action of the receiver inoperative.

Broadcast Alignment; #1 Range:

1. Set the test oscillator to exactly 1700 kc.

2. Loosely couple the output of the test oscillator to the antenna lead of the receiver, with the antenna connected.

3. Turn the variable condenser plates all the way out and adjust the broadcast oscillator trimmer for maximum output. The location of this trimmer is shown in the Service Illustration.

4. Set the test oscillator to 1400 kc and tune in its signal. Adjust the broadcast translator coil trimmer and the trimmer on the antenna section of the variable condenser for maximum output.

5. Set the test oscillator to 600 kc and tune in its signal. Then slowly rotate the variable condenser back and forth a degree or two and, at the same time, adjust the padder until maximum output is obtained.

6. Repeat all of the adjustments, always using the lowest possible output from the test oscillator.

Short Wave Alignment; #2 Range:

1. Set the test oscillator to 5250 kc, leaving it coupled to the set's antenna lead, as for broadcast alignment.

2. Open the variable condenser plates all the way and turn the wave switch to the #2 range position.

3. Adjust the #2 range oscillator coil trimmer for maximum output.

4. Set the test oscillator to 4500 kc and tune in its signal. Then adjust the #2 range translator coil trimmer.

5. Set the test oscillator to 1750 kc and tune in its signal. If necessary, turns on the #2 range translator coil may be shifted to secure maximum output. If turns are shifted it will be necessary to repeat the 4500 kc trimmer adjustment.

Short Wave Alignment; #3 Range:

1. Set the test oscillator to 15,800 kc, leaving it coupled to the set's antenna lead as for the lower frequency ranges.

2. Open the variable condenser plates all the way and turn the wave switch to the #3 range position.

3. Adjust the #3 range oscillator coil trimmer for maximum output.

4. Set the test oscillator to 14,000 kc and adjust the #3 range translator coil trimmer.

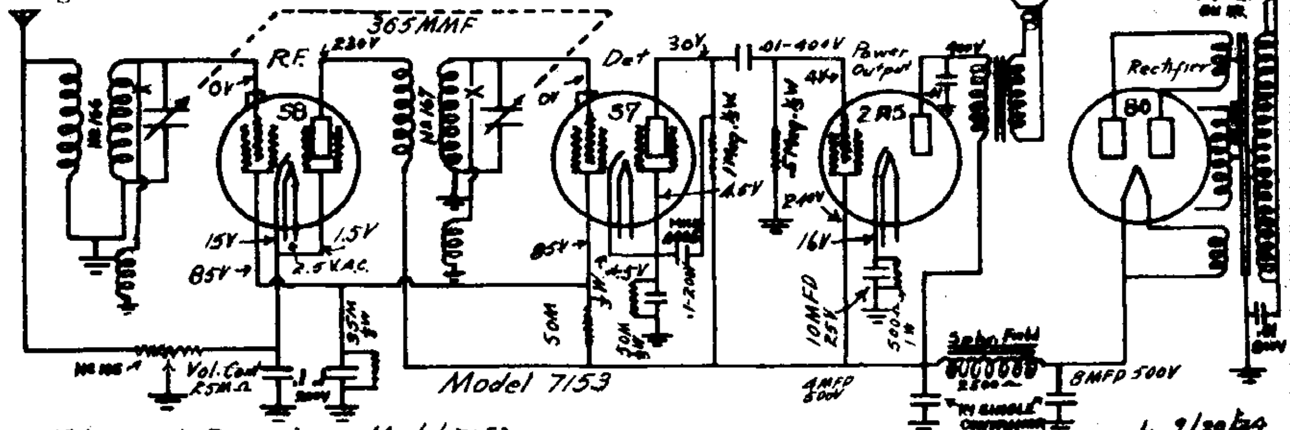
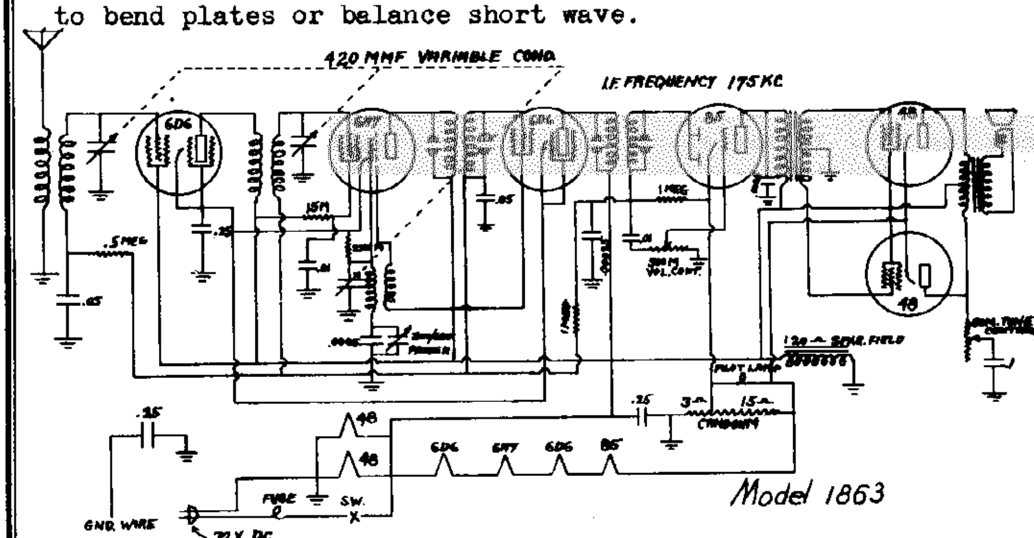
MODEL 186
MODEL 715



Alignment Procedure *Model 7153*

1. Turn volume control all the way up, then back down until oscillation stops.
2. Turn variable condenser all the way open (Minimum capacity)
3. Apply a 1720 K C oscillator note into antenna.
4. Adjust variable condenser trimmers to maximum output - it will not be necessary to bend plates or balance short wave.



This set is designed to operate on 32V D.C., and does not have a separate power supply. The plate voltage is 32 V.

Parts may be secured direct from Echophone Radio Corp. 2611 Indiana Ave. Chicago, Ill.

1 - Rebalance I.F. Transformers, applying a 175 K.C. note at 6A7 control grid.
2 - Open variable condenser all the way (minimum capacity) apply a 1720 K C note an oscillator at the antenna of receiver.
3 - Check oscillator section of variable to 1720 K C, then adjust Interstage and antenna to maximum peak.
4 - Adjust low frequency padder by applying a 600 K C oscillator note into antenn and while rocking variable condenser across signal adjust padder until maximu output is obtained.

AVERAGE INSTALLATIONS ON 32 VOLT D C SYSTEMS.

CAUTION: Disconnect the batteries from the generator before installing suppressor equipment.

Connect one of the .5 mfd 200 V condensers between the positive brush and the generator frame, and the other .5 mfd condenser between one negative brush and the generator frame, as shown in Fig. 1. For four cylinder plants attach condensers as shown in Fig. 2.

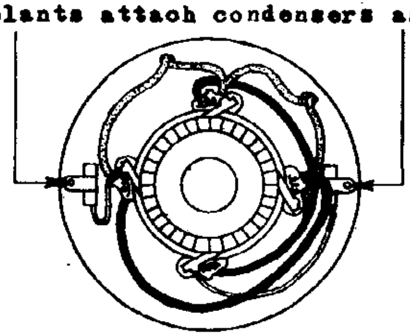

Fig.1

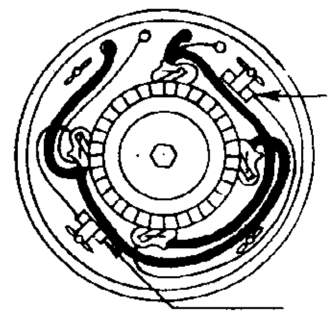

Fig.2

Connect the spark plug suppressor between the top of the spark plug and the high tension lead coming from the coil. When four cylinder plants are used to operate generator, three more .5 mfd, Part No. 617 may be obtained and attach one to each spark plug.

In extreme cases it may be necessary to shield the high tension lead coming from the coil to the spark plug. This should be done by using 3/8 copper shielded loom and ground each end of the shielding to the generator frame.

Some cases may require a good grounding of the system. This may be best accomplished by using No. 12 gauge solid copper wire and running it from the frame of the generator to a very good ground making the lead as short as possible.

Do not attempt to ground one side of the line unless it is absolutely necessary and great care must be taken that the opposite side of the line is not grounded in some unknown place.

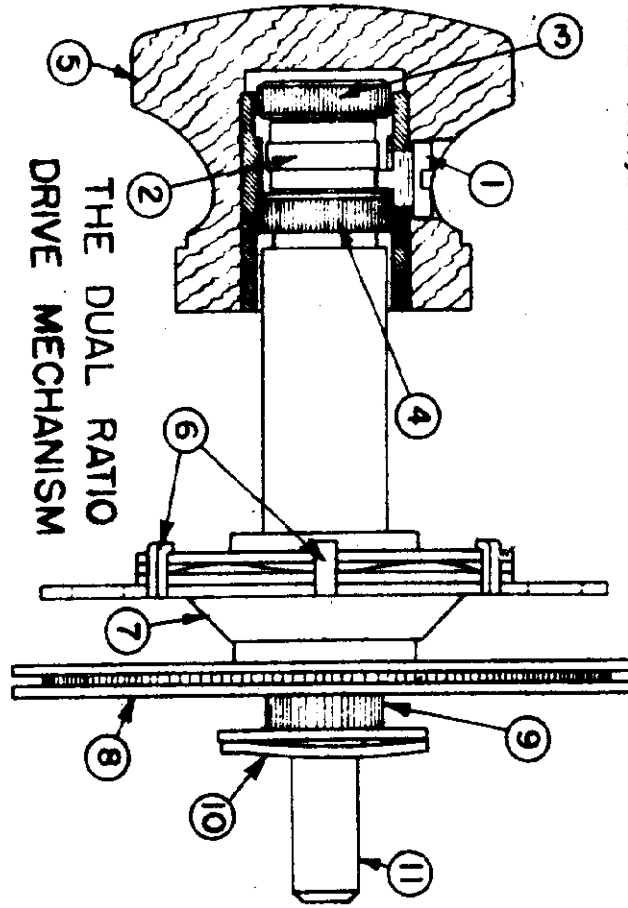
Dual Ratio
Drive Data



THE DUAL RATIO DRIVE MECHANISM

1 KNOB SET SCREW
2 FLOATING SLEEVE
3 SLOW MOTION SPLINE
4 FAST MOTION SPLINE
5 KNOB
6 PLANETARY HOUSING TABS
7 PLANETARY DRIVE HOUSING
8 BAND SPREAD GEAR
9 CONDENSER DRIVE GEAR
10 U SHAPED TENSION WASHER
11 SHAFT END

THE DUAL RATIO CONDENSER DRIVE SHAFT

There are two positions in which the Station Selector knob can be put before turning it. When the knob is pushed in the condenser drive ratio is approximately 17 to 1. When the knob is pulled out, the dial ratio becomes approximately 70 to 1, making possible very precise tuning.

The mechanism proper is of the planetary drive type, using ball bearings in contact with a cone shaped retainer. Do not attempt to take the mechanism apart. Should any difficulty with slippage occur, it can be corrected as described in the following paragraph. Slippage that occurs when the condenser reaches its limit of rotation in either direction is normal. However, if there is slippage at any other part of the condenser travel, proceed as follows:

Determine whether or not the Shaft End (11) is turning. See the illustration. If the shaft end turns but the gears (8 & 9) do not turn, remove the U shaped tension washer (10) and bend it to increase its curvature and tension. Then replace it. Note that the convex side of the washer should face the shaft end and the concave side should face the gears. If the shaft end does not turn, the slippage is occurring in the planetary drive mechanism. This will occur only when the knob is in its "out" or slow position. In this case, squeeze the tabs (6) slightly with a pair of pliers to increase the pressure. Do not squeeze them too much or the drive will become stiff and hard to turn.

When placing the knob on its shaft be careful not to use force in pressing it on or the splines (3 & 4) will become burred. The floating sleeve (2) must be centered on the shaft in order to permit the knob to slip over it. If the knob does not go on easily, do not force it, but try it several times until the sleeve gets into such position that it allows the knob to slip on. Care must be taken when tightening the set screw, that it is not tightened down on the splines but comes in the space between the two splines. This is best done by removing the set screw, positioning the knob so that the set screw hole comes over the sleeve, between the splines. Then insert and tighten the set screw.

MODELS 1905,1915,1955,1965
Alignment,Chassis,Trimmers SEARS-ROEBUCK & CO.

ALIGNMENT PROCEDURES

IF ALIGNMENT

1. Connect the output meter across the speaker voice coil. The low scale of the meter should be used (approximately 3 volts). Turn the wave switch to the BROADCAST position.

2. Turn the Variable Selectivity and Tone Control knob all the way to the right (clockwise). Loosen the set screws holding the flexible cables that change the IF coupling. Push the cables into the tubes as far as possible and tighten the set screws. Be sure the knob is kept at its extreme clockwise position during this procedure. Be careful when tightening the set screws that they are not screwed down so far that the cable wires are cut.

3. Set the test oscillator to 175 kc. Connect the ground lead of the test oscillator in series with .1 MFD condenser, to the receiver chassis. Attach the "hot" lead of the test oscillator to the control grid cap of the 6K7 tube.

4. Turn the Variable Selectivity control all the way to the left (sharpest position). Then carefully tune the IF output transformer for maximum output. The IF output transformer is the square can unit nearer the rear of the chassis. The volume control of the receiver should be turned all the way on during the adjustment and the output from the test oscillator kept at the lowest possible value.

5. Change the test oscillator connection from the control grid cap of the 6K7 to the control grid cap of the 6D6 tube. Then adjust the IF input transformer for maximum output meter reading. The receiver volume control must be all the way on and the output from the test oscillator kept at its lowest value, as mentioned in the preceding paragraph.

6. Change the test oscillator connection back to the 6K7 tube and repeat the IF output transformer adjustment for greater accuracy. Then change the test oscillator connection back to the 6D6 tube and repeat the IF input transformer adjustment for greater accuracy.

7. Connect the "hot" lead of the test oscillator to the control grid of the 6D6 tube and turn the variable Selectivity and tone control knob all the way to the right (broadest position). Starting with the test oscillator adjusted to about 150 KC., slowly increase the frequency of the test oscillator until it goes through resonance with the receiver and then on beyond resonance. It will be found that as resonance is approached a peak reading is had on the output meter. As the frequency of the test oscillator is increased, the output meter reading decreases and then increases again as the test oscillator frequency is further increased. That is, the resonance curve of the IF transformers, in the broad position, has a peak at either side and a hollow in the center. The output meter readings of the two peaks should be the same. If they are not, tune the test oscillator to resonance with the weaker peak. Then adjust the upper of the two tuning condensers of the IF output transformer (the square unit nearer the rear of the chassis) to increase the output meter reading. Only a very slight adjustment is necessary. Recheck the relative readings of the two peaks by tuning the test oscillator through resonance with the receiver as before. When properly adjusted, the two peaks will give equal output meter readings.

RF ALIGNMENT

Preliminary:

Alignment must be made in the same sequence as described below. During all of the alignment, the Variable Selectivity and Tone Control should be turned all the way to the left (sharpest position). Connect the ground lead of the test oscillator, in series with a .1 MFD condenser to the receiver chassis. Connect the output meter across the loud speaker voice coil as for IF alignment. The volume control of the receiver should be turned all the way on and the output from the test oscillator kept at its lowest possible value during all of the alignment procedure. Fully mesh the variable condenser and see that the station selector dial is horizontal. The Band Spread pointer should point straight up.

Short Wave (C) Band:

1. Turn the wave band switch to the "C" position. Connect the "hot" lead of the test oscillator, in series with a 400 Ohm resistor. to the terminal marked "A" on the antenna terminal block at the rear of the chassis.

2. Set the test oscillator to 15,000 kc. and tune in its signal. Adjust C5 for maximum output. The Variable Condenser should be rocked back and forth a degree or two while making the adjustment. It may be found that two peaks can be obtained at two different settings of the trimmer. Use the one in which the trimmer is screwed further in (greater capacity).

3. Change the signal generator frequency to 6,000 kc. and tune in its signal. Then adjust C4 for minimum output meter reading. (Note that this adjustment is to be for minimum output meter reading, not maximum reading).

Short Wave (B) Band:

1. Turn the wave band switch to the "B" position. Leave the test oscillator leads connected as for alignment on the "C" band.

2. Set the test oscillator to 3,900 kc. and adjust the translator trimmer condenser on the variable condenser section nearest the dial. Also adjust the antenna trimmer in the round can unit mounted behind the Variable Selectivity and Tone Control shaft. The variable should be rocked back and forth a degree or two while making the adjustments. If two peaks can be obtained, use the adjustment in which the trimmers are screwed furthest in.

CAUTION:- All of the adjustments must be made in the order stated and must not be changed during succeeding operations.

3. Repeat operation #2 of Short wave "C" band for greater accuracy.

Broadcast (A) Band:

1. Disconnect the 400 Ohm resistor from the "hot" lead of the test oscillator and in its place, connect a .00075 MFD condenser. The condenser in turn is connected to the "A" terminal on the antenna terminal block at the rear of the chassis.

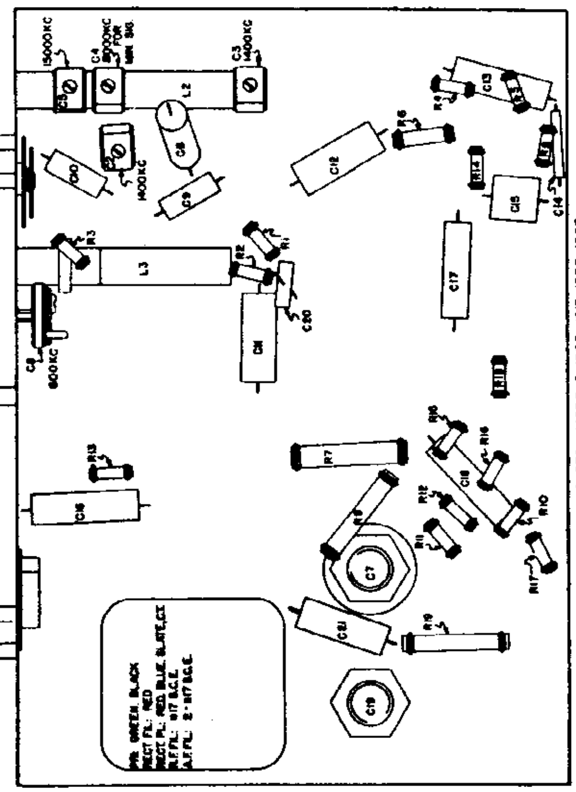
2. Turn the wave band switch to the BROADCAST position. Set the test oscillator to 600 kc. and tune in its signal. Then adjust the broadcast oscillator padder, C8, for maximum output meter reading. The variable condenser should be rocked a degree or two while making the adjustments.

3. Set the test oscillator to 1400 kc. and tune in its signal. Then adjust C2 and C3 for maximum output meter reading. The variable should be rocked back and forth a degree or two while making the adjustments. If two peaks can be obtained, use the adjustments in which the trimmers are screwed furthest in.

4. Repeat operation #2 for greater accuracy.

SERVICE NOTE ON DIAL DRIVE RATIO MECHANISM

There is a "U" shaped tension washer which fits into a groove at the back end of the variable selectivity control shaft. This washer must be placed on the shaft so that the convex side of the washer faces the back end of the shaft. If the washer is put on wrong, with the concave side facing the back of the shaft, the washer will work itself off the shaft and the shaft then will become loose and can be pulled off.



LOCATION OF PARTS - MODELS 1905-1915-1955-1965

TO REDUCE IMAGE RESPONSE

To reduce image response, turn the variable selectivity and tone control to its sharpest position (all the way to the left) and turn the volume control all the way one. Couple a test oscillator, adjusted to 1000 KC, to the antenna lead of the receiver and tune in its signal. The test oscillator must be adjusted to give high output.

Leaving the receiver tuned to 1000 KC, change the test oscillator frequency to approximately 1350 KC. Carefully adjust the test oscillator frequency so that its signal (the image) will be heard loudest in the receiver.

There is a wire that runs from the stator of the trimmer, C3, to a lug on the wave switch. Using a piece of bakelite or wood, to prevent hand capacity effects, push this wire up under the coil, L2. The wire should be to hug the coil closely. By pushing just the right amount of this lead under the coil, the image response can be balanced out.

It is not necessary to change any of the alignment adjustments of the receiver.

If a test oscillator is not available and a strong station of about 1350 KC, can be tuned in, this adjustment to eliminate image response can be made as follows:

Turn the volume control of the receiver all the way on and turn the variable selectivity control to its sharpest position, as before. Tune in the image of the station at a frequency 350 KC lower than the assigned frequency of the station. For example, if a station's assigned frequency is 1350 KC, tune in its image at a dial setting of 1000 KC on the receiver and balance out the image by shifting the wire in the same manner as described above for the method using a test oscillator.

MODELS 1909,1912,1962
MODELS 1942,1944,1972
Alignment

SEARS-ROEBUCK & CO.

ALIGNMENT PROCEDURE

IF Alignment:

1. Connect a jumper wire between terminals "D" and "G" on the antenna terminal block. Turn the Wave Band switch to the BROADCAST (A) position, the dial pointer to 900 kc, and the Tone Control to the #1 position. Connect the low scale of the output meter across the loud speaker voice coil. Connect the ground lead of the test oscillator to the receiver chassis. Turn the receiver volume control all the way on and keep the output from the test oscillator at the lowest value consistent with a satisfactory output meter reading.

2. Set the test oscillator to 175 kc. Connect the output lead of the test oscillator, in series with a .1 mfd condenser, to the control grid of the 6K7MG IF tube. Then peak the IF transformer, T2, for maximum output meter reading. This transformer is the square can unit mounted at the extreme left rear corner of the chassis, as one faces the rear of the chassis.

3. Change the test oscillator output lead connection (and the .1 mfd condenser) to the control grid of the 6A8MG oscillator-translator tube. Peak the IF transformer, T1, for maximum output meter reading. This transformer is the square can unit with a grid lead coming out of its top.

4. Repeat the adjustments in their original order for greater accuracy. Always keep the test oscillator output at its lowest possible value.

RF ALIGNMENT

Important:

Alignment of band "B" or "C" affects the alignment of the other lower frequency bands. Therefore band "C" must be aligned first, then band "B", then band "A".

Short Wave Band "C":

1. Connect the ground lead of the test oscillator to the receiver chassis. Connect a jumper wire between antenna block terminals "D" and "G", as for IF alignment. Connect the output lead of the test oscillator, in series with a 400 ohm resistor, to the "A" terminal of the antenna terminal block. Turn the Wave Band switch to position "C" and the Tone Control to position "1". During all of the alignment the receiver volume control should be turned all the way on and the output from the test oscillator kept at its lowest possible value.

2. Set the test oscillator to 14,000 kc and tune in its signal. Then adjust the short wave translator trimmer, C3, for maximum output meter reading. The locations of all of the trimmers are shown in the Location of Parts Illustration. The variable should be rocked a degree or two while making the adjustment. If two peaks are found at two different settings of C3, use the adjustment in which the trimmer is screwed further in (greater capacity).

Short Wave Band "B":

1. Turn the Wave Band switch to position "B". All other receiver connections and control settings remain the same as for band "C" alignment.

2. Set the test oscillator to 4500 kc and tune in its signal. Then peak the translator trimmer, C2, for maximum output meter reading. The variable should be rocked a degree or two during the adjustment. If two peaks can be obtained at two different settings of the trimmer, use the adjustment in which the trimmer is screwed further in (greater capacity).

Broadcast Band "A":

1. Remove the 400 ohm resistor that was connected in series with the test oscillator output lead, for alignment on the other two bands. Replace this resistor with a .00025 mfd mica condenser. Turn the Wave Band switch to the "A" position. Other connections and settings remain the same as for previous alignment.

2. Set the test oscillator to 1400 kc and tune in its signal. Then adjust the broadcast antenna and translator trimmers for maximum output meter reading. The antenna trimmer is the one on the middle section of the variable condenser. The broadcast translator trimmer, C1, is mounted on the translator coil as shown in the Location of Parts Illustration.

3. Set the test oscillator to 600 kc and tune in its signal. Then adjust the broadcast oscillator padding condenser, C8, for maximum output meter reading. The variable should be rocked a degree or two during the adjustment.

4. Repeat the 1400 kc adjustments and then the 600 kc adjustments for greater accuracy. Always keep the test oscillator at its lowest possible value.

5. Recheck the setting of band "C" translator trimmer, C3, at 14,000 kc.

Dial Calibration:

Set the test oscillator to 900 kc and tune in its signal, or tune in a 900 kc station. Then set the dial pointer to 900 kc without changing the setting of the variable.

Adjustment To Minimize Image Response:

1. Set the test oscillator to 1000 kc and tune in its signal. If the test oscillator output is calibrated it should be set to .1 volts. Leaving the receiver tuned to 1000 kc, change the test oscillator frequency until the image is heard. This will occur when the test oscillator is tuned to 1350 kc.

2. There is a yellow lead running from the wave switch to one side of the translator trimmer condenser, C3, The image response can be minimized by placement of this yellow lead.

SENSITIVITIES

The following are average sensitivities and they will serve as a guide in trouble shooting. In order to make the measurements a test oscillator having a calibrated attenuator must be used. The figures given are those required to obtain an output meter reading of 1.1 volts. Readings for the IF stage are to be made with a .1 mfd condenser, in series with the test oscillator output lead. Readings for the Broadcast band are with a .00025 mfd mica condenser, and for the Short Wave bands with a 400 ohm resistor in series with the test oscillator output lead, as used during the alignment procedure. The receiver volume control must be left on full.

6K7MG	IF Grid (175 kc) - 2000 uv.	
6A8MG	Translator (175 kc) - 30 uv.	
6A8MG	Translator (1000 kc, and with a .00025 mfd mica condenser in series with test oscillator output lead) - 35 uv.

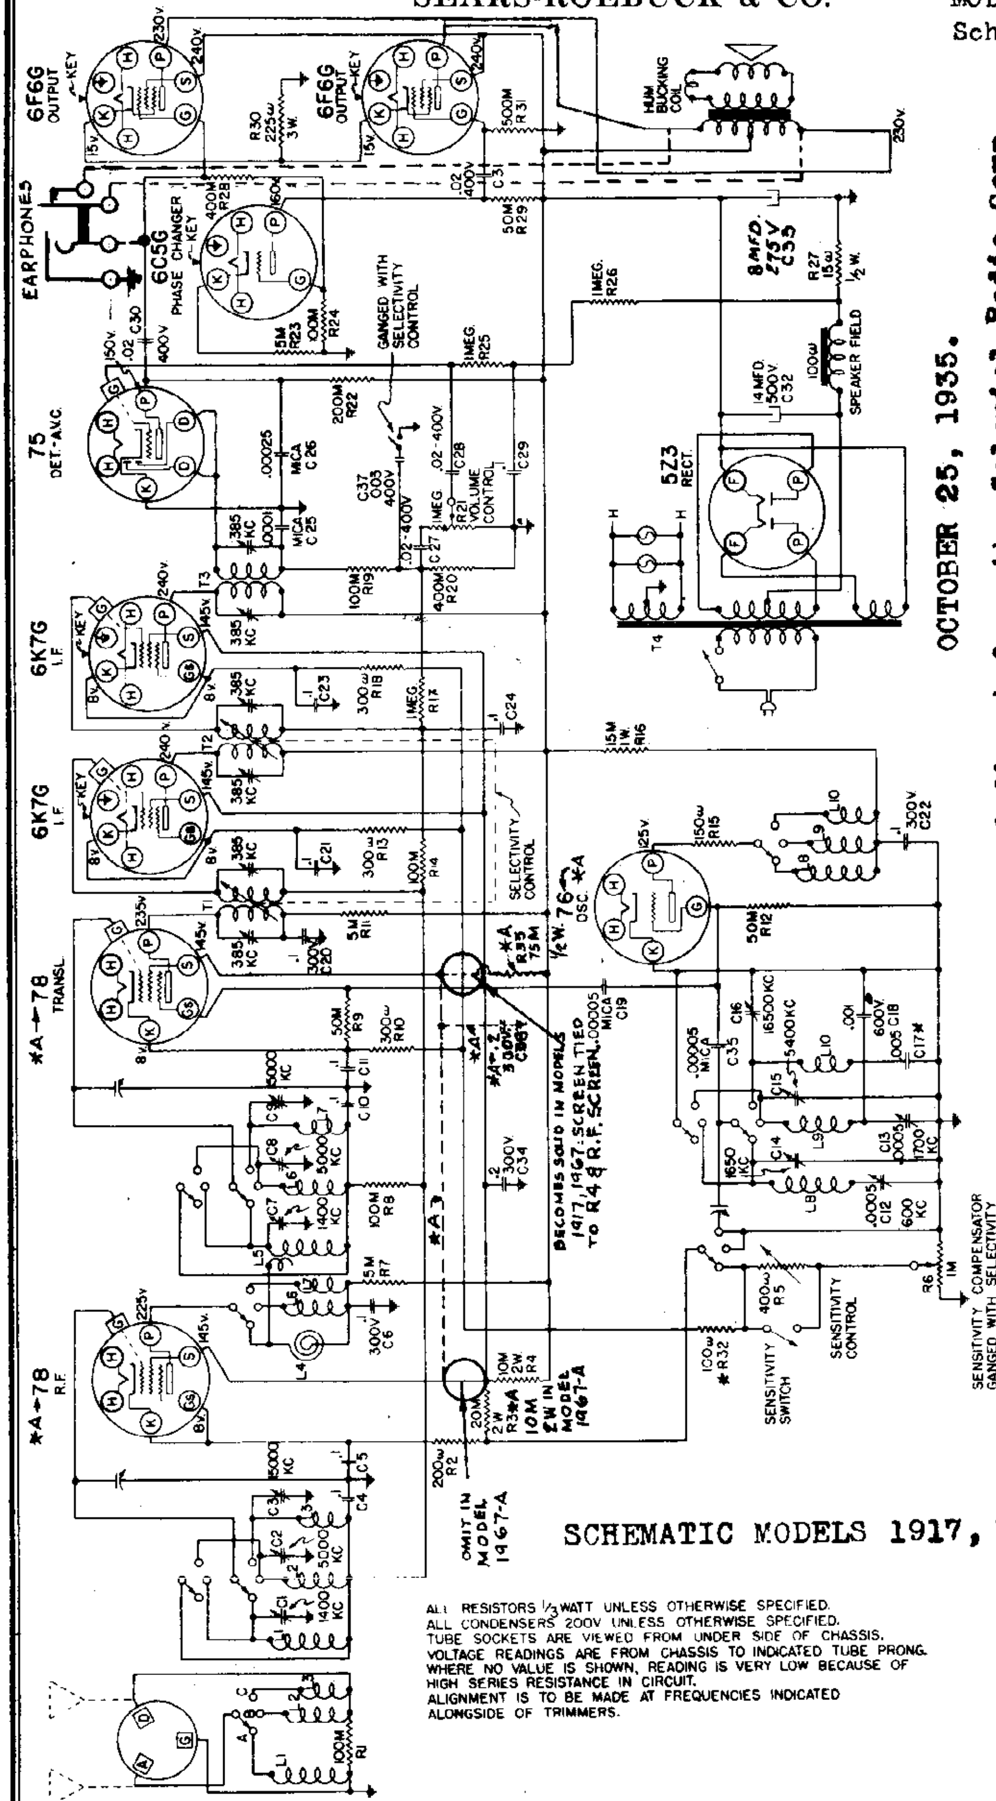
Schematic,Changes



OCTOBER 25, 1935.

Parts may be secured direct from the Colonial Radio Corp., 254 Rano Street, Buffalo, New York.

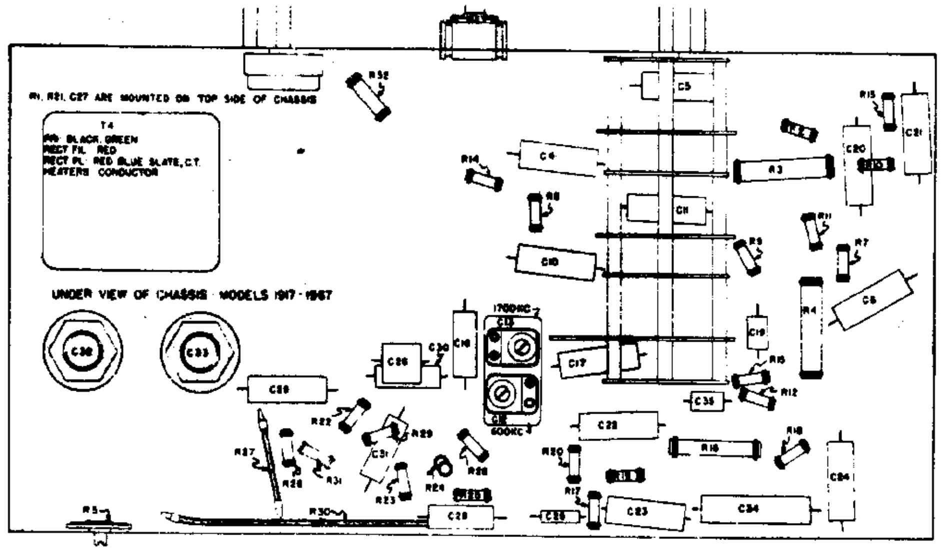
***NOTE:** Refers to changes made during production. I.e., C17 was .01mfd. now .005mfd., and R32, 100 ohm resistor was added.

***A NOTE:** Refers to changes and added parts in MODEL 1967-A only. In MODEL 1967-A tube types have been inter-changed as follows: 6K7MG for 78 R.F., 6L7MG for 78 Trans., 6C5MG for 76 Osc. IF PEAK 385 KC.

SCHEMATIC MODELS 1917, 1967, 1967-A.

MODELS 1917,1967,1967A
Chassis,Trimmers,Notes

SEARS-ROEBUCK & CO.



The Variable Selectivity And Tone Control:

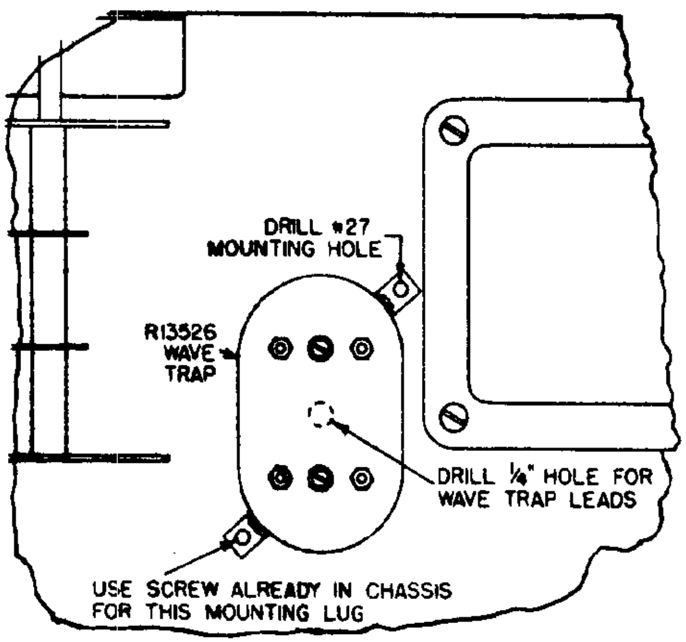
Earlier production used a bakelight cam for varying the coupling of the IF transformers. In sets using the bakelight cam it is necessary to turn the control all the way to the left (the sharpest position) before tuning in any broadcast station. For short wave reception the knob should be turned all the way to the left so that the numeral "1" comes opposite the marker pin.

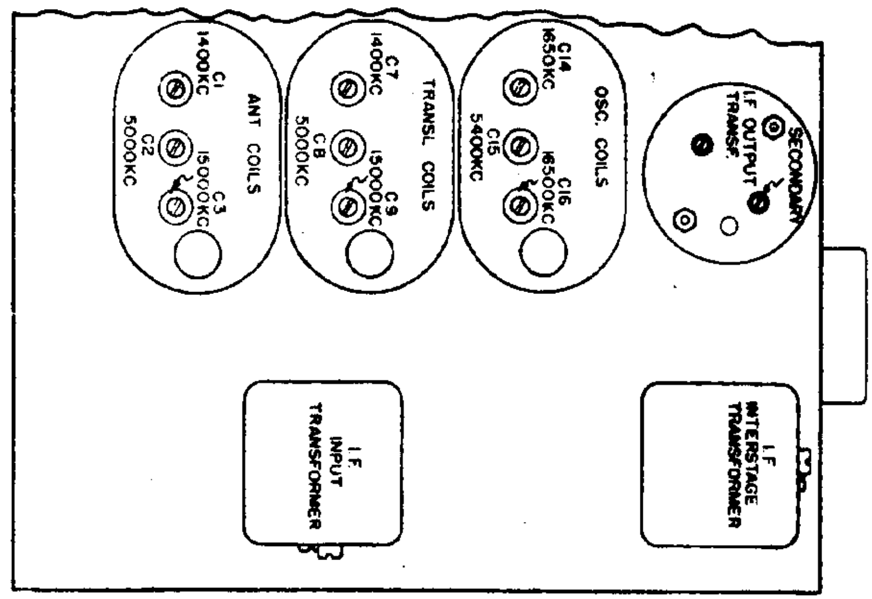
Later production used a metal rack and pinion for actuating the variable coupling of the IF transformers. In sets using the metal rack and pinion the Variable Selectivity and Tone Control knob may be left in the "F" position for simplified operation of the receiver. This position is an "average" one giving excellent tone quality and sufficient selectivity. However, to obtain the full range of adjustment possible with this control it must be operated the same as the bakelight cam type of control. That is, the control knob must be turned all the way to the left before tuning in any station and then turned to the point giving the desired tone after the station has been tuned in properly.

In some of these sets when the Variable Selectivity and Tone Control knob is turned all the way to the left an additional .003 mfd. condenser is switched into the circuit. This results in a still further deepening of the tone thereby increasing the tone control range provided by the Variable Selectivity and Tone Control knob.

The AVC Circuit:

The diode current of the 75 tube, flowing through the 100M ohm resistor, R19, creates a voltage drop across it. This voltage is applied to the control grids of the 78 and 6K7G tubes to provide AVC.





SEARS-ROEBUCK & CO.

MODELS 1917,1967,1967A
Alignment,Note

ALIGNMENT PROCEDURE

IF Alignment:

1. Connect the output meter (low scale) across the loud speaker voice coil. Turn the wave band switch to the broadcast position and the "On-Off" switch knob only far enough to turn the receiver on.

2. Turn the Variable Selectivity and Tone Control knob all the way to the left (sharpest position). Loosen the set screws holding the flexible cables that actuate the variable coupling of the IF transformers. Push the cables all the way into the tubes and tighten the set screws. Be sure the Variable Selectivity and Tone Control knob remains in its extreme clockwise position during the operation. Be careful when tightening the set screws that they are not screwed down so far that the cable wires are cut.

3. Connect the ground lead of the test oscillator, in series with .1 mfd. condenser, to the receiver chassis. Set the test oscillator to [illegible] kc.

4. Connect the "hot" lead of the test oscillator to the control grid of the 78 translator tube. With the Variable Selectivity and Tone Control knob turned all the way counter clockwise (sharpest position), adjust the IF output transformer for maximum output meter reading. This transformer is the round can unit mounted at the top rear of the chassis. The Volume Control of the receiver should be turned all the way on and the output of the test oscillator kept at its lowest possible value during the adjustment.

5. Leaving the receiver controls and the test oscillator connections the same as in the preceding paragraph, adjust the IF interstage transformer for maximum output meter reading. This transformer is the square can unit at the rear left of the chassis (as one faces the rear of the chassis).

6. Leaving all connections and controls as before, tune the IF input transformer for maximum output meter reading. This transformer is the square can unit at the front left of the chassis (as one faces the rear of the chassis).

7. Repeat operations #4, #5, #6 in the order named to insure accurate alignment. Always use the lowest possible output from the test oscillator to render the AVC action of the receiver inoperative and to insure precise alignment.

8. Leave the "hot" lead of the test oscillator connected to the control grid of the 78 translator tube and turn the Variable Selectivity and Tone Control knob all the way to the right (broadcast position). Starting with the test oscillator adjusted to about 380 kc, slowly increase its frequency until it goes through resonance with the receiver and then on past resonance. It will be found that the output meter registers a peak as the test oscillator approaches resonance with the IF stages. The output meter reading decreases as the test oscillator goes through resonance and then increases again as the test oscillator frequency is increased beyond resonance. In other words, the resonance curve of the IF transformers, in the broad position, has a peak at either side and a hollow in the middle. These two peaks, as indicated on the output meter, should be equal in value. If they are not, tune the test oscillator to resonance with the weaker peak. Then adjust the IF output transformer secondary to increase the output meter reading. Only a slight adjustment is necessary. The location of the IF output transformer secondary adjustment is shown in the service illustration.

RF ALIGNMENT

During all of the alignment the Variable Selectivity and Tone Control should be turned all the way to the left (sharpest position). The "On-Off" switch should be turned only far enough to turn the receiver on. Connect the ground lead of the test oscillator, in series with a .1 mfd. condenser, to the receiver chassis. The output meter is to be connected across the loud speaker voice coil, as for IF alignment. The Volume Control of the receiver should be turned all the way on and the output from the test oscillator kept at its lowest possible value during all of the alignment procedure. Fully mesh the variable condenser and see that the Station Selector dial pointer is horizontal. The Band Spread pointer should point straight up.

Broadcast (A) Band:

1. Turn the wave band switch to the "A" position. Connect the "hot" lead of the test oscillator, in series with a .00025 mfd. condenser, to the terminal marked "A" on the antenna terminal block at the rear of the chassis.

2. Set the test oscillator to 1550 kc. Open the variable condenser all the way and tune in the test oscillator signal. Adjust the broadcast oscillator trimmer condenser, C14, for maximum output meter reading. The locations of all of the trimmers are shown in the Service Illustrations. It may be found that two peaks can be obtained at two different settings of the trimmer. Use the one in which the trimmer is screwed further out (lesser capacity).

3. Set the test oscillator to 1400 kc and tune in its signal. Then adjust the antenna and translator trimmer condensers, C1 and C7. The variable condenser should be rocked a degree or two while making this adjustment. If two peaks can be obtained, use the adjustment in which the trimmers are screwed further in (greater capacity).

4. Set the test oscillator to 600 kc and tune in its signal. Then adjust the broadcast oscillator padder, C12, for maximum output. This padder is mounted under the chassis. Rock the condenser back and forth a degree or two while making the adjustment.

5. Repeat the 1550 kc and 1400 kc adjustments for greater accuracy. Always keep the output from the test oscillator at its lowest possible value in order to render the AVC action of the receiver inoperative and to insure precise alignment.

Short Wave (B) Band:

1. Turn the wave band switch to the "B" position. Leave the "hot" lead of the test oscillator connected, in series with a .00025 mfd. condenser, to the "A" terminal of the antenna terminal block, as for BROADCAST alignment.

2. Set the test oscillator to 5400 kc. Open the variable condenser all the way and adjust the oscillator trimmer, C15, for maximum output meter reading. It may be found that two peaks can be obtained at two different settings of the trimmer. Use the one in which the trimmer is screwed further out (lesser capacity).

3. Set the test oscillator to 5000 kc and tune in its signal. Then adjust the antenna and translator trimmers, C2 and C8, for maximum output meter reading. The variable should be rocked during the adjustment. If two peaks can be obtained, use the adjustment in which the trimmers are screwed further in (greater capacity).

4. Set the test oscillator to 1700 kc and tune in its signal. Then adjust the padding condenser, C13, for maximum output meter reading. The variable condenser is mounted under the chassis.

Short Wave (C) Band:

1. Connect the "hot" lead of the test oscillator, in series with a 400 ohm resistor, to the "A" terminal on the antenna terminal block at the rear of the chassis. This 400 ohm resistor replaces the .00025 mfd. condenser used for the other two bands.

2. Set the test oscillator to 16500kc. Open the variable condenser plates all the way and adjust the oscillator trimmer, C16, for maximum output meter reading. It may be found that two peaks can be obtained at two different settings of the trimmer. Use the one in which the trimmer is screwed further out (lesser capacity).

3. Set the test oscillator to 15000 kc and tune in its signal. Then adjust the antenna and translator trimmers, C3 and C9, for maximum output. The variable should be rocked during the adjustment. If two peaks can be obtained use the adjustment in which the trimmers are screwed further in (greater capacity).

Adjustment of The Sensitivity Control At The Rear Of The Receiver:

There is a Sensitivity Control adjustment at the rear of the receiver. This control determines the sensitivity of the receiver when the Sensitivity Control knob at the front of the cabinet is in the "NORMAL" position. When the Sensitivity Control knob is in the "HIGH" position the maximum possible sensitivity of the receiver is obtained regardless of the setting of the control at the rear of the chassis. The adjustment is correctly set for average conditions and ordinarily should not be touched. However, if the receiver is installed in an electrically noisy location it may be desirable to decrease the sensitivity to prevent between-station noise as the receiver is tuned from station to station. This adjustment can also be used to increase the sensitivity of the receiver, when the front Sensitivity Control knob is in the "NORMAL" position, for locations remote from broadcasting stations. However, this should be done only if there is no difficulty with between-station noise. The maximum sensitivity of the receiver can always be had, regardless of the setting of the Sensitivity Control adjustment at the rear of the chassis, by turning the front control knob to the "HIGH" position. To make the adjustment proceed as follows:

Turn the front Sensitivity Control knob to the "NORMAL" position. Turn the Variable Selectivity and Tone Control, knob so that the numeral "1" is opposite the marker pin and tune in some broadcast station from which satisfactory reception can be had. Adjust the Volume Control to the level ordinarily used. Leaving all other controls untouched turn the Station Selector knob to some point where no station will be heard. If one part of the scale seems noisier than the rest of the scale turn the pointer to this noisier position. It will be found that turning the screw driver adjustment at the rear of the chassis, near the speaker socket, either increases or decreases the noise, depending upon which direction the adjustment is turned. Turn the adjustment to that point where the noise is reduced enough to be no objectionable. Do not turn the control further than necessary to eliminate the objectionable noise.

Installing A Jack For The Use Of Earphones:

A hole is provided in the rear of the chassis, near the speaker socket, for installing an earphone jack when desired by the customer. This hole is plugged with a brass insert that can be removed. The connections are shown on SCHEMATIC IN DOTTED LINES.

ELIMINATING CODE INTERFERENCE FROM AIRPORT BEACONS

Under certain conditions code interference from airport beacons may be experienced. These conditions are:

1. When the receiver is located very near to the airport.

2. When the beacon transmitter frequency is near the IF frequency of the receiver.

This type of interference can be identified through the fact that it occurs only when the Wave band switch of the receiver is in the BROADCAST position and also that it occurs at all settings of the Station Selector pointer.

When this type of interference is encountered it can be eliminated by adding a wave-trap to the receiver as described below. (Part #R13526 - $2.10 each.)

1. Mount the wave-trap as shown in the illustration. It will be necessary to drill a hole for the mounting screw next to the power transformer. There is a screw already in the chassis that can be used for the other mounting lug of the wave-trap. It also will be necessary to drill a 1/4" hole in the chassis, under the wave-trap, for the wave-trap leads.

2. Remove the coil shield nearest the front of the chassis.

3. There is a green wire running from the broadcast antenna coil primary to the wave switch. Unsolder this wire from the wave switch.

4. Solder the blue lead of the wave-trap to the antenna coil primary lead which originally ran to the wave switch. A piece of spaghetti or tape should be placed over the soldered connection.

5. Solder the yellow lead of the wave-trap to the wave switch terminal from which the original antenna coil lead was removed. It may be necessary to splice on an additional piece of wire if the yellow lead does not reach to the wave switch.

6. Connect the green lead of the wave-trap to ground (chassis).

7. The wave-trap is pre-tuned to the IF frequency of the receiver. Therefore, it is not necessary to make any tuning adjustments after it is installed. Neither is it necessary to change any of the alignment adjustments of the receiver.

The Dual Ratio Condenser Drive Shaft:

There are two positions in which the Station Selector knob can be put before turning it. When the knob is pushed in, the condenser drive ratio is approximately 17 to 1. When the knob is pulled out, the dial ratio becomes approximately 70 to 1, making possible very precise tuning.

The mechanism proper is of the planetary drive type, using ball bearings in contact with a cone shaped retainer. Do not attempt to take the mechanism apart. Should any difficulty with slippage occur, it can be corrected as described in the following paragraph. Slippage that occurs when the condenser reaches its limit of rotation in either direction is normal. However, if there is slippage at any other part of the condenser travel, proceed as follows:

Determine whether or not the shaft end (11) is turning. See the illustration. If the shaft end turns but the gears (8 and 9) do not, remove the U shaped tension washer (10) and bend it to increase its curvature and tension. Then replace it. Note that the convex side of the washer should face the shaft end and the concave side should face the gears. It is advisable to put a drop of solder across the open end of the U washer to prevent all possibility of its working off the shaft.

If the shaft end does not turn, the slippage is occuring in the planetary drive mechanism. This will occur only when the knob is in its "out" or slow position. In this case, squeeze the tabs (6) slightly, with a pair of pliers to increase the pressure. Do not squeeze them too much, or the drive will become stiff and hard to turn.

When placing the knob on its shaft, be careful not to use force in pressing it on or the splines (3 and 4) will become burred. The floating sleeve (2) must be centered on the shaft in order to permit the knob to slip over it. If the knob does not go on easily, do not force it but try it several times, until the sleeve falls into such a position that it allows the knob to slip on. Care must be taken when tightening the set screw that it is not tightened down on the splines, but comes in the space between the two splines. This is best done by removing the set screw and positioning the knob so that the set screw hole comes over the sleeve. between the splines. Then insert and tighten the set screw.

SILVERTONE MODELS 1918, 1968

ELIMINATING CODE INTERFERENCE FROM AIRPORT BEACONS

Under certain conditions code interference from airport beacons may be experienced. These conditions are:

1. When the receiver is located very near to the airport.

2. When the beacon transmitter frequency is near the IF frequency of the receiver.

This type of interference can be identified through the fact that it occurs only when the Wave Band switch of the receiver is in the BROADCAST position and also that it occurs at all settings of the Station Selector pointer.

When this type of interference is encountered it can be eliminated by adding a wave-trap to the receiver as described below. (Part #R13526 - $2.10 each.)

1. Mount the wave-trap at the back of the chassis as shown in the illustration. In addition to the holes for the mounting screws it will be necessary to drill a 1/4" hole under the wave-trap for the wave-trap leads.

2. Remove the round shield covering the Broadcast Antenna coil. This shield is at the top front of the chassis, left of the variable condenser.

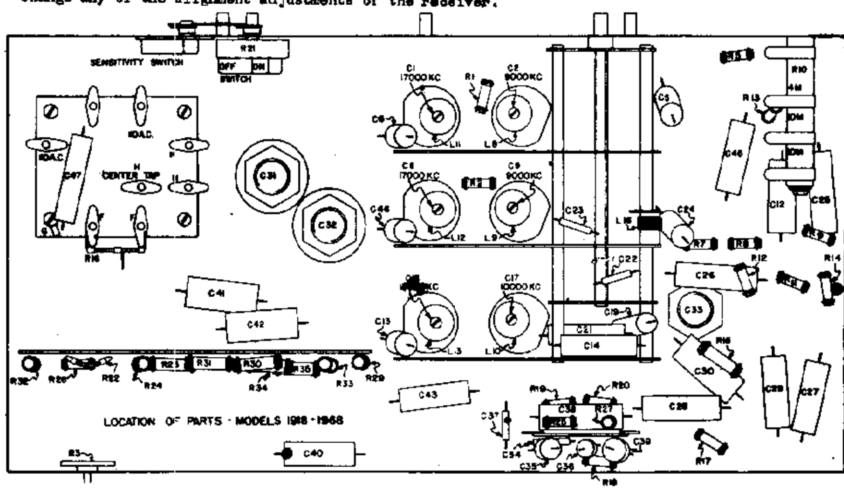
3. There is a green lead running from the antenna coil primary to the wave switch. (This lead comes from the front right hand lug of the antenna coil.) Remove this wire from the wave switch and from the coil.

4. Solder the blue lead of the wave-trap to the broadcast antenna coil primary lug from which the original wire was removed in operation #3.

5. Solder the yellow lead of the wave-trap to the wave switch terminal from which the original wire was removed in operation #3. If the wave-trap leads are not long enough, solder additional lengths of wire to them.

6. Connect the green lead of the wave-trap to ground (chassis).

7. The wave-trap is pre-tuned to the IF frequency of the receiver. Therefore, it is not necessary to make any tuning adjustments after it is installed. Neither is it necessary to change any of the alignment adjustments of the receiver.

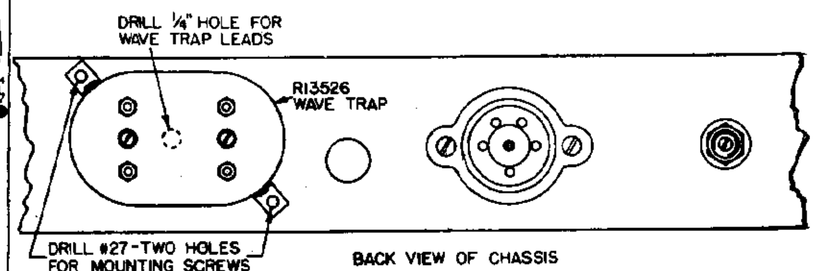


The AVC Circuit:

The diode current of the 75 tube, flowing through the 150M ohms of R18, creates a voltage drop across this resistor. This voltage is applied to the control grid of the 6D6, 6A7 and 6K7s tubes to provide AVC. R20, R14, R9 and R2 are filter resistors to isolate the grid circuits of each stage.

The Audio Circuit:

The output of the triode section of the 75 tube is used to drive the 6C5G tubes which act as a push pull driver stage. These in turn drive the 4-45A's which are connected in parallel push pull.



BACK VIEW OF CHASSIS
1918 - 1968

MODELS 1918,1968
Alignment

SEARS-ROEBUCK & CO.

ALIGNMENT PROCEDURE

IF Alignment:

1. Turn the receiver Volume Control all the way on, the Sensitivity Control lever to the right and the lower left knob turned only far enough to switch the receiver on. Connect a wire between terminals "D" and "G" on the antenna terminal block at the rear of the chassis. Turn the wave band switch knob to the BROADCAST, "A", position.

2. Turn the Variable Selectivity and Tone Control knob all the way to the right (sharpest position). Loosen the set screws holding the flexible cables that actuate the variable coupling of the IF transformers. Push the cables all the way into the tubes and re-tighten the set screws. Be sure the Variable Selectivity and Tone Control knob remains in its extreme clockwise position during the operation. Be careful when tightening the set screws that they are not screwed down so far that the cable wires are cut. The Variable Selectivity and Tone Control Knob must be left at its sharpest position (all the way left) during all of the alignment procedure unless otherwise stated in the procedure.

3. Connect the ground lead of the test oscillator, in series with a .1 mfd. condenser, to the receiver chassis. Set the test oscillator to 385 kc.

4. Connect the "hot" lead of the test oscillator to the control grid of the 6K7G second IF tube. This is the tube that is next to the type 76 tube. Adjust the IF output transformer for maximum output meter reading. The locations of all of the tuning adjustments are shown in the Service Illustrations. Be sure that the Volume Control of the receiver is turned all the way on during all adjustments and that the output of the test oscillator is kept at its lowest possible value.

5. Connect the "hot" lead of the test oscillator to the control grid of the 6K7G first IF tube and adjust the IF interstage transformer. As before, the output from the test oscillator must be kept at its lowest possible value in order to render the AVC ineffective and to insure precise alignment.

6. Connect the "hot" lead of the test oscillator to the control grid cap of the 6A7 oscillator-translator tube and adjust the IF input transformer for maximum output meter reading.

7. Carefully repeat operations #4, #5, and #6 for greater accuracy. As the sensitivity of the receiver is brought up by alignment, the output from the test oscillator should be decreased so that it is always kept at the lowest value that will give a satisfactory reading on the output meter.

8. Connect the "hot" lead of the test oscillator to the control grid cap of the 6A7 oscillator-translator tube and turn the Variable Selectivity and Tone Control knob all the way to the right (broadest position). Starting with the test oscillator adjusted to about 350 kc, slowly increase its frequency until it goes through resonance with the receiver (385 kc) and then on past resonance. It will be found that the output meter registers a peak as the test oscillator approaches resonance with the IF stages. The output meter reading decreases as the test oscillator goes through resonance and then increases again as the test oscillator frequency is increase beyond resonance. In other words, the resonance curve of the IF transformers, in the broad position, has a peak at either side and a hollow in the middle. These two peaks, as indicated on the output meter, should be equal in value. If they are not, tune the test oscillator to resonance with the weaker peak. Then, adjust the secondary of the IF output transformer (the upper of the two tuning adjustments) to increase the output meter reading. Only a very slight adjustment is necessary. Recheck the relative readings of the two peaks by tuning the test oscillator through resonance with the receiver, as before. When properly adjusted the two peaks will give equal output meter readings.

9. Leave the "hot" lead of the test oscillator connected to the control grid cap of the 6A7 oscillator-translator tube. With the test oscillator set accurately at 385 kc and the Variable Selectivity and Tone Control all the way to the left (sharp) position, note the output meter reading. Then, turn the Variable Selectivity and Tone Control knob all the way to the right and note the output meter reading. Use as low an output from the test oscillator as is consistent with a satisfactory output meter reading. There should be little or no difference in output meter readings for the two positions of the Variable Selectivity and Tone Control knob. Any great difference indicates improper alignment or improper setting of the IF coupling control cables.

RF ALIGNMENT

Preliminary:

1. Turn the receiver Volume Control all the way on; the Sensitivity Control lever to the right and the lower left knob turned only far enough to switch the receiver on. Connect a wire between terminals "D" and "G" on the antenna terminal block at the rear of the chassis. Keep the output from the test oscillator at its lowest possible value during all of the alignment. Fully mesh the variable condenser and see that the Station Selector dial pointer is horizontal. The band spread pointer should point straight up.

Broadcast (A) Band:

1. Turn the Wave Band Switch knob to the "A" position. Connect the "hot" lead of the test oscillator, in series with a .00025 mfd. condenser, to the terminal marked "A" on the antenna terminal block at the rear of the chassis.

2. Set the test oscillator to 1520 kc and open the variable condenser plates all the way. Adjust the broadcast oscillator trimmer condenser, C44, for maximum output meter reading. It may be found that two peaks can be obtained at two different settings of the trimmer. Use the one in which the trimmer is screwed further out (lesser capacity).

3. Connect a .0001 mfd. mica condenser from the stator of the RF section of the variable to ground. The RF section is the one second from the dial end of the condenser.

4. Set the test oscillator to 1400 kc and tune in its signal. Then, adjust the broadcast antenna trimmer, C4, for maximum output meter reading. This trimmer is the one on the variable condenser section nearest the dial. The variable should be rocked a degree or two during the adjustment. If two peaks can be obtained use the adjustment in which the trimmer is screwed further in (greater capacity).

5. Remove the .0001 mfd. mica condenser that was used in the preceding operation.

7. Set the test oscillator to 1400 kc and tune in its signal. Then, adjust the RF and translator trimmers, C7 and C11, for maximum output meter reading. The variable should be rocked a degree or two during the adjustment. If two peaks can be obtained, use the adjustment in which the trimmers are screwed further in (greater capacity).

8. Set the test oscillator to 600 kc and tune in its signal. Then, adjust the broadcast oscillator padder, C15, for maximum output meter reading. The variable should be rocked a degree or two during the adjustment.

10. Repeat operations #2 to #9 for greater accuracy. Always keep the test oscillator at its lowest possible value and the Volume Control of the receiver on full.

Short Wave (B) Band:

1. Turn the Wave Band Switch knob to the "B" position. Replace the .00025 mfd. condenser, that was used in the "hot" lead of the test oscillator for the BROADCAST band, with a 400 ohm resistor.

2. Screw the oscillator padding condenser, C80, down tightly.

3. Set the test oscillator to 4250 kc and open the variable condenser plates all the way. Then, adjust the oscillator trimmer, C18, for maximum output meter reading. It may be found that two peaks can be obtained at two different settings of the trimmer. Use the one in which the trimmer is screwed further out (lesser capacity).

4. Set the test oscillator to 4000 kc and tune in its signal. Then, adjust the RF and translator trimmers, C3 and C10, for maximum output meter reading. The variable should be rocked a degree or two during the adjustment. If two peaks can be obtained, use the adjustment in which the trimmers are screwed further in (greater capacity).

5. Set the test oscillator to 1700 kc and tune in its signal. Then, adjust the oscillator padding condenser, C80, for maximum output meter reading. The variable should be rocked a degree or two during the adjustment to insure proper peaking.

6. Repeat operations #3, #4, and #5. Always keep the test oscillator output at its lowest possible value.

Short Wave (C) Band:

1. Leave the "hot" lead of the test oscillator connected to the receiver through a 400 ohm resistor as for "B" band alignment

2. Turn the wave band switch knob to the "C" position. Set the test oscillator to 10,000 kc. Open the variable condenser plates all the way and adjust the oscillator trimmer, C17, for maximum output meter reading. If two peaks can be obtained at two different settings of the trimmer, use the adjustment in which the trimmer is screwed further out (lesser capacity).

3. Set the test oscillator to 9000 kc and tune in its signal. Then, adjust the RF and translator trimmers, C2 and C9, for maximum output meter reading. The variable should be rocked during the adjustment. If two peaks can be obtained at two different settings of the trimmers use the adjustment in which the trimmers are screwed further in (greater capacity).

4. Set the test oscillator to 4500 kc and tune in its signal. If necessary, shift turns on L8 and L9. If turns are shifted it will be necessary to repeat operation #3.

Short Wave (D) Band:

1. Leave the test oscillator connected as for "C" band alignment. Turn the Wave Band Switch knob to the "D" position.

2. Set the test oscillator to 19,000 kc. Open the variable condenser plates all the way and adjust the oscillator trimmer, C16, for maximum putput meter reading. If two peaks can be obtained at two different settings of the trimmer, use the adjustment in which the trimmer is screwed further out (less capacity).

3. If the calibration of the test oscillator is accurate, set it to exactly 18,000 kc. If the calibration cannot be depended upon, tune in an 18,000 kc station. (This step in the procedure is for the purpose of accurately setting the calibration. If the test oscillator calibration cannot be depended upon and if no 18,000 kc station can be tuned in, this step in the procedure should be omitted). With an 18,000 kc signal tuned in and the dial pointer set to 18,000 kc, readjust C16, if necessary, to secure maximum output meter reading.

4. Set the test oscillator to 9000 kc and tune in its signal. If the dial calibration is off more than one division, shift the turns on the oscillator coil, L13, to make the dial pointer come to its correct dial reading. If it is found necessary to shift turns, operation #3 should be repeated.

5. Set the test oscillator to 17,000 kc and tune in its signal. Then, adjust the RF and translator trimmers, C1 and C8, for maximum output meter reading. The variable should be rocked during the adjustment. If two peaks can be obtained at two different settings of the trimmers, use the adjustment in which the trimmers are screwed further in (greater capacity).

6. Set the test oscillator to 9000 kc and adjust the turns of L11 and L12, if necessary. The use of a "Tuning Wand" is of great help in determining whether shifting of turns is necessary. If it is found necessary, operation #5 must be repeated.

Overall Test:

Connect the test oscillator to the receiver through a .00025 mfd. condenser as for BROADCAST (A) band alignment. Set the test oscillator to 600 kc and tune in its signal with the Variable Selectivity and Tone Control in the sharp position. Leave the Station Selector at 600 kc and turn the Variable Selectivity and Tone Control to the broad position. Change the test oscillator frequency to 580 kc. Then, slowly increase the frequency of the test oscillator until it goes through resonance (600 kc) with the receiver and on beyond resonance to about 620 kc. It will be found that the output meter registers a peak as the test oscillator approaches resonance (600 kc). The meter reading then decreases as the test oscillator goes through resonance and then increases again as the test oscillator frequency is increased beyond resonance. Care must be used in making these observations since the two peaks lie quite close together. The two peaks as indicated on the output meter should be equal in value. If they are not, tune the test oscillator to resonance with the weaker peak. Then, adjust the broadcast oscillator padder, C15, to increase the reading of the weaker peak. Only a very slight adjustment should be necessary. When properly adjusted the two peaks should give equal output meter readings. If any great adjustment of C15 seems necessary it is an indication that alignment has not been properly made.

LOCATION OF PARTS - MODELS 1918A-1968A

Adjustment Of The Sensitivity Control At The Rear Of The Receiver:

There is a Sensitivity Control adjustment at the rear of the receiver. This control determines the sensitivity of the receiver when the Sensitivity Control lever at the front of the cabinet is in the "NORMAL" position (lever to the right). When the Sensitivity Control lever is in the "HIGH" position (lever to the left) the maximum possible sensitivity of the receiver is obtained regardless of the setting of the control at the rear of the chassis. The adjustment is correctly set for "average" conditions and ordinarily should not be touched. However, if the receiver is installed in an electrically noisy location it may be desirable to decrease the sensitivity to prevent between-station noise as the receiver is tuned from station to station. This adjustment also can be used to increase the sensitivity of the receiver with the front control

SEARS-ROEBUCK & CO.

ALIGNMENT PROCEDURE

IF Alignment:

1. Turn the receiver Volume Control all the way on, the Sensitivity Control lever to the right and the lower left knob turned only far enough to switch the receiver on. Connect a wire between terminals "D" and "G" on the antenna terminal block at the rear of the chassis. Turn the wave band switch knob to the BROADCAST, "B", position.

2. Turn the Variable Selectivity and Tone Control knob all the way to the right (broadest position). Loosen the set screws holding the flexible cables that actuate the variable coupling of the IF transformers. Push the cables all the way into the tubes and retighten the set screws. Be sure the Variable Selectivity and Tone Control knob remains in its extreme clockwise position during the operation. Be careful when tightening the set screws that they are not screwed down so far that the cable wires are cut. The Variable Selectivity and Tone Control knob must be left at its sharpest position (all the way left) during all of the alignment procedure unless otherwise stated in the procedure.

3. Connect the ground lead of the test oscillator, in series with a .1 mfd condenser, to the receiver chassis. Set the test oscillator to 385 kc.

4. Connect the output lead of the test oscillator to the control grid of the 6K7MG second IF tube. This is the tube that is next to the type 75 tube. Adjust the IF output transformer for maximum output meter reading. The locations of all of the tuning adjustments are shown in the Service Illustrations. Be sure that the Volume Control of the receiver is turned all the way on during all adjustments and that the output of the test oscillator is kept at its lowest possible value.

5. Connect the output lead of the test oscillator to the control grid of the 6K7MG first IF tube and adjust the IF interstage transformer. As before, the output from the test oscillator must be kept at its lowest possible value in order to render the AVC ineffective and to insure precise alignment.

6. Connect the output lead of the test oscillator to the control grid cap of the 6A8MG oscillator-translator tube and adjust the IF input transformer for maximum output meter reading.

7. Carefully repeat operations #4, #5, and #6 for greater accuracy. As the sensitivity of the receiver is brought up by alignment, the output from the test oscillator should be decreased so that it is always kept at the lowest value that will give a satisfactory reading on the output meter.

8. Connect the output lead of the test oscillator to the control grid cap of the 6A8MG oscillator-translator tube. With the test oscillator set accurately at 385 kc and the Variable Selectivity and Tone Control all the way to the left (sharp) position, note the output meter reading. Then, turn the Variable Selectivity and Tone Control knob all the way to the right and note the output meter reading. Use as low an output from the test oscillator as is consistent with a satisfactory output meter reading. There should be little or no difference in output meter readings for the two positions of the Variable Selectivity and Tone Control knob. Any great difference indicates improper alignment or improper setting of the IF coupling control cables.

RF ALIGNMENT

Preliminary:

1. Turn the receiver Volume Control all the way on; the Sensitivity Control lever to the right and the lower left knob turned only far enough to switch the receiver on. Connect a wire between terminals "D" and "G" on the antenna terminal block at the rear of the chassis. Keep the output from the test oscillator at its lowest possible value during all of the alignment. All adjustments of trimmers should be made with the bottom chassis plate on.

Broadcast (B) Band:

1. Turn the Wave Band Switch to the "B" position. Connect the output lead of the test oscillator, in series with a .00025 mfd mica condenser, to the terminal marked, "A", on the antenna terminal block at the rear of the chassis.

2. Set the test oscillator to 1520 kc and open the variable condenser plates all the way. Adjust the broadcast oscillator trimmer condenser, C26, for maximum output meter reading.

3. Connect a .0001 mfd mica condenser from the stator of the RF section of the variable to ground. The RF section is the one second from the dial end of the condenser.

4. Set the test oscillator to 1400 kc and tune in its signal Then adjust the broadcast antenna trimmer, C7, for maximum output meter reading. This trimmer is the one on the variable condenser section nearest the dial.

5. Remove the .0001 mfd mica condenser that was used in the preceeding operation.

6. There is a "link" connection, mounted at the bottom of the Variable Selectivity control, as shown in the Service Illustration. Remove the screw and open the link connection before preceeding with the next operation, #7.

7. Leave the test oscillator at 1400 kc and tune in its signal. Then adjust the RF and translator trimmers, C8 and C16, for maximum output meter reading.

8. Close the link connection that was opened in operation #6.

9. Leave the receiver tuned accurately to 1400 kc and set the dial pointer to 1400 kc. The pointer is merely held by friction and can be moved without turning the variable condenser plates.

10. Set the test oscillator to 600 kc and tune in its signal. Then adjust the Broadcast oscillator padder, C27, for maximum output meter reading. The variable should be rocked a degree or two during the adjustment.

11. Repeat operations #2 to #10 for greater accuracy. Always keep the test oscillator at its lowest possible value and the Volume Control of the receiver on full.

Weather (A) Band:

1. Turn the Wave Band Switch to the "A" position. Leave the test oscillator connected to the receiver, as for Broadcast band alignment.

2. Set the test oscillator to 370 kc. Open the variable condenser plates all the way and adjust the oscillator trimmer, C28, for maximum output meter reading. This trimmer is mounted under the chassis, as shown in the Service Illustration.

3. Set the test oscillator to 360 kc and tune in its signal. Adjust the antenna and translator trimmers, C1 and C2, for maximum output meter reading. These trimmers are mounted under the chassis, as shown in the Service Illustration.

4. Set the test oscillator to 230 kc and adjust the oscillator padding condenser, C29, for maximum output meter reading. The variable should be rocked a degree or two during the adjustment. C29 is mounted under the chassis, as shown in the Service Illustration.

5. Repeat all of the operations in their original order to insure proper alignment.

Short Wave (C) Band:

1. Turn the Wave Band Switch to the "C" position. Remove the .00025 mfd condenser, that was used in the output lead of the test oscillator for alignment on bands "A" and "B". Connect a 400 ohm resistor in place of the .00025 mfd condenser.

2. Set the test oscillator to 4250 kc and open the variable condenser plates all the way. Then adjust the oscillator trimmer, C23, for maximum output meter reading. It may be found that two peaks can be obtained at two different settings of the trimmer. Use the one in which the trimmer is screwed further out (lesser capacity).

3. Set the test oscillator to 4000 kc and tune in its signal. Adjust the RF and translator trimmers, C5 and C15, for maximum output meter reading. The variable should be rocked a degree or two during the adjustment. If two peaks can be obtained, use the adjustment in which the trimmers are screwed further in (greater capacity).

4. Set the test oscillator to 1700 kc and tune in its signal. Adjust the oscillator padding condenser, C25, for maximum output meter reading. The variable should be rocked a degree or two during the adjustment to insure proper peaking.

5. Repeat all of the operations in their original order. Always keep the test oscillator output at its lowest possible value.

Short Wave (D) Band:

1. Leave the test oscillator connected to the receiver, as for "C" band alignment.

2. Turn the Wave Band Switch knob to the "D" position. Set the test oscillator to 10,000 kc. Open the variable condenser plates all the way and adjust the oscillator trimmer, C22, for maximum output meter reading. If two peaks can be obtained at two different settings of the trimmer, use the adjustment in which the trimmer is screwed further out (lesser capacity).

3. Set the test oscillator to 9000 kc and tune in its signal. Adjust the RF and translator trimmers, C4 and C14, for maximum output meter reading. The variable should be rocked during the adjustment. If two peaks can be obtained at two different settings of the trimmers, use the adjustment in which the trimmers are screwed further in (greater capacity).

4. Set the test oscillator to 4500 kc and tune in its signal. If necessary, shift turns on L3 and L9. If turns are shifted it will be necessary to repeat operation #3. A "Tuning Wand" is of great help in determining whether or not it is necessary to shift turns.

Short Wave (E) Band:

1. Leave the test oscillator connected as for "C" and "D" band alignment. Turn the Wave Band Switch knob to the "E" position.

2. Set the test oscillator to 19,000 kc. Open the variable condenser plates all the way and adjust the oscillator trimmer, C19, for maximum output meter reading. If two peaks can be obtained at two different settings of the trimmer, use the adjustment in which the trimmer is screwed further out (lesser capacity).

3. Set the test oscillator to 9000 kc and tune in its signal. If the dial calibration is off more than one division, shift the turns on the oscillator coil, L12, to make the dial pointer come to its correct dial reading. If it is found necessary to shift turns, operation #2 should be repeated.

4. Set the test oscillator to 17,000 kc and tune in its signal. Adjust the RF and translator trimmers, C3 and C13, for maximum output meter reading. The variable should be rocked during the adjustment. If two peaks can be obtained at two different settings of the trimmers, use the adjustment in which the trimmers are screwed further in (greater capacity).

5. Set the test oscillator to 9000 kc and adjust the turns on L2 and L8, if necessary. The use of a "Tuning Wand" is of great help in determining whether shifting of turns is necessary. If it is found necessary, operation #4 must be repeated.

MODELS 1923,1933
1983,1993
Chassis 334,334X
Chassis,Alignment
Parts,Notes

Circuit Description:

These SILVERTONE Models are 7 tube, battery powered superheterodynes, having a "WEATHER", or long wave range; a broadcast range; and a short wave range. A filament Ballast tube is used to maintain the filament voltage at its proper value when the receiver is supplied by a 3 volt "A" block or an air cell. If a 2 volt storage battery is to be used, the Ballast tube should be replaced by a 4 prong plug having its filament prongs connected together.

The AVC Circuit:

The 230 AVC tube is used as a diode with its plate connected to one of the filament prongs so that the usual grid acts as the diode plate. A portion of the IF signal is applied to the tube through C20. The resulting diode current, flowing through R8, creates a voltage drop which is applied to the control grids of the 1C6 and 1A4 tubes to secure AVC.

1. Connect the high range of the output meter across the loud speaker. Connect a 175 kc test oscillator between the chassis and the control grid of the 1C6. A .1 mfd. condenser should be connected in series with one of the test oscillator leads.

2. Turn the volume control of the receiver full "on" and put the tone control in its "brilliant" position. Then adjust the IF output stage for maximum output. The tuning adjustment for the primary of this stage (T9) is accessible from the rear of the chassis. The secondary, T10, is the single adjustment unit mounted on top of the chassis. The output from the test oscillator must be kept at its lowest possible value.

ALIGNMENT PROCEDURE

The IF Stages:

3. Adjust the IF input transformer to secure maximum deflection on the output meter.

4. Repeat the output stage adjustments and then the input stage adjustments for greater accuracy. Always keep the test oscillator at its lowest possible value and the volume control of the receiver at its full "on" position.

RF Alignment; Band A:

1. Loosely couple the test oscillator to the antenna of the receiver, leaving the antenna connected. The volume control of the receiver should be in its full "on" position and the tone control in its "brilliant" position.

2. Set the test oscillator to 400 kc and open the variable condenser plates all the way. Then adjust C13 for maximum output. The locations of the trimmers are shown in the Service Diagrams.

3. Set the test oscillator to 370 kc and tune in its signal. Then adjust C2 and C4 for maximum output. The variable should be rocked back and forth a degree or two while making this adjustment. Always keep the test oscillator output at its lowest possible value.

4. Repeat the 400 kc adjustment and then the 370 adjustments to secure greater accuracy.

RF Alignment; Band B:

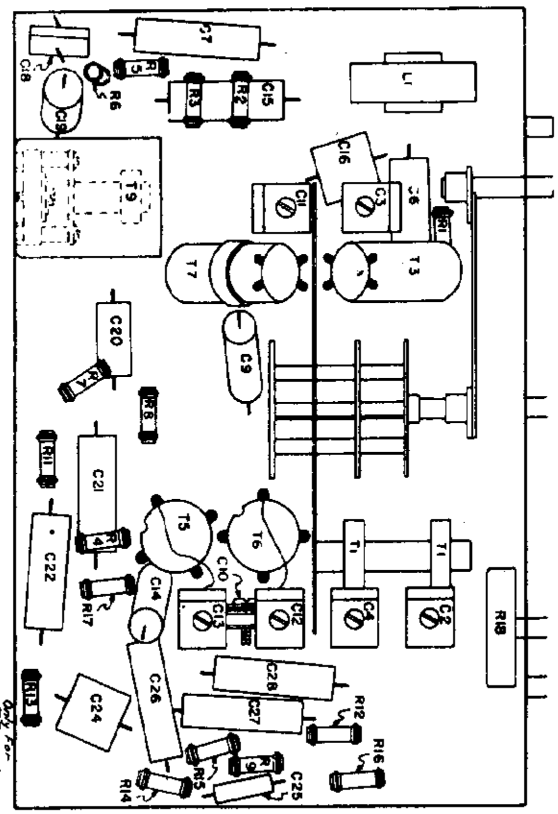
1. Leave the test oscillator coupled to the antenna lead; the volume control on full; and the tone control in its "Brilliant" position, as for Band A.

2. Set the test oscillator to 1600 kc. Open the variable condenser plates all the way and adjust C12 for maximum output.

3. Set the test oscillator to 1400 kc and adjust C5 and C8 for maximum output. The variable should be rocked back and forth during this adjustment.

4. Set the test oscillator to 600 kc and tune in its signal. Then adjust C10 for maximum output. The variable should be rocked during the adjustment.

5. Repeat the 1600 kc adjustment, then the 1400 kc adjustments, and then the 600 kc adjustment for greater accuracy. Always keep the test oscillator at its lowest possible value.



NOTE. T2, T4, T8, T10, C5, C8, C17, & C23 ARE MOUNTED ON TOP OF CHASSIS. Only For 1st Production

RF Alignment; Band C:

1. Leave the test oscillator loosely coupled to the antenna lead; the volume control on full; the tone control in its "brilliant" position, as for alignment on the other bands.

2. Set the test oscillator to 15,500 kc. Open the variable condenser plates all the way and adjust C11 for maximum output.

3. Set the test oscillator to 14,000 kc and tune in its signal. Then adjust C3 for maximum output. The variable should be rocked during the adjustment.

4. Repeat the 15,500 kc and 14,000 kc adjustments for greater accuracy. Always keep the test oscillator at its lowest possible value.

Occasionally, a set is found in which the condenser-drive gears do not mesh properly. To correct this, proceed as follows:

Remove the dial pointers, the Station Selector dial, and the metal pointer-drive gear. Then adjust the lower bracket, that mounts the small condenser-drive gear, by slightly loosening its two mounting screws and shifting the bracket until proper meshing of the gears is secured. Then re-assemble the dial and pointers. Correct dial calibration can be secured either by tuning in a station of known frequency and setting the pointer to that frequency, or by fully meshing the condenser plates and putting the dial pointer horizontal.

MODELS 1925,1935,1985,1995
SEARS-ROEBUCK & CO. Chassis,Alignment,Notes

Because of the low voltage at which these models are operated, more than usual care must be used in selecting 6A7 and 75 tubes that will operate properly on the short wave band. This will be particularly true for installations where the line voltage is lower than average. Tubes which do not operate properly in these models may be entirely satisfactory for use in other sets operating at a higher voltage.

General:

During all of the alignment procedure, the tone control and the volume control must be turned all the way to the right. The ground lead of the test oscillator should be connected to the chassis through a .1 mfd. condenser. The other lead of the test oscillator is to be connected to the grid clip of the proper tube as described in the procedure. It is important to leave the grid clip attached to the clip and to leave the tube shields in place. The oscillator tube of the receiver also should be in its socket. In the case of 6A7 oscillator-translators, no attempt should be made to "kill" the oscillator section.

The output from the test oscillator should always be kept at the lowest possible value and the coupling between it and the receiver should be made as loose as possible. In the case of RF alignment, where the test oscillator is coupled to the antenna lead of the receiver, alignment will be most accurate if the coupling to the antenna is made very loose. (The antenna lead and the oscillator lead separated.) If the test oscillator has a variable control for its power output, it is better to turn this control to its high position and then decrease the signal input to the receiver by decreasing the amount of coupling between the test oscillator and the receiver's antenna lead.

IF Alignment:

1. Connect the test oscillator lead to the control grid of the 6D6 tube. Set the test oscillator to 456 kc and tune the IF output transformer, T3.

2. Change the test oscillator connection to the control grid of the 6A7 tube and tune the IF input transformer, T2.

3. Repeat the IF output transformer adjustment and then the IF input transformer adjustment.

Broadcast RF Alignment:

1. Loosely couple the output of the test oscillator to the antenna lead of the receiver, leaving the antenna connected.
2. Set the test oscillator to 600 kc and adjust the broadcast oscillator padding condenser, C4, for maximum output. The variable condenser should be continuously rocked back and forth a degree or two while the padder is being adjusted.

3. Set the test oscillator to 1720 kc. Open the variable condenser plates all the way and adjust C3 for maximum output.

4. Set the test oscillator to 1400 kc and tune in its signal. Then adjust the trimmer on the variable condenser for maximum output. The variable should be rocked back and forth a degree or two while the trimmer is being adjusted.

5. Repeat the 600 kc oscillator padder condenser adjustment to secure greater accuracy.

6. Repeat the 1720 kc and the 1400 kc adjustments for greater accuracy.

Short Wave RF Alignment:

1. Leave the test oscillator loosely coupled to the antenna lead as for broadcast RF alignment.

2. Set the test oscillator to 14,500 kc and tune in its signal. Then adjust C2 for maximum output. The variable should be rocked a degree or two during the adjustment to insure most accurate peaking. Two peaks may be found, one of them with the trimmer screwed out further than the other. The correct setting is the one with the trimmer screwed further in, (greater capacity).

Tube Voltages:

The proper voltage reading to be obtained from each of the tube prongs to chassis is indicated on the schematic, immediately alongside of the respective tube prong.

ALIGNMENT PROCEDURE

IF ALIGNMENT

1. Connections:

Connect the ground lead of the test oscillator to the receiver chassis. Connect the output lead of the test oscillator, in series with a .1 mfd condenser, to the tube grid caps indicated below under ALIGNMENT. Connect the output meter, in series with a .5 mfd condenser across the loud speaker terminals. The meter should be switched to a scale of approximately 10 volts.

2. Receiver Settings:

Turn the Wave Band switch to the BROADCAST position and the Station Selector to about 550 kc. Turn the receiver Volume Control all the way on, and the Tone Control to its brilliant position (clockwise)

3. Alignment:

(a) Set the test oscillator to 175 kc. Connect its output (through the .1 mfd condenser) to the control grid of the 1A4 tube. Peak the IF output transformer, T2.

(b) Change the test oscillator output connection to the control grid cap of the 1C6 tube. Peak the IF input transformer, T1.

(c) Change the test oscillator output connection back to the control grid cap of the 1A4 tube and repeat the T2 adjustment. Then change the test oscillator output connection to the 1C6 tube again and repeat the T1 adjustment for greater accuracy. Always keep the test oscillator output at its lowest possible value and the receiver Volume Control all the way on.

RF ALIGNMENT

Important:

The Broadcast band must be aligned before the Weather band or the Short Wave band.

BROADCAST (B) BAND ALIGNMENT

1. Connections:

Connections for Broadcast band alignment are the same as for IF alignment except that the .1 mfd condenser is disconnected from the output lead of the test oscillator. In its place a .0002 mfd mica condenser is connected from the test oscillator output lead to the green antenna lead on the chassis.

2. Receiver Settings:

Turn the Volume Control all the way on, the Tone Control all the way to the right, and the Wave Band switch to the BROADCAST (B) position.

3. Alignment:

(a) Set the test oscillator to 1600 kc. Open the variable condenser plates all the way and peak the broadcast oscillator trimmer, C6. The locations of the trimmers are shown in the Service Illustration.

(b) Set the test oscillator to 1400 kc and tune in its signal. Then peak the antenna trimmer and the translator trimmer, C3. The antenna trimmer is the one on the variable condenser section nearest the dial. The translator trimmer is accessible through the hole in the top of the translator shield can mounted on top of the chassis next to the 1C6 tube.

(c) Set the test oscillator to 600 kc and tune in its signal. Then peak the broadcast oscillator padder, C7. The variable should be rocked a degree or two during the adjustment.

(d) Repeat the 1600 kc adjustment, then the 1400 kc adjustments, and then the 600 kc adjustment for greater accuracy. Always keep the test oscillator output at its lowest possible value.

WEATHER (A) BAND ALIGNMENT

1. Connections:

All connections remain the same as for Broadcast band alignment.

2. Receiver Settings:

Turn the Wave Band switch to the "A" position. All other settings remain the same as for Broadcast band alignment.

3. Alignment:

(a) Set the test oscillator to 400 kc. Open the variable condenser plates all the way and peak the oscillator trimmer, C8.

(b) Set the test oscillator to 385 kc and tune in its signal. Peak the antenna trimmer, C1, and the translator trimmer, C2.

(c) Repeat the 400 kc adjustment and then the 385 kc adjustments for greater accuracy.

SHORT WAVE (C) BAND ALIGNMENT

Note: The oscillator frequency on this band is 175 kc lower than the translator frequency, instead of being 175 kc higher, as is usual.

1. Connections:

Remove the .0002 mfd condenser used in series with the output lead of the test oscillator for alignment on the other two bands. Replace this condenser with a 400 ohm carbon resistor.

2. Receiver Settings:

Turn the Wave Band switch to the "C" position. Other receiver settings remain the same as for previous alignment.

3. Alignment:

(a) The top frequency for this band must not go higher than 16,000 kc. This is governed entirely by positioning of the leads. If the top frequency is allowed to go higher than 16,000 kc, the calibration for the band will be incorrect. Check the top frequency by opening the variable condenser plates all the way, setting the test oscillator to 16,000 kc, and positioning leads so that a peak reading is had on the output meter.

(b) Set the test oscillator to 14,000 kc and tune in its signal Peak the translator trimmer, C5.

SENSITIVITIES

The figures in the following chart, although approximate, will serve as an indication of the sensitivities that should be had at various points in the receiver and at various frequency settings. They will be useful for trouble shooting. It is necessary to have a test oscillator with an accurately calibrated attenuator so that its output power can be known. The figures in the last column represent the output voltage from the test oscillator necessary to secure an output meter reading of 8½ volts, with a .5 mfd condenser in series with the meter. The meter should have a resistance of 4000 ohms or more.

The Wave Band switch must be turned to the BROADCAST position and the Variable Condenser to about 550 kc for the measurements at 175 kc.

The value of condenser or resistor shown in the second column of the chart must be connected in series with the test oscillator output lead.

The receiver Volume Control must be turned all the way on and the Tone Control all the way to the right for all measurements.

Test Oscillator Connected To:	Dummy Antenna In Test Oscillator Output Lead	Frequency	Microvolts Input
1C6 - Grid Cap	.1 mfd	175 kc	65
1A4 - Grid Cap	.1 mfd	175 kc	4000
1C6 - Grid Cap	.1 mfd	1000 kc	90
Stator, Var. Cond. Section nearest dial	.1 mfd	1000 kc	200
Antenna Lead	.0002 mfd	600 kc	35
Antenna Lead	.0002 mfd	1000 kc	40
Antenna Lead	.0002 mfd	1400 kc	60
Antenna Lead	.0002 mfd	225 kc	125
Antenna Lead	.0002 mfd	385 kc	35
Antenna Lead	.0002 mfd	400 kc	30
Antenna Lead	400 ohms	6000 kc	55
Antenna Lead	400 ohms	10000 kc	20
Antenna Lead	400 ohms	14000 kc	25

SILVERTONE MODELS 1936, 1996

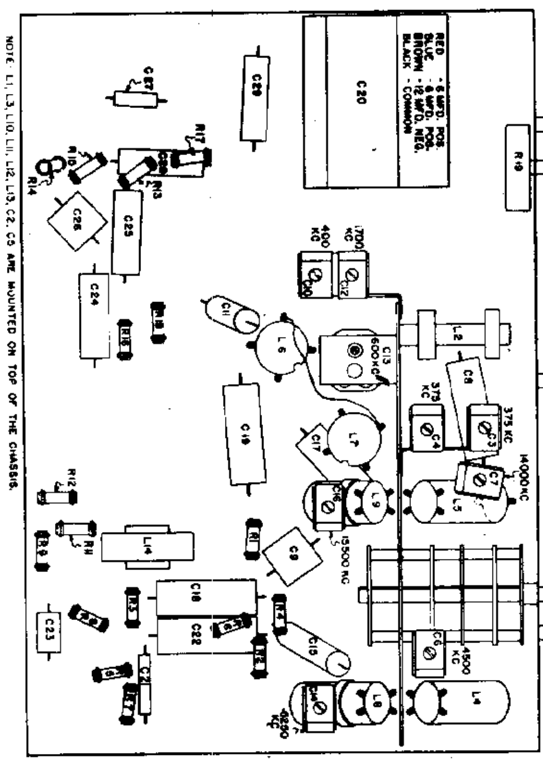
CIRCUIT CHANGES (359X CHASSIS) TO MINIMIZE SENSITIVITY VARIATIONS DUE TO VARIATIONS IN 961 TUBES

APRIL 7, 1936

Circuit changes were incorporated in later production and the chassis designation changed to 359X (marked on the license sticker and on back of the chassis). These circuit changes are for the purpose of minimising the effect that variations in type 961 tubes have on the uniformity of receiver sensitivity in production. It is not necessary to attempt to make these changes on earlier production receivers in the field.

As shown in the attached schematic, the circuit changes are:

R15 changed from 50M ohms to 200M ohms
.2 mfd condenser, C30, added
500M ohm resistor, R20, added
1 megohm resistor, R13, added
500M ohm resistor, R21, added
2 megohm resistor, original R13, previously connected from detector screen to B plus, removed from circuit



NOTE: L1, L3, L10, L11, L12, L13, C2, C5 ARE MOUNTED ON TOP OF THE CHASSIS.

LOCATIONS OF PARTS - MODELS 1936-1996 (EARLY)

ALIGNMENT PROCEDURE

General:

During all of the alignment procedure, the tone control and the volume control must be turned all the way to the right. The ground lead of the test oscillator should be connected to the chassis through a .1 mfd. condenser. The other lead of the test oscillator is to be connected in the manner described in the procedure. Where connection is made to a control grid cap, it is important to leave the grid clip attached to the grid cap and to leave the tube shields in place. No attempt should be made to "kill" the oscillator section of the 106 during the alignment.

The output from the test oscillator always should be kept at the lowest possible value that will give a satisfactory output meter reading and the coupling between the test oscillator and the receiver should be made as loose as possible. In the case of RF alignment on any of the bands, where the test oscillator is coupled to the antenna lead of the receiver with an antenna connected, alignment will be most accurate if the coupling to the antenna lead is made very loose. (The antenna lead and the oscillator lead separated.) If the test oscillator has a variable control for its power output, it is better to turn this control to its high position and then decrease the signal input to the receiver by decreasing the amount of coupling between the test oscillator and the receiver's antenna lead. If an actual antenna is not used and is replaced by a condenser or resistor, as described in the procedure, the input to the receiver should be kept low by decreasing the power output from the test oscillator.

When peaking the antenna and translator trimmers, for all wave bands, the variable condenser should be "rocked" back and forth a degree or two while the trimmer is being adjusted. This should not be done when peaking the oscillator trimmers; in this case, the variable condenser is turned so that the plates are completely out of mesh and left in this position during the adjustment. When adjusting the oscillator trimmers, if it is found that two peaks can be obtained, use the one in which the trimmer is screwed further out (less capacity). When adjusting the antenna and translator trimmers, if two peaks are found, use the adjustment in which the trimmer is screwed in furthest. Note that this is exactly opposite to the procedure for the oscillator trimmers.

IF Alignment:

1. Connect the test oscillator lead, in series with a .00025 mfd. condenser, to the control grid of the 106 tube. Turn the wave switch to position, "B". With the test oscillator set at 175 kc peak the IF output transformer, L11, L12, and then the IF input transformer, L10. L10 is the square can unit mounted at the right hand end of the chassis. L11 is the round can unit mounted behind the variable condenser and which does not have a grid lead. L12 is the other round can unit with a grid lead.

2. Repeat the IF adjustments in the same order as mentioned in (1). As the output meter reading is increased by aligning, the test oscillator power should be decreased. This will prevent the AVC action from interfering with accurate alignment.

RF Alignment, Band A:

1. Loosely couple the output of the test oscillator to the antenna lead of the receiver, leaving the antenna connected. If it is impractical to use an actual antenna, it can be duplicated by connecting the test oscillator lead to the receiver's antenna lead, in series with a .00025 mfd. condenser.

2. Turn the wave switch to Band A. Set the test oscillator to 400 kc and couple it to the antenna lead of the receiver by either of the two methods mentioned in the preceding paragraph.

3. Open the variable condenser plates all the way and adjust the oscillator trimmer, C10, for maximum output. Trimmer condenser locations are shown in the Location of Parts Diagram.

4. Set the test oscillator to 375 kc and tune in its signal. Then peak the antenna and translator trimmers, C3 and C4. The variable should be "rocked" during the adjustment, as described in the third paragraph of General Alignment Information.

RF Alignment, Band B:

1. Couple the test oscillator to the antenna lead of the receiver with the antenna connected, or connect the oscillator directly to the receiver antenna lead, in series with a .00025 mfd. condenser, as mentioned in (1) under "RF Alignment, Band A".

2. Set the test oscillator to 1700 kc. Open the variable condenser plates all the way and peak the oscillator trimmer, C12.

3. Set the test oscillator to 1400 kc and tune in its signal. Then adjust the antenna and translator trimmers, C8 and C5. C2 is contained in the round can immediately alongside of the variable condenser. C5 is contained in the round can unit mounted behind the "On-Off" switch.

4. Set the test oscillator to 600 kc and tune in its signal. Then adjust the padder condenser, C13, for maximum output. The variable should be continuously "rocked" a degree or two while making the padder condenser adjustment.

5. Repeat the 1700 kc and then the 1400 kc adjustments.

RF Alignment, Band C:

1. Loosely couple the test oscillator lead to the antenna lead of the receiver, leaving the antenna connected. If it is impractical to use an actual antenna, the test oscillator can be connected directly to the antenna lead of the receiver, in series with a 400 ohm resistor and with no antenna connected to the receiver.

2. Set the test oscillator to 5250 kc. Turn the wave switch to Band C, open the variable condenser plates all the way and peak the oscillator trimmer, C14.

3. Set the test oscillator to 4500 kc and tune in its signal. Then peak the translator trimmer, C6.

4. Substitute a .00025 mfd. condenser for the 400 ohm resistor in the test oscillator lead. Set the test oscillator to 1700 kc and tune in its signal. If necessary, shift turns on the translator coil, L4.

5. Repeat the entire procedure for greater accuracy.

RF Alignment, Band D:

1. Loosely couple the test oscillator lead to the antenna lead of the receiver, leaving the antenna connected or else connect the test oscillator directly to the antenna lead of the receiver, in series with a 400 ohm resistor, without using an actual antenna.

2. Turn the wave switch to Band D. Set the test oscillator to 15500 kc. Open the variable condenser plates all the way and peak the oscillator trimmer, C16.

3. Set the test oscillator to 14000 kc and tune in its signal. Then peak the translator trimmer, C7.

4. Set the test oscillator to 6000 kc and tune in its signal. If necessary, shift turns on the translator coil, L5.

5. Repeat the procedure for greater accuracy.

FAILURE TO OPERATE WHEN SWITCHED OFF AND THEN ON AGAIN

It sometimes happens that the receiver will fail to operate after it is switched off and then switched on again within approximately a second. This is due to blocking of the 25C AF tubes. It happens only when the receiver is switched on after exactly the right interval which will vary with different tubes. The condition will seldom be encountered since the interval of time between switching the receiver off and then on is very critical. If the receiver is left switched off for a half minute or more, it will resume operation when turned on without any trouble. The condition can be entirely eliminated by connecting another 500M ohm resistor in series with the detector plate resistor, R14, and then connecting a .2 mfd. 200 volt condenser from the junction of these two resistors to the chassis.

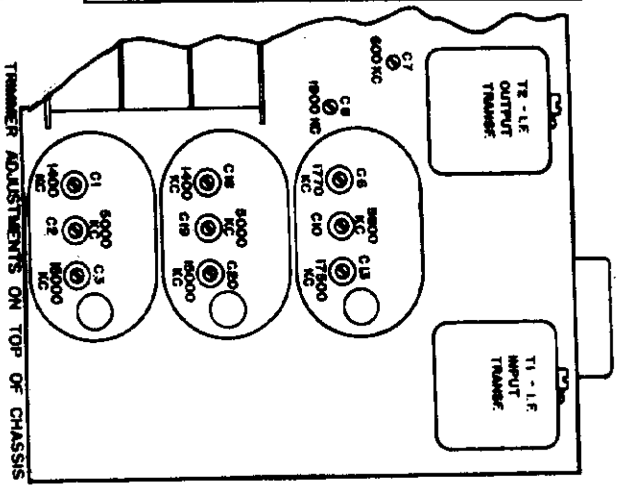
LOCATIONS OF PARTS UNDER CHASSIS - MODEL 1945



TRIMMER ADJUSTMENTS ON TOP OF CHASSIS

IF ALIGNMENT

1. Connections:

Connect the ground lead of the test oscillator to the receiver chassis. Connect the output lead of the test oscillator, in series with a .1 mfd condenser, to the various points mentioned below for alignment. Connect the low scale of an output meter across the loud speaker voice coil. A reading of one volt or less will be obtained during most of the alignment. Connect a jumper between the "D" and "G" terminals of the antenna terminal block at the rear of the chassis.

2. Receiver Settings:

Turn the Wave Band switch to the BROADCAST position and the Station Selector to about 550 kc. Turn the receiver Volume Control all the way on, the Tone Control to its brilliant position (clockwise), and the Selectivity Control to its SHARP position (counter clockwise).

3. Alignment:

(a) Turn the Variable Selectivity Control all the way to the right (broad position). Loosen the set screw that binds the flexible cable and push the cable all the way into its tube. Then tighten the set screw. Be careful that it is not tightened so much that the flexible cable is cut. Be sure that the Variable Selectivity Control knob remains at its full clockwise position during the operation.

After this has been done turn the Variable Selectivity Control knob all the way to the left (sharpest position) and leave it in this position for the remainder of the alignment procedure.

(b) Set the test oscillator to 385 kc. Connect its output (through the .1 mfd condenser) to the control grid of the 6K7MG IF tube. Adjust the IF output transformer, T2, for maximum output meter reading.

(c) Change the test oscillator output connection to the control grid of the 6L7MG translator tube and adjust the IF input transformer, T1, for maximum output meter reading.

(d) Change the test oscillator output connection back to the 6K7MG tube and repeat the IF output transformer adjustment. Then repeat the IF input transformer adjustment with the test oscillator connected to the 6L7MG tube. The output power from the test oscillator should be kept at the lowest possible value consistent with a satisfactory output meter reading.

BROADCAST BAND ALIGNMENT

1. Connections:

Connections for Broadcast band alignment are the same as for IF alignment except that the .1 mfd condenser is disconnected from the output lead of the test oscillator. In its stead a .00025 mfd mica condenser is connected from the test oscillator output lead to the "A" terminal on the antenna terminal block at the rear of the chassis.

2. Receiver Settings:

Turn the Volume Control all the way on, the Tone Control all the way to the right, and the Wave Switch to the BROADCAST position. Turn the Variable Selectivity Control to its sharp position (counter clockwise).

3. Alignment:

(a) Set the test oscillator to 1770 kc. Open the variable condenser all the way and peak the broadcast oscillator trimmer, C6. The locations of all of the trimmers are shown in the Illustrations.

(b) Set the test oscillator to 1400 kc and tune in its signal. Peak the broadcast antenna and translator trimmers, C1 and C18.

(c) Set the test oscillator to 600 kc and tune in its signal. Peak the broadcast oscillator padder, C7. The variable should be rocked a degree or two during the adjustment.

(d) Repeat the 1770 kc and then the 1400 and 600 kc adjustments for greater accuracy. Always keep the test oscillator output at its lowest possible value, to render the AVC action inoperative.

SHORT WAVE BAND "B" ALIGNMENT

1. Connections:

Connections remain the same as for Broadcast band alignment except that the .00025 mfd condenser in series with the test oscillator output lead is disconnected and a 400 ohm resistor connected in its stead.

2. Receiver Settings:

Turn the Wave Band switch to the "B" position. Other settings remain the same as for Broadcast band alignment.

3. Alignment:

(a) Set the test oscillator to 5800 kc. Open the variable condenser all the way and peak the oscillator trimmer, C10.

(b) Set the test oscillator to 5000 kc and tune in its signal. Peak the antenna and translator trimmers, C2 and C19.

(c) Set the test oscillator to 1900 kc and tune in its signal. Peak the oscillator padder, C8. The variable should be rocked a degree or two during the adjustment.

(d) Repeat the 5800 kc and then the 5000 kc and 1900 kc adjustments. Always keep the test oscillator output power at its lowest possible value.

SHORT WAVE BAND "C" ALIGNMENT

1. Connections:

All connections remain the same as for band "B".

2. Receiver Settings:

Turn the Wave Band switch to the "C" position. Other receiver settings remain the same as for band "B" alignment.

3. Alignment:

(a) Set the test oscillator to 17500 kc. Open the variable condenser all the way and peak the oscillator trimmer, C13.

(b) Set the test oscillator to 15000 kc and tune in its signal. Peak the antenna and translator trimmers, C3 and C20. Keep the test oscillator output power at its lowest possible value.

SENSITIVITIES

The following figures are given as an indication of the sensitivities that should be had at various frequency settings of the receiver. It is necessary to have a test oscillator with an accurately calibrated attenuator so that its output power can be known. The figures represent the input voltage necessary to secure an output meter reading of 1 volt.

For measurements on the broadcast band the test oscillator output lead is to be connected, in series with a .00025 mfd condenser, to the "A" terminal at the rear of the chassis, as for alignment. For Short Wave band measurements a 400 ohm resistor is to be connected instead of the .00025 mfd condenser. Turn the receiver Volume Control knob all the way on, the Tone Control all the way to the right, and the Selectivity Control all the way to the left.

	Frequency	MICROVOLTS INPUT
Broadcast Band:	600 kc	[illegible]
	1000 kc	[illegible]
	1400 kc	[illegible]
Band "B":	1900 kc	35
	3000 kc	15
	4000 kc	9
	5000 kc	6
Band "C":	6000 kc	20
	10000 kc	20
	15000 kc	8

Tubes And Their Functions:

6K7MG - RF
6C5MG - Oscillator
6L7MG - Translator
6K7MG - IF
6Q7MG - AVC - Detector - AF
6C5MG - Phase Changer
2-6F6MG - Push Pull Output
5Z4MG - Rectifier
6E5 - Tuning Eye

General Description:

This is a ten tube (including Tuning Eye) superheterodyne. In addition to the BROADCAST band it incorporates POLICE and FOREIGN SHORT WAVE bands. A Variable Tone Control is incorporated as well as a separate Variable Selectivity Control. The 6E5 Tuning Eye simplifies accurate tuning.

Antenna And Ground Connections:

These receivers are designed for use with either a conventional type of antenna or with a Doublet Antenna. There is a terminal block at the rear of the chassis. When a conventional antenna is used, the leadin from the antenna is to be connected to the terminal marked, "A", on the terminal block. The end of the ground wire should be bared for a great enough length so that it can be connected both under the terminal marked, "G" and under the terminal marked, "D".

When a Doublet Antenna is used, one wire of the twisted down lead should be connected under the terminal marked, "A" and the other wire under the terminal marked, "D". Either wire may be connected to either terminal. The ground connection is made to the terminal marked, "G".

The Fuse:

There is a 1½ ampere fuse mounted under the cover marked, "FUSE", at the rear of the chassis. Remove the power cord plug from its receptacle before taking off the fuse cover. The 5Z4MG tube should be tested before replacing the fuse since a defect in this tube will cause the fuse to blow.

The AVC Circuit:

The diode current of the 6Q7MG tube flowing through the 200M ohm resistor, R16, creates a voltage drop across it. This voltage is applied to the control grids of the RF, Translator, and IF tubes to provide AVC.

APRIL 14, 1936

TUBE SOCKETS ARE VIEWED FROM UNDER SIDE OF CHASSIS. VOLTAGE READINGS AT INDICATED SOCKET PRONGS ARE TO CHASSIS. ALIGNMENT IS TO BE MADE AT THE FREQUENCIES SHOWN AT THE TRIMMER CONDENSERS. WHERE NO VOLTAGE READING IS SHOWN AT SOCKET PRONG, IT INDICATES A VERY LOW READING.

LOCATION OF TUBES VIEWED FROM REAR OF CABINET

Installing a Jack for The Use of Earphones:

A hole is provided in the rear of the chassis, near the speaker socket, for installing an earphone jack. This hole is plugged with a brass insert that can be removed. The connections for installing such a jack are shown in the above schematic.

Alignment, Sensitivity

ALIGNMENT PROCEDURE

IF Alignment

1. **Connections:**

Connect the ground lead of the test oscillator to the receiver chassis. Connect the output lead of the test oscillator, in series with a .1 mfd condenser, to the positions mentioned below under "Alignment". Connect the low scale of an output meter across the loud speaker voice coil. Connect a jumper between terminals "D" and "G" of the antenna terminal block at the rear of the chassis.

2. **Receiver Settings:**

Turn the Wave Band switch to the BROADCAST position and the Station Selector to about 550 kc. Turn the receiver Volume Control all the way on and the Variable Selectivity Control to its sharpest position (all the way counter clockwise).

3. **Alignment:**

(a) Turn the Variable Selectivity Control all the way to the right. Loosen the set screws that clamp the IF transformer flexible cables and push the cables as far as possible into their copper tubes. Then re-tighten the set screws, making sure that the Variable Selectivity Control remains in its extreme clockwise position. Do not tighten the set screws so much that they cut the flexible cables. Then turn the Variable Selectivity Control all the way counter clockwise and leave it in this position for the remainder of the alignment procedure.

(b) Set the test oscillator to 385 kc and connect its output lead (in series with a .1 mfd condenser) to the control grid of the 6K7MG second IF tube. Peak the IF output transformer, T3.

(c) Change the test oscillator output lead to the 6K7MG first IF tube and peak the IF interstage transformer, T2.

(d) Change the test oscillator output lead to the control grid of the 6L7MG translator tube and peak the IF input transformer, T1.

(e) Repeat operations (b), (c) and (d), connecting the test oscillator output lead to the second IF tube, then to the first IF tube and then to the translator tube, as was done originally. Always keep the test oscillator output power at its lowest possible value to render the AVC action inoperative.

BROADCAST BAND ALIGNMENT

1. **Connections:**

Disconnect the .1 mfd condenser from the output lead of the test oscillator. Connect a .00025 mfd mica condenser in series with the test oscillator output lead and the "A" terminal of the antenna terminal block at the rear of the chassis. All other connections remain the same as for IF alignment.

2. **Receiver Settings:**

Turn the Wave Band switch to the BROADCAST position, the Volume Control all the way on, and the Variable Selectivity Control to its sharpest position, as for IF alignment.

3. **Alignment:**

(a) Set the test oscillator to 1770 kc. Open the Variable Condenser plates all the way and peak the broadcast oscillator trimmer, C8.

(b) Set the test oscillator to 1400 kc and tune in its signal. Peak the Broadcast antenna trimmer, C1, and the Broadcast translator trimmer, C17. The locations of all the trimmers are shown in the Service Illustrations.

(c) Set the test oscillator to 600 kc and tune in its signal. Peak the Broadcast oscillator padder, C7. The variable should be rocked a degree or two while making this adjustment.

(d) Repeat the 1770 kc, then the 1400 kc, and then the 600 kc adjustment for greatest accuracy. Always keep the test oscillator output at its lowest possible value.

(e) To check the dial calibration, set the test oscillator at 1000 kc and tune in its signal. If necessary, turn the dial pointer to 1000 kc, being careful not to allow the variable condenser to turn.

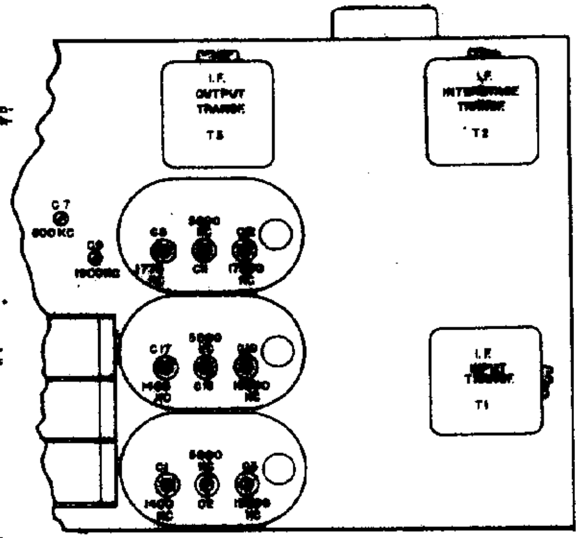
SHORT WAVE BAND "B" ALIGNMENT

1. **Connections:**

Disconnect the .00025 mfd mica condenser from the output lead of the test oscillator and replace it with a 400 ohm carbon resistor. Other connections remain the same as for Broadcast alignment.

2. **Receiver Settings:**

Turn the Wave Band switch to the "B" position. Other settings remain the same as for Broadcast Band alignment.



3. **Alignment:**

(a) Set the test oscillator to 5800 kc. Open the Variable Condenser plates all the way and peak the oscillator trimmer, C11.

(b) Set the test oscillator to 5000 kc and peak the antenna trimmer, C2, and the translator trimmer, C18.

(c) Set the test oscillator to 1800 kc and tune in its signal. Peak the oscillator padder, C9. The variable should be rocked a degree or two during the adjustment.

(d) Repeat the alignment operations in their original order for greatest accuracy. Always keep the test oscillator output at its lowest possible value.

SHORT WAVE BAND "C" ALIGNMENT

1. **Connections:**

All connections remain the same as for band "B" alignment.

2. **Receiver Settings:**

Turn the Wave Band switch to the "C" position. Other settings remain the same as for band "B" alignment.

3. **Alignment:**

(a) Set the test oscillator to 17,000 kc. Open the Variable Condenser plates all the way and adjust the oscillator trimmer, C12.

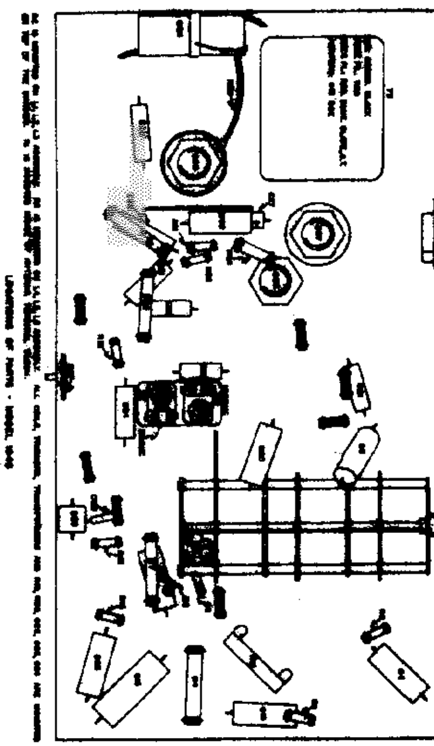
(b) Set the test oscillator to 18,000 kc and tune in its signal. Peak the antenna trimmer, C3, and the translator trimmer, C19.

(c) Repeat the 17,000 kc adjustment and then the 18,000 kc adjustment for greater accuracy. Always keep the test oscillator output power at its lowest possible value.

SENSITIVITY

The following figures are given as an indication of the approximate sensitivities that should be had at various settings of the receiver. It is necessary to have a test oscillator with an accurately calibrated attenuator so that the power output can be known. The output meter is to be connected across the loud speaker voice coil. An output meter reading of 2.6 volts should be obtained for each of the input voltages shown for the frequencies listed.

The Volume Control of the receiver must be all the way on, and the Variable Selectivity Control in its sharpest position (all the way counter clockwise). Terminals "D" and "G" on the antenna terminal block must be connected together with a jumper. The ground lead of



LOCATIONS OF PARTS - MODEL 1946

the test oscillator is to be connected to the receiver chassis. The output lead of the test oscillator, in series with the value of condenser or resistor shown below, is to be connected as indicated for the particular frequency at which the measurement is being made.

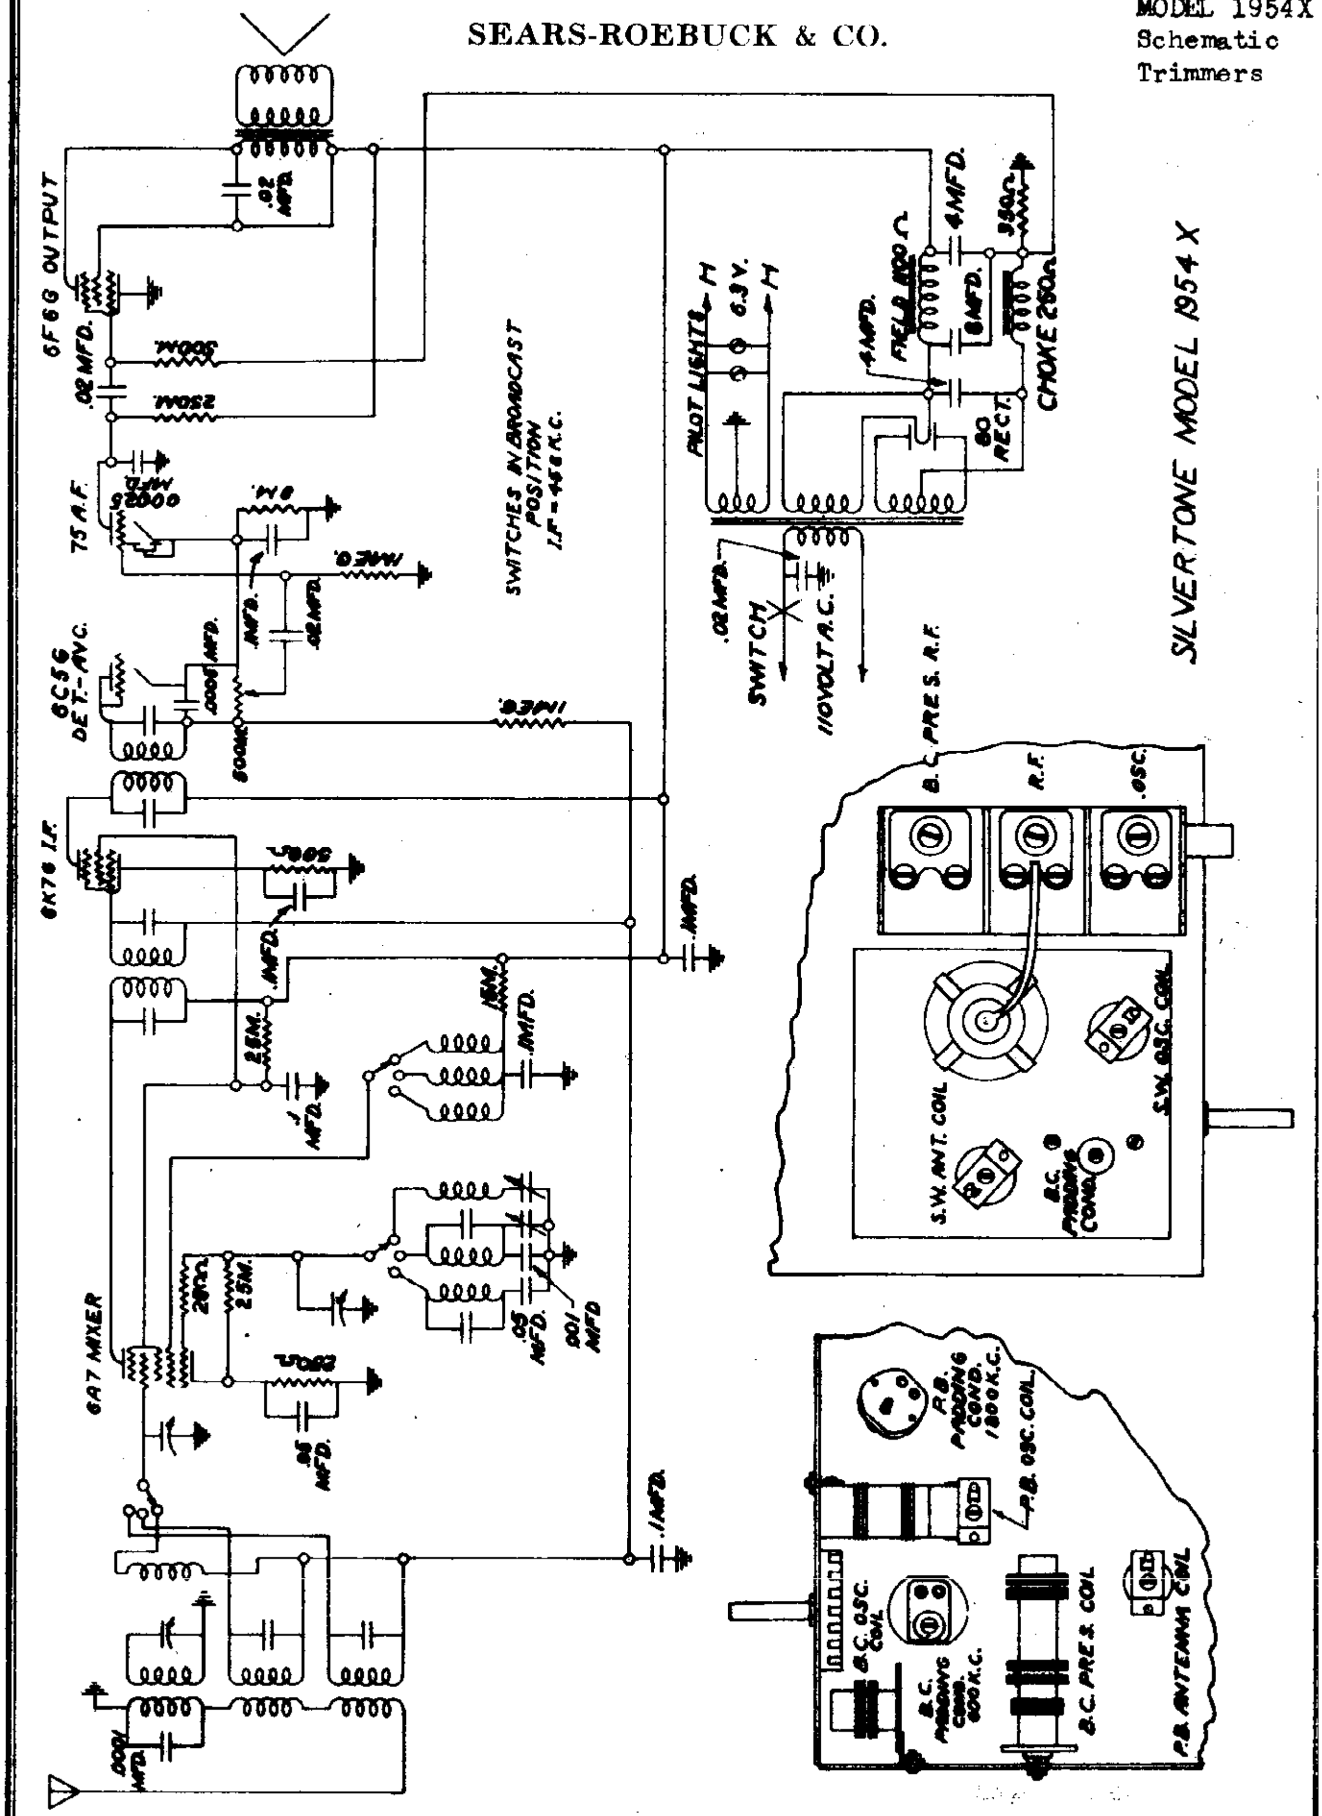
The Sensitivity Control at the rear of the chassis is to be adjusted so that an output meter reading of 2.6 volts is obtained with a 400 microvolt input connected to the translator grid.

[illegible]	[illegible]	[illegible]	[illegible]
Translator Grid	.1 mfd	385 kc	400
Antenna Terminal "A"	.00025 mfd	600 kc	[illegible]
Antenna Terminal "A"	.00025 mfd	1000 kc	**[illegible]
Antenna Terminal "A"	.00025 mfd	1400 kc	[illegible]
Antenna Terminal "A"	400 ohms	1800 kc	100
Antenna Terminal "A"	400 ohms	[illegible] kc	[illegible]
Antenna Terminal "A"	400 ohms	[illegible] kc	[illegible]
Antenna Terminal "A"	400 ohms	[illegible] kc	[illegible]
Antenna Terminal "A"	400 ohms	[illegible] kc	45
Antenna Terminal "A"	400 ohms	[illegible] kc	[illegible]
Antenna Terminal "A"	400 ohms	18000 kc	10

** FINAL SENSITIVITY CONTROL ADJUSTMENT

After all bands have been aligned, repeat the 1000 kilocycle adjustment, and reset the sensitivity control so that an output meter reading of 2.6 volts is obtained with a 10 microvolt input from the test-oscillator.

SEARS-ROEBUCK & CO.



MODEL 1954X
Alignment

SEARS-ROEBUCK & CO.

Parts

The alignment of this receiver requires the use of a test oscillator that will cover the frequencies of 456, 600, 1400, 1800, 4000, 6000 and 14,000 K.C. and an output meter to be connected across the primary or secondary of the output transformers. If possible, all alignment should be made with the volume control on maximum and the test oscillator output as low as possible, to prevent the AVC from operating and giving false readings.

I. F. ALIGNMENT: Adjust the test oscillator to 456 K.C. and connect the output to the grid of the first detector tubes (6A7) through a .05 or .1 mfd. condenser, The ground on the test oscillator can be connected to the chassis ground. Align all four I.F. trimmers to peak or maximum reading on the output meter.

R. F. ALIGNMENT: Adjust the oscillator to 1400 K. C. and connect the output to the antenna post through a .0001 mfd. mica condenser to give the equivalent of an antenna about 60 feet. Set the receiver pointer to 1400 K. C. and adjust the rear gang condenser trimmer to peak. Next re-set the dial pointer on the receiver and the test oscillator to 600 K.C. Slowly increase or decrease the oscillator padding condenser and at the same time continuously tuning back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment seems a little complicated but is the easiest way to adjust the oscillator to the pre-selector or R.F. section. The padding condenser is located on the top of the removable R. F. assembly. Return to 1400 K.C. and again go over the adjustments at that frequency to be sure they have not been thrown out of adjustment.

SHORT WAVE BANDS

The foreign band of 19 to 49 meters can be adjusted by the two trimmers on the short wave coil located on the top of the chassis. Set the test oscillator to 14 megacycles. The oscillator coil is located near the dial.

The police and aviation band can be adjusted by the trimmers on the two coils underneath the chassis. Adjust the oscillator coil (the one near the wave change switch) so that the dial pointer is on the scale at 4000 K.C., then adjust the R. F. coil to resonance. The low frequency end or 1800 K.C. can be adjusted by the police band padding condenser using the same method as the 600 K.C. adjustment. The gang condenser trimmers are not to be used for alignment of either of the short wave bands.

MODELS 1927X,1937X
MODEL 1992X
MODEL 1993X
Alignment

SEARS-ROEBUCK & CO.

Models 1927X and 1937X

INTERMEDIATE ALIGNMENT:

1. Connect the high side of the test oscillator output to the control grid of the 1C6 modulator tube through a .02 Mfd. condenser. Leave the grid cap connected to the grid terminal of the tubes, and connect the ground side of the test oscillator to the receiver ground.

2. Set the test oscillator frequency to 465 kilocycles (this must be accurate).

3. Align the second intermediate transformer by turning one of the trimmer screws accessible through holes in the top of the transformer shields up and down (increasing and decreasing capacity) until maximum reading is obtained on the output meter, after which adjust the other trimmer screw of the same transformer for maximum sensitivity.

4. Adjust the first intermediate transformer in the same manner as the second I.F. transformer.

TO ALIGN THE VARIABLE CONDENSER: It is important when aligning the gang condenser, padding and trimmer condensers to follow the procedure carefully, otherwise the receiver will be insensitive and the dial calibration will be incorrect. The padding and trimmer condensers located underneath the chassis will be referred to by their functions as indicated on the circuit diagram.

1. Connect the high output side of the test oscillator through a 400 ohm resistor to the receiver antenna lead and the low side to the set ground.

2. Place the band selector switch for operation on the 5.8 to 18 megacycle band, tune the receiver dial, and set the test oscillator frequency to exactly 15 megacycles. Twist and untwist neutralizing link for best 15 megacycle signal response. Note: This adjustment will be found to be broad. Next adjust the 15 megacycle antenna trimmer for maximum 15 megacycle signal sensitivity.

3. Replace the 400 ohm resistor in series with test oscillator lead with a 200 mmfd. condenser, place the band selector switch for operation on the 540 to 1720 kilocycle band and set test oscillator frequency to exactly 1720 kilocycles.
Rotate gang condenser so that plates are completely out of mesh and bring in the 1720 kilocycle signal to maximum output by adjusting 1720 kilocycle oscillator trimmer.

4. With band selector switch placed for operation on the 540 to 1720 kilocycle band set test oscillator frequency and receiver dial to exactly 1400 kilocycles. Adjust 1400 kilocycle preselector and antenna trimmers for maximum 1400 kilocycle signal sensitivity.

5. Leave band selector switch for operation on 540 to 1720 kilocycle band, tune receiver dial and set test oscillator frequency to approximately 600 kilocycles. While rocking gang condenser slightly to right and left adjust 600 kilocycle oscillator padder for maximum sensitivity.

Model 1993X

INTERMEDIATE ALIGNMENT:

1. Connect the high side of the test oscillator output to the control grid of the 1C6 modulator tube through a .02 Mfd. condenser. Leave the grid cap connected to the grid terminal of the tube, and connect the ground side of the test oscillator to the receiver ground.

2. Set the test oscillator frequency to 465 kilocycles (this must be accurate).

3. Align the second intermediate transformer by turning one of the trimmer screws accessible through holes in the top of the transformer shields up and down (increasing and decreasing capacity) until maximum reading is obtained on the output meter, after which adjust the other trimmer screw of the same transformer for maximum sensitivity.

4. Adjust the first intermediate transformer in the same manner as the second I. F. transformer.

TO ALIGN THE VARIABLE CONDENSER: It is important when aligning the gang condenser, padding and trimmer condensers to follow the procedure carefully, otherwise the receiver will be insensitive and the dial calibration will be incorrect. The padding and trimmer condensers located underneath the chassis will be referred to by their function as indicated on the circuit diagram.

1. Connect the high output side of the test oscillator through a 400 ohm resistor to the receiver antenna lead and the low side to the set ground.

2. Place the band selector switch for operation on the 6 to 18 megacycle band, tune the receiver dial, and set the test oscillator frequency to exactly 15 megacycles. Adjust 15 megacycle antenna trimmer for maximum 15 megacycle signal sensitivity.

3. Replace the 400 ohm resistor in series with test oscillator lead with a 200 mmfd. condenser, place the band selector switch for operation on the 540 to 1720 kilocycle band and set test oscillator frequency to exactly 1720 kilocycles.
Rotate gang condenser so that plates are completely out of mesh and bring in the 1720 kilocycle signal to maximum output by adjusting 1720 kilocycle oscillator trimmer.

4. With band selector switch placed for operation on the 540 to 1720 kilocycle band set test oscillator frequency and receiver dial to exactly 1400 kilocycles. Adjust 1400 kilocycle preselector and antenna trimmers for maximum 1400 kilocycle signal sensitivity.

5. Leave band selector switch for operation on 540 to 1720 kilocycle band, tune receiver dial and set test oscillator frequency to approximately 600 kilocycles. While rocking gang condenser slightly to right and left adjust 600 kilocycle padder for maximum sensitivity.

6. Place band selector switch for operation on the 390-140 kilocycle band, rotate gang condenser so plates are completely out of mesh, and set test oscillator frequency to exactly 390 kilocycles. Bring in 390 kilocycle signal to maximum output with 390 oscillator trimmer.

7. With band selector switch for operation on 390-140 kilocycle band, tune receiver dial and set test oscillator frequency to exactly 350 kilocycles. Adjust 350 kilocycle antenna preselector trimmers for maximum 350 kilocycle signal response.

8. Leave band selector switch for operation on the 390-140 kilocycle band, tune receiver dial and set test oscillator frequency to approximately 150 kilocycles. Then while rocking gang condenser slightly to right and left adjust 150 kilocycle padding condenser for maximum sensitivity.

Model 1992X

INTERMEDIATE ALIGNMENT:

1. Connect the high side of the test oscillator output to the control grid of the 1C6 modulator tube through a .02 Mfd. condenser. Leave the grid cap connected to the grid terminal of the tube, and connect the ground side of the test oscillator to the receiver ground.

2. Set the test oscillator frequency to 465 kilocycles (this must be accurate).

3. Align the second intermediate transformer by turning one of the trimmer screws accessible through holes in the top of the transformer shields up and down (increasing and decreasing capacity) until maximum reading is obtained on the output meter, after which adjust the other trimmer screw of the same transformer for maximum sensitivity.

4. Adjust the first intermediate transformer in the same manner as the second I. F. transformer.

TO ALIGN THE VARIABLE CONDENSER: It is important when aligning the gang condenser, padding and trimmer condensers to follow the procedure carefully, otherwise the receiver will be insensitive and the dial calibration will be incorrect. The padding and trimmer condensers located underneath the chassis will be referred to by their function as indicated on the circuit diagram.

1. Connect the high output side of the test oscillator through a 400 ohm resistor to the receiver antenna lead and the low side to the set ground.

2. Place the band selector switch for operation on the 5.8 to 18 megacycle band, tune the receiver dial, and set the test oscillator frequency to exactly 18 megacycles.
Rotate gang condenser so that plates are completely out of mesh and then tune in the 18 megacycle signal to maximum output by adjusting the 18 megacycle oscillator trimmer. When adjusting this trimmer, two peaks, the fundamental and the image peak will be noticed. Care must be taken that the fundamental peak and not the image peak is used for aligning the receiver at 18 megacycles. Always back off the trimmer to minimum capacity, then screw down the trimmer (add capacity) until the first peak which is the fundamental and the proper one to use is tuned in. If the trimmer is screwed down beyond the point where the first peak is received, the incorrect image peak will be tuned in. After completing adjustment of the oscillator trimmer at 18 megacycles always check to see if the proper peak has been used. To do this leave the test oscillator frequency at 18 megacycles, increase the output of the test oscillator and tune the receiver dial to approximately 17 megacycles. Then vary the receiver dial slightly to the right and left of 17 megacycles, and if the fundamental peak was used in aligning at 18 megacycles the test oscillator signal will be heard at approximately 17 megacycles on the receiver dial. If it is not possible to receive the signal, then the fundamental peak was not used and the 18 megacycle oscillator trimmer must be properly readjusted.

3. With band selector switch set for operation on 5.8 to 18 megacycle band tune the receiver dial and set test oscillator frequency to exactly 15 megacycles and adjust 15 megacycle antenna trimmer for maximum 15 megacycle signal sensitivity.

4. Replace the 400 ohm resistor in series with test oscillator lead with a 200 mmfd. condenser, place the band selector switch for operation on the 540 to 1720 kilocycle band and set test oscillator frequency to exactly 1720 kilocycles.
Rotate gang condenser so that plates are completely out of mesh and bring in the 1720 kilocycle signal to maximum output by adjusting 1720 kilocycle oscillator trimmer.

5. With band selector switch placed for operation on the 540 to 1720 kilocycle band set test oscillator frequency and receiver dial to exactly 1400 kilocycles. Adjust 1400 kilocycle preselector and antenna trimmers for maximum 1400 kilocycle signal sensitivity.

6. Leave band selector switch for operation on 540 to 1720 kilocycle band, tune receiver dial and set test oscillator frequency to approximately 600 kilocycles. While rocking gang condenser slightly to right and left adjust 600 kilocycle oscillator padder for maximum sensitivity.

GENERAL INFORMATION

DIFFERENCES IN VOLUME CONTROL CIRCUITS:

Earlier production used a 250M ohm volume control and the circuit shown in Fig. 1. In later production, shown in the circuit of Fig. 2, the volume control value was changed to one megohm. Also, R6 and C15 were added; the value of C17 changed from .006 to .05; the value of R9 changed from 500M ohms to one megohm. The effect of this change is to remove the DC diode current from the volume control to prevent noisy operation of the control.

CHASSIS MARKED 407F AND LATER:

Chassis that are rubber stamped 407F or any later letter incorporate the circuit shown in Fig. 3. The differences as compared to Fig. 2 are:

C15 changed from .006 mfd. to .05 mfd.
C17 changed from .05 mfd. to .1 mfd. and its location changed.
The resistors R9, R10, and R11 shown in Fig. 2 were removed.
A new 1M ohm resistor was added and R9 designation assigned to it.
A new 50M ohm resistor was added and R10 designation assigned to it.
A new 500 ohm resistor was added and R11 designation assigned to it.
R4 changed from 25M ohms to 20M ohms.

These changes were made to provide more uniform operation with different makes of tubes.

HEATER CIRCUIT:

Earlier production used a center tapped power transformer heater winding. Later production omitted the center tap and grounded one end of the heater winding.

MODULATION HUM:

Modulation hum, which occurs only when a station is tuned in, can be eliminated by connecting a .003 mfd. 600 volt condenser from one side of the power transformer primary to ground.

"F"	7 mc	7 mc	400 ohms	Antenna Terminal	Loop at bracket end of L5	80

IMAGE ADJUSTMENT

Set the generator to 1524 kc and tune in the signal image at about 1000 kc on the receiver. The generator should be adjusted for high output (.1 volts). There is a lead running from L1 through a hole in the chassis to the wave switch. Adjust the position of this lead under the chassis for minimum image response.

IMPORTANT ALIGNMENT NOTES

Where indicated by the word, "rock", the variable should be rocked back and forth a degree or two while making the adjustment.

It is advisable to repeat the entire alignment procedure band by band and in the original order to insure greater accuracy.

Always keep the output from the test oscillator at its lowest possible value. As the sensitivity is increased by alignment, the generator output should be reduced correspondingly.

After the alignment procedure has been completed, tune in a broadcast signal at about 1000 kc. If necessary shift the dial pointer so that it indicates this frequency.

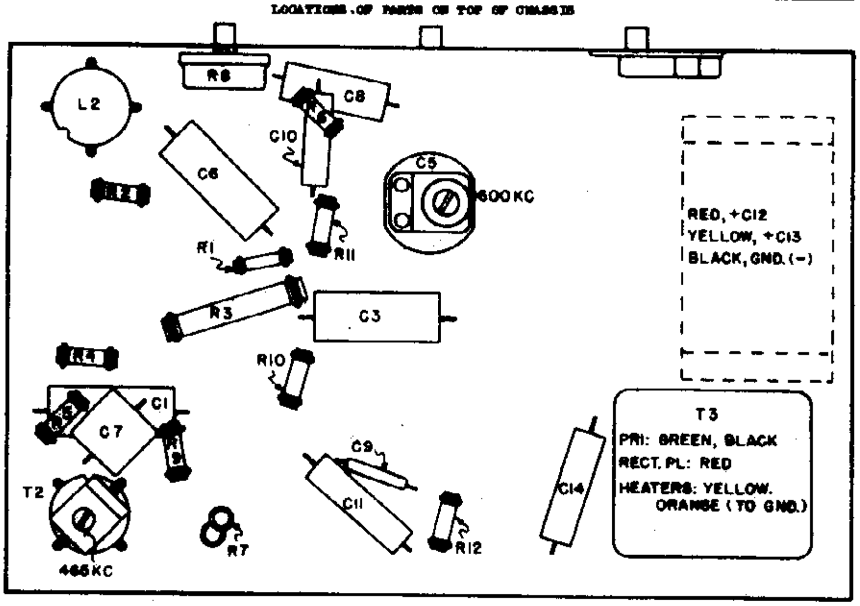
LOCATIONS OF PARTS ON TOP OF CHASSIS



LOCATIONS OF PARTS UNDER CHASSIS

SUBJECT: ELIMINATING WHISTLE AT 930 KC:

A whistle, due to a beat between the second harmonic (930 kc) of the 465 kc IF, and a 930 kc signal may be experienced. In localities where the 930 kc station is one that is frequently listened to, it will be desirable to shift the whistle to some other point where it will not be objectionable. This can be done by shifting the IF frequency of the receiver.

Determine at what point between 900 kc and 960 kc the whistle will be least objectionable. Dividing this frequency by two will give the new IF frequency to which the receiver should be aligned. For example, if it is determined that a whistle at 915 kc would not be objectionable, the IF should be realigned at 915/2 or 457.5 kc.

Align the IF at the new frequency and then realign the rest of the receiver as described in Service Instructions #57RL 8 for this receiver.

ELECTROLYTIC CONDENSERS IN 25 CYCLE MODELS:

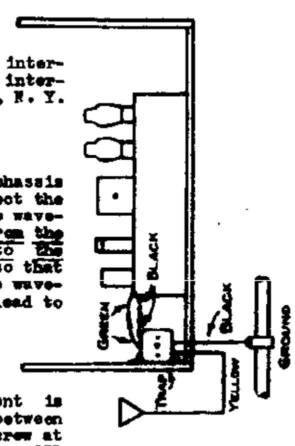
The 25 cycle models use 15 mfd. wet electrolytic condensers, C12 and C13, instead of the dual dry electrolytic used in the 60 cycle models.

SUBJECT: WAVE-TRAP TO ELIMINATE INTERFERENCE FROM SHIP OR AIRPORT TRANSMITTERS

In locations near ship transmitters or airports or air beacon stations, code interference may be experienced. Part #1013114256 wave-trap is designed to eliminate such interference. It can be ordered from Colonial Radio Corporation, 254 Rano Street, Buffalo, N. Y. Use Purchase Order blank, form F5254. The retail selling price is $1.00.

INSTALLATION OF THE TRAP:

Mount the trap, by means of two wood screws, at any convenient place on the chassis shelf or cabinet where it will be near the antenna terminal of the receiver. Connect the yellow lead of the wave-trap to the antenna download. Splice the green lead of the wave-trap to the green antenna lead of the receiver. Cut off any excess length of wire from the trap and from the chassis antenna lead so that the green lead from the wave trap to the chassis is as short as possible. The yellow lead from the wave-trap should be run so that it is as far as possible from the green lead. Splice one of the black leads from the wave-trap to the black ground lead of the receiver. Connect the other wave-trap black lead to the ground used for the installation.



ADJUSTMENT OF THE TRAP:

The trap is pre-tuned to the IF frequency so that normally no further adjustment is necessary. However, should interference still be experienced, tune the receiver between approximately 550 and 600 kc. Then adjust the wave-trap, by means of the trimmer screw at the bottom of the container, until the interference is eliminated. Addition of the trap will reduce the sensitivity of the receiver around 600 kc by approximately 50%. The customer should be forewarned of this to avoid complaints of reduced sensitivity.

GENERAL INFORMATION

ADJUSTMENT OF POWER ECONOMIZER:

A series filament rheostat, termed a POWER ECONOMIZER, is mounted on the top rear of the chassis. The arrow of the knob should always be kept as near the "NEW" position as possible, consistent with satisfactory reception This will result in greater life for the batteries and the tubes. As the batteries grow older and reception becomes poorer it will be necessary to turn the knob toward the "OLD" position to compensate. When the knob must be turned all the way to the "OLD" position the "A" battery is exhausted and should be replaced.

NOTE: ECONOMIZER SHOULD BE IN "OLD" POSITION AT ALL TIMES WHEN USING 2 VOLT STORAGE BATTERY.

SUBJECT: ELIMINATING WHISTLE AT 930 KC:

A whistle, due to a beat between the second harmonic (930 kc) of the 465 kc IF, and a 930 kc signal may be experienced. In localities where the 930 kc station is one that is frequently listened to, it will be desirable to shift the whistle to some other point where it will not be objectionable. This can be done by shifting the IF frequency of the receiver.

Determine at what point between 900 kc and 960 kc the whistle will be least objectionable. Dividing this frequency by two will give the new IF frequency to which the receiver should be aligned. For example, if it is determined that a whistle at 915 kc would not be objectionable, the IF should be realigned at 915/2 or 457.5 kc.

Align the IF at the new frequency and then realign the rest of the receiver as described in Service Instructions #57RL 7 for this receiver.

SPEAKER ADJUSTMENT

There are two adjusting screws at the rear of the speaker, as shown in the illustration. Speaker rattle can be corrected by turning these screws. Tighten one and loosen the other slightly until the rattle is eliminated.

ALIGNMENT PROCEDURE

IF ALIGNMENT

1. Connections:

Connect the low scale of the output meter across the loud speaker voice coil. Connect the ground lead of the test oscillator to the receiver chassis. Connect the output lead of the test oscillator, in series with a .1 mfd condenser, to the positions indicated below under "Alignment". Connect a jumper between terminals "D" and "G" of the antenna terminal block at the rear of the chassis.

2. Receiver Settings:

Turn the Volume Control all the way on, the Tone Control to position "1", the Wave Band switch to the BROADCAST position, and the Station Selector to about 550 kc.

3. Alignment:

(a) Connect the test oscillator output lead (in series with the .1 mfd condenser) to the control grid of the 6K7MG IF tube. Set the test oscillator to 262 kc and peak the IF output transformer, T2.

(b) Change the test oscillator output lead connection to the control grid of the 6A8MG translator tube and peak the IF input transformer, T1.

(c) Change the test oscillator output connection back to the 6K7MG tube and repeat the IF output transformer adjustment. Then change the test oscillator connection to the 6A8MG tube and repeat the IF input transformer adjustment. Always keep the test oscillator output at its lowest possible value.

BROADCAST BAND "A" ALIGNMENT

1. Connections:

Remove the .1 mfd condenser from the output lead of the test oscillator. Connect a .0002 mfd mica condenser between the test oscillator output lead and the "A" terminal of the antenna terminal block at the rear of the chassis. All other connections remain the same as for IF Alignment.

2. Receiver Settings:

Turn the Volume Control all the way on, the Tone Control to the "1" position, and the Wave Band switch to the "A" position, as for IF Alignment.

3. Alignment:

(a) Set the test oscillator to 1400 kc and tune in its signal. Peak the broadcast translator trimmer, C3, and the broadcast antenna trimmer, C2. The variable should be rocked a degree or two during the adjustment. The broadcast antenna trimmer is the one on the middle section of the Variable Condenser. The locations of all of the other trimmers are shown in the Location of Parts diagram.

(b) Set the test oscillator to 600 kc and tune in its signal. Peak the broadcast oscillator padder, C9. The variable should be rocked a degree or two during the adjustment.

4. Dial Calibration:

Set the test oscillator to 900 kc and tune in its signal. If necessary, turn the dial pointer so that it reads 900 kc. Do not allow the variable condenser plates to turn while moving the dial pointer.

5. Image Adjustment:

Set the test oscillator to 1000 kc and tune in its signal. Adjust the test oscillator output to 10 microvolts and note the output meter reading. Leaving the set tuned to 1000 kc, change the test oscillator frequency to 1524 kc and increase its output to 100,000 microvolts. If necessary, slightly change the test oscillator frequency so that the image heard in the receiver will be loudest. Then note the output meter reading. It should not be greater than that noted with the test oscillator at 1000 kc and its output at 10 microvolts. If the output meter reading at 1524 kc is greater, proceed as follows:

There is a yellow lead that runs from the Wave Band switch to C3. Move this lead until the lowest reading is had on the output meter. (With the test oscillator at 1524 kc and 100,000 microvolts and the receiver at 1000 kc.) When the yellow lead is properly positioned, the output meter reading (image) with the test oscillator at 1524 kc should not be greater than it was with the test oscillator at 1000 kc and its output at 10 microvolts.

If it is found necessary to make the image adjustment, repeat the alignment procedure, since alignment may be slightly affected.

SHORT WAVE BAND "B" ALIGNMENT

1. Connections:

Remove the .0002 mfd m condenser used in series with the test oscillator output lead for Broadcast alignment. In its stead connect a 400 ohm carbon resistor. All other connections remain the same as for Broadcast Band Alignment.

2. Receiver Settings:

Turn the Wave Band switch to the "B" position. Other receiver settings remain the same as for Broadcast Band Alignment.

3. Alignment:

(a) Turn the Station Selector knob so that the dial pointer reads exactly 4500 kc.

(b) Set the test oscillator to 4500 kc. Peak the oscillator trimmer, C12. (Be careful not to allow the Variable Condenser to turn during the operation.)

(c) Leave the test oscillator set at 4500 kc and peak the translator trimmer, C4. The variable should be rocked during this adjustment. Always keep the test oscillator output at its lowest possible value.

SHORT WAVE BAND "C" ALIGNMENT

1. Connections:

Connections remain the same as for band "B" alignment.

2. Receiver Settings:

Turn the Wave Band switch to the "C" position. Other receiver settings remain the same as for band "B" alignment.

3. Alignment:

(a) Set the test oscillator to 15,000 kc and tune in its signal. Adjust the translator trimmer, C5. The variable should be rocked during the adjustment.

SENSITIVITIES

The following figures are given as an indication of the approximate sensitivities that should be had at various settings of the receiver. It is necessary to have a test oscillator with an accurately calibrated attenuator so that its power output can be known. The output meter is to be connected across the loud speaker voice coil. An output meter reading of 1 volt should be obtained for each of the input voltages shown for the frequencies listed.

The Volume Control of the receiver must be all the way on and the Tone Control in its "1" position. Terminals "D" and "G" on the antenna terminal block are to be connected together with a jumper. The ground lead of the test oscillator is to be connected to the receiver chassis. The output lead of the test oscillator is to be connected to the "A" terminal of the antenna terminal block, in series with a .0002 mfd mica condenser, for Broadcast Band measurements. The .0002 mfd condenser is to be disconnected and a 400 ohm carbon resistor used instead for the two Short Wave bands.

	Frequency	Microvolts Input
Broadcast Band	600 kc	35
	1000 kc	30
	1400 kc	35
Band "B"	1800 kc	60
	2500 kc	45
	3600 kc	30
	4500 kc	30
Band "C"	6000 kc	70
	10000 kc	50
	15000 kc	18

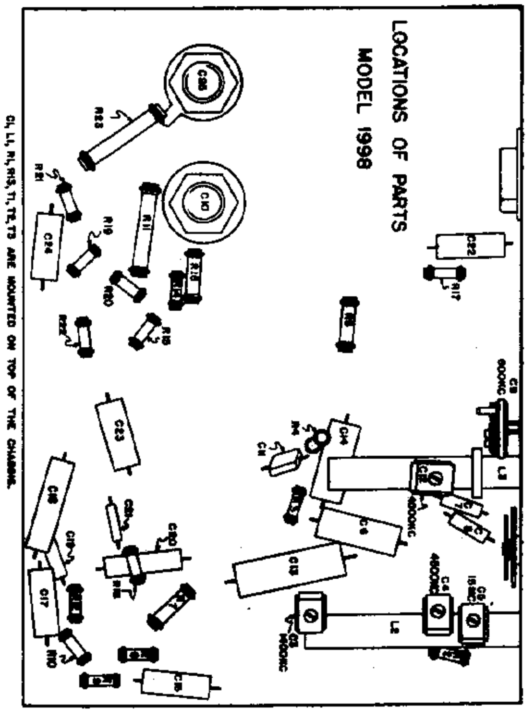
The Fuse:

There is a 3/4 ampere fuse at the rear of the chassis, under the cover marked, "Fuse". A spare fuse is contained in the envelope tacked to the inside of the cabinet. Be sure to remove the power supply cord from its receptacle before replacing the fuse. The 5Z4MG rectifier tube should be tested before replacing the fuse since a defective tube will cause the fuse to blow. Repeated blowing of the fuse indicates a fault that should be corrected before making further fuse replacements. Use none but a 3/4 ampere fuse for replacement.

Antenna And Ground Connections:

This receiver is designed for use with either a conventional type of antenna or a Doublet Antenna. There is a terminal block at the rear of the chassis. When a conventional antenna is used, its leadin is to be connected to the terminal marked, "A", on the terminal block. The ground wire should be bared for a sufficient length so that it can be clamped under terminals "D" and "G".

When a Doublet Antenna is used, one wire of its twisted downlead is to be connected under the terminal marked, "A", and the other wire under the terminal marked, "D". Either downlead wire may be connected to either terminal. The ground connection is made to the terminal marked, "G". Where space permits of its installation, a Doublet Antenna is recommended as giving very much better, noise-free short wave reception.



CL, L1, RL, R13, T1, T2, T3 ARE MOUNTED ON TOP OF THE CHASSIS.

CIRCUIT CHANGES TO REDUCE HUM WHEN TONE CONTROL IS IN BASS POSITION

1. Remove the .01 condenser, C20, which is connected from the triode plate of the 6Q7MG to a tie lug. (This tie lug connects to the Tone Control switch.)

2. Connect a .05 mfd 600 volt condenser (Part #R9145) from the tie lug to the plate of the 6F6MG tube near the 5Z4MG tube.

3. Remove the lead from the 6Q7MG cathode to the Tone Control switch.

4. Ground the switch lug from which this wire was removed to the ground lug of the broadcast antenna coil.

INSTALLATION OF A WAVE-TRAP TO ELIMINATE CODE INTERFERENCE

If the receiver is located near an airport that uses a transmitter operating on or near the IF frequency of the receiver (262 kc), interference from the transmitter may be encountered.

To eliminate such interference a wave trap, part #R14477 - $1.00, should be ordered from COLONIAL RADIO CORPORATION, 254 Rano Street, Buffalo, N. Y.

This trap may be mounted in any convenient place in the cabinet by means of two small wood screws. Mount the trap so that its adjustment screw is accessible. Connect one lead of the trap (either one) to the "A" terminal on the antenna terminal block at the rear of the chassis. The other lead of the trap is to be connected to the antenna leadin or doublet lead which originally was connected to the antenna terminal block.

Turn the Wave Band switch to the BROADCAST position and the Variable Condenser to approximately 550 kc. If interference still is encountered, adjust the wave-trap with an insulated screw driver until the interfering signal is eliminated.

ALIGNMENT PROCEDURE

PRELIMINARY:

Output meter connection - Across speaker voice coil.

Output meter reading to indicate 50 milliwatts - - - - - - - - - - - - - - - - - .47 volts

Generator ground lead connection - Receiver chassis

Dummy antenna value to be in series with generator output - - - - - - - - See chart below

Connection of generator output lead - See chart below

Position of volume control - All the way on

Position of tone control - Fully clockwise

WAVE BAND SWITCH POSITION	POSITION OF VARIABLE	GENERATOR FREQUENCY	DUMMY ANTENNA	GENERATOR CONNECTION	TRIMMER ADJUSTMENTS (IN ORDER SHOWN)
"A"	-	465 kc	.1 mfd.	1C6 Grid	T2,T1
"A"	Fully open	1730 kc	.0002 mfd.	Antenna Lead	C6
"A"	1400 kc	1400 kc	.0002 mfd.	Antenna Lead	V1
"A"	600 kc (rock)	600 kc	.0002 mfd.	Antenna Lead	C7
"W"	Fully open	400 kc	.0002 mfd.	Antenna Lead	C8
"W"	215 kc	365 kc	.0002 mfd.	Antenna Lead	C2
"W"	275 kc (rock)	275 kc	.0002 mfd.	Antenna Lead	C9
"F"	16 mc (rock)	16 mc	400 ohms	Antenna Lead	C1

IMPORTANT ALIGNMENT NOTES

Alignment must be made in this sequence:

1. IF
2. Broadcast Band ("A")
3. Weather Band ("W")
4. Short Wave Band ("F")

The 1400 kc and 600 kc adjustments for the "A" band should be repeated for greater accuracy.

The complete alignment procedure for band "W" should be repeated two or three times for greater accuracy.

Always keep the output from the signal generator at its lowest possible value.

After the alignment procedure has been completed, tune in a signal of about 1000 kc and set the dial pointer to that frequency.

The receiver should go to 17,400 kc on band F. If it fails to do so, move the oscillator plate and grid leads into the clear, to reduce distributed capacity. The receiver then will have the proper frequency coverage.

ALIGNMENT PROCEDURE

PRELIMINARY:

Output meter connection - Across speaker voice coil

Output meter reading to indicate 50 milliwatts - - - - - - - - - - - - - - - - - - .47 volts

Generator ground lead connection - Receiver chassis

Dummy antenna value to be in series with generator output - - - - - - - - - See chart below

Connection of generator output lead - See chart below

Position of volume control - All the way on

Position of tone control - Fully clockwise

WAVE BAND SWITCH POSITION	POSITION OF VARIABLE	GENERATOR FREQUENCY	DUMMY ANTENNA	GENERATOR CONNECTION	TRIMMER ADJUSTMENTS (IN ORDER SHOWN)
"A"	-	465 kc	.1 mfd.	IF tube grid cap	T2
"A"	-	465 kc	.1 mfd.	Translator tube grid cap	T1
"A"	Fully open	1750 kc	.0002 mfd.	Antenna Lead	C8
"A"	1400 kc	1400 kc	.0002 mfd.	Antenna Lead	C3,C2
"A"	600 kc (Do not rock)	600 kc	.0002 mfd.	Antenna Lead	C9
"W"	Fully open	400 kc	.0002 mfd.	Antenna Lead	C10
"W"	385 kc	385 kc	.0002 mfd.	Antenna Lead	C4
"W"	275 kc (rock)	275 kc	.0002 mfd.	Antenna Lead	C11
"F"	Fully open	17.5 mc	400 ohms	Antenna Lead	*
"F"	15 mc	15 mc	400 ohms	Antenna Lead	C1

* Twist or untwist the blue and yellow leads on the short wave oscillator coil, L5, for maximum output meter reading.

IMPORTANT ALIGNMENT NOTES

Alignment must be made in this sequence:

1. IF
2. Broadcast Band ("A")
3. Weather Band ("W")
4. Short Wave Band ("F")

The 1400 kc and 600 kc adjustments for the "A" band should be repeated for greater accuracy. Do not rock the variable while making the 600 kc padder adjustment.

The complete alignment procedure for band "W" should be repeated two or three times for greater accuracy.

Always keep the output from the signal generator at its lowest possible value.

After the alignment procedure has been completed, tune in a signal of about 1000 kc and set the dial pointer to that frequency.

GENERAL INFORMATION

Two types of this model have been built. One uses conventional glass tubes. The other type uses octal base glass tubes.

A plug-in type vibrator is used. It is non-synchronous, with an 84 or 6X5G tube serving as the rectifier. The vibrator and the rectifier tube are contained in a rectangular metal shield with removable top cover, mounted on top of the chassis.

SEARS-ROEBUCK & CO.

ELIMINATING WHISTLE AT 930 KC:

A whistle, due to a beat between the second harmonic (930 kc)of the 465 kc IF,and a 930 kc signal may be experienced. In localities where the 930 kc station is one that is frequently listened to, it will be desirable to shift the whistle to some other point where it will not be objectionable. This can be done by shifting the IF frequency of the receiver.

Determine at what point between 900 kc and 960 kc the whistle will be least objectionable. Dividing this frequency by two will give the new IF frequency to which the receiver should be aligned. For example, if it is determined that a whistle at 915 kc would not be objectionable, the IF should be realigned at 915/2 or 457.5 kc.

Align the IF at the new frequency and then realign the rest of the receiver as described under, "ALIGNMENT PROCEDURE".

IMPORTANT ALIGNMENT NOTES

Where indicated by the word, "Rock", the variable should be rocked back and forth a degree or two while making the adjustment.

Alignment must be made in the sequence indicated.

All of the adjustment should be repeated in their original order for greater accuracy. In particular, the band "W" adjustments should be gone over two or three times since one adjustment affects the others.

Always keep the output from the signal generator at its lowest possible value in order to make the AVC action of the receiver ineffective.

After the alignment procedure has been completed, tune in a signal at about 900 kc and, if necessary, shift the dial pointer to the station's indicated frequency on the dial.

MODELS 7166,7166X
Schematic,Socket

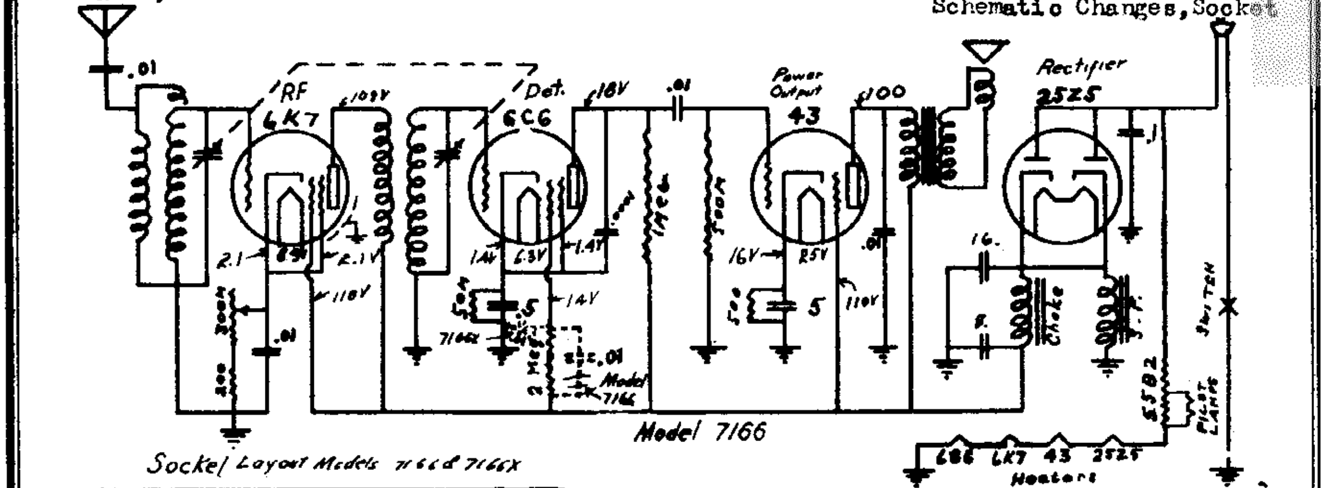
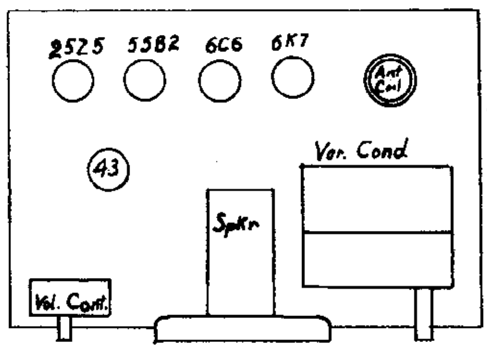
MODEL 7127,Early
MODELS 7127,Late,7133,7139
Schematic Changes,Socket



Model 7166

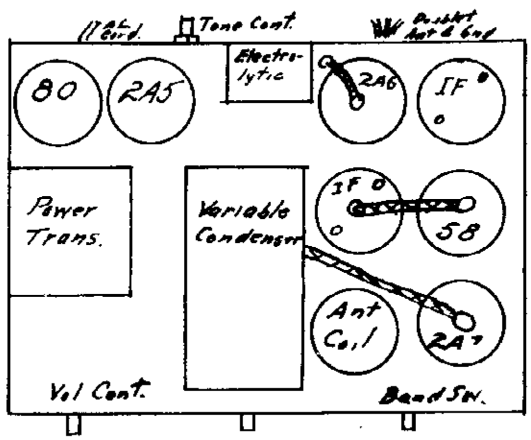
Socket Layout Models 7166 & 7166X



Model 7166X Changes from above schematic for 7166.

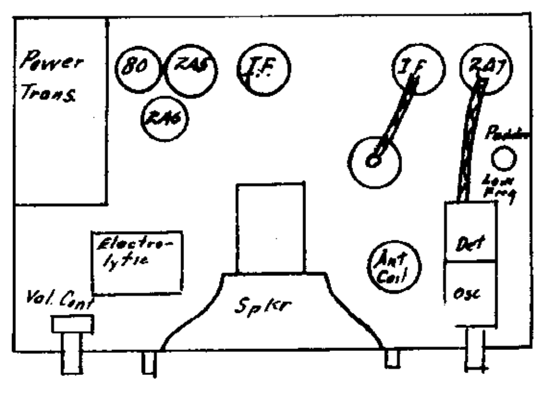
1. 6D6 Tube is used instead of 6K7
2. The .01 Mfd. Condenser in the screen circuit of the 6C6 is shown dotted and marked
3. The filter condensers are 14 & 8
4. A .1 Mfd. is not connected from plates of rectifier to ground.

Rebalancing - to align receiver, proceed as follows:
1 - Remove chassis from its cabinet, open condenser all the way and adjust the trimmers on variable condenser, applying a 1712 KC note at the antenna.



Model 7139

FOR SCHEMATIC SEE INDEX



Model 7127-7133

EARLY MODEL 7127 is similar to Echophone 143 except for the following changes:

1. 25M resistor previously connected from cathode of 2A7 to screen now goes from cathode to negative end of 100 ohm resistor in screen circuit.
2. Tone control of 50M variable resistor in series with .05 condenser connected from plate of 2A5 to ground.
3. .01 mfd. condenser added on switch side of line to ground.
4. 420 mmfd. tuning condensers are now 16-385 mmfd.

7133, 7139, & Late 7127 are similar to Echophone 143 except for the following changes:

1. A Doublet antenna is used: 2- A .0018 mf cond. changed to .0027.
3. 16-385 mmf tuning cond. changed to 16-420 MMF.
4. 3-40 MMF S.W. ant. cond. changed to 3-30 MMF.

Parts for this model may be ordered from Echophone Radio Corp., 2611 Indiana Avenue, Chicago, Ill.

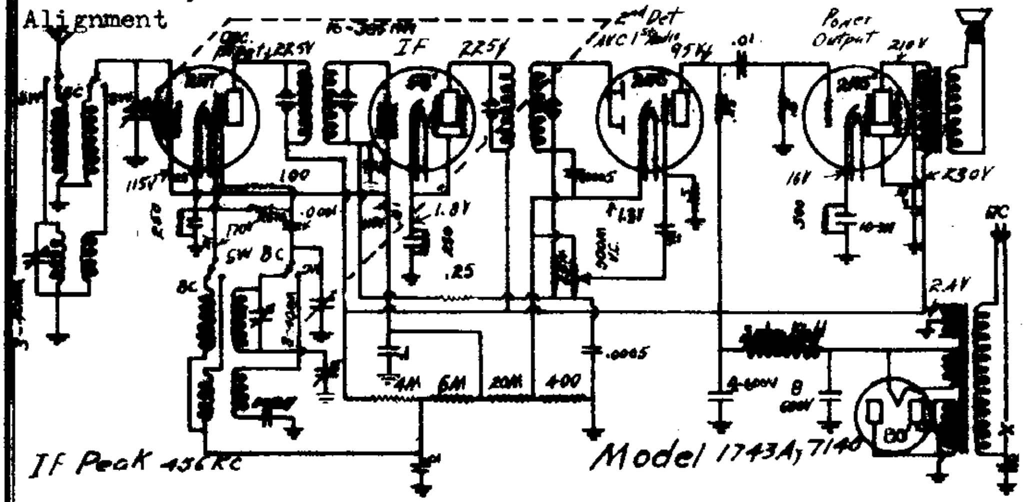
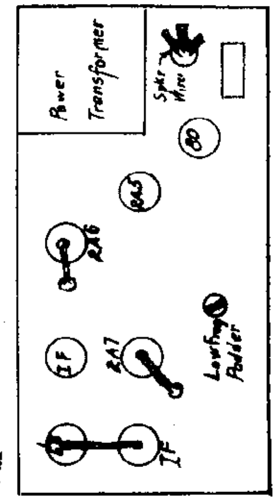
MODELS 1743A,7140
Schematics,Socket
Alignment

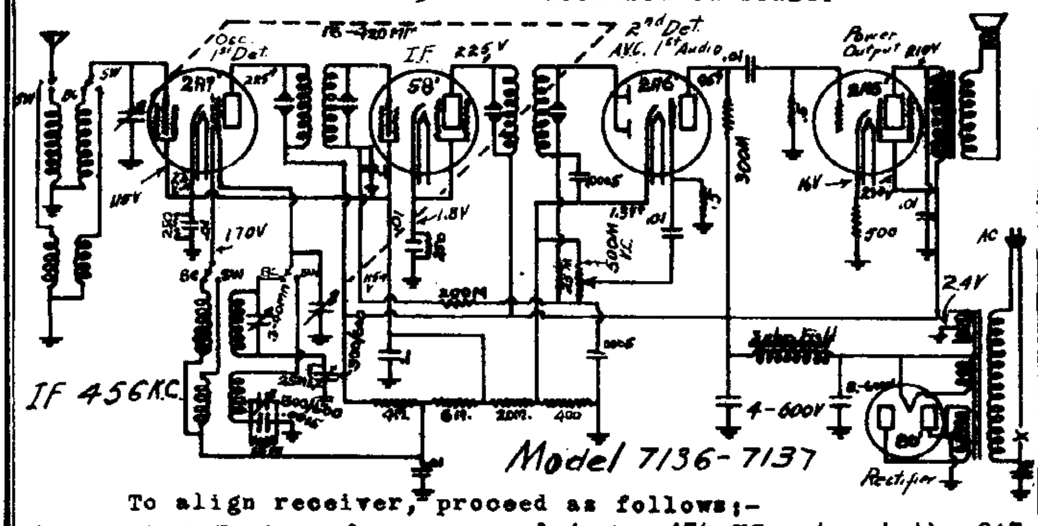
SEARS-ROEBUCK & CO.

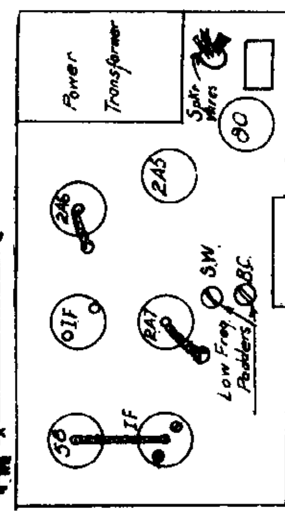




To align receiver, proceed as follows:

1 - Peak I.F. transformers, applying a 456 KC note at the 2A7 control grid.
2 - Turn variable condenser way open and apply a 1712 KC oscillator note at the antenna; set oscillator trimmer on oscillator coil first, then RF section on variable condenser.
3 - Adjust low frequency padder at 600 KC, rocking condenser back and forth across 600KC signal, and adjusting padder to maximum output.
4 - Go back and check at 1400 KC for alignment.
5 - Short Wave - adjust the small trimmer found underneath chassis on short wave antenna coil to maximum output. If short wave does not track with dial calibration, adjust trimmer on oscillator section of variable condenser until correct. Make all adjustments for short wave with variable tuned to center of 25 meter location on scale.





To align receiver, proceed as follows:-

1 - Peak I.F. transformers, applying a 456 KC note at the 2A7 control grid.
2 - Turn variable condenser all the way open, (minimum capacity) and apply a 1712 KC note at the antenna, set oscillator trimmer to peak output then the R F section of variable condenser, these two being found on the tuning condenser.
3 - Adjust low frequency padder marked B.C. at 600 KC, rocking condenser back and forth across 600 KC signal while adjusting padder to get maximum output.
4 - Short Wave - Short wave will not have to be adjusted except low frequency padder, this should be checked on noise level or some signal near 175 meters.

Parts may be secured from Echophone Radio Corp. 2611 Indiana Ave Chicago Ill.

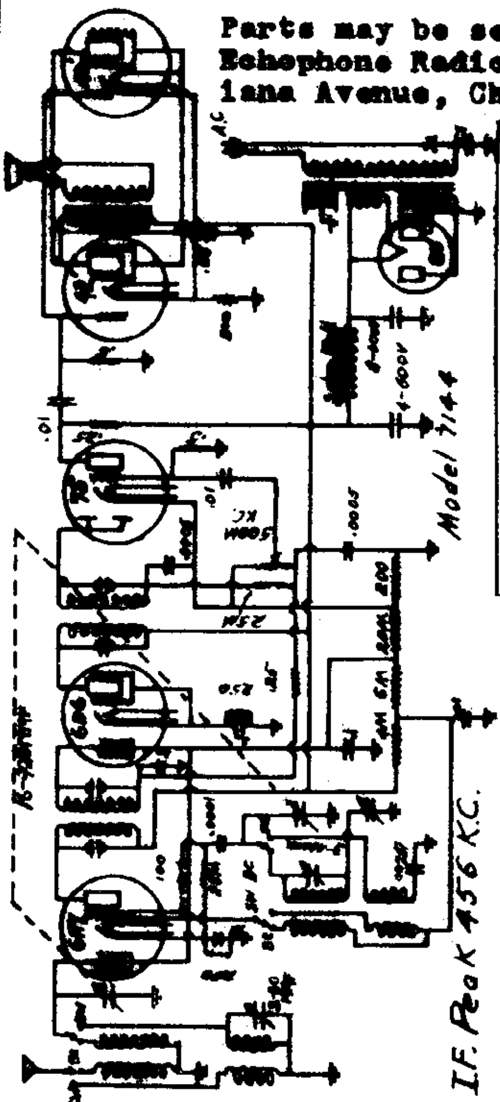
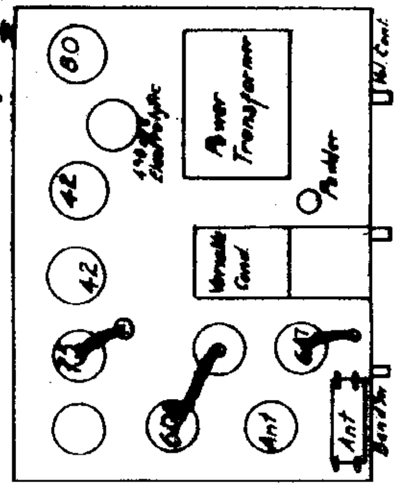
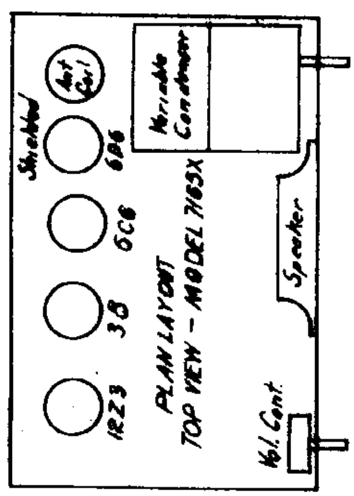
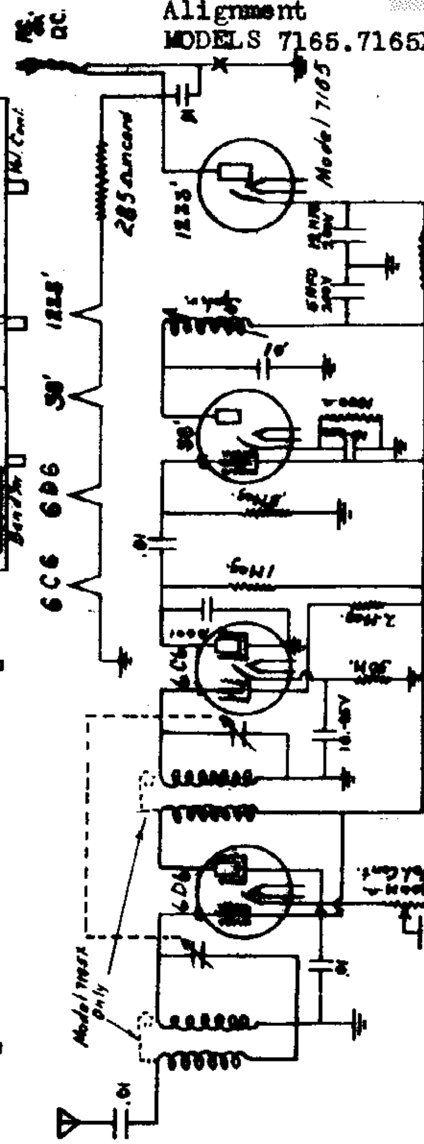
MODEL 7144
Schematic, Socket
Alignment
MODELS 7165.7165X

Parts may be secured direct from Echophone Radio Corp., 2611 Indiana Avenue, Chicago, Illinois.









To Align receiver, proceed as follows;-

Model 7144

1 - Peak I.F. transformers, applying a 456 KC note from an oscillator to the 6A7 Control grid.

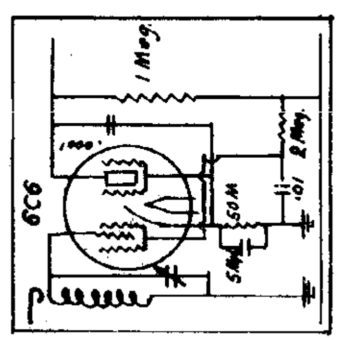
2 - Turn variable condenser all the way open and apply a 1720 Kc oscillator note at the antenna; set oscillator trimmers on oscillator coil to reach center of note, then adjust R.F. section of variable condenser to maximum output.

3 - Adjust low frequency padder at 600 KC, adjust padder while rocking condenser back and forth across 600 KC signal until maximum signal is obtained.

4 - Go back and check B.C. Band at 1400 KC, do not bend plates of Gang condenser.

5 - Short Wave. - Adjust the small trimmer (3 to 30 mmf) found beside S.W. Antenna Coil to maximum output. If short wave does not track with dial calibration, adjust trimmer on oscillator section of variable condenser until correct. Make all adjustments for short wave with variable tuned to center of 25 meter location on scale.

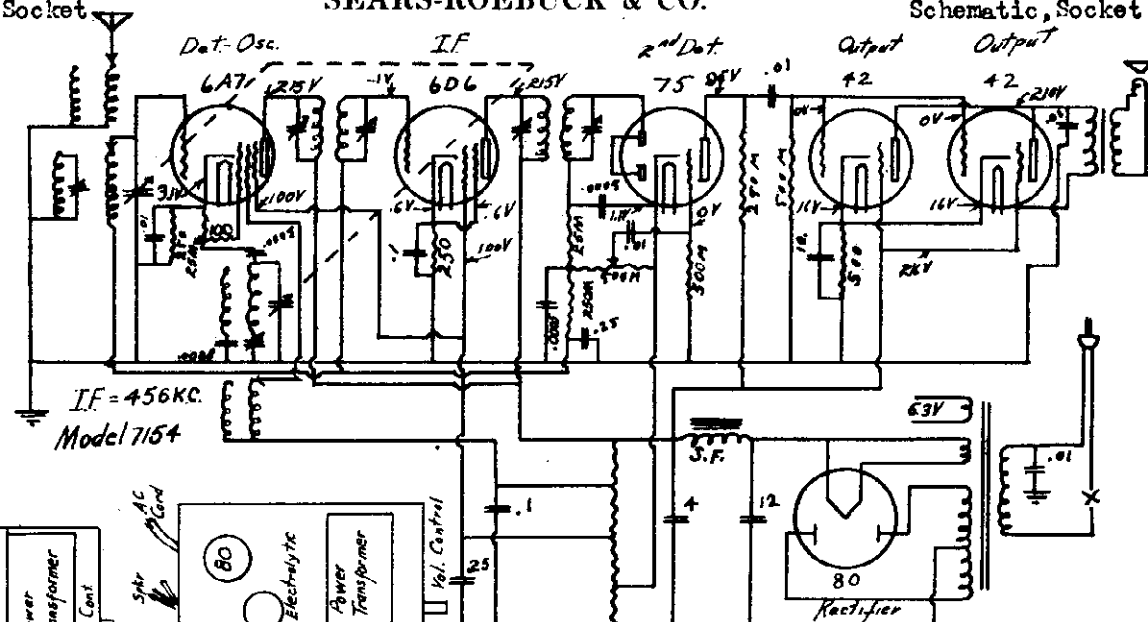
Model 7165X differs from 7165 by the change shown to the left, the addition of Capacity turns to the ant. & R.F. coils, and the substitution of a 5 Mfd condenser in the grid bias of the 38

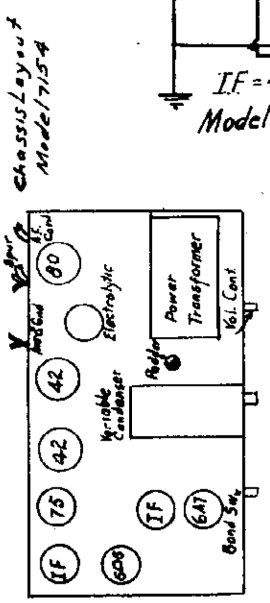


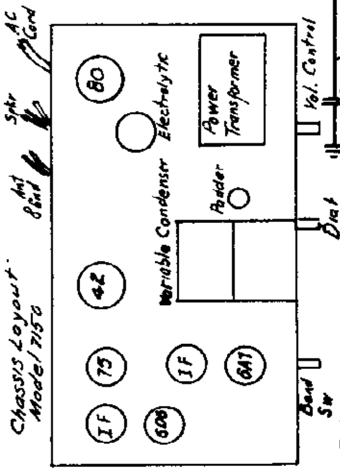
MODEL 7150
Schematic, Socket
Alignment

SEARS-ROEBUCK & CO.

MODEL 7154
Schematic, Socket







To Align receiver, proceed as follows: *Model 7150*

1 - Peak I.F. transformers, applying a 456 KC note from an oscillator to the 6A7 control grid.

2 - Turn variable condenser all the way open and apply a 1720 KC oscillator note at the antenna; set oscillator trimmers on oscillator coil to reach center of note, then adjust R.F. section of variable condenser to maximum output.

3 - Adjust low frequency padder at 600 KC, adjust padder while rocking condenser back and forth across 600 KC signal until maximum signal is obtained.

4 - Go back and check B.C. Band at 1400 KC, do not bend plates of Gang condenser.

5 - Short wave. - Adjust the small trimmer (3 to 30 MMF) found beside S.W. Antenna coil to maximum output. If short wave does not track with dial calibration, adjust trimmer on oscillator section of variable condenser until correct. Make all adjustments for short wave with variable tuned to center of 25 meter location on scale.

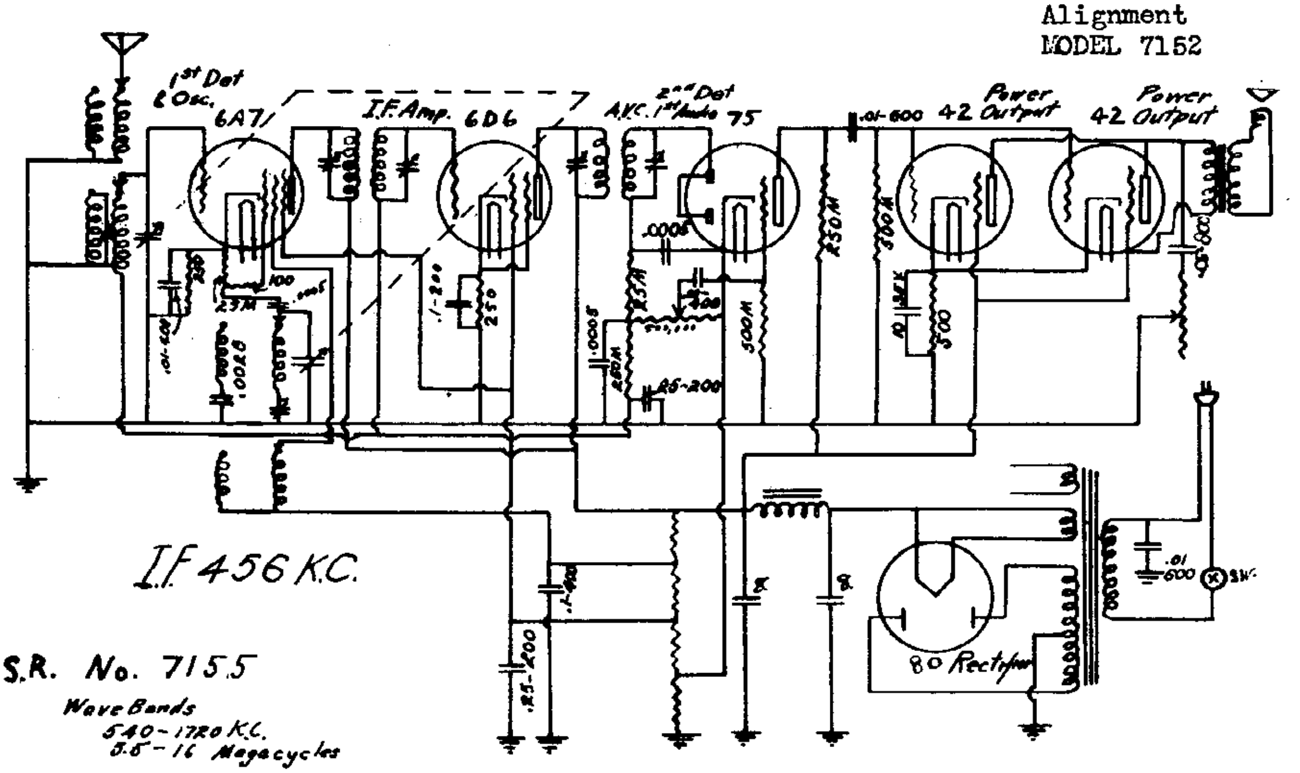
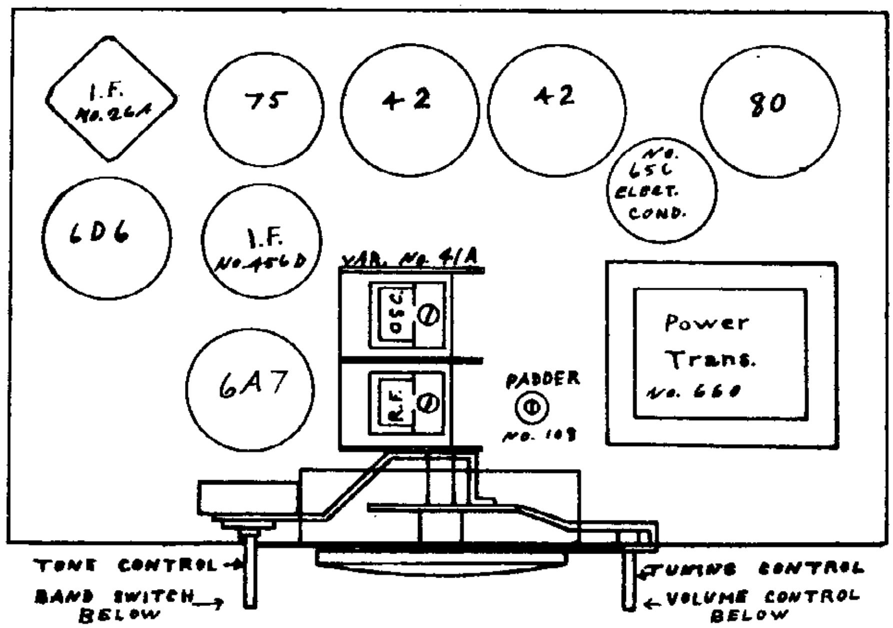
Alignment
MODEL 7152



Parts for this model may be ordered from
Echophone Corp., 2611 Indiana Ave., Chicago, Ill.

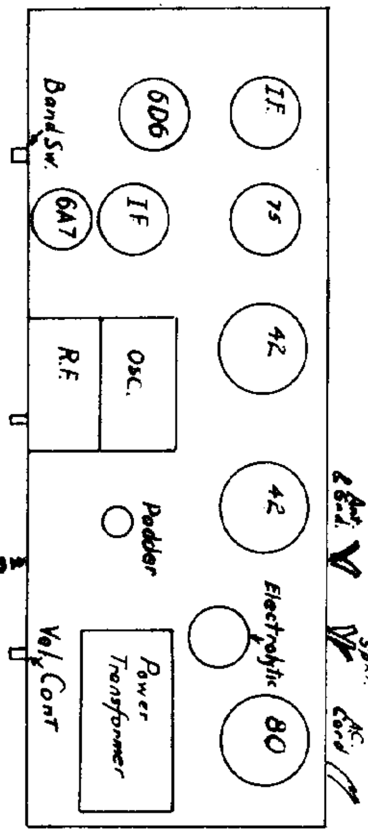


Alignment
1. Apply 456 kc. signal to control grid of 6A7 and peak i-f trimmers for maximum signal.
2. Apply 1400 kc. signal to antenna input and ground and align trimmers for maximum gain.
3. Apply 600 kc. signal to input and adjust padder for maximum output, rocking the tuning condenser during the operation.
4. Check alignment at 1400 kc.
5. Check alignment on short waves at 12. megacycles.

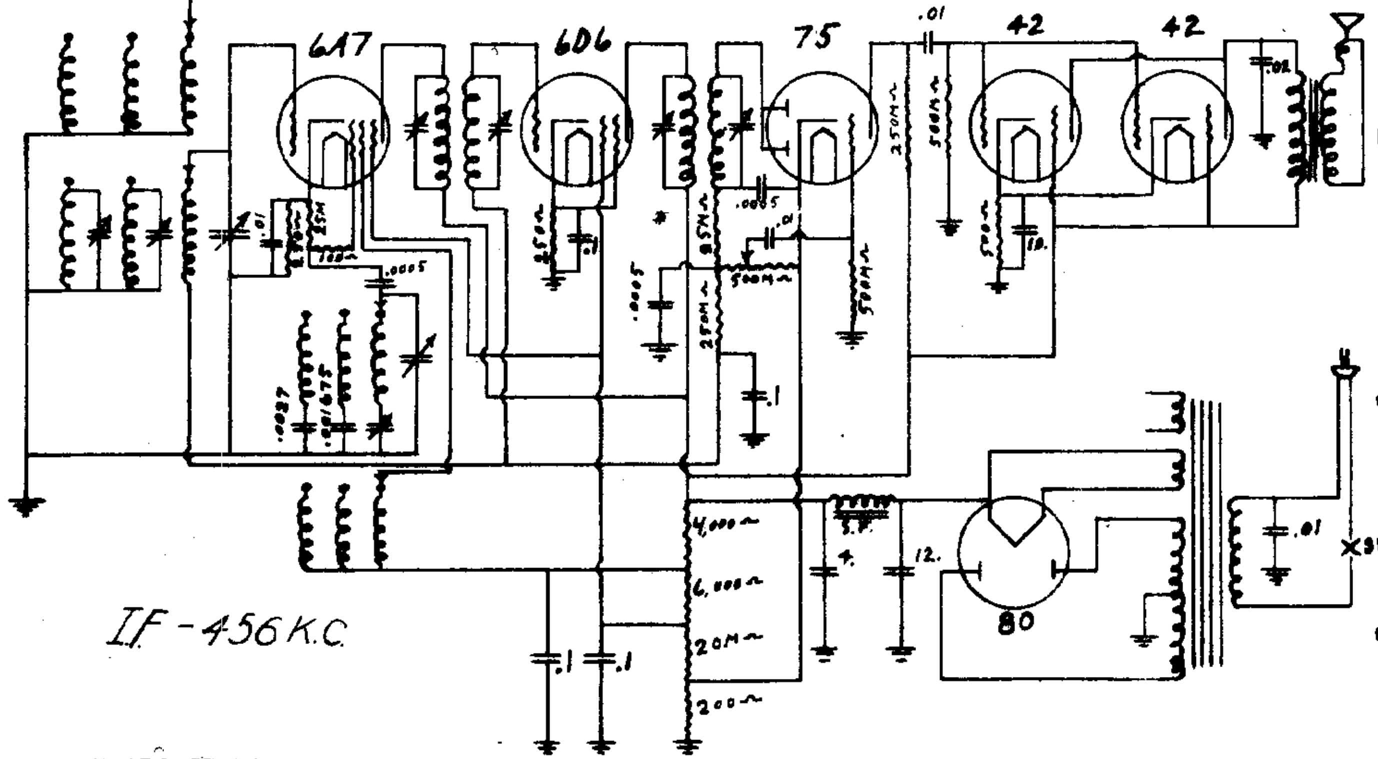
Models 1900-1910 are similar to Echophone Model 139, 139C page 6-1
Error on drawing - Connect tone control on plate only.
Change - Tone control knob was shown on left front side of chassis instead of on rear of chassis.
Model 7152 is similar to Echophone Model 128 page 5-1.
Change - 5 MFD condenser across speaker field taken out.

MODEL 7158
Schematic, Trimmers
Socket, Alignment

SEARS-ROEBUCK & CO.



Parts may be secured direct from Echophone Radio Corp., 2611 Indiana Avenue, Chicago, Illinois.



BROADCAST BAND

1 - Peak I.F. transformers, applying a 456 KC note from a service oscillator to the grid of the 6A7 tube.

2 - Rotate condenser all the way open, apply a 1720 KC note to the antenna wire, then adjust oscillator trimmer on variable condenser to the signal and then peak the R.F. section of the variable.

3 - Apply a 600 KC note to antenna wire. Adjust padder for maximum gain while rocking the variable condenser back and forth across the 600 KC signal.

4 - Go back and check around 1400 KC for alignment. Do not bend plates.

SECOND BAND - S.W.

5 - Adjust trimmer, found on top of chassis next to ant coil, for maximum noise level at 4 megacycles.

THIRD BAND - S.W.

6 - Adjust trimmer, found underneath the chassis next to the antenna coil, for maximum noise level at 12 megacycles.

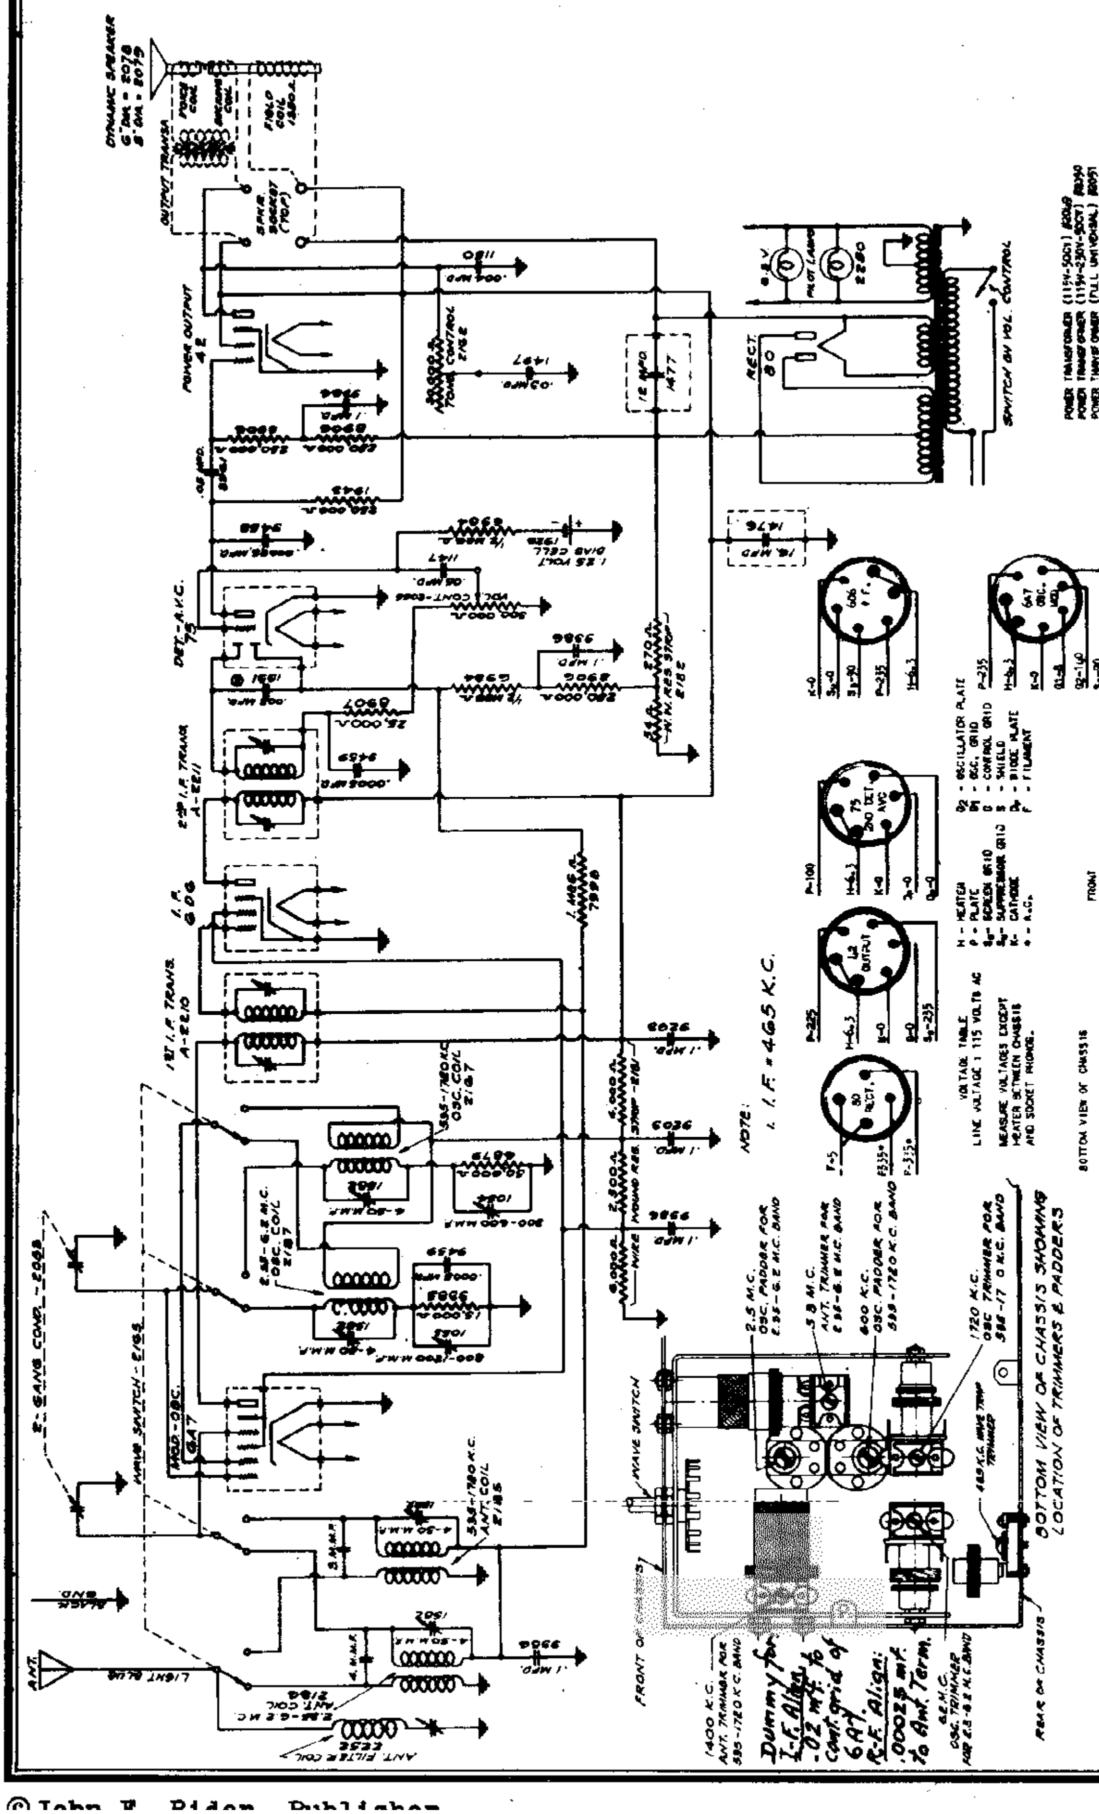
ALIGNMENT PROCEDURE

Apply a 456 kc note to grid of 6A7 tube and adjust IF transformers for maximum response noted on output meter.
Apply a 1400 kc note to antenna wire and adjust trimmers on variable condenser for greatest gain.
Apply a 600 kc note to antenna wire and adjust padder condenser, at end of chassis, for maximum gain, swinging the variable condenser back and forth across signal while adjusting.
Go back to 1400 kc and check for alignment.

Parts for this model may be ordered from Echophone Radio Corporation, 2611 Indiana Ave., Chicago, Ill.

SENTINEL RADIO CORP.

MODEL 20A
Schematic, Voltage
Trimmers, Alignment



Some code and aircraft signals are broadcast on a frequency the same or near the intermediate frequency of the receiver. To eliminate interference from these signals a 465 kilocycle antenna filter is incorporated in the set. To adjust, tune receiver dial to approximately 1000 kilocycles and set test oscillator frequency to **EXACTLY 465 KILOCYCLES**. Then adjust the 465 kilocycle wavetrap trimmer condenser for **MINIMUM 465 KILOCYCLE SIGNAL RESPONSE.**

MODEL 47A
Voltage
Alignment

SENTINEL RADIO CORP.

ALIGNING I. F. STAGE AT 465 KILOCYCLES:

(a) Attach the ground lead of the test oscillator to the chassis. Connect the other lead to the grid cap of the 6L7 tube through a .02 Mfd. series condenser. DO NOT REMOVE GRID CLIP.
(b) Set test oscillator to EXACTLY 465 kilocycles and turn receiver volume control on full.
(c) Peak each of the second I. F. transformer trimmers.
(d) Peak each of the first I. F. transformer trimmers.

To assure most accurate trimmer setting repeat above adjustment several times always using lowest possible test oscillator output consistent with readable output meter scale deflection.

ALIGNING 1800-540 KILOCYCLE BAND:

(a) Adjust band selector switch for operation on the 1800-540 kilocycle band, remove test oscillator lead from grid of 6L7 tube and connect to receiver antenna terminal through a .00025 Mfd. series condenser.
(b) Set test oscillator frequency and receiver dial to EXACTLY 1800 kilocycles, and bring in 1800 kilocycle test oscillator signal to maximum output by adjusting 1800 kilocycle oscillator trimmer.
(c) Tune receiver dial and set test oscillator frequency to EXACTLY 1500 kilocycles. Adjust 1500 K. C. R. F. and ant. trimmers for maximum sensivity.
(d) Set test oscillator frequency and receiver dial to approximately 600 kilocycles. Then while rocking gang condenser slightly to right and left, adjust 600 K. C. oscillator padder for maximum signal response.

ALIGNING 1.8-6.3 MEGACYCLE BAND:

(a) Replace .00025 Mfd. antenna series condenser with 400 ohm resistor, adjust band selector switch to 1.8-6.3 megacycles band, tune receiver dial and set test oscillator frequency to EXACTLY 6.3 megacycles. Bring in 6.3 megacycle test oscillator signal to maximum output by adjusting 6.3 M.C. oscillator trimmer.
(b) Tune receiver dial and set test oscillator frequency to EXACTLY 6 megacycles. Then adjust 6 M.C. ant. and R.F. trimmers for maximum sensitivity.

ALIGNING 6.1-21 MEGACYCLE BAND:

(a) Place band selector switch for operation on 6.1-21 megacycle band, tune receiver dial and set test oscillator frequency to EXACTLY 21 megacycles.
(b) Adjust 21 M. C. oscillator trimmer to bring in 21 megacycle test signal to maximum output.

NOTE: When adjusting this trimmer two peaks, the fundamental and the image peak will be noticed. CARE MUST BE TAKEN THAT THE FUNDAMENTAL PEAK AND NOT THE IMAGE PEAK IS USED FOR ALIGNING THE RECEIVER AT 21 MEGACYCLES. Always back off the trimmer to minimum capacity, then screw down the trimmer (add capacity) until the first peak which is the fundamental and the proper one to use is tuned in. If the trimmer is screwed down beyond the point where the first peak is received, the incorrect image peak will be tuned in. After completing adjustment of the oscillator trimmer at 21 megacycles always check to see if the proper peak has been used. To do this leave test oscillator frequency at 21 megacycles, increase the output of the test oscillator and tune receiver dial to approximately 20 megacycles. Then vary the receiver dial slightly to the right and left of 20 megacycles, and if the fundamental peak was used in aligning at 21 megacycles the test oscillator signal will be heard at approximately 20 megacycles on the receiver dial.

(c) Tune receiver dial and set test oscillator frequency to EXACTLY 18 megacycles.
(d) Adjust 18 M. C. antenna and R. F. trimmers for maximum 18 megacycle test signal response.

ALIGNING 390-140 KILOCYCLE BAND:

(a) Adjust band selector switch for operation on 390 to 140 kilocycle band, tune receiver dial and set test oscillator frequency to EXACTLY 390 kilocycles.
(b) Bring in 390 Kilocycle test signal to maximum output by adjusting 390 K. C. oscillator trimmer.
(c) Tune receiver dial and set test oscillator frequency to EXACTLY 350 kilocycles. Adjust 350 K. C. ant. and R. F. trimmers for maximum sensitivity.
(d) Tune receiver dial and set test oscillator frequency to approximately 150 kilocycles, then while rocking gang condenser slightly to right and left adjust 150 kilocycle oscillator padder for maximum sensitivity.

Alignment

SENTINEL RADIO CORP.

NOTE: NEVER LIFT THE RECEIVER BY GRASPING THE CATACOMB SHIELD, TO DO SO MAY MOVE THE SHIELD THEREBY DETUNING THE RECEIVER.

ALIGNMENT PROCEDURE:

It is important when aligning to carefully follow the procedure in the order given, otherwise the receiver will lack sensitivity and the dial calibration will be incorrect. IT IS IMPERATIVE THAT AN ACCURATELY CALIBRATED OSCILLATOR BE USED WITH SOME TYPE OF OUTPUT MEASURING DEVICE.

INTERMEDIATE ALIGNMENT:

1. Connect the high side of the oscillator output to the control grid of the 6A7 tube, leaving the grid cap disconnected. Connect the ground side of the oscillator to the receiver chassis.

2. Set the test oscillator frequency to 465 kilocycles. (This must be accurate).

3. Align the first intermediate transformer by turning one of the trimmer screws up and down (increasing and decreasing capacity) until maximum reading is obtained on the output meter, after which adjust the other trimmer screw of the same transformer for maximum sensitivity.

4. Adjust the other intermediate transformer in the same manner.

NOTE: Two type intermediate transformer trimmers have been used in this receiver. One type has two parallel holes in the top of the shield, one for each trimmer. The other type has a brass hex nut for adjusting one trimmer, the other intermediate trimmer being adjusted with the trimmer screw located inside of the brass hex nut. Regardless of which type trimmer is used, the procedure is the same.

TO ALIGN THE VARIABLE CONDENSER:

Adjustment of the trimmer condensers, located inside of and accessible through the holes found in the top of the catacomb shield (mounted on top and in the left hand front corner of the receiver) will be referred to by numbers as indicated on the circuit diagram showing the relative location of these trimmers.

1. Connect the high output side of the test oscillator to the receiver antenna post through a 250 MMFD (.00025 MFD) condenser and the ground to the set ground post.

2. Place the band selector switch for operation on the 1520 to 530 kilocycle (broadcast) band. Tune the receiver to exactly 1400 kilocycles on the dial and set the test oscillator frequency to exactly 1400 kilocycles. THEN BRING IN THE 1400 KILOCYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING THE TRIMMER MARKED NO. 2 ON CATACOMB DIAGRAM, after which adjust No. 1 and No. 3 trimmers in the order named for maximum sensitivity.

3. Leave the band selector switch for operation on the broadcast band (1520 to 530 kilocycles) and tune the receiver and set the oscillator to approximately 600 kilocycles. Then adjust the 600 kilocycle padding condenser No. 9 which is located on and accessible through the hole in the left hand side of the chassis for maximum sensitivity. As this adjustment is quite critical, it is necessary to rock the variable condenser slightly to the right and to the left to find the point of greatest sensitivity.

4. Recheck the alignment at 1400 kilocycles as the 600 kilocycle adjustment may have changed the alignment at 1400 kilocycles.

5. Place the band selector switch for operation on the 1.5 to 4.2 megacycle band and set the test oscillator frequency and tune the receiver dial to exactly 3.8 megacycles. THEN TUNE IN THIS 3.8 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING CATACOMB TRIMMER NO. 4, next adjust trimmer No. 5 for maximum sensitivity.

6. With the band selector switch in the same position (1.5 to 4.2 megacycle band) tune the receiver dial and set the oscillator frequency to approximately 1.7 megacycles and then while rocking the variable condenser slightly to the right and left, adjust the 1.7 megacycle trimmer No. 10 (located on the left hand side of the chassis) for maximum sensitivity.

7. Recheck 3.8 megacycle adjustments.

8. Adjust the band selector switch for operation on the 5.2 to 16 megacycle band and tune the receiver dial and set the oscillator frequency to exactly 15 megacycles. When adjusting catacomb trimmer No. 6 two peaks (the fundamental and the image peak) will be noticed. CARE MUST BE TAKEN SO THAT THE FUNDAMENTAL PEAK AND NOT THE IMAGE PEAK IS USED FOR ALIGNING THE RECEIVER AT 15 MEGACYCLES. First back off catacomb trimmer No. 6 to minimum capacity, next screw down the trimmer (add capacity) until the first peak which is the fundamental and the one you are to use is tuned in. If the trimmer is screwed down beyond the point where this first peak is received the incorrect image peak will be tuned in. When the first peak has been located adjust catacomb trimmer No. 6 to BRING IN THE 15 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT. After completing this adjustment always check to see if the proper peak has been used. To do this leave the test oscillator frequency at 15 megacycles and increase the output of the test oscillator, then tune the receiver dial to approximately 14 megacycles. Vary the receiver dial slightly to the right and left of 14 megacycles and if the fundamental peak was used in aligning at 15 megacycles the test oscillator signal will be heard at approximately 14 megacycles on the set dial. If it is not possible to receive the signal then the fundamental peak was not used and the 15 megacycle adjustment of trimmer No. 6 must be gone over and properly adjusted. After correctly completing catacomb trimmer No. 6 adjustment adjust catacomb trimmer No. 7 to maximum sensitivity. Should two peaks be noticed with this trimmer always adjust trimmer No. 7 to the one that requires the most capacity to tune in.

9. Leave the band selector switch for operation on 5.4 to 16 megacycle band, set the oscillator frequency and tune the receiver dial to approximately 6 megacycles. While rocking the variable condenser slightly to the right and left, adjust the 6 megacycle trimmer No. 8 (located on the left hand side of the chassis) for maximum sensitivity.

10. Recheck 15 megacycle adjustments.

11. Some code and aircraft signals are broadcast on a frequency exactly the same or near the IF frequency of the receiver. To eliminate interference from these signals a 465 kilocycle filter (mounted in the coil shield located underneath and towards the front of the chassis) is incorporated in the set. To adjust, set the oscillator frequency (with oscillator output connected to set antenna and ground) TO EXACTLY 465 KILOCYCLES turn the receiver on end and adjust the trimmer located on and accessible through the top of the filter shield for MINIMUM 465 KILOCYCLE SIGNAL.

MODEL 7100B

Read all voltages from socket to chassis with 1000 ohm per vo
* Triode plate. Comparative voltage only.

INTERMEDIATE ALIGNMENT:

1. Connect the high side of the oscillator output to the control grid of the 2A7 tube. Leave the grid ca disconnected and connect a 1 meg ohm resistor from the modulator grid to the chassis base. Connect the ground side of the oscillator to the receiver ground post.

2. Set the test oscillator frequency to 465 kilocycles. (This must be accurate).

3. Align the first intermediate transformer by turning one of the trimmer screws up and down (increasing and decreasing capacity) until maximum reading is obtained on the output meter, after which adjust the other trimmer screw of the same transformer for maximum sensitivity.

4. Adjust the other intermediate transformers in the same manner.

TO ALIGN THE VARIABLE CONDENSER:

1. Connect the high output side of the test oscillator through a .00025 Mfd. condenser to the set antenn lead and the ground to the set ground.

2. Place the band selector switch for operation on the 16 to 5.2 megacycle band, tune the receiver to ex actly 14 megacycles on the receiver dial, and set the test oscillator frequency to exactly 14 megacycles. THEN TUNE IN THE 14000 KILOCYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING THE TRIMMER CONDENSER LOCATED ON TOP OF THE OSCILLATOR SECTION OF THE GANG CONDENSER. Looking at the front of the receiver the first section of the gang condenser tunes the antenna coil and the second section the oscillator coil. When adjusting this trimmer two peaks (the fundamental and the image peak) will be noticed. CARE MUST BE TAKEN SO THAT THE FUNDAMENTAL PEAK AND NOT THE IMAGE PEAK IS USED FOR ALIGNING THE RECEIVER AT 14 MEGACYCLES. First back off the trimmer to minimum capacity, next screw down the trimmer (add capacity) until the first peak which is t fundamental and the one you are to use is tuned in. If the trimmer is screwed down beyond the point where this first peak is received the incorrect image peak will be tuned in. When the first peak has been locate adjust the trimmer to BRING IN THE 14 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT. After completing this adjustment always check to see if the proper peak has been used. To do this leave the test oscillator frequency fre- quency at 14 megacycles and increase the output of the test oscillator and then tune the receiver dial to a proximately 13 megacycles. Vary the receiver dial slightly to the right and left of 13 megacycles and if the fundamental peak was used in aligning at 14 megacycles the test oscillator signal will be heard at ap- proximately 13 megacycles on the set dial. If it is not possible to receive the signal then the fundamenta

tmeter.

eak was not used and the 14 megacycle adjustment of the trimmer must be gone over and properly adjusted. FTER CORRECTLY COMPLETING THE 14 MEGACYCLE ALIGNMENT TURN THE RECEIVER ON END AND WHILE ROCKING THE GANG ONDENSER SLIGHTLY TO THE RIGHT AND LEFT ADJUST THE TRIMMER CONDENSER MOUNTED ON THE SW (5.2-16 M.C. band) NTENNA COIL LOCATED UNDERNEATH THE CHASSIS FOR MAXIMUM SENSITIVITY.

3. Adjust the band selector switch for operation on the 1715 to 535 kilocycle band and set the receiver al and the test oscillator frequency to EXACTLY 1400 KILOCYCLES. Then turn the receiver chassis on end d bring in the 1400 kilocycle signal to maximum output by adjusting the trimmer condenser mounted on the C. (1715-535 K.C. band) oscillator coil. Next adjust the trimmer condenser mounted on top of the first ction of the gang condenser for maximum 1400 kilocycle signal sensitivity.

4. Leave the band selector switch for operation on the 1715 to 535 kilocycle band and tune the receiver d set the test oscillator frequency to approximately 600 kilocycles. Then while rocking the condenser ightly to the right and left adjust the 600 kilocycle B. C. padding condenser, which is located on and ac- ssible through the hole in the front of the chassis, for maximum sensitivity.

5. Recheck the 1400 kilocycle adjustment.

6. Recheck the 14 megacycle adjustment.

7. Place the band selector switch for operation on the 340 to 130 kilocycle band, and set the test os- llator frequency and the receiver dial to EXACTLY 320 KILOCYCLES. THEN BRING IN THIS 320 KILOCYCLE SIGNAL MAXIMUM OUTPUT BY ADJUSTING THE TRIMMER CONDENSER LOCATED ON THE L. W. (340-130 K.C. band) oscillator il located underneath the receiver chassis, after which adjust the trimmer condenser mounted on the L. W. 40-130 K.C. band) antenna coil also located underneath the chassis.

8. Leave the band selector switch for operation on the 340 to 130 kilocycle band and tune the receiver l and set the test oscillator frequency to approximately 150 kilocycles. Then while rocking the variable ndenser slightly to the right and left adjust the L. W. oscillator coil padding condenser, located on and cessible through the hole in the right hand side of the chassis, for maximum sensitivity.

SENTINEL RADIO CORP.

MODEL 710CB
Alignment

NOTE: NEVER LIFT THE RECEIVER BY GRASPING THE CATACOMB SHIELD, TO DO SO MAY MOVE THE SHIELD THEREBY DETUNING THE RECEIVER.

ALIGNMENT PROCEDURE:

It is important when aligning to carefully follow the procedure in the order given, otherwise the receiver will lack sensitivity and the dial calibration will be incorrect. IT IS IMPERATIVE THAT AN ACCURATELY CALIBRATED OSCILLATOR BE USED WITH SOME TYPE OF OUTPUT MEASURING DEVICE.

INTERMEDIATE ALIGNMENT:

1. Connect the high side of the oscillator output to the control grid of the 6A7 tube, leaving the grid cap disconnected. Connect the ground side of the oscillator to the receiver chassis.

2. Set the test oscillator frequency to 465 kilocycles. (This must be accurate).

3. Align the first intermediate transformer by turning one of the trimmer screws up and down (increasing and decreasing capacity) until maximum reading is obtained on the output meter, after which adjust the other trimmer screw of the same transformer for maximum sensitivity.

4. Adjust the other intermediate transformer in the same manner.

NOTE: Two type intermediate transformer trimmers have been used in this receiver. One type has two parallel holes in the top of the shield, one for each trimmer. The other type has a brass hex nut for adjusting one trimmer, the other intermediate trimmer being adjusted with the trimmer screw located inside of the brass hex nut. Regardless of which type trimmer is used, the procedure is the same.

TO ALIGN THE VARIABLE CONDENSER:

Adjustment of the trimmer condensers, located inside of and accessible through the holes found in the top of the catacomb shield (mounted on top and in the left hand front corner of the receiver) will be referred to by numbers as indicated on the circuit diagram showing the relative location of these trimmers.

1. Connect the high output side of the test oscillator to the receiver antenna post through a 250 MMFD. (.00025 Mfd.) condenser and the ground to the set ground post.

2. Place the band selector switch for operation on the 1520 to 530 kilocycle (broadcast) band. Tune the receiver to exactly 1400 kilocycles on the dial and set the test oscillator frequency to exactly 1400 kilocycles. THEN BRING IN THE 1400 KILOCYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING THE TRIMMER MARKED NO. 2 ON CATACOMB DIAGRAM, after which adjust No. 1 and No. 3 trimmers in the order named for maximum sensitivity.

3. Leave the band selector switch for operation on the broadcast band (1520 to 530 kilocycles) and tune the receiver and set the oscillator to approximately 600 kilocycles. Then adjust the 600 kilocycle padding condenser No. 11, which is located on and accessible through the hole in the left hand side of the chassis, for maximum sensitivity. As this adjustment is quite critical it is necessary to rock the variable condenser slightly to the right and to the left to find the point of greatest sensitivity.

4. Recheck the alignment at 1400 kilocycles as the 600 kilocycle adjustment may have changed the alignment at 1400 kilocycles.

5. Place the band selector switch for operation on the 1.5 to 4.2 megacycle band and set the test oscillator frequency and tune the receiver dial to <u>exactly 3.8 megacycles</u>. THEN TUNE IN THIS 3.8 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING CATACOMB TRIMMER NO. 5, next adjust trimmers No. 4 and 6 for maximum sensitivity.

6. With the band selector switch in the same position (1.5 to 4.2 megacycle band) tune the receiver dial and set the oscillator frequency to approximately 1.6 megacycles, and then while rocking the variable condenser slightly to the right and left adjust the 1.6 megacycle trimmer No. 12 (located on the left hand side of the chassis) for maximum sensitivity.

7. Recheck 3.8 megacycle adjustments.

8. Adjust the band selector switch for operation on the 5.2 to 16 megacycle band and tune the receiver dial and set the oscillator frequency to exactly 15 megacycles. When adjusting catacomb trimmer No. 8 two peaks (the fundamental and the image peak) will be noticed. CARE MUST BE TAKEN SO THAT THE FUNDAMENTAL PEAK AND NOT THE IMAGE PEAK IS USED FOR ALIGNING THE RECEIVER AT 15 MEGACYCLES. First back off catacomb trimmer No. 8 to minimum capacity, next screw down the trimmer (add capacity) until the first peak which is the fundamental and the one you are to use is tuned in. If the trimmer is screwed down beyond the point where this first peak is received the incorrect image peak will be tuned in. When the first peak has been located adjust catacomb trimmer No. 8 to BRING IN THE 15 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT. After completing this adjustment always check to see if the proper peak has been used. To do this leave the test oscillator frequency at 15 megacycles and increase the output of the test oscillator, then tune the receiver dial to approximately 14 megacycles. Vary the receiver dial slightly to the right and left of 14 megacycles and if the fundamental peak was used in aligning at 15 megacycles the test oscillator signal will be heard at approximately 14 megacycles on the set dial. If it is not possible to receive the signal then the fundamental peak was not used and the 15 megacycle adjustment of trimmer No. 8 must be gone over and properly adjusted. After correctly completing catacomb trimmer No. 8 adjustment, adjust catacomb trimmers No. 7 and 9 for maximum sensitivity.

9. Leave the band selector switch for operation on 5.2 to 16 megacycle band, set the oscillator frequency and tune the receiver dial to approximately 6 megacycles. While rocking the variable condenser slightly to the right and left, adjust the 6 megacycle trimmer No. 10 (located on the left hand side of the chassis) for maximum sensitivity.

10. Recheck 15 megacycle adjustments.

MODEL 8100B
Alignment, Trimmers

SENTINEL RADIO CORP.

INTERMEDIATE ALIGNMENT:
1. Connect the high side of the oscillator output to the control grid of the 6A7 oscillator & modulator tube. Leave the grid cap disconnected and connect a 1 meg ohm resistor from the modulator grid to the chassis base.

2. Set the test oscillator frequency to 465 kilocycles. (This must be accurate).

3. Align the first intermediate transformer by turning one of the trimmer screws accessible through the holes in the top of the coil shield up and down (increasing and decreasing capacity) until maximum reading is obtained on the output meter, after which adjust the other trimmer screw of the same transformer for maximum sensitivity.

4. Adjust the other intermediate transformer in the same manner.

TO ALIGN THE VARIABLE CONDENSER: It is important when aligning the gang condensers, padder condensers, and trimmer condensers to follow the procedure carefully, otherwise the receiver will be insensitive and the dial calibration will be incorrect. The trimmer and padder condensers will be referred to by number as indicated on the diagram which shows their relative locations on the chassis.

1. Connect the high output side of the test oscillator through a .00025 Mfd. condenser to the set antenna post, and the ground to the set ground.

2. Place the band selector switch for operation on the 10 to 24 megacycle band, tune the receiver dial to EXACTLY 22 MEGACYCLES AND SET THE TEST OSCILLATOR FREQUENCY TO EXACTLY 22 MEGACYCLES. THEN TUNE IN THE 22 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING TRIMMER NO. 14. Next rock the gang condenser slightly to the right and left and adjust trimmers No. 13 and 15 for maximum 22 megacycle signal sensitivity. CARE MUST BE TAKEN SO THAT THE FUNDAMENTAL AND NOT THE IMAGE PEAK IS USED FOR ALIGNING THE RECEIVER AT 22 MEGACYCLES. When adjusting trimmer No. 14 always back off the trimmer to minimum capacity and then screw down the trimmer (add capacity) until the first peak, which is the fundamental and the one you are to use is tuned in. If the trimmer is screwed down beyond the point where the first peak is received, the incorrect image peak will be tuned in. After completing adjustment of trimmers No. 14, 13, and 15 always check to see if the proper peak has been used. To do this leave the test oscillator frequency at 22 megacycles, increase the output of the test oscillator, and tune the receiver dial to approximately 21 megacycles. Vary the receiver dial slightly to the right and left of 21 megacycles, and if the fundamental peak was used in aligning at 22 megacycles the test oscillator signal will be heard at approximately 21 megacycles on the receiver dial. If it is not possible to receive the signal at approximately 21 megacycles, then the fundamental peak was not used and the 22 megacycle adjustment of trimmers No. 13, 14, and 15 must be gone over and properly adjusted.

3. Place the band selector switch for operation on the 4 to 11 megacycle band and set the receiver dial and the test oscillator frequency to EXACTLY 9.5 MEGACYCLES. When adjusting trimmer No. 10 the fundamental and the image peak will be noticed. CARE MUST BE TAKEN SO THAT THE FUNDAMENTAL AND NOT THE IMAGE PEAK IS USED FOR ALIGNING THE RECEIVER AT 9.5 MEGACYCLES. First back off trimmer No. 10 to minimum capacity then screw down the trimmer (add capacity) until the first peak, which is the fundamental and the proper one to use is tuned in. When the first peak has been located adjust trimmer No. 10 TO BRING IN THE 9.5 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT. Next adjust trimmers No. 9 and 11 for maximum 9.5 megacycle sensitivity. After completing adjustment of trimmers No. 10, 11, and 9 always check to see if the proper peak has been used. To do this leave the test oscillator frequency at 9.5 megacycles and increase the test oscillator output. Vary the receiver dial slightly to the right and left of 8.5 megacycles and if the fundamental peak of trimmer No. 10 was used in aligning at 9.5 megacycles the test oscillator signal will be heard at approximately 8 megacycles on the receiver dial. If it is not possible to receive the signal, then the fundamental peak was not used and the 9.5 megacycle adjustment of trimmers No. 9, 10, and 11 must be gone over and properly adjusted.

4. Leave the band selector switch for operation on the 4 to 11 megacycle band and tune the receiver and set the test oscillator frequency to approximately 4.6 megacycles. Then while rocking the gang condenser slightly to the right and left adjust padder condenser No. 12 for maximum sensitivity.

5. Place the band selector switch for operation on the 1.5 to 4.2 megacycle band and tune the receiver dial and set the test oscillator frequency to EXACTLY 3.8 MEGACYCLES. THEN BRING IN THE 3.8 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING TRIMMER NO. 6, after which adjust trimmers No. 5 and 7 for maximum 3.8 megacycle signal sensitivity.

6. With the band selector switch in the same position (1.5 to 4.2 megacycle band) tune the receiver dial and set the test oscillator frequency to approximately 1.6 megacycles. Then while rocking the gang condenser slightly to the right and left, adjust padder condenser No. 8 for maximum 1.6 megacycle signal sensitivity.

7. Adjust the band selector switch for operation on the 1550 to 535 kilocycle band, tune the receiver dial and set the test oscillator frequency to EXACTLY 1400 KILOCYCLES. THEN BRING IN THE 1400 KILOCYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING TRIMMER NO. 2, after which adjust trimmers No. 1 and 3 for maximum sensitivity.

8. With the band selector switch set for operation on the 1550 to 535 kilocycle band tune the receiver dial and set the test oscillator frequency to approximately 600 kilocycles. Next while rocking the gang condenser slightly to the right and left adjust padder condenser No. 4 for maximum 600 kilocycle signal response.

SENTINEL RADIO CORP.

INTERMEDIATE ALIGNMENT:

1. Connect the high side of the oscillator output to the control grid of the 1C6 tube, leaving the grid cap disconnected. Connect the ground side of the oscillator to the receiver ground post.

2. Set the test oscillator frequency to 465 kilocycles. (This must be accurate).

3. Align the first intermediate transformer by turning one of the trimmer screws up and down (increasing and decreasing capacity) until maximum reading is obtained on the output meter, after which adjust the other trimmer screw of the same transformer for maximum sensitivity.

4. Adjust the other intermediate transformers in the same manner.

TO ALIGN THE VARIABLE CONDENSER:

Adjustment of the trimmer condensers, located inside of and accessible through the holes found in the top of the catacomb (mounted on top and in the left hand front corner of the receiver) will be referred to by numbers as indicated on the circuit diagram showing the relative location of these trimmers.

1. Connect the high output side of the oscillator through a 250 mmfd. (.00025 Mfd.) to the receiver antenna post and the ground to the ground post.

2. Place the band selector switch for operation on the 1520 to 535 kilocycle band (broadcast), tune the receiver to exactly 1400 kilocycles on the dial and set the test oscillator frequency to exactly 1400 kilocycles. THEN BRING IN THE 1400 KILOCYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING TRIMMER MARKED No. 2 ON CATACOMB DIAGRAM, after which adjust No. 1 and No. 3 trimmers in the order named for maximum sensitivity.

3. Leave the band selector switch for operation on the broadcast band (1520-535 kilocycles) and tune the receiver and set the test oscillator to approximately 600 kilocycles. Then while rocking the condenser slightly to the right and left adjust the 600 kilocycle padding condenser No. 11, which is located on and accessible through the hole provided on the left hand side of the chassis, for maximum sensitivity.

4. Recheck the alignment at 1400 kilocycles as the 600 kilocycle adjustment may have changed the alignment at 1400 kilocycles.

5. Place the band selector switch for operation on the 1.5 to 4.2 megacycle band and set the test oscillator frequency and tune the receiver dial to EXACTLY 3.8 MEGACYCLES. THEN TUNE IN THIS 3.8 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING CATACOMB TRIMMER NO. 7. Next adjust catacomb trimmer No. 4 for maximum sensitivity.

6. With the band selector switch in the same position (1.5-4.2 megacycle band) tune the receiver dial and set the oscillator frequency to approximately 1600 kilocycles, and then while rocking the variable condenser slightly to the right and left adjust the 1600 kilocycle trimmer No. 12 located on the left hand side of the chassis for maximum sensitivity.

7. Recheck 3.8 megacycle adjustments.

8. Adjust the band selector switch for operation on the 4 to 11 megacycle band and tune the receiver dial and set the oscillator frequency to exactly 10.5 megacycles. When adjusting catacomb trimmer No. 5 two peaks (the fundamental and the image peak) will be noticed. CARE MUST BE TAKEN SO THAT THE FUNDAMENTAL PEAK AND NOT THE IMAGE PEAK IS USED FOR ALIGNING THE RECEIVER AT 10.5 MEGACYCLES. First back off catacomb trimmer No. 5 to minimum capacity, next screw down the trimmer (add capacity) until the first peak which is the fundamental and the one you areto use is tuned in. If the trimmer is screwed down beyond the point where this first peak is received the incorrect image peak will be tuned in. When the first peak has been located adjust catacomb trimmer No. 5 to BRING IN THE 10.5 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT After completing this adjustment always check to see if the proper peak has been used. To do this leave the test oscillator frequency at 10.5 megacycles, increase its output, and tune the receiver dial to approximately 9.5 megacycles. Vary the receiver dial slightly to the right and left of 9.5 megacycles and if the fundamental peak was used in aligning at 10.5 megacycles the test oscillator signal will be heard at approximately 9.5 megacycles on set dial. If it is not possible to receive the signal then the fundamental peak was not used and the 10.5 megacycle adjustment of trimmer No. 5 must be gone over and properly adjusted. After correctly completing catacomb trimmer No. 5 adjustment adjust catacomb trimmer No. 6 for maximum sensitivity. Should two peaks be noticed with this trimmer always adjust trimmer No. 6 to the one that requires the most capacity.

9. With the band selector switch adjusted for operation on the same band (4-11 megacycles) set the test oscillator frequency and tune the receiver dial to approximately 4.8 megacycles. Then while rocking the variable condenser slightly to the right and left adjust the 4.8 megacycle trimmer No. 10, located on the left hand side of the chassis for maximum sensitivity.

10. Recheck the 10.5 megacycle adjustment.

11. Adjust the band selector switch for operation on the 10 to 20 megacycle band, tune the receiver dial and set the oscillator frequency to exactly 19 megacycles. When adjusting catacomb trimmer No. 8 two peaks (the fundamental and the image peak) will be noticed. CARE MUST BE TAKEN SO THAT THE FUNDAMENTAL PEAK AND NOT THE IMAGE PEAK IS USED FOR ALIGNING THE RECEIVER AT 19 MEGACYCLES. First back off catacomb trimmer No. 8 to minimum capacity, next screw down the trimmer (add capacity) until the first peak which is the fundamental and the one you are to use is tuned in. If the trimmer is screwed down beyond the point where this first peak is received the incorrect image peak will be tuned in. When the first peak has been located adjust catacomb trimmer No. 8 to BRING IN THE 19 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT. After completing this adjustment always check to see if the proper peak has been used. To do this leave the test oscillator frequency at 19 megacycles, increase its output, and tune the receiver dial to approximately 18 megacycles. Vary the receiver dial slightly to the right and left of 18 megacycles and if the fundamental peak was used in aligning at 19 megacycles the test oscillator signal will be heard at approximately 18 megacycles on set dial. If it is not possible to receive the signal then the fundamental peak was used and the 19 megacycle adjustment of trimmer No. 8 must be gone over and properly adjusted. After correctly completing catacomb trimmer No. 8 adjustment adjust catacomb trimmer No. 9 for maximum sensitivity. Should two peaks be noticed with this trimmer always adjust trimmer No. 9 to the one that requires the most capacity.

12. Some code and aircraft signals are broadcast on a frequency exactly the same or near the IF frequency of the receiver. To eliminate interference from these signals a 465 kilocycle filter (mounted in the coil shield located underneath and towards the front of the chassis) is incorporated in the set. To adjust, set the oscillator frequency (with oscillator output connected to set antenna and ground) TO EXACTLY 465 KILOCYCLES, turn the receiver on end and adjust the trimmer located on and accessible through the top of the filter shield for MINIMUM 465 KILOCYCLE SIGNAL.

MODELS 72
Trimmers,Alignment

A. ALIGNMENT OF THE I.F. EQUALIZING CONDENSERS.

1. Connect the aerial terminal of the oscillator to the control grid terminal (terminal on top of tube) of the first detector-oscillator tube, and the ground terminal to the ground connection of the receiver, and set oscillator for 172.5 kilocycles. (**MODELS 71, 71-B - 456 K.C.**)

2. Turn the volume control on full.

3. Turn the attenuator or volume control on the oscillator to the position where the oscillator is heard faintly. If the oscillator is not heard at all, even with the control full on, the condensers of the stage requiring adjustment should be manipulated until it is heard at the loudest. The control should then be reduced so that only a faint sound from the oscillator is audible.

4. All intermediate frequency adjustable condensers should be adjusted if the adjustment of one is necessary. When adjustment of the stage that requires such has been made, the other stages should be adjusted in rotation. Each pair of condensers should be adjusted before proceeding to the next.

5. Correct alignment is obtained when reduction of the oscillator output and readjustment of the condensers is continued until maximum deflection of the output meter is obtained with a minimum of oscillator input. The numerical value of the deflection on the output meter scale is of no consequence, for the object is to set the output of the oscillator at a certain value and adjust the condenser until maximum deflection is obtained. If the meter goes off scale or does not give a large enough reading, adjust the oscillator accordingly.

6. It may be necessary to repeat the entire adjustment once or twice, to be sure the adjustments are correct.

B. ALIGNMENT OF THE R.F. AND OSCILLATOR EQUALIZING CONDENSERS.

1. Connect the oscillator to the antenna and ground connections of the receiver, tune the oscillator to a frequency between 1400 and 1500 kilocycles.

NOTE - ON MODEL 72-PQ (POLICE SET) TUNE OSCILLATOR TO THE DESIRED FREQUENCY AND TURN DIAL UNTIL SIGNAL IS HEARD.

2. Turn condenser gang until this signal is heard.

3. Adjust oscillator and R.F. trimmers for maximum output.

C. ALIGNMENT OF ANTENNA EQUALIZING CONDENSER.

The antenna equalizing condenser should always be adjusted when the receiver is installed and with the regular aerial and ground connected. It is the purpose of this condenser to resonate the first tuned circuit with the antenna system to which the receiver is connected, thereby providing a maximum transfer of energy. The procedure of adjustment is as follows:

1. Tune in a weak distant station or oscillator signal between 1300 and 1400 kilocycles, turn the volume control on full.

2. Turn the hex nut on the condenser or the screw in the condenser with an insulated handle screw driver to the position where the volume from the station "tuned-in" or the oscillator signal is the loudest. Once made, this adjustment need not be changed unless the antenna system is altered, the receiver is moved from one location to another, or the other condensers are re-adjusted.

NOTE: When antenna equalizing condenser is adjusted on oscillator signal, adjustment will not hold true when receiver is connected to aerial; this condenser must be aligned to antenna system.

MODEL 55

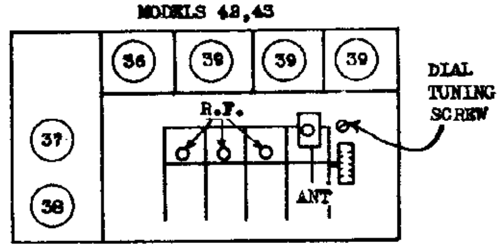
MODELS 42,43



ALIGNMENT INSTRUCTIONS

MODELS 40,40A

1. Turn condenser gang to a dial setting between 1200 and 1400 kilocycles and turn volume control to full on position.

2. Connect oscillator to antenna terminal and adjust oscillator so that signal is heard at maximum volume.

3. Adjust R.F. trimmers for maximum signal response.

4. With the set installed and with antenna connected tune in a weak station between 1200 and 1400 kilocycles with volume control on full position.

5. Adjust antenna trimmer for maximum signal response.

MODEL 55

The procedure of adjustment is as follows: When a broadcast is being received, retard the volume control to a point where the signal is just audible and then adjust the R.F. and antenna equalizing condensers for maximum signal response. This adjustment should always be made when the Radio Receiving Set is installed and once made the adjustment should not be changed, unless the antenna system is altered, or the receiving set moved from one location to another.

ALARM CIRCUIT RELAY CONTROL

With the receiving set in operation and a broadcast being received, the Alarm Circuit should be adjusted so it will indicate when a broadcast is to be made. This adjustment is made by turning the slotted shaft visible through the small opening in the forward left hand corner of the power converter unit, to a position where static and interference will not operate the alarm, but the broadcast signal will give the proper indication.

If the Interference is particularly bad, the bell may be replaced by a .45 ampere 2.5, or six volt miniature lamp. This will eliminate any annoyance caused by tinkling of the bell.

While the light may glow at intervals from static impulses, the actual broadcast will be indicated by a steady illumination. When the signal-switch control knob is turned to the signal position the volume control is automatically disconnected, thus regardless of the position of the Volume Control, the alarm is always ready to operate at maximum volume.

MODELS 41, 41A, 42, 43

With the cover on the receiving unit turn the dial with a screw driver by means of the slotted shaft, to the frequency of the station to be received. Retard the volume control to a point where the station is just audible, then carefully retune the dial to the point where the station is heard the loudest. Again retard the volume control to a point where the station is just audible, then using a small wooden or insulated handle screw driver, turn the screw in the antenna compensating condenser to the right or the left until the maximum amount of volume has been obtained. Then again retard the volume control and with a hex-socket insulated adjusting wrench, adjust each R.F. equalizing condenser to a point where the volume from the station is the loudest.

This adjustment should always be made when the receiver is installed, and should not be changed unless the antenna system is altered, the receiver is moved from one location to another, or a different station is "tuned in". In each case the adjustment must then be repeated.

A more accurate adjustment of the compensating and equalizing condensers can be made by using a voltmeter as an indicator.

To do this proceed as follows:

Connect a 1,000 ohm per volt, 0-50 scale D.C. voltmeter from the cathode of the detector tube to the ground (plus of meter to cathode, minus to ground). Correct adjustment of the condenser is then obtained when the indicating needle on the voltmeter deflects to a maximum position.

SPARTON MODELS 73-AX, 73-BX.

Due to the fact that the ear cannot distinguish small changes in sound intensity, an output meter is essential to the proper adjustment of the various condensers.

Unless otherwise specified, the adjusting of any condenser consists of turning the adjusting screw or nut to the right or left until the output meter registers the greatest deflection.

STEP BY STEP PROCEDURE FOR COMPLETE ALIGNMENT OF MODELS.

NOTE: For proper alignment of these chassis the procedure should be followed in the same order as given.

A. ALIGNMENT OF INTERMEDIATE-FREQUENCY STAGES.

(1) Turn on receiver and test oscillator, and allow both to operate several minutes before attempting to align any condensers.

(2) Connect "antenna" of test oscillator to grid cap of Type 78 first detector-oscillator tube and "ground" of test oscillator to chassis frame of receiver.

(3) Turn the band selector switch to the "broadcast" position and adjust the tone control completely to the left so that the "brilliant" tone is obtained.

(4) Adjust condenser C_4 (see Fig.) so that the adjusting nut is screwed all the way down and then turned back one-quarter turn.

(5) Adjust condenser C_8 so that the nut is turned about one-half way down.

(6) The dial pointer should point to the last line on the scale past 550 meters when the variable condenser rotor plates are completely meshed with the stator plates. If the dial pointer reads incorrectly it may be reset by first loosening the set-screws on the hub of the dial scale, holding the rotor plates fully in mesh and moving the dial scale until the last line on the scale past 550 meters is opposite the pointer on the escutcheon.

(7) Turn the condenser rotor plates all the way out and with the test oscillator adjusted for generating a signal of 456 kilocycles (657.8 meters) adjust condensers C_1, C_2, and C_3.

B. ALIGNMENT OF BROADCAST BAND AND LONG-WAVE BAND.

(1) Disconnect "antenna" lead of test oscillator from grid cap of first detector-oscillator tube and connect to the antenna terminal of the chassis.

(2) Tune the test oscillator and receiver to a wave-length of 200 meters (1500 kilocycles) and adjust condensers C_6 and C_7.

CAUTION: Extreme care should be taken in the preceding step so that the condensers are not adjusted to any other signal except the 200 meter wave-length of the signal generator or test oscillator.

(3) Turn the band selector switch to the "long-wave" position.

(4) Tune the test oscillator and receiver to 1,000 meters (300 kilocycles) and adjust condenser C_4.

(5) Adjust condenser C_8 (mounted on the side of the variable condensers) for maximum deflection of the output meter with the test oscillator adjusted for 1,000 meters.

(6) Tune the test oscillator and receiver to 1740 meters (172.5 kilocycles) and adjust condenser C_5 for maximum deflection of the output meter regardless of the dial setting.

(7) Repeat steps 5 and 6 until the adjustment of condenser C_5 does not affect the adjustment made in Step 5 (1,000 meters).

(8) Tune test oscillator and receiver for a wave length of 2,000 meters (150 kilocycles) and check for operation of the receiver.

(9) Turn band selector switch back to "broadcast" position and tune test oscillator and receiver to 500 meters (600 kilocycles) and readjust condenser C_1 for maximum deflection of the output meter.

(10) Tune test oscillator and receiver to 200 meters (1500 kilocycles) and check for calibration and operation of the receiver. Repeat this procedure at 333 meters (900 kilocycles) and 500 meters (600 kilocycles.)

NOTE: Slight readjustments of the condenser C_6 will be required after the receiver is connected to the antenna with which it is to be used. This condenser should be adjusted by tuning in a weak distant station between 200 and 250 meters, and adjusting the condenser to a point of maximum volume. Once adjusted, it need not be changed unless the antenna system is altered. This adjustment ideally matches the receiver to operate on any antenna.

NOTES: Voltage and resistance readings are for schematic diagram shown. Allow 15% + or — on all measurements. Always use meter scale which will give greatest deflection within scale limits. All measurements made with Weston Selective Analyzer No. 665, Type 1.

*Cannot be measured with Weston No. 665, Type 1.

SPARTON MODEL 73

The use of quality test equipment is highly recommended, and a good test oscillator becomes a virtual necessity when aligning the all-wave or short-wave type of receiver. Due to the fact that the ear cannot distinguish small changes in sound intensity, an output meter is essential to the proper adjustment of the various condensers.

Unless otherwise specified, the adjusting of any condenser consists of turning the adjusting screw or nut to the right or left until the output meter registers the greatest deflection.

1. EQUIPMENT REQUIRED.

A. Modulated test oscillator (crystal controlled or accurately calibrated) capable of generating signals with wave lengths from 200 to 2000 meters (100 to 1500 kilocycles).

NOTE: The above range is approximately that of the SPARTON Export Model 75. A good test oscillator or miniature signal generator is capable of generating signals from 12 to 3000 meters (100 to 25,000 kilocycles).

B. Output meter.

C. Sparton Part A-8737 and A-9851 adjusting wrenches.

2. STEP BY STEP PROCEDURE FOR COMPLETE ALIGNMENT OF MODELS.

IMPORTANT: An outdoor antenna fifty feet in length including lead-in and twenty-five to fifty feet in height will give good results. A longer aerial may be used to some advantage if not in the locality of a powerful local station. The yellow wire is the antenna terminal, and should be connected to the antenna lead-in wire. The joint should be taped so as to prevent grounding to the chassis body. Should an aerial of fifty feet or longer be used, the red and black lead adjacent to the antenna lead should be tied to the black or ground lead. With a short aerial, this red and black lead may be neglected. To determine the necessity of it, tune in some distant station about 600 meters in wave length and see if the connecting of this lead to ground improves the signal strength.

NOTE: For proper alignment of this chassis the procedure should be followed in the same order as given.

A. ALIGNMENT OF INTERMEDIATE-FREQUENCY STAGES.

(1) Turn on receiver and test oscillator, and allow both to operate several minutes before attempting to align any condensers.

(2) Connect "antenna" of test oscillator to grid cap of Type 6D6 first detector tube and "ground" of test oscillator to chassis frame of receiver.

NOTE: It is advisable to read carefully the operating instructions included with the test oscillator.

(3) Turn the band selector switch to the "broadcast" position and adjust the tone control completely to the left so that the "brilliant" tone is obtained. Connect the black lead and the black and red tracer lead to chassis.

(4) Adjust condenser C_4 so that the adjusting nut is screwed all the way down and then turned back one-quarter turn.

(5) Adjust condenser C_5 so that the nut is turned about one-half way down.

(6) The dial pointer should point to the last line on the scale past 550 meters when the variable condenser rotor plates are completely meshed with the stator plates. If the dial pointer reads incorrectly it may be reset by first loosening the set-screws on the hub of the dial scale, holding the rotor plates fully in mesh and moving the dial scale until the last line on the scale past 550 meters is opposite the pointer on the escutcheon.

(7) Turn the condenser rotor plates all the way out and with the test oscillator adjusted for generating a signal of 456 kilocycles (657.8 meters) adjust I.F. trimmers for maximum output.

B. ADJUSTING 456 KC REJECTOR CIRCUIT.

(1) Connect oscillator antenna lead to yellow wire (antenna) of set and ground of oscillator to chassis.

(2) Tune test oscillator to 456 KC.

(3) With volume control on full position adjust wave trap condenser C_2 for minimum output.

(1) Disconnect "antenna" lead of test oscillator from grid cap of first detector tube and connect to the antenna terminal of the chassis.

(2) Tune the test oscillator and receiver to a wave-length of 200 meters (1500 kilocycles) and adjust condensers C_6 and C_7.

CAUTION: Extreme care should be taken in the preceding step so that the condensers are not adjusted to any other signal except the 200 meter wave-length of the signal generator or test oscillator.

(3) Turn the band selector switch to the "long wave" position.

(4) Tune the test oscillator and receiver to 1,000 meters (300 kilocycles) and adjust condenser C_4.

(5) Adjust condenser C_8 and C_4 for maximum deflection of the output meter with the test oscillator adjusted for 1,000 meters.

(6) Tune the test oscillator and receiver to 1740 meters (172.5 kilocycles) and adjust condenser C_5 for maximum deflection of the output meter regardless of the dial setting.

(7) Repeat steps 5 and 6 until the adjustment of condenser C_5 does not affect the adjustment made in Step 5 (1,000 meters).

(8) Tune test oscillator and receiver for a wave length of 2,000 meters (150 kilocycles) and check for operation of the receiver.

(9) Turn band selector switch back to "broadcast" position and tune test oscillator and receiver to 500 meters (600 kilocycles) and readjust condenser C_1 for maximum deflection of the output meter.

(10) Tune test oscillator and receiver to 200 meters (1500 kilocycles) and check for calibration and operation of the receiver. Repeat this procedure at 333 meters (900 kilocycles) and 500 meters (600 kilocycles).

NOTE: Slight readjustments of the condenser C_6 will be required after the receiver is connected to the antenna with which it is to be used. This condenser should be adjusted by tuning in a weak distant station between 200 and 250 meters, and adjusting the condenser to a point of maximum volume. Once adjusted, it need not be changed unless the antenna system is altered. This adjustment ideally matches the receiver to operate on any antenna.

SPARTON ENSEMBLE MODEL 85-X, 105-X PHONOGRAPH MECHANISM

FOREWORD.

The automatic record changer in the SPARTON Models 85-X and 105-X is carefully built and assembled, and will operate satisfactorily without attention other than the oiling of the motor. This bulletin describes the mechanism and will assist in making any minor adjustments.

1. OPERATING INSTRUCTIONS.

The "On and Off" switch (see Paragraph 5) must be turned "on" as for radio reception. Allow about 50 seconds for tubes to heat up.

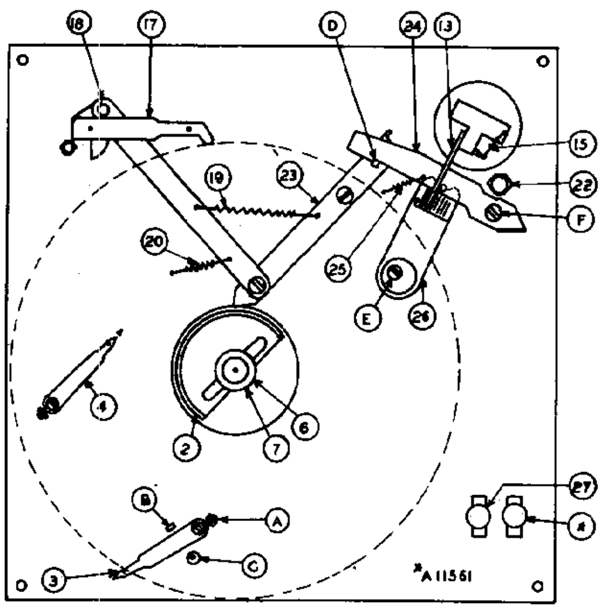
The toggle switch at the extreme right of the turntable is a master switch and must be snapped to the "on" position (away from the operator) for playing records and to the "off" position (towards operator) for operating the radio receiver.

Swing the tone arm and pickup to the right and lift it to the catch where it will remain clear from the turntable. If 10-inch records are to be played, move the thumb stop (on the right-hand side of the tone arm) back towards the tone arm pivot. If 12-inch records are to be played, move this stop forward.

Place one to eight records on the turntable.

Insert needle in pick-up and tighten firmly by means of the clamping screw in the end of the pick-up.

Snap the toggle switch at the left of the master switch to the "on" position (away from the operator). This starts the motor and turntable. CAUTION: Be sure the speed-change lever, located at the edge of the turntable at the front left-



JUNE 1, 1936

FIG-1

SPARTON ENSEMBLE MODEL 85-X, 105-X, PHONOGRAPH MECHANISM (Continued)

hand corner points to the No. 78.

Start the pick-up needle in the first groove of the record. Adjust the radio volume control for satisfactory volume. NOTE: If it is desired to increase or decrease the record speed slightly, remove the turntable by lifting straight up and shift the lever located directly to the left of the turntable shaft to the letter "F" for increased speed and to the letter "S" for slower speed.

10-inch records will be rejected automatically. To reject 12-inch records when they have finished playing, or to reject either 10-inch or 12-inch records at any time in order to play the next record below, pull the reject lever forward. This lever is located on the base plate just below the thumb stop of the tone arm.

Any record may be repeated indefinitely by lifting the throw-off arm (located at the back left-hand corner) to an upright position.

The last record on the turntable is not rejected and will continue to repeat as long as the switches are left in the "on" position. CAUTION: Use only a good grade of needle and do not play them more times than recommended by the needle manufacturer. Satisfactory results are seldom obtained with scratched, worn-out, or warped records

To play the large slow-speed records of the transcription type, the speed change lever must be moved to the No. 33-1/3. The lever automatically changes the speed of the turntable from 78 r.p.m.

CAUTION: Use only the special needles designed for playing 33-1/3 r.p.m. records. The speed change lever must be moved back to the "78" position for playing the regular 10-inch and 12-inch records.

2. MOTOR AND SPEED REGULATOR MECHANISM.

The Motor installed in this Record Changer is governor-controlled with all gearing enclosed and leaves the factory lubricated for proper operation under ordinary weather conditions for considerable time.

The main bearings of the motor are fed with lubricating oil by means of wicks which are completely installed.

The governor disc engages with a complete ring of hard felt which is impregnated with lubricating solution sufficient for proper operation for approximately a year under normal weather conditions; however, if the motor has a tendency to "chatter" or "waver", a drop or two of very light lubricating oil should be placed on this felt ring.

Motor Speed. - To adjust the speed at 78.26 r.p.m., the speed adjustment lever (Figure 1, No. 5) should be set above the legend "78" as marked on the base plate, the speed being adjusted by means of a speed regulator lever (Figure 1, No. 4) which is mounted under the turntable and is indicated for direction of swing to fast or slow by the legends "F" and "S" on the base plate.

Speed Lever Adjustment. - To adjust the speed adjustment lever for 33-1/3 r.p.m., remove the turntable and loosen the screw (A) which fastens the lever on to the motor shaft which protrudes through the base plate, and which is provided with a screw driver slot in the top. Turn the shaft to the stop in a clockwise direction, which places the motor in 33-1/3 r.p.m. position. Then set the change lever against the lug (B) and opposite the 33-1/3 legend on the base plate, and tighten the clamp screw (A). Then loosen the screw which holds the eccentric bushing stop (C) and allow the lever to be swung to its farthest position in 78 r.p.m. Then turn the eccentric bushing around until it touches the side of the long lever and tighten the screw which holds the eccentric.

5. TRIP MECHANISM.

Care should be taken that the Notch (D) Figure 1, fits properly and latches when the latch bar (No. 23) over-travels against the latch spring (No. 25). This spring should have sufficient tension so that when the trip unlatches, the lift lever (No. 24) from the square pin, the point of the latch bar (No. 23) is properly swung in front of the operating cam (No. 2). A re-setting spring (No. 20) and a trip spring (No.19) both have loops on the ends to take care of the over-travel of the moving parts in re-setting the latch.

When latched, the engaging notch should be engaged approximately one-half its depth which is adjusted by means of the eccentric washer and lock screw (E). Care should be taken that these parts work freely in order that the mechanism will re-latch when the change cycle is completed.

The Record Changer is adjusted at the factory to trip on an eccentric trip groove record when the phonograph needle is 1-3/4" from the edge of the hole in the center. The eccentric trip is affected by means of the hardened steel pin pressed into the end of the tone arm lift crank (No. 13) riding on the serrated block located on the trip lever (No. 26). Care should be taken that there is a minimum of 1/32" clearance between the end of the pin and the block with a short phonograph needle in the pick-up and riding on top of one record on the turntable.

The oval head pivot screw (F) which serves as a pivot at the rear of the lift lever (No. 24) should be set at such a height to allow

SPARTON ENSEMBLE MODEL 85-X,105-X PHONOGRAPH MECHANISM (Continued)

the lift lever to be raised by the latch bar (No. 3) and the roller to pass under the end of the lever without binding but without additional play.

4. RECORD REJECT MECHANISM.

The Record Changer is intended to be operated without removing the first (bottom) record on the turntable in order to prevent the phonograph needle from damaging the covering on the turntable.

The height of the assembly should be so adjusted that the turntable with one record on it measures ONE INCH FROM THE BASE PLATE TO THE TOP OF THE FIRST RECORD.

The screw shown at (G) Figure 2, allows the adjustment to be made so that the unloading finger will separate the second record from the first or, in other words, barely rises over the top edge of the first record in removing the second record.

Care should be taken that this assembly works freely and that no binding occurs in pivots or bearings, and that in normal playing position the unloading arm assembly rests on the stop screw.

Care should be taken that the distance between the edge of the unloading finger (H) at the point at which it engages with the record and the unloading lever (I) is 3/32 inch.

FIGURE 3.

Lift Adjustment. - To adjust the lift of the unloading lever, the latch bar should be placed in a position at its farthest throw against the face of the cam mounted on the turntable spindle.

Place a record between the unloading finger ball on the underside of the unloading lever (I). In this position the record should clear the turntable spindle. This adjustment is made by means of the eccentric stud which is rotated to adjust the proper height and locked by means of a nut on the underside of the base plate at (J).

5. TONE ARM MECHANISM.

To Adjust Lift of Tone Arm. - To adjust for proper lift of the tone arm, rotate the motor to the position with the latch bar against the cam face with the tone arm lifted. In this position, and with the tone arm stopped against the hub of the dash pot at No. 4, the point of the phonograph needle should be suspended 1-3/4 inches from the top of the base plate. This adjustment is made at the factory but, if for any reason the lift lever (Figure 1, No. 24) becomes bent, it should be raised at the point where the lift crank roller rests in above-described position until this dimension is obtained.

To adjust for the proper lowering of the tone arm on the edge of the 10-inch record, a 10-inch record should be placed on the turntable and the screw (shown at "X") is provided for adjusting the tone arm in or out until the needle lowers approximately 5/32 of an inch from the edge of the record.

FIGURE 4.

In order to set the tone arm pivot bearing to take up the vertical play, two jam nuts (shown at "L") are provided on the pivot sleeve in the bottom of the tone arm base as a means for taking up the play and also for locking in permanent position.

6. DASH POT MECHANISM.

The dash pot, located at the right and in front of the tone arm, is provided to allow the tone arm to come down slowly as shown in Figure 4.

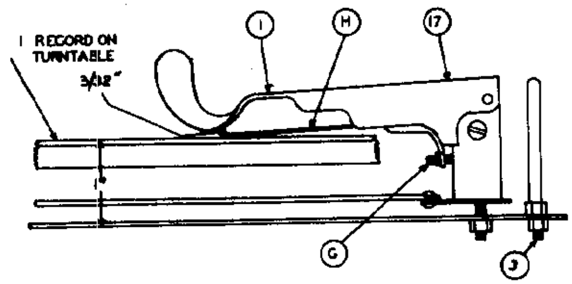

FIG. 2

JUNE 1, 1938

SPARTON ENSEMBLE MODEL 85-X, 105-X PHONOGRAPH MECHANISM (Continued)

With the tone arm of the Record Changer in the position as described under the tone arm adjustments, the dash pot should be adjusted for height by loosening the nut on top of the base plate as shown at (N), and should be raised or lowered until the tip of the dash pot shaft merely touches the lift shelf as shown at (O) WHILE IN 10-INCH RECORD-PLAYING POSITION.

IF TONE ARM FAILS TO TRIP WHEN A SPIRAL TYPE RECORD IS FINISHED PLAYING, check the latch mechanism (Figure 1, D) for depth of notch adjustment and determine whether the trip mechanism is binding anywhere; also check the pressure of springs (Figure 1, No. 19 and No. 20). Check the distance of the phonograph needle to the turntable spindle to make sure that the latch is disengaged at 1-3/4 inches. This may also be caused by a worn needle, worn record or a record without a trip groove.

IF TONE ARM FAILS TO TRIP AT THE END OF PLAYING AN ECCENTRIC GROOVE RECORD (VICTOR TYPE), check the lift crank assembly (Figure 3, No. 13) and determine whether it glides across the top of the serrated block (Figure 3, M). Be sure that there is sufficient clearance between the end of the pin in the lift crank which should be approximately 1/32 inch with a short phonograph needle in the pick-up, resting on the top of one record on the turntable.

The pressure of the needle on the serrated block as shown at Figure 3, M, is controlled by the pressure spring (Figure 3, No. 15), care being taken that this pressure is sufficient without binding to hold in the notches when the serrated groove rocks the tone arm.

IF TONE ARM FAILS TO LOWER PROPERLY ON THE RECORD, it may be caused by the dash pot's being improperly adjusted for height, resulting in the tone arm's bouncing against the dash pot cap. This can be readily eliminated as explained in adjustments for the dash pot (Figure 4).

IF TONE ARM LOWERS TOO SLOWLY, it may be caused by the leather binding in the cylinder of the dash pot due to too much oil or the leather being expanded too tightly against the cylinder. Remove the leather and remove the surplus oil. The mechanism should allow the tone arm to "float" down slowly.

MODELS 516, 516X, 546X
Voltage, Alignment
Socket, Trimmers
Resistance

SPARKS WITHINGTON CO.

The use of quality test equipment is highly recommended, and a good test oscillator becomes a virtual necessity when aligning a receiver of this type. Due to the fact that the ear cannot distinguish small changes in sound intensity, an output meter is essential to the proper adjustment of the various condensers.

Unless otherwise specified, the adjusting of any condenser consists of turning the adjusting screw or nut to the right or left until the output meter registers the greatest deflection.

1. EQUIPMENT REQUIRED

A. Modulated test oscillator (crystal controlled or accurately calibrated) capable of generating frequencies from 400 kc. to 20 mc.

B. Output meter.

C. SPARTON Part A-5732 Adjusting Wrench.

D. Dummy antennae consisting of a 800 ohm non-inductive, non-capacitive resistor.

2. STEP BY STEP PROCEDURE

For proper alignment of these receivers, the procedure should be followed in the same order as given.

A. Alignment of Intermediate-Frequency Stages.

(1) Turn on receiver and test oscillator and allow both to operate several minutes before attempting to align any condensers.

(2) Connect "antenna" of test oscillator to the grid cap of the type 6A7 first detector-oscillator tube, and "ground" of test oscillator to chassis frame of receiver. Connect output meter across the speaker input terminals.

NOTE: It is advisable to read carefully the operating instructions included with test oscillator.

(3) Tune test oscillator to obtain a signal of 456 kc.

(4) Turn the volume control of the receiver on full and short circuit the oscillator section of the variable condenser to ground.

(5) Adjust I-F condensers (C10 and C11). See Fig. 10.

NOTE: The condenser which is adjusted by means of the nut should first be brought to resonance; after which the condenser adjusted by the screw should be peaked.

(6) Adjust condensers C8 and C9 by first adjusting the grid circuit or nut adjustment and then adjusting the plate circuit or screw adjustment.

NOTE: As the gain of the receiver increases upon reaching resonance in the I-F circuit, the output of the signal generator should be constantly attenuated so that the indicating needle of the output meter is not thrown off scale or otherwise damaged.

Do not reduce the volume of the receiver to cut down the amount of output. This precaution will insure a type of peak not affected or broadened by the A.V.C. action.

(7) The above adjustment should be repeated with great care to insure accurate adjustment of the I-F condensers.

B. Alignment of Broadcast Band

The dial pointer should be exactly parallel with the horizontal lines of the kilocycle scale when the condenser plates are fully meshed. If the pointer does not read correctly, loosen the set screw which holds the dial disc to the condenser shaft, hold the rotor plates fully meshed with the stator plates and set the pointer so that it is parallel with the horizontal lines on the kilocycle scale, then tighten the set screw.

(1) Disconnect "antenna" lead of test oscillator from grid cap of first detector-oscillator tube and connect in series with the dummy antenna to the antenna binding post at the rear of the receiver.

(2) Turn the band selector switch to the extreme counter-clockwise position (broadcast band).

(3) Tune test oscillator and receiver to 1400 kc. and adjust trimming condensers C3, C2 and C1 in the order mentioned.

(4) Tune the receiver and the test oscillator to a frequency of 600 kc. and adjust condenser C4.

(5) Retune the receiver and the test oscillator to 1400 kc. and recheck the adjustments made on condensers C3, C2 and C1.

Sensitivity and calibration should be checked at 1000 kc., and if necessary, corrections may be made by bending the slotted plates of the variable condenser.

C. Alignment of Band No. 2 (MODELS 516 AND 516-X)

(1) Turn the band selector switch to the police band or central position for the knob.

(2) Tune test oscillator and receiver to a frequency of 3700 kc. and adjust condenser C31, which is reached from the front of the chassis.

(3) Tune test oscillator and receiver to a frequency of 1750 kc. and adjust condenser C5, also reached from the front of the chassis.

(4) Tune test oscillator and receiver to a frequency of 3700 kc. and adjust condenser C6.

C. Alignment of Band No. 2 (MODEL 546-X)

(1) Turn the band selector switch to the long wave or extreme left-hand position.

(2) Tune test oscillator and receiver to a frequency of 350 kc. and adjust condenser C31.

(3) Tune receiver and test oscillator to a frequency of 150 kc. and adjust condenser C5.

(4) Retune test oscillator and receiver to a frequency of 350 kc. and re-adjust condenser C31.

All adjustments made for long wave band should be carefully rechecked to assure accuracy and stability of adjustment.

D. Alignment of Band No. 3

(1) Turn the band selector switch to the short wave or extreme right-hand position.

(2) Tune the test oscillator and receiver to a frequency of 14 mc. and adjust condenser C7.

While this adjustment is being made, the tuning control of the signal generator should be moved slowly back and forth across the resonance point of the receiver. This will assist in obtaining a proper adjustment of this condenser. There are no oscillator, trimming or padder condensers for the foreign short wave band.

If trouble is experienced in obtaining proper alignment of these receivers, it may be due to the condition of the Type 6A7 first detector-oscillator tube, in which case the receiver should be re-aligned at 1000 kc. as follows:

With the band selector switch set to the broadcast position, tune the test oscillator and receiver to 1000 kc.

Carefully adjust either the receiver or the test oscillator so that maximum deflection of the output meter is obtained. Then, adjust condensers C8 and C9 in the first intermediate frequency transformer.

SPARKS WITHINGTON CO.

Detailed Alignment Instructions for 536 and 536-X

The use of quality test equipment is highly recommended and a good test oscillator becomes a virtual necessity when aligning the all-wave or short-wave type of receiver. Due to the fact that the ear cannot distinguish small changes in sound intensity, an output meter is essential to the proper adjustment of the various condensers.

Unless otherwise specified, the adjusting of any condenser consists of turning the adjusting screw or nut to the right or left until the output meter registers the greatest deflection.

1. EQUIPMENT REQUIRED

A. Modulated test oscillator (crystal controlled or accurately calibrated) capable of generating frequencies from 345 to 15,000 kilocycles.

B. Output meter.

C. Part A-5732 adjusting wrench.

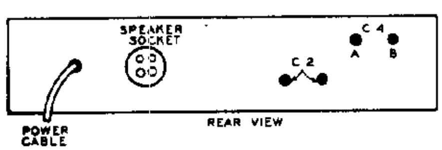
D. Dummy antennas, consisting of a 150 mmf. condenser and a 400 ohm non-inductive resistor.

2. STEP BY STEP PROCEDURE

Note: For proper alignment of these chassis, the procedure should be followed in the same order as given.

In the following procedure, the broadcast band will be termed Band No. 1; the first short-wave band (green section of the dial), Band No. 2; the second short wave band (blue section of the dial), Band No. 3.

The dial pointer should be exactly parallel with the horizontal line of the kilocycle scale when the condenser plates are fully meshed. If the pointer does not read correctly, loosen the set screws in the large brass collar directly between the dial lights, hold the rotor plates fully meshed with the stator plates and set the pointer so that it is parallel with the horizontal lines on the kilocycle scale, then tighten the set screws.



A. Alignment of Intermediate-Frequency Stages

(1) Turn on receiver and test oscillator and allow both to operate several minutes before attempting to adjust any condensers.

(2) Turn the band selector switch to the No. 1 (broadcast) position and turn the station selector knob until the rotor plates are completely out of mesh with the stator plates.

(3) Connect "antenna" of test oscillator to grid cap of Type 6A7 1st detector-oscillator tube and "ground" of test oscillator to chassis frame of receiver. Connect output meter "high tap" from plate of Type 6F6 tube to ground (See Fig. 1, Page 1, Bulletin No. 3-E). Note: It is advisable to read carefully the operating instructions included with the test oscillator.

(4) Tune test oscillator to obtain a signal of 345 kilocycles.

(5) Turn the volume control of receiver on full and adjust I.F. condensers C3 and C2. (See Fig. 10). Note: The intermediate frequency circuits are quite selective and care must be taken to insure proper adjustment.

B. Alignment of Broadcast Band

(1) Disconnect "antenna" lead of test oscillator from grid cap of first detector-oscillator tube and connect in series with a 150 mmf. condenser dummy antenna to the antenna terminal of the chassis.

(2) Tune test oscillator and receiver to a frequency of 1350 kilocycles, and without disturbing the setting of the test oscillator or the station selector, adjust condensers C4A, C5B and C6 in the order given.

(3) Tune test oscillator and receiver to 600 kilocycles and adjust condenser C4B.

(4) Retune test oscillator and receiver to 1350 kilocycles and check the adjustments of condensers C4A, C5B and C6.

(5) Calibration of the broadcast band should also be checked at 900 kilocycles and 600 kilocycles.

C. Alignment of Band No. 3

(1) Turn the band selector switch to the second short wave band (blue section of the dial).

(2) Remove the 150 mmf. condenser from "antenna" lead of test oscillator and replace with a 400 ohm non-inductive resistor dummy antenna.

(3) Tune test oscillator and receiver to 15 megacycles and adjust condensers C7 and C5A.

CAUTION: On this band care must be taken to adjust the various condensers to the fundamental of the signal and not to the image. The image signal is equal to the fundamental minus twice the intermediate frequency of the receiver.

A set that is adjusted to the image frequency instead of to the fundamental may be detected by tuning over the band and checking the sensitivity at various points. If a dead spot appears near the center of the band, the adjustable condensers for that band have probably been adjusted to the image instead of the fundamental.

This type of mis-alignment may also be detected by tuning the test oscillator to a frequency of 15 megacycles and the station selector to approximately 15,700 kilocycles. If a strong signal is found approximately at this frequency, it indicates that the band has been adjusted to the image frequency. The normal image frequency for 15,000 kilocycles would be 15,000 kilocycles minus twice 345 kilocycles or approximately 14,300 kilocycles. Therefore a signal of this frequency may be found with the test oscillator generating a 15,000 kilocycle signal.

(4) Retune the test oscillator and receiver to 9 megacycles and check sensitivity and calibration. (There is no oscillator padder for this band.)

D. Alignment of Band No. 2

Note: There are no adjustable condensers for this band. However, it is advisable to check the calibration of the dial and the general operation of the receiver at both 1.7 megacycles and 3.6 megacycles. CAUTION: All adjustments should be rechecked to assure accuracy and stability of adjustment and calibration.

STEP BY STEP PROCEDURE

In the following procedure, the broadcast band will be termed Band No. 1; the first short wave band (green section of the dial), Band No. 2; the second short wave band (red section of the dial), Band No. 3; the third short wave band (blue section of the dial), Band No. 4. The dial pointer should be exactly parallel with the horizontal line of the kilocycle scale when the condenser plates are fully meshed. If the pointer does not read correctly, loosen the set screws in the large brass collar directly between the dial lights, hold the rotor plates fully meshed with the stator plates and set the pointer so that it is parallel with the horizontal lines on the kilocycle scale, then tighten the set screws.

A. Alignment of Intermediate Frequency Stages

(1) Turn on receiver and test oscillator and allow both to operate several minutes before attempting to adjust any condensers.

(2) Turn the band selector switch to the No. 1 (broadcast) position and turn the station selector knob until the rotor plates are completely out of mesh with the stator plates.

(3) Connect "antenna" of test oscillator to grid cap of Type 6A7 1st detector-oscillator tube and "ground" of test oscillator to chassis frame of receiver. Connect output meter "high tap" from plate of Type 6F6 tube to ground.

NOTE: It is advisable to read carefully the operating instructions included with test oscillator.

(4) Tune test oscillator to obtain a signal of 345 kilocycles.

(5) Turn the volume control of receiver on f. 1 and adjust I.F. condensers C3 and C2. (See Fig. 13). Note: The intermediate frequency circuits are quite selective and care must be taken to insure proper adjustment.

B. Alignment of Broadcast Band

(1) Disconnect "antenna" lead of test oscillator from grid cap of first detector-oscillator tube and connect in series with a 150 mmf. condenser dummy antenna to the antenna terminal of the chassis.

(2) Tune test oscillator to obtain a signal of 1350 kilocycles.

(3) Turn the station selector of the receiver to 1350 kilocycles and without disturbing the setting of the test oscillator or the station selector, adjust condensers C4A, C7B and C9 in the order given.

(4) Tune test oscillator and receiver to 600 kilocycles and adjust condenser C4B at the same time the station selector knob is moved back and forth to obtain maximum deflection of the output meter.

(5) Retune test oscillator and receiver to 1350 kilocycles and check the adjustments of condensers C4A, C7B and C9.

(6) Calibration of the broadcast band should also be checked at 900 kilocycles and 600 kilocycles.

C. Alignment of Band No. 4

(1) Turn the band selector switch to the third short wave band (blue section of the dial).

(2) Disconnect "antenna" lead of test oscillator from antenna terminal, remove the 150 mmf. condenser and replace with a 400 ohm non-inductive resistor dummy antenna and connect to grid cap of Type 78 R.F. tube.

(3) Tune test oscillator and receiver to 18 megacycles and adjust condenser C8 and condenser C7A.

CAUTION: On this band care must be taken to adjust the various condensers to the fundamental of the signal and not to the image. The image signal is equal to the fundamental minus twice the intermediate frequency of the receiver. A set that is adjusted to the image frequency instead of to the fundamental may be detected by tuning over the band and checking the sensitivity at various points. If a dead spot appears near the center of the band, the adjustable condensers for that band have probably been adjusted to the image instead of the fundamental.

This type of mis-alignment may also be detected by tuning the test oscillator to a frequency of 15 megacycles and the station selector to approximately 15,700 kilocycles. If a strong signal is found approximately at this frequency, it indicates that the band has been adjusted to the image frequency. The normal image frequency for 15,000 kilocycles would be 15,000 kilocycles minus twice 345 kilocycles or approximately 14,300 kilocycles. Therefore a signal of this frequency may be found with the test oscillator generating a 15,000 kilocycle signal.

(4) Disconnect the "antenna" of the test oscillator from the grid cap of the Type 78 R.F. tube and, using the 400 ohm resistor in series, connect to the antenna terminal.

(5) Adjust condenser C6A. Note: Due to the inter-action between the various circuits, it is necessary to move the station selector knob slightly while adjusting these trimmers in order to realize the maximum possible gain.

(6) Retune the test oscillator and receiver to 9 megacycles and check sensitivity and calibration.

D. Alignment of Band No. 3

(1) Turn the band selector switch to the second short wave band (red section of the dial).

(2) Tune test oscillator and receiver to 7.2 megacycles.

(3) Adjust condensers C5 and C6B.

(4) Tune test oscillator and receiver to 3.6 megacycles and check calibration and sensitivity.

E. Alignment of Band No. 2

Note: There are no adjustable condensers for this band. However, it is advisable to check the calibration of the dial and the general operation of the receiver at both 1.7 megacycles and 3 megacycles. CAUTION: All adjustments should be rechecked to assure accuracy and stability of adjustment and calibration.

NOTES: Voltage and resistance readings are for schematic diagram shown on back of sheet. Allow 10% + or - on all measurements. Always use meter scale which will give greatest deflection within scale limits. All measurements made with Weston Selective Analyzer No. 665, Type 1.
* 6.3 or zero volts, depending on twist of filament hook-up wire.

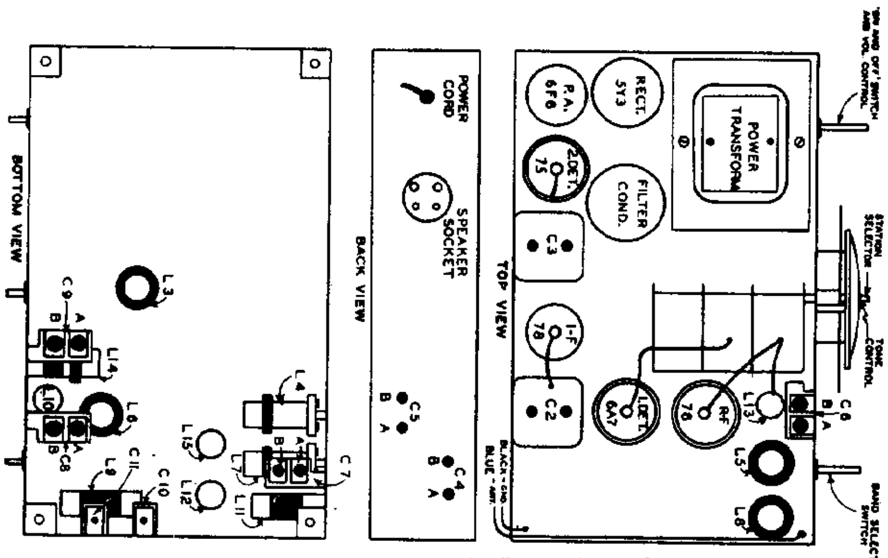

FIG. 17

Unless otherwise specified, the adjusting of any condenser consists of turning the adjusting screw or nut to the right or left until the output meter registers the greatest deflection.

1. EQUIPMENT REQUIRED

A. Modulated test oscillator (crystal controlled or accurately calibrated) capable of generating frequencies from 345 to 18,000 kilocycles (869.5 to 16.6 meters).

B. Output meter.

C. Part A-7615 adjusting screw driver.

D. Dummy antennas, consisting of a 150 mmf. condenser and a 400 ohm non-inductive resistor.

2. STEP BY STEP PROCEDURE

Note: For proper alignment of these chassis, the procedure should be followed in the same order as given.

In the following procedure, the long wave band will be termed Band No. 1; the broadcast band, Band No. 2; the first short-wave band, Band No. 3; the second short-wave band, Band No. 4; and the third short-wave band, Band No. 5. The dial pointer should be exactly parallel with the horizontal line of the kilocycle scale when the condenser plates are fully meshed. If the pointer does not read correctly, loosen the set screws in the large brass collar on the drive shaft, hold the rotor plates fully meshed with the stator plates and set the pointer so that it is parallel with the horizontal lines on the tuning scale, and then tighten the set screws.

A. Alignment of Intermediate-Frequency Stages.

(1) Turn on receiver and test oscillator and allow both to operate several minutes before attempting to adjust any condensers.

(2) Turn the band selector switch to the No. 2 (broadcast) position and turn the station selector knob until the rotor plates are completely out of mesh with the stator plates.

(3) Connect "antenna" of test oscillator to grid cap of Type 6A7 1st detector-oscillator tube and "ground" of test oscillator to chassis frame of receiver. Connect output meter "low tap" across voice coil of speaker (See Fig. 1, Page 1, Bulletin No. 3-E). Note: It is advisable to read carefully the operating instructions included with the test oscillator.

(4) Tune test oscillator to obtain a signal of 869.5 meters.

(5) Turn the volume control of receiver on full and adjust I.F. condensers C3 and C2 which are reached from the top of the chassis. (See Fig. 17.) Note: The intermediate frequency circuits are quite selective and extreme care must be taken to insure proper adjustment, otherwise the set will be weak on the high frequency bands.

B. Alignment of Broadcast Band

(1) Disconnect "antenna" lead of test oscillator from grid cap of 1st detector-oscillator tube and connect in series with a 150 mmf. condenser dummy antenna to the antenna terminal of the chassis.

(2) Tune the test oscillator and receiver to a wavelength of 222.1 meters and adjust condensers C4A, C8A and C5A.

(3) Tune test oscillator and receiver to 499.7 meters and adjust condenser C4B.

(4) Retune the receiver and test oscillator to 222.1 meters and make any necessary adjustments on condensers C4A, C8A and C5A.

(5) Calibration and sensitivity of the broadcast band should also be checked at 333.1 meters and 499.7 meters.

C. Alignment of Band No.

(1) Turn the band selector switch to Band No. 1 (long wave band).

(2) Tune test oscillator and receiver to a wavelength of 999.4 meters and adjust condensers C5A, C9A and C11.

(3) Tune test oscillator and receiver to a wavelength of 1999 meters and adjust condenser C5B.

(4) Retune test oscillator and receiver to 999.4 meters and retrim condensers C5A, C9A and C11.

(5) Calibration of this band should also be checked at 1739 meters.

D. Alignment of Band No.

(1) Turn the band selector switch to the No. 5 band and replace the 150 mmf. condenser dummy antenna with a 400 ohm non-inductive resistor dummy antenna.

(2) Tune the test oscillator and receiver to a wavelength of 16.6 meters and adjust condensers C9B and C8B.

(3) Calibration and sensitivity of this band should also be checked at 33.3 meters.

E. Alignment of Band No. 4

(1) Turn the band selector switch to Band No. 4 (third short-wave band).

(2) Tune test oscillator and receiver to a wavelength of 41.6 meters and adjust condensers C7B, C8B and C10.

(3) Calibration and sensitivity of this band should also be checked at a frequency of 83.3 meters.

F. Alignment of Band No. 3

(1) Turn the band selector switch to the 1st short-wave band.

(2) Tune test oscillator and receiver to a wavelength of 99.9 meters and adjust condenser C7A.

This band has no adjustable condensers for the antenna or R.F. circuits and no padder condenser for the oscillator circuit.

Sensitivity and calibration of this band should be also checked at 176.4 meters.

All adjustments should be re-checked to assure accuracy and stability of adjustment and calibration.

Warning: Extreme care must be taken when adjusting any of the short-wave bands so that the condensers are not adjusted to the image of the signal rather than the fundamental. The image signal is equal to the fundamental minus twice the intermediate frequency of the receiver. A set that is adjusted to the image frequency instead of to the fundamental may be detected by tuning over the band and checking the sensitivity at various points. If a dead spot appears near the center of the band, the adjustable condensers for that band have probably been adjusted to the image instead of the fundamental.

This type of mis-alignment may also be detected by tuning the test oscillator to a wavelength of 19.9 meters and the station selector to approximately 19.1 meters. If a strong signal is found approximately at this frequency, it indicates that the band has been adjusted to the image frequency. The normal image frequency for 19.9 meters would be 19.9 meters (15,000 k.c.) minus twice 345 kilocycles or approximately 20.9 meters. Therefore, a signal of this frequency may be found with the test oscillator generating a 19.9 meter signal.

MODELS 716X,766,766XP
766XS
MODELS 966,966X
Alignment,Trimmers

SPARKS WITHINGTON CO.

Foreword: Before attempting to realign the circuits of the above SPARTON Models, the serviceman should read carefully the information contained in Section 1 of Bulletin No. 3-E, pages 1 to 5 inclusive, especially the paragraphs pertaining to the use of a test oscillator, output meter, method of adjusting the various trimming and padding condensers and the bending of split condenser plate sections.

Unless otherwise specified, the adjusting of any condenser consists of turning the adjusting screw or nut to the right or left until the output meter registers the greatest deflection.

Alignment Instructions

1. EQUIPMENT REQUIRED

A. Modulated test oscillator (crystal controlled or accurately calibrated) capable of generating frequencies from 456 to 18,000 kilocycles.

B. Output meter.

C. Part A-5732 adjusting wrench.

D. Dummy antennas, consisting of a 150 mmf. condenser and a 400 ohm non-inductive resistor.

2. STEP BY STEP PROCEDURE

Note: For proper alignment of these chassis, the procedure should be followed in the same order as given.

In the following procedure, the broadcast band will be termed Band No. 1; the first short wave band (green section of the dial), Band No. 2; the second short wave band (red section of the dial), Band No. 3; the third short wave band (blue section of the dial), Band No. 4. The dial pointer should be exactly parallel with the horizontal line of the kilocycle scale when the condenser plates are fully meshed. If the pointer does not read correctly, loosen the set screws in the large brass collar directly between the dial lights, hold the rotor plates fully meshed with the stator plates and set the pointer so that it is parallel with the horizontal lines on the kilocycle scale, then tighten the set screws.

A. Alignment of Intermediate-Frequency Stages.

(1) Turn on receiver and test oscillator and allow both to operate several minutes before attempting to adjust any condensers.

(2) Turn the band selector switch to the No. 1 (broadcast) position and turn the station selector knob until the rotor plates are completely out of mesh with the stator plates.

(3) Connect "antenna" of test oscillator to grid cap of Type 6A7 1st detector-oscillator tube and "ground" of test oscillator to chassis frame of receiver. Connect output meter "low tap" across voice coil of speaker (See Fig.1) Note: It is advisable to read carefully the operating instructions included with the test oscillator.

(4) Tune test oscillator to obtain a signal of 456 kilocycles.

(5) Turn the volume control of receiver on full and adjust I.F. condensers C4, C3 and C2 which are reached from the top of the chassis. (See Fig's.) Note: The intermediate frequency circuits are quite selective and care must be taken to insure proper adjustment.

B. Alignment of Broadcast Band.

(1) Disconnect "antenna" lead of test oscillator from grid cap of first detector-oscillator tube and connect in series with a 150 mmf. condenser dummy antenna to the antenna terminal of the chassis.

(2) Tune test oscillator to obtain a signal of 1350 kilocycles.

(3) Turn the station selector of the receiver to 1350 kilocycles and without disturbing the setting of the test oscillator or the station selector, adjust condensers C5A, C7B and C9 in the order given.

(4) Tune test oscillator and receiver to 600 kilocycles and adjust condenser C5B, at the same time the station selector knob is moved back and forth to obtain maximum deflection of the output meter.

(5) Retune test oscillator and receiver to 1350 kilocycles and check the adjustments of condensers C5A, C7B and C9.

(6) Calibration of the broadcast band should also be checked at 900 kilocycles and 600 kilocycles.

C. Alignment of Band No. 4 (6.5 to 20 Megacycles).

(1) Turn the band selector switch to the third short wave band (blue section of the dial).

(2) Disconnect "antenna" lead of test oscillator from antenna terminal, remove the 150 mmf. condenser and replace with a 400 ohm non-inductive resistor dummy antenna and connect to grid cap of Type 78 (Type 6K7 in Model 966) R.F. tube.

(3) Tune test oscillator and receiver to 18 megacycles and adjust condenser C8 and condenser C7A.

CAUTION: On this band care must be taken to adjust the various condensers to the fundamental of the signal and not to the image. The image signal is equal to the fundamental minus twice the intermediate frequency of the receiver. A set that is adjusted to the image frequency instead of to the fundamental may be detected by tuning over the band and checking the sensitivity at various points. If a dead spot appears near the center of the band, the adjustable condensers for that band have probably been adjusted to the image instead of the fundamental.

This type of mis-alignment may also be detected by tuning the test oscillator to a frequency of 15 megacycles and the station selector to approximately 15,900 kilocycles. If a strong signal is found approximately at this frequency, it indicates that the band has been adjusted to the image frequency. The normal image frequency for 15,000 kilocycles would be 15,000 kilocycles minus twice 456 kilocycles or approximately 14,100 kilocycles. Therefore a signal of this frequency may be found with the test oscillator generating a 15,000 kil cycle signal.

(4) Disconnect the "antenna" of the test oscillator from the grid cap of the Type 78 (Type 6K7 in Model 966) R.F. tube and, using the 400 ohm resistor in series, connect to the antenna terminal.

(5) Adjust condenser C6A. Note: Due to the inter-action between the various circuits, it is necessary to move the station selector knob slightly while adjusting these trimmers in order to realize the maximum possible gain.

(6) Retune the test oscillator and receiver to 9 megacycles and check sensitivity and calibration.

D. Alignment of Band No. 3 (3.2 to 8.0 Megacycles).

(1) Turn the band selector switch to the second short wave band (red section of the dial).

(2) Tune test oscillator and receiver to 7.2 megacycles.

(3) Adjust condenser C11 and C6B.

(4) Tune test oscillator and receiver to 3.6 megacycles and check calibration and sensitivity.

E. Alignment of Band No. 2 (1.3 to 3.8 Megacycles).

Note: There are no adjustable condensers for this band. However, it is advisable to check the calibration of the dial and the general operation of the receiver at both 1.7 megacycles and 3 megacycles. CAUTION: All adjustments should be rechecked to assure accuracy and stability of adjustment and calibration.

The use of quality test equipment is highly recommended and a good test oscillator becomes a virtual necessity when aligning the all-wave or short-wave type of receiver. Due to the fact that the ear cannot distinguish small changes in sound intensity, an output meter is essential to the proper adjustment of the various condensers.

Notes: Voltage and resistance readings are for schematic diagram shown on back of sheet. Allow 15% + or - on all measurements. Always use meter scale which will give greatest deflection within scale limits. All measurements made with Weston Selective Analyzer No. 665. Type 2.

* Reading will be 6.3 or zero volts, depending on twist of filament hook-up wire.

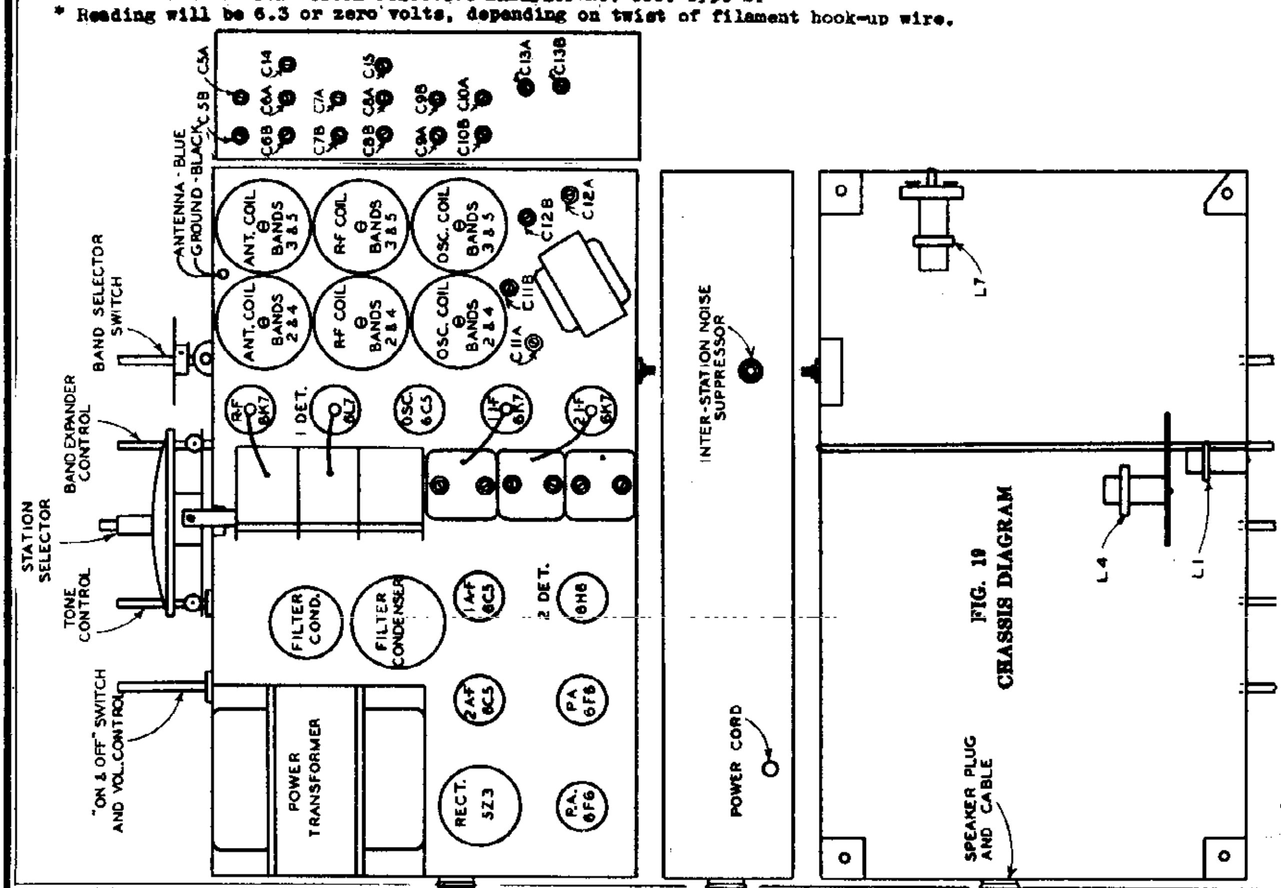

FIG. 19
CHASSIS DIAGRAM

SPARKS WITHINGTON CO.

The use of quality test equipment is highly recommended and a good test oscillator becomes a virtual necessity when aligning the all-wave type of receiver. Due to the fact that the ear cannot distinguish small changes in sound intensity, an output meter is essential to the proper adjustment of the various condensers.

Unless otherwise specified, the adjusting of any condenser consists of turning the adjusting screw or nut to the right or left until the output meter registers the greatest deflection.

1. EQUIPMENT REQUIRED

A. Modulated test oscillator (crystal controlled or accurately calibrated) capable of generating frequencies from 456 to 18,000 kilocycles (18 megacycles).

B. Output meter.

C. Part A-7612 adjusting wrench.

D. Dummy antenna, consisting of a 150 mmf. condenser and a 400 ohm non-inductive resistor.

2. STEP BY STEP PROCEDURE

Note: For proper alignment of these chassis, the procedure should be followed in the same order as given.

In the following procedure, the long wave band (brown section of the dial) will be termed Band No. 1; the broadcast band (black section of the dial), Band No. 2; the first short wave band (green section of the dial), Band No. 3; the second short wave band (red section of the dial), Band No. 4; and the third short wave band (blue section of the dial), Band No. 5.

meshed with the stator plates and set the pointer so that it is parallel with the horizontal lines on the kilocycle scale, and then tighten the set screws.

A. Alignment of Intermediate-Frequency Stages.

(1) Turn on receiver and test oscillator and allow both to operate several minutes before attempting to adjust any condensers.

Note: It is advisable to read carefully the operating instructions which accompany the test oscillator before proceeding with any alignment work.

(2) Turn the band selector switch to the No. 2 (broadcast) position and turn the station selector knob until the rotor plates are completely out of mesh with the stator plates.

(3) Connect "antenna" of test oscillator to grid cap of the Type 6L7 1st detector tube and "ground" of test-oscillator to chassis frame of receiver. Connect output meter "high tap" from plate of Type 6F6 tube in 11-tube sets or from plate of Type 6A6 in 14-tube sets, to ground. (See Fig. 1, Page 1, Bulletin No. S-R.)

(4) Tune test oscillator to obtain a signal of 456 kilocycles.

(5) Turn the volume control of the receiver on full and adjust I-F condensers C4, C7 and C8 in the order mentioned. (See Fig. 19). Note: The intermediate-frequency circuits are quite selective and extreme care must be taken to insure proper adjustment, otherwise the set will be weak on the high frequency bands.

Note: It is advisable to retard the inter-station noise suppressor so that the output of the receiver is reduced as the intermediate-frequency circuits are aligned, otherwise the set will be too sensitive to obtain an accurate reading on the output meter.

B. Alignment of Broadcast Band

(1) Disconnect "antenna" lead of oscillator from grid cap of Type 6L7 tube and connect in series with the 150 mmf. condenser dummy antenna to the antenna terminal of the chassis.

The dial pointer should be exactly parallel with the horizontal lines of the kilocycle scale when the condenser plates are fully meshed. If the pointer does not read correctly, loosen the set screws in the large brass collar on the drive shaft. hold the rotor plates fully

(2) Tune the test oscillator and receiver to a frequency of 1350 kilocycles and adjust condensers C9B, C7A and C5A.

(3) Tune test oscillator and receiver to a frequency of 600 kilocycles and adjust condenser C12B.

(4) Retune the receiver and test oscillator to 1350 kilocycles and make any necessary adjustments on condensers C9B, C7A and C5A.

(5) Calibration and sensitivity of the broadcast band should also be checked at 600 kilocycles, 900 kilocycles and 1350 kilocycles.

C. Alignment of Band No. 1

(1) Turn the band selector switch to Band No. 1 (orange band).

(2) Tune test oscillator and receiver to a frequency of 345 kilocycles and adjust condensers C13B, C15 and C14.

(3) Tune test oscillator and receiver to a frequency of 150 kilocycles and adjust condenser C13A.

(4) Retune test oscillator and receiver to 345 kilocycles and retrim condensers C13B, C15 and C14.

(5) Calibration and sensitivity of this band should also be checked at 150 kilocycles, 172.5 kilocycles and 345 kilocycles.

D. Alignment of Band No. 3

(1) Replace the 150 mmf. condenser dummy antenna with a 400 ohm non-inductive resistor dummy antenna.

(2) Turn the band selector switch to the No. 3 Band position (green section of the dial).

(3) Tune test oscillator and receiver to a frequency of 3 megacycles (3000 kilocycles) and adjust condensers C10A, C8A and C6A.

(4) Tune test oscillator and receiver to a frequency of 1.7 megacycles (1700 kilocycles) and adjust condenser C12A.

(5) Retune test oscillator and receiver to 3 megacycles and check the adjustment of the condensers C10A, C8A and C6A.

(6) Calibration and sensitivity of this band should also be checked at 1.7 megacycles and 3 megacycles.

E. Alignment of Band No. 4

(1) Turn the band selector switch to the No. 4 Band position (red section of the dial).

(2) Tune test oscillator and receiver to a frequency of 7.2 megacycles and adjust condensers C9A, C7B and C5B.

(3) Tune test oscillator and receiver to a frequency of 3.6 megacycles and adjust condenser C11B.

(4) Retune test oscillator and receiver to 7.2 megacycles and re-adjust condensers C9A, C7B and C5B.

(5) Calibration and sensitivity of this band should also be checked at 7.2 megacycles, 6 megacycles and 3.6 megacycles.

Warning: Extreme care must be taken when adjusting condenser C11B in order that adjustment is not made to the image of the signal rather than the fundamental. The image signal is equal to the fundamental minus twice the intermediate-frequency of the receiver. A set that is adjusted to the image frequency instead of the fundamental may be detected by tuning over the band and checking the sensitivity at various points. If a dead spot appears near the center of the band, the adjustable condensers for that band have probably been adjusted to the image instead of the fundamental.

This type of mis-alignment may also be detected by tuning the test oscillator to a frequency of 6 megacycles and the station selector to approximately 6900 kilocycles. If a strong signal is found approximately at this frequency, it indicates that the band has been adjusted to the image frequency. The normal image frequency for 6000 kilocycles would be 6000 kilocycles minus twice 456 kilocycles or approximately 5100 kilocycles. Therefore, a signal of this frequency may be found with a test oscillator generating a 6000 kilocycle signal.

F. Alignment of Band No. 5

(1) Turn the band selector switch to the last short wave band (No. 5 Band position).

(2) Tune test oscillator and receiver to a frequency of 18 megacycles and adjust condensers C10B, C8B and C6B.

(3) Tune test oscillator and receiver to a frequency of 9 megacycles and adjust condenser C11A.

(4) Retune test oscillator and receiver to 18 megacycles and re-check the adjustment of condensers C10B, C8B and C6B.

(5) Calibration and sensitivity of this band should also be checked at 9 megacycles, 12 megacycles and 18 megacycles.

Warning: This band, like Band No. 4, may easily be aligned to the image frequency instead of the fundamental. This may be checked by tuning the test oscillator to a frequency of 15 megacycles and the station selector to approximately 15900 kilocycles. If a strong signal is found approximately at this frequency, it indicates that the band has been adjusted to the image frequency. The normal frequency for 15 megacycles would be 15,000 kilocycles minus twice 456 kilocycles or approximately 14,100 kilocycles. Therefore, the signal of this frequency may be found with a test oscillator generating a 15 megacycle signal.

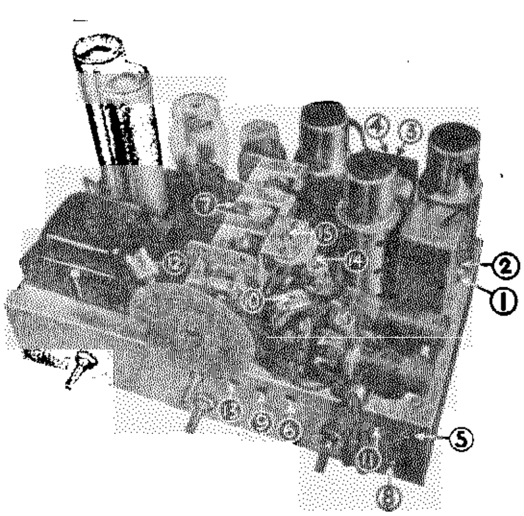
1. This checks dial position. Mesh condenser fully. Push condenser rotor with fingers to full mesh. Dial should read 53.
2. Connect 400 ohm 1 Watt resistor in series with signal generator lead to antenna.
3. Retune receiver and again readjust trimmers 6 and 7.
4. If there are two peaks -- the correct one is with the trimmer farthest out.
5. This is image signal. If trimmer 9 is correctly adjusted image will be heard. If not heard, repeat 4000 kc. adjustment.
6. This is image signal test. If signal is as strong or stronger than previous 4.0 mc. signal, trimmer 10 is not correctly adjusted. 3.1 mc. signal should be much weaker than 4.0 mc. signal when adjusting trimmer #10.
7. Two peaks possible. Correctly setting is with trimmer farthest out.
8. Image signal test. See item 5 except that test applies to adjustment of trimmer 11.
9. This is test similar to item #6 -- except that trimmer is #12.



*NOTE: This cut shows the R-127 A.C. operated chassis. Trimmer condensor locations are the same on the R-128-D with the exception of the 1st. I.F. trimmors. In the R-128-D the 1st I. F. is contained in a cylindrical can with the trimmors at the top.

On the R-128-D there are no elec-trolytic condensors and the "C" battery is mounted in the approximate position of the R-127 power transformer.

MODELS 1341 to 1340
Chassis R-134
Final schematic note
Trimmers, Alignment

The temporary schematic is the same as the final, except that the fixed condenser that is shunted across the Broadcast Osc. coil (upper coil in No.38) has a value of 11 mmf. The resistance of the speaker field (#11) is 1300 ohms warm.

ALIGNING EQUIPMENT

For the proper alignment of this receiver, an output meter and a high grade modulated service oscillator are essential.

The oscillator should be capable of generating the frequencies of 456 KC., 600 KC., 1400 KC. and a short-wave range extending to 6000 KC. The test oscillator calibration should be checked, using broadcast station signals as standards.

In order that alignment may be carried out without actuating the A.V.C. of the receiver, it must be possible to reduce the output of the test oscillator to a very low value.

For trimmer adjustment, it is advisable to use an all-bakelite screw driver, although one with a small metal tip may be used.

ALIGNING PROCEDURE

The step by step routine given below should be carefully followed. The trimmer numbers referred to are shown in the illustration.

ALIGNING THE I. F. CIRCUIT

1. (a) Connect the output meter across the primary of the output transformer (red and yellow lead terminals on the speaker terminal strip.)

(b) Turn the receiver volume control to maximum volume position.

(Note: The volume control should be kept in this position throughout the entire alignment procedure.) Ground the antenna lead to the chassis.

(c) Adjust the test oscillator to exactly 456 KC. and connect its output to the modulator grid of the 6A7 tube and the chassis.

(d) Adjust all four I.F. trimmers (trimmer groups 1 and 2) for maximum output as indicated on the output meter. Adjust the test oscillator output to give about one half full-scale deflection on the output meter.

(e) Repeat all four adjustments since the changing of each I.F. trimmer affects the others to a certain extent, thus necessitating readjustment.

BROADCAST RANGE CALIBRATION

If the set should require calibration, proceed as follows:

2. (a) Turn the gang condenser to full mesh and check to see that the dial pointer indicates 540 KC. If not, remove the dial glass and turn the pointer to the correct position.

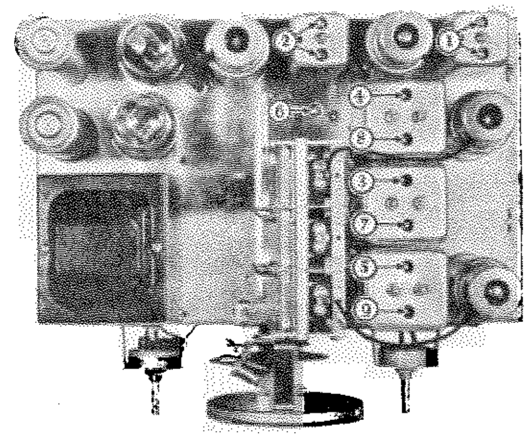
(b) Turn the range switch to the clockwise position.

(c) Connect a 400 or 500 ohm carbon resistor in series with the test oscillator output and the receiver antenna terminal, and connect the oscillator ground lead to the chassis.

(d) Adjust the test oscillator to 1400 KC.

(e) Turn the receiver dial pointer to indicate 1400 KC. on the dial.

(f) Adjust trimmer No. 3 (broadcast oscillator shunt trimmer) for maximum output without changing the setting of the main condenser. Maintain the level of the test oscillator output at a value which gives about one half full-scale deflection on the output meter.



BROADCAST RANGE ALIGNMENT

3. (a) Adjust the test oscillator to 1400 KC. and tune the receiver for maximum output.

(b) Adjust trimmers No. 4 and 5 (broadcast detector and antenna shunt trimmers respectively) for maximum output.

4. (a) Adjust the test oscillator to 600 KC. and tune the receiver to the signal.

(b) Adjust trimmer No. 6 (broadcast oscillator series padder) for maximum output.

(c) Retune the condenser gang to a peak and readjust trimmer No. 6 for maximum output.

(d) Continue to readjust trimmer No. 6 and retune until maximum output is obtained.

SHORT WAVE RANGE CALIBRATION

5. (a) Turn the receiver range switch to the counter-clockwise position.

(b) Adjust the test oscillator output to 6 MC.

(c) Turn the receiver dial pointer to indicate 6 MC. on the dial.

(d) Adjust trimmer No. 7 (short wave oscillator shunt trimmer) for maximum output.

(e) To check for possible adjustment of the receiver to the image frequency, turn the dial pointer to approximately 5.1 megacycles where a repeat signal should be heard. If no response is received here even with greatly increased test oscillator output, retune the dial pointer to 6 MC. and readjust trimmer No. 7 to a peak, with the trimmer screw farther out.

SHORT WAVE RANGE ALIGNMENT

1. Adjust the test oscillator to 6 MC. and carefully tune the receiver to the signal.

2. Adjust trimmers No. 8 and 9 (short wave detector and antenna shunt trimmers respectively) for maximum output.

MODELS 1361 to 1369
Chassis R-136

STEWART-WARNER CORP.

Final Schematic Note
Alignment, Changes
Chassis R-136P, R-136X
Phonograph Circuits

Stewart Warner R-136 Chassis Alignment

Connect the output indicator across the primary of the output transformer (red and yellow wires on the speaker terminal strip) located under the speaker field cover.

I-f. Alignment:

Turn volume control to maximum and keep it there for entire alignment procedure. Set test oscillator to 456 kc., the i-f. peak, and connect to the 6A8 control grid and the chassis. Adjust the four i-f. trimmers (shown at 1 and 2 on the chassis layout on *page 6-18 of Rider's Volume VI*) for maximum output deflection. Recheck the adjustments.

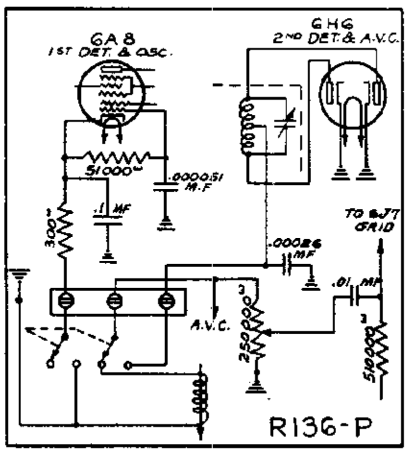
Broadcast Band Calibration:

Check position of dial pointer on shaft by turning the rotor plates to full mesh. The pointer should indicate 540 kc. Turn the range switch to extreme clockwise position. Connect the output of the test oscillator to the set's A and G terminals and ground both set and oscillator. Adjust test oscillator and dial to 1400 kc. Adjust trimmer No. 3 for maximum output without changing the setting of the condenser gang.

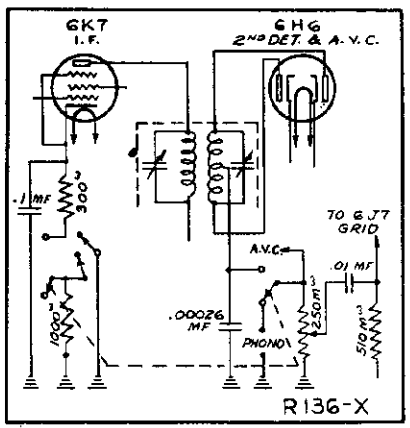
Broadcast Band Alignment:

Connect a 500-ohm carbon resistor in series with the test oscillator output and the set's antenna terminal and let it remain connected for the rest of the adjustments that are outlined below. Set oscillator at 1400 kc. and tune the receiver to the signal for maximum output. Adjust trimmers Nos. 4 and 5 for maximum output. Do not touch trimmer No. 3 as this will change calibration.

Adjust test oscillator to 600 kc. and tune set to this signal. Adjust trimmer No. 6 for maximum output. Retune gang condenser to a peak and readjust trimmer No. 6 for maximum output. Continue to do this until maximum output is obtained.



Schematic diagram of the Stewart Warner R-136-P chassis with phonograph pickup indicated.



The phonograph connections for the Stewart Warner chassis R-136-X.

First S-W. Band Calibration:

Turn range switch to center position. Adjust test oscillator to 5.5 mc. and set the set's dial to the same frequency. Adjust trimmer No. 7 for maximum output. If there are two peaks, the proper one is that with the trimmer screw farthest out.

First S-W. Band Alignment:

Set test oscillator to 5.5 mc. and tune receiver to maximum output. Adjust trimmers Nos. 8 and 9 for maximum output.

Second S-W. Band Calibration:

Be certain that the D to G connector on the receiver terminal strip is in place. Turn the range switch to the extreme counter-clockwise position. Adjust test oscillator to 16 mc. and the dial of the set to the same frequency.

Adjust trimmer No. 10 for maximum output. Check this by tuning the receiver to about 15.1 mc. If a repeat signal is not heard at this point, even with increased test oscillator output, retune the receiver to 16 mc. and adjust trimmer No. 10 to the proper peak with the screw farther out.

Second S-W. Band Alignment:

Adjust test oscillator to 16 mc. and tune set for maximum output. Adjust trimmers Nos. 11 and 12 for maximum output. Check to see if these trimmers are adjusted to the proper signal rather than the image, by tuning the set to approximately 15.1 mc. If the repeat signal is equal to or stronger than that at 16 mc., retune to 16 mc. and readjust Nos. 11 and 12 to the proper peak with the trimmer screws further in.

On *page 6-18 of Rider's Volume VI* appeared the temporary schematic of this chassis, which is used in Models 1361 to 1369 inclusive. The final diagram has now been released with the following changes:

Condenser No. 8, connected between the arm of the tone control and ground, was 0.015 mf. and is now 0.006 mf. The resistance of the tone control, No. 20, is 500,000 ohms.

Condenser No. 9, connected from the plate of the 6J7 to ground, has been changed from 0.00026 mf. to 0.00011 mf.

The left portion of tapped resistor No. 18 is 275 ohms and the right-hand part, that connected to ground, is 25 ohms.

The resistance of the volume control is 250,000 ohms. This is part No. 19A.

The notation was omitted from the diagram of voltages that the grid bias on the 6J7 tube is—1.7 volts, measured across the 25-ohm portion of resistor No. 18.

The resistance of the speaker field is 1300 ohms with the coil warm.

Chassis R137-P,R-137-X
Phonograph Circuits

STEWART-WARNER CORP.

MODELS 1371 to 1379
Chassis R-137
Final schematic note

The temporary schematic is the same as the final,except for the identification of the following condensers:
The fixed condenser shunting Osc.Coil 35 has a value of 0.000026 mf.
The fixed condenser shunting Osc.Coil 29 has a value of 0.000011 mf.
The resistance of the speaker field(#53) is 430 ohms,warm.

CALIBRATION AND ALIGNMENT

The following procedure on the proper adjustment of the **various trimmers** is divided into two classifications, calibration **and alignment.** Calibration is the adjustment of certain **trimmers so that** the radio signals can be received at the proper dial settings. Calibration of the R-137 is made at the high-frequency end of the dial. Alignment is the adjustment of trimmers so that the antenna and detector circuits are tuned to give maximum sensitivity and selectivity.

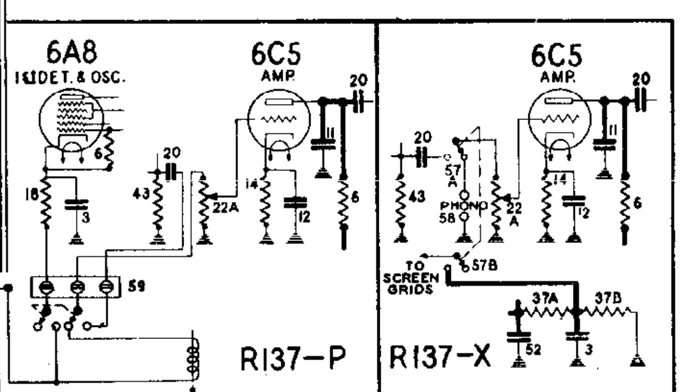
The R. F. calibration and alignment of each band is independent of all others, so that one band may be re-calibrated or re-aligned without affecting the trimmer adjustments on any of the other bands.

ALIGNMENT OF THE I. F. AMPLIFIER

1. (a) Turn the volume control to maximum volume position and keep it in this position throughout the entire alignment procedure.
(b) Connect the test oscillator output leads to the 6A8 control grid and the chassis, and set the test oscillator to exactly 456 KC. Adjust the output of the test oscillator to give about half of full scale deflection on the output meter.
(c) Adjust the four I. F. transformer trimmers (trimmer groups 1 and 2) for maximum output meter deflection.
(d) Repeat the four trimmer adjustments, since the adjustment of each trimmer has some effect on the others.

BAND NO. 1 (LONG WAVE) CALIBRATION

2. (a) Check the position of the dial pointer on its shaft by turning the rotor plates of the gang condenser to full mesh. The upper dial pointer should then coincide with the 540 KC. mark on the broadcast band scale. If it does not, hold the dial gear and turn the pointer to the correct position.
(b) Turn the range switch control to the extreme right position. (Clockwise)
(c) Connect a 400 or 500 ohm carbon resistor in series with the test oscillator output and the receiver antenna terminal (Note: This resistor should remain connected for all subsequent adjustments).
(d) Ground the receiver.
(e) Adjust the test oscillator to exactly 360 KC.
(f) Turn the receiver dial pointer to 360 KC. on the tuning dial.
(g) Adjust trimmer No. 3 for maximum output without changing the setting of the condenser gang.



PHONOGRAPH MODEL CIRCUITS

BAND NO. 1 (LONG WAVE) ALIGNMENT

3. (a) With the test oscillator set at 360 KC., tune the receiver to the signal for maximum output.
(b) Adjust trimmers No. 4 and No. 5 for maximum output. Do not touch trimmer No. 3 as this will change the calibration.
4. (a) Set the test oscillator to 180 KC. and tune the receiver to this signal.
(b) Adjust trimmer No. 6 for maximum output.
(c) Retune the set to get maximum output, and readjust trimmer No. 6 for maximum output. Continue to readjust trimmer No. 6 and retune until maximum output is obtained.

BAND NO. 2 (BROADCAST) CALIBRATION

5. (a) Turn the range switch control to the position second from the right.
(b) Adjust the test oscillator to exactly 1400 KC.
(c) Turn the receiver dial pointer to 1400 KC. on the tuning dial.
(d) Adjust trimmer No. 7 for maximum output without changing the setting of the condenser gang.

BAND NO. 2 (BROADCAST) ALIGNMENT

6. (a) With the test oscillator set at 1400 KC. tune the receiver to the signal for maximum output.
(b) Adjust trimmers No. 8 and 9 for maximum output.
Do not touch trimmer No. 7 as this will change the calibration.
7. (a) Adjust the test oscillator to 600 KC. and tune the receiver to this signal.
(b) Adjust trimmer No. 10 for maximum output.
(c) Retune the set and readjust trimmer No. 10 for maximum output. Continue to readjust trimmer No. 10 and retune until maximum output is obtained.

BAND NO. 3 CALIBRATION

8. (a) Turn the range switch control to the position third from the right.
(b) Adjust the test oscillator to 5.5 MC.
(c) Turn the receiver dial pointer to 5.5 MC. on the tuning dial.
(d) Adjust trimmer No. 11 for maximum output. If there are two peaks the proper one is that with the trimmer screw farthest out.

BAND NO. 3 ALIGNMENT

9. (a) With the test oscillator set at 5.5 megacycles, tune the receiver for maximum output.
(b) Adjust trimmers No. 12 and 13 for maximum output.

BAND NO. 4 CALIBRATION

10. (a) Be sure the D to G connector on the receiver terminal strip is in place.
(b) Turn the range switch control to the extreme left (counter-clockwise).
(c) Adjust the test oscillator to 16 MC.
(d) Turn the receiver dial pointer to 16 MC. on the tuning dial.
(e) Adjust trimmer No. 14 for maximum output. Check to see that it has been adjusted to the proper peak, by tuning the receiver to approximately 15.1 MC. If a repeat signal is not heard at this point, even with greatly increased oscillator output, retune the receiver to 16 MC. and adjust trimmer No. 14 to the proper peak with the trimmer screw farther out.

BAND NO. 4 ALIGNMENT

11. (a) Adjust the test oscillator to 16 MC.
(b) Tune the receiver for maximum output.
(c) Adjust trimmers No. 15 and 16 for maximum output.

CALIBRATION AND ALIGNMENT

The following procedure on the proper adjustment of the various trimmers is divided into two classifications, calibration and alignment. Calibration is the adjustment of certain trimmers so that the radio signals can be received at the proper dial settings. Calibration of the R-138 is made at the high-frequency end of the dial. Alignment is the adjustment of trimmers so that the antenna and detector circuits are tuned to give maximum sensitivity and selectivity.

The R.F. calibration and alignment of each band is independent of all others, so that one band may be re-calibrated or re-aligned without affecting the trimmer adjustments on any of the other bands.

ALIGNMENT OF THE I. F. AMPLIFIER

1. (a) Turn the volume control to maximum volume position and keep it in this position throughout the entire alignment procedure.

(b) Connect the test oscillator output leads to the 6A8 control grid and the chassis, and set the test oscillator to exactly 456 KC. Adjust the output of the test oscillator to give about half of full scale deflection on the output meter.

(c) Adjust the six I. F. transformer trimmers (trimmer groups 1, 2 and 3) for maximum output meter deflection.

(d) Repeat the six trimmer adjustments, since the adjustment of each trimmer has some effect on the others.

BAND NO. 1 (LONG WAVE) CALIBRATION

2. (a) Check the position of the dial pointer on its shaft by turning the rotor plates of the gang condenser to full mesh. The upper dial pointer should then coincide with the 540 KC. mark on the broadcast band scale. If it does not, hold the dial gear and turn the pointer to the correct position.

(b) Turn the range switch control to the extreme right position. (Clockwise)

(c) Connect a 400 or 500 ohm carbon resistor in series with the test oscillator output and the receiver antenna terminal (Note: this resistor should remain connected for all subsequent adjustments).

(d) Ground the receiver.

(e) Adjust the test oscillator to exactly 360 KC.

(f) Turn the receiver dial pointer to 360 KC. on the tuning dial.

(g) Adjust trimmer No. 4 for maximum output without changing the setting of the condenser gang.

BAND NO. 1 (LONG WAVE) ALIGNMENT

3. (a) With the test oscillator set at 360 KC., tune the receiver to the signal for maximum output.

(b) Adjust trimmers No. 5 and No. 6 for maximum output. Do not touch trimmer No. 4 as this will change the calibration.

4. (a) Set the test oscillator to 180 KC. and tune the receiver to this signal.

(b) Adjust trimmer No. 7 for maximum output.

(c) Retune the set to get maximum output, and readjust trimmer No. 7 for maximum output. Continue to readjust trimmer No. 7 and retune until maximum output is obtained.

BAND NO. 2 (BROADCAST) CALIBRATION

5. (a) Turn the range switch control to the position second from the right.

(b) Adjust the test oscillator to exactly 1400 KC.

(c) Turn the receiver dial pointer to 1400 KC. on the tuning dial.

(d) Adjust trimmer No. 8 for maximum output without changing the setting of the condenser gang.

BAND NO. 2 (BROADCAST) ALIGNMENT

6. (a) With the test oscillator set at 1400 KC. tune the receiver to the signal for maximum output.

(b) Adjust trimmers No. 9 and 10 for maximum output. Do not touch trimmer No. 8 as this will change the calibration.

7. (a) Adjust the test oscillator to 600 KC. and tune the receiver to this signal.

(b) Adjust trimmer No. 11 for maximum output.

(c) Retune the set and readjust trimmer No. 11 for maximum output. Continue to readjust trimmer No. 11 and retune until maximum output is obtained.

BAND NO. 3 CALIBRATION

8. (a) Turn the range switch control to the position third from the right.

(b) Adjust the test oscillator to 5.5 MC.

(c) Turn the receiver dial pointer to 5.5 MC. on the tuning dial.

(d) Adjust trimmer No. 12 for maximum output. If there are two peaks the proper one is that with the trimmer screw farthest out.

BAND NO. 3 ALIGNMENT

9. (a) With the test oscillator set at 5.5 MC., tune the receiver for maximum output.

(b) Adjust trimmers No. 13 and 14 for maximum output.

BAND NO. 4 CALIBRATION

10. (a) Be sure the D to G connector on the antenna terminal strip is in place.

(b) Turn the range switch control to the extreme left (counter-clockwise).

(c) Adjust the test oscillator to 16 MC.

(d) Turn the receiver dial pointer to 16 MC. on the tuning dial.

(e) Adjust trimmer No. 15 for maximum output. Check to see that it has been adjusted to the proper peak, by tuning the receiver to approximately 15.1 MC. If a repeat signal is not heard at this point, even with greatly increased oscillator output, retune the receiver to 16 MC. and adjust trimmer No. 15 to the proper peak with the trimmer screw farther out.

BAND NO. 4 ALIGNMENT

11. (a) Adjust the test oscillator to 16 MC.

(b) Tune the receiver for maximum output.

(c) Adjust trimmers No. 16 and 17 for maximum output.

The temporary schematic is the same as the final, except for the identification of the following condensers:
The fixed condenser shunting Osc. Coil 36 has a value of 0.000026 mf.
The fixed condenser shunting Osc. Coil 30 has a value of 0.000011 mf.
The resistance of the speaker field (59) is 430 ohms warm.

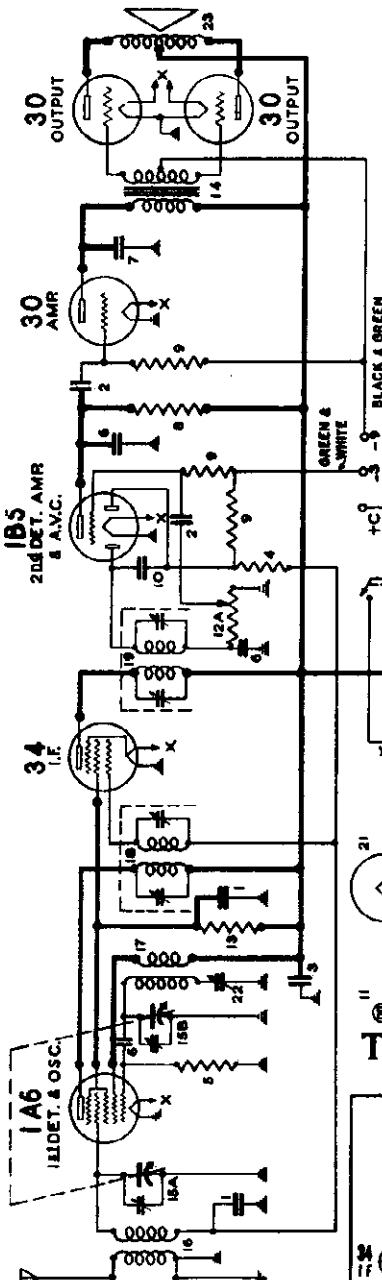
Alignment, Parts



DETECTOR AND OSCILLATOR CIRCUIT ALIGNMENT

1. Connect a 400 ohm carbon resistor in series with the test oscillator output and the blue antenna lead.
2. Set the test oscillator to 1400 kc. and tune the receiver for maximum output.
3. Adjust the broadcast detector shunt trimmer which is located on the top of the section of the condenser gang second from the front, for maximum output.
4. Set the test oscillator to 600 kc. and tune the receiver to the signal.
5. Adjust the oscillator padding trimmer, which is located in the front lower right-hand corner of the chassis, for maximum output.
6. Retune the condenser gang to a peak and readjust the padding trimmer for maximum output.
7. Keep on readjusting the padding trimmer and retuning until maximum output is obtained.

BATTERIES

Batteries required for operation consist of: 1. Either an Eveready air cell, a large 3 volt dry cell "A" pack, or a 2 volt storage battery. 2. Three 45 volt "B" batteries. 3. Two 4½ volt "C" batteries.

The function of the type 1G1 tube (No. 21 in the circuit diagram is to regulate the voltage applied to the filaments of the various tubes and to maintain it at the proper value throughout the life of the "A" battery. This tube is especially designed to meet the requirements of the receiver.

If an ordinary 2 volt lead storage cell is used for "A" supply, it is necessary that the regulator tube be removed and the two large socket contacts connected together with a short length of wire.

The two 4½ volt "C" batteries are essential to the proper operation of the receiver and for good "B" battery life.

If so desired, a combination "B" and "C" battery "plug in" pack, such as the Burgess G-90-D6, may be used with the R-139-D chassis. The "B" and "C" pack will fit into the console cabinet only, however.

To use the R-139-D chassis with the "B" and "C" pack, it is necessary that the regular battery cables be replaced with the special cables shown in the parts list and having the part numbers 85938 and 85939. These cables have the same color code as the regular cable and can be easily installed. When installing these cables, the green C+ lead is omitted since this connection is made inside the "B" and "C" unit.

ALIGNING THE I. F. CIRCUIT

1. Turn the receiver volume control to maximum position. (Note: The volume control should be kept in this position throughout the entire alignment procedure.) Ground the antenna lead to the chassis.
2. Adjust the test oscillator to 456 kc. and connect its output to the modulator grid of the 1A6 and the chassis.
3. Adjust all four I. F. trimmers located at the top of the I. F. transformers, for maximum output as indicated on the output meter. Adjust the test oscillator output to give about one half full scale deflection on the output meter. For trimmer adjustment, it is advisable to use an all-bakelite screw driver, although one with a small metal tip may be used.

No inward or sideward pressure should be applied to the alignment tool or the condenser may spring back to a different setting as soon as the tool is removed.

4. Go back and repeat all four adjustments since the changing of each I. F. trimmer affects the others to a certain extent, thus necessitating readjustment.

DIAL CALIBRATION

If the set should require calibration, proceed as follows:

1. Turn the gang condenser to full mesh and check to see that an indicator on a line directly above the control shaft indicates 540 kc. on the dial. If not, loosen the dial set screw and adjust the dial to the correct position.
2. Connect the test oscillator output to the receiver antenna lead and the chassis, and ground the chassis.
3. Adjust the test oscillator to 1400 kc.
4. Turn the receiver dial to 1400 kc.
5. Adjust the broadcast oscillator shunt trimmer located on the top of the gang condenser section closest to the front, for maximum output without changing the setting of the main condenser. Maintain the level of the test oscillator output at a value which gives about one half full scale deflection on the output meter.

NOTE: When a 2 volt storage cell is to be used for filament supply, remove the 1G1 voltage regulator and connect the large socket contacts with a short wire.

CIRCUIT DESCRIPTION

The R-139-D Battery Receiver is a seven tube superheterodyne with a tuning range from 540 to 1750 KC. which covers the broadcast and first police bands.

The R. F. signal picked up by the antenna is tuned and applied to the modulator grid of the type 1A6 tube, where frequency conversion to 456 KC. takes place. The 456 KC. signal is amplified in the I F. stage which employs a type 34 tube and is then passed on to the 1B5/25S combination second detector, amplifier and A. V. C. tube.

For A. V. C. action, a portion of the I. F. signal is passed from the second I. F. transformer secondary to one of the diode plates through a condenser (No. 10 in the diagram). Rectification takes place in the diode section and a D. C. potential is developed across the diode load resistor (No. 9 on the circuit diagram). This potential is applied through a resistance-capacity filter to the grid returns of the 1A6 and 34 tubes. A slight delay bias is obtained for the A.V.C. action by use of the diode plate which is closest to the positive leg of the filament.

Rectification of the signal takes place in the other diode section of the 1B5 tube also, and results in a modulated D. C. potential which develops across the volume control resistor (No. 12A in the circuit diagram). Any desired portion of the audio component of this voltage may then be applied to the grid of the triode section of the 1B5 where it is still further amplified. The triode is resistance coupled to the type 30 driver tube, which in turn is transformer coupled to two type 30 tubes operating in push-pull Class A prime.

Alignment, Parts

ALIGNING EQUIPMENT

For the proper alignment of this receiver, an output meter and a high grade modulated service oscillator are essential.

The oscillator should be capable of generating the frequencies of 456 KC., 600 KC., 1400 KC. and a short wave range extending to 4000 KC. The test oscillator calibration should be checked, using broadcast station signals as standards.

In order that alignment may be carried out without actuating the A.V.C. of the receiver, it must be possible to reduce the output of the test oscillator to a very low value.

ALIGNING PROCEDURE

The step by step routine given below should be carefully followed. The trimmer numbers referred to are shown in the illustration.

ALIGNING THE I. F. CIRCUIT

1. Connect the output meter between the plate of the 42 tube and the chassis through a .25 mfd. condenser or across the voice coil, depending on its type.
2. Turn the receiver volume control to maximum position. (Note: The volume control should be kept in this position throughout the entire alignment procedure.) Ground the antenna lead to the chassis.
3. Adjust the test oscillator to 456 KC. and connect its output to the modulator grid of the 6A7 tube and the chassis.
4. Adjust all four I.F. trimmers shown at 1 and 2, for maximum output as indicated on the output meter. Adjust the test oscillator output to give about one half full scale deflection on the output meter. For trimmer adjustment, it is advisable to use an all-bakelite screw driver, although one with a small metal tip may be used.

No inward or sideward pressure should be applied to the alignment tool or the condenser may spring back to a different setting as soon as the tool is removed.

5. Go back and repeat all four adjustments since the changing of each I. F. trimmer affects the others to a certain extent, thus necessitating readjustment.

BROADCAST RANGE CALIBRATION

If the set should require calibration, proceed as follows:

1. Turn the gang condenser to full mesh and check to see that the dial indicates 540 KC. If not, loosen the dial set screw and adjust the dial to the correct position.
2. Turn the range switch to the clockwise position.
3. Connect the test oscillator output to the receiver antenna lead and the chassis, and ground the chassis.
4. Adjust the test oscillator to 1400 KC.
5. Turn the receiver dial to 1400 KC.
6. Adjust trimmer No. 3 (broadcast oscillator shunt trimmer) for maximum output without changing the setting of the main condenser. Maintain the level of the test oscillator output at a value which gives about one half full scale deflection on the output meter.

BROADCAST RANGE ALIGNMENT

1. Connect a 500 ohm carbon resistor in series with the test oscillator output and the blue antenna lead.
2. Set the test oscillator to 1400 KC. and tune the receiver for maximum output.
3. Adjust trimmer No. 4 (broadcast detector shunt trimmer) for maximum output.
4. Set the test oscillator to 600 KC and tune the receiver to the signal.
5. Adjust trimmer No. 5 (broadcast oscillator series padder) for maximum output.
6. Retune the condenser gang to a peak and readjust trimmer No. 5 for maximum output.
7. Keep on readjusting trimmer No. 5 and retuning until maximum output is obtained.

SHORT WAVE RANGE CALIBRATION

1. Turn the receiver range switch to the counterclockwise position.
2. Adjust the test oscillator output to 4000 KC.
3. Set the receiver dial to 4000 KC.
4. Adjust trimmer No. 6 (short wave oscillator shunt trimmer) for maximum output.
5. To check for possible adjustment of the receiver to the image frequency, tune the dial to approximately 3.1 megacycles where a repeat signal should be heard. If no response is received here even with greatly increased test oscillator output, retune the dial to 4000 KC. and readjust trimmer No. 6 to a peak with the trimmer screw farther out.

SHORT WAVE RANGE ALIGNMENT

1. Connect a 500 ohm carbon resistor in series with the test oscillator output and the blue antenna lead.
2. Set the test oscillator for 4000 KC. and carefully tune the receiver to the signal.
3. Adjust trimmer No. 7 (short wave detector shunt trimmer) for maximum output.

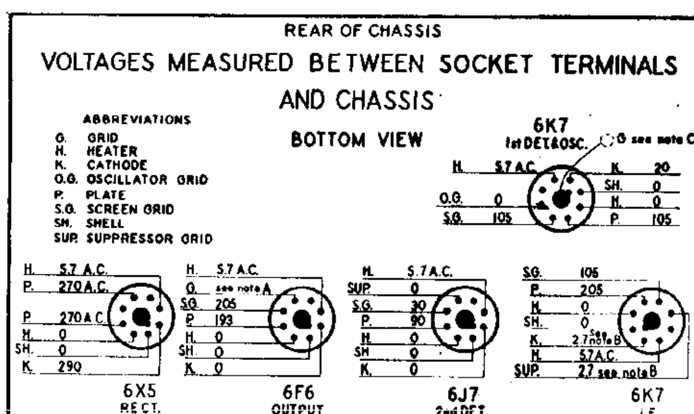
LINE VOLTAGE 115 VOLTS. VOLUME CONTROL ON FULL. ANTENNA GROUNDED
RANGE SWITCH SET ON BROADCAST POSITION. SET TUNED TO 530 KC.



IMPORTANT: Use a high resistance voltmeter of 1000 ohms per volt. Readings will vary depending upon voltage range of meter, being higher for higher range instruments. This variation is most marked for second detector plate voltage.

NOTE A: The bias on the 6F6 output is —14 volts measured across the flexible wire wound resistor No. 15 in the circuit diagram.

NOTE B: The cathode voltage varies with the setting of the volume control, from +2.5 volts for maximum volume to +30 volts for minimum volume.

NOTE C: Grid voltage for the 6K7 first detector is +17 volts measured across resistor No. 1 in the cathode circuit. Grid bias is —3 volts measured across resistor No. 12.

CIRCUIT DESCRIPTION

The Stewart-Warner chassis Models 142A and 142AS differ only in that the 142AS chassis includes a speaker that is mounted directly on the chassis.

These receivers use a superheterodyne circuit which employs five metal tubes. The intermediate frequency is 456 KC. The tuning range of these chassis includes, in addition to the standard broadcast band, the two police radio bands.

The signal picked up by the antenna is impressed on the primary of the antenna transformer, which has connected across it a wave trap for the purpose of eliminating 456 KC. interference. The signal is then tuned and impressed on the control grid of the 6K7 oscillator and first detector. The suppressor, or No. 3 grid of the 6K7, is used as the oscillator grid. The 456 KC. output of the first detector is amplified in the I. F. stage, using a 6K7 tube.

The second detector is of the grid leak-grid condenser type, and uses a 6J7 tube. The 6J7 is resistance coupled to the 6F6 pentode power amplifier. Bias for the output tube is obtained by grid return connection to the negative end of a resistor connected between the center tap of the power transformer high-voltage winding and ground. The bias potential so obtained is filtered by a resistance-capacity filter.

The volume control is double acting. It simultaneously changes the antenna signal input and the I. F. stage bias. Because of the sensitivity of this receiver, and due to the fact that it does not have A.V.C., it requires an antenna that is shorter than usual. The short antenna is particularly necessary where interference from powerful local stations is encountered, and where difficulty is experienced in properly controlling the volume.

When tuning on the short wave band, local broadcast stations can be heard in the background at their regular positions on the dial. This is a normal condition, and is due to the tapped coil method of tuning the antenna coil secondary to the short wave band. No aligning adjustments are required on the short wave band.

ALIGNING THE I.F. CIRCUIT

1. Connect the output meter in series with a .25 mfd. condenser between the plate of the 6F6 tube and ground, or across the voice coil, depending on the type of meter.
2. Turn the volume control to the maximum volume position. (Note: The volume control should be kept in this position throughout the entire alignment procedure.) Ground the antenna lead to the chassis.
3. Turn the range switch to the right (clockwise) to the broadcast position.
4. Adjust the test oscillator to exactly 456 KC. and connect its output to the control grid of the 6K7 first detector tube and the chassis.
5. Align I. F. trimmers No. 1, 2, 3 and 4 for maximum output as indicated on the output meter. No inward or sideward pressure should be applied to the alignment tool or the condenser may spring back to a different setting as soon as the tool is removed.
6. Repeat all I. F. trimmer adjustments since the changing of each trimmer will affect the others to a certain extent.

456 KC. WAVE TRAP ADJUSTMENT

1. Disconnect the antenna lead from ground.
2. Connect the test oscillator output in series with a 400 ohm carbon resistor to the receiver antenna lead, and connect the test oscillator ground lead to the receiver chassis. Ground the chassis.
3. Without changing the test oscillator from the frequency setting used in aligning the I. F. stage, adjust trimmer No. 5 for **MINIMUM** output. Increase the test oscillator output as a minimum is reached, in order to obtain a clearly defined setting of the trimmer. **NOTE:** If code interference is troublesome on a frequency in the neighborhood of 456 KC., the wave trap should be adjusted for **MINIMUM** output with the test oscillator set to the same frequency as the signal that is causing interference.

DIAL CALIBRATION

If the receiver should require calibration, proceed as follows:
1. Turn the gang condenser to full mesh and check to see that the dial pointer indicates 530 KC. If it does not, remove the dial knob and turn the pointer to the correct position by means of a sharp tool inserted in the pointer slots which may be reached through the dial glass. Replace the dial knob.
2. Adjust the test oscillator to 1400 KC.
3. Turn the condenser gang until the dial pointer indicates 1400 KC.
4. Adjust trimmer No. 6 (oscillator shunt trimmer) for maximum output without changing the setting of the gang condenser.

R. F. ALIGNMENT

1. Set the test oscillator to 1400 KC. and apply the signal to the receiver antenna lead through a 400 ohm carbon resistor.
2. Tune the receiver to the signal for maximum output.
3. Adjust trimmer No. 7 (detector shunt trimmer) for maximum output.

MODEL R-144AS CHASSIS (Receiver Models 1441 to 1449)

CIRCUIT DESCRIPTION

The Stewart-Warner chassis Model 144 includes a speaker that is mounted directly on the chassis.

This receiver uses a superheterodyne circuit which employs five tubes. The intermediate frequency is 456 KC. The tuning range of this chassis includes, in addition to the standard broadcast band, the two police radio bands.

The signal picked up by the antenna is impressed on the primary of the antenna transformer, which has connected across it a wave trap for the purpose of eliminating 456 KC. interference. The signal is then tuned and impressed on the control grid of the 6D6 oscillator and first detector. The suppressor, or No. 3 grid of the 6D6, is used as the oscillator grid. The 456 KC. output of the first detector is amplified in the I. F. stage, using a 6D6 tube.

The second detector is of the grid leak-grid condenser type, and uses a 6C6 tube. The 6C6 is resistance coupled to the 41 pentode power amplifier. Bias for the output tube is obtained by grid return connection to the negative end of a resistor connected between the center tap of the power transformer high-voltage winding and ground. The bias potential so obtained is filtered by a resistance-capacity filter.

The volume control is double acting. It simultaneously changes the antenna signal input and the I. F. stage bias. Because of the sensitivity of this receiver, and due to the fact that it does not have A.V.C., it requires an antenna that is shorter than usual. The short antenna is particularly necessary where interference from powerful local stations is encountered, and where difficulty is experienced in properly controlling the volume.

When tuning on the short wave band, local broad ast stations can be heard in the background at their regular positions on the dial. This is a normal condition, and is due to the tapped coil method of tuning the antenna coil secondary to the short wave band. No aligning adjustments are required on the short wave band.

ALIGNING EQUIPMENT

For proper alignment of this receiver, an output meter and a high grade modulated service oscillator are essential. The oscillator should be capable of generating the frequencies of 456 KC., 600 KC. and 1400 KC. The test oscillator calibration should be checked, using broadcast station signals as standards. For trimmer adjustment, it is advisable to use an all bakelite screwdriver, although one with a small metal tip may be used.

ALIGNING PROCEDURE

The step by step routine given below should be carefully followed. The trimmer numbers referred to are shown in the illustration.

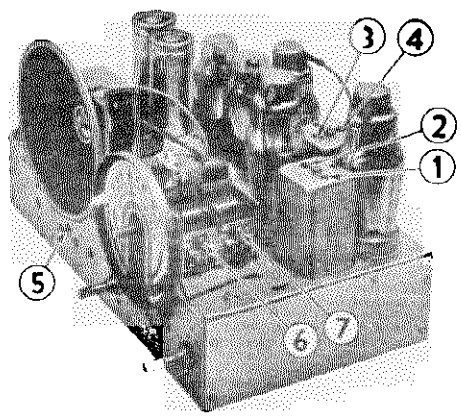
ALIGNING THE I.F. CIRCUIT

1. Connect the output meter in series with a .25 mfd. condenser between the plate of the 41 tube and ground, or across the voice coil, depending on the type of meter.
2. Turn the volume control to the maximum volume position. (Note: The volume control should be kept in this position throughout the entire alignment procedure.) Ground the antenna lead to the chassis.
3. Turn the range switch to the right (clockwise) to the broadcast position.
4. Adjust the test oscillator to exactly 456 KC. and connect its output in series with a .1 mfd. condenser to the control grid of the 6D6 first detector tube and the chassis.
5. Align I. F. trimmers No. 1, 2, 3 and 4 for maximum output as indicated on the output meter. No inward or sideward pressure should be applied to the alignment tool, or the condenser may spring back to a different setting as soon as the tool is removed.
6. Repeat all I. F. trimmer adjustments since the changing of each trimmer will affect the others to a certain extent.

Form 7666 Printed in U.S.A. 7-20-36

456 KC. WAVE TRAP ADJUSTMENT

1. Disconnect the antenna lead from ground.
2. Connect the test oscillator output in series with a .00025 mfd. condenser to the antenna lead, and connect the test oscillator ground lead to the receiver chassis. Ground the chassis.
3. Without changing the test oscillator from the frequency setting used in aligning the I. F. stage, adjust trimmer No. 5 for **MINIMUM** output. Increase the test oscillator output as a minimum is reached, in order to obtain a clearly defined setting of the trimmer. **NOTE:** If code interference transmitted on a frequency in the neighborhood of 456 KC. is troublesome, the wave trap should be adjusted for **MINIMUM** output with the test oscillator set to the same frequency as the signal that is causing interference.



DIAL CALIBRATION

If the receiver should require calibration, proceed as follows:

1. Turn the gang condenser to full mesh and check to see that the dial pointer indicates 530 KC. If it does not, remove the dial knob and turn the pointer to the correct position by means of a sharp tool inserted in the pointer slots which may be reached through the dial glass. Replace the dial knob.
2. Adjust the test oscillator to 1400 KC.
3. Turn the condenser gang until the dial pointer indicates 1400 KC.
4. Adjust trimmer No. 6 (oscillator shunt trimmer) for maximum output without changing the setting of the gang condenser.

R. F. ALIGNMENT

1. Set the test oscillator to 1400 KC. and apply the signal to the receiver antenna lead through a .00025 mfd. condenser.
2. Tune the receiver to the signal for maximum output.
3. Adjust trimmer No. 7 (detector shunt trimmer) for maximum output.

MODEL R-145 CHASSIS (Receiver Models 1451 to 1459)

CALIBRATION AND ALIGNMENT

ALIGNING EQUIPMENT: For proper alignment, an output meter and an accurately calibrated oscillator with a tuning range from 456 KC. to 16 MC. are required.

Connect the output meter from the plate of the output tube to chassis. A convenient point to make the plate connection is to the yellow wire on speaker socket.

ALIGNING THE I. F. AMPLIFIER: Turn the volume control to maximum volume position and keep it in this position throughout the entire alignment procedure. Turn the range switch to the broadcast position (fully clockwise).

Connect the test oscillator output leads to the 6A8 control grid and chassis with a **.1 mfd. condenser in series with the oscillator output.** Set the oscillator to exactly 456 KC. Set the receiver dial at any point where it has no tuning effect on the oscillator signal.

Adjust the four I.F. trimmers, Nos. 1, 2, 3 and 4, for maximum output meter deflection, then repeat the trimmer adjustment.

BROADCAST BAND CALIBRATION AND ALIGNMENT: With the gang condenser in full mesh, the dial pointer should be on the white horizontal line below 530 KC. on the dial scale.

Turn the range switch to the extreme clockwise position and connect the test oscillator output to the A and G terminals of the receiver with a 400 ohm carbon resistor in series with the A terminal and the oscillator output.

Adjust the test oscillator to exactly 1500 KC. and turn the receiver dial pointer to 1500 KC. on the tuning dial. To calibrate the dial, adjust trimmer No. 5 for maximum output.

Carefully tune the receiver to the signal and adjust trimmers Nos. 6 and 7 for maximum output.

Adjust the test oscillator to 600 KC. and tune the receiver to the signal. Adjust trimmer No. 8 for maximum output. Then try to increase the output meter reading by detuning No. 8 slightly and retuning the receiver dial. If the output goes down, detune the trimmer in the opposite direction. Continue detuning the trimmer and retuning the receiver dial until maximum output meter deflection is secured. This operation is commonly known as "rocking" and when performed as described will give maximum selectivity and sensitivity even though the dial may be slightly off calibration at 600 KC.

WAVE-TRAP ADJUSTMENT: (included only in chassis stamped "S"). The wave-trap adjusting trimmer, No. 13, is located on the back of the chassis. Leave the test oscillator connected to the A and G terminals through a 400 ohm resistor and set the oscillator at 456 KC. Then adjust the wave-trap trimmer No. 13 for **minimum** output. If some particular station with a frequency near 456 KC. causes code interference, it may be desirable to adjust the wave-trap on the actual frequency of the interfering station.

Check the adjustment of trimmers 5, 6, and 7 at 1500 KC.

BAND NO. 2 CALIBRATION AND ALIGNMENT: Turn the range switch to the center position.

Adjust the test oscillator to exactly 5.0 MC. and turn the receiver dial pointer to exactly 5.0 MC. on the tuning dial.

To calibrate the dial, adjust trimmer No. 9 for maximum output. If two peaks are found, the proper one is that with the trimmer screw farthest **out.**

Carefully tune the receiver to the signal and adjust trimmer No. 10 for maximum output. Then try to increase the output by detuning No. 10 slightly and retuning the receiver dial. Continue detuning No. 10 and retuning the dial until the output meter deflection is a maximum.

BAND NO. 3 CALIBRATION AND ALIGNMENT: Turn the range switch to the extreme counter-clockwise position. Be sure the D and G terminals on the antenna terminal strip are connected together.

Set the test oscillator to 16 MC. and turn the receiver dial pointer to exactly 16 MC. on the tuning dial.

To calibrate the dial, adjust trimmer No. 11 for maximum output. Check to see that it has been adjusted to the proper peak by tuning the receiver to approximately 15.1 MC. A repeat signal should be heard at this point. If none is present, even with greatly increased oscillator output, retune the receiver to 16 MC. and adjust trimmer No. 11 to the proper peak with the trimmer screw farther **out.**

Carefully tune the receiver to the signal and adjust trimmer No. 12 to a peak. Then try to increase the output by detuning the trimmer slightly and retuning the dial until a maximum output meter deflection is secured. Check the adjustment by tuning the receiver to the image at about 15.1 MC. The image should be much weaker than the 16 MC. signal. If the signal at 15.1 MC. dial setting is equal to or stronger than the 16 MC. signal, trimmer No. 12 is not set to the proper peak. Turn the trimmer in a turn or so, then readjust as above.

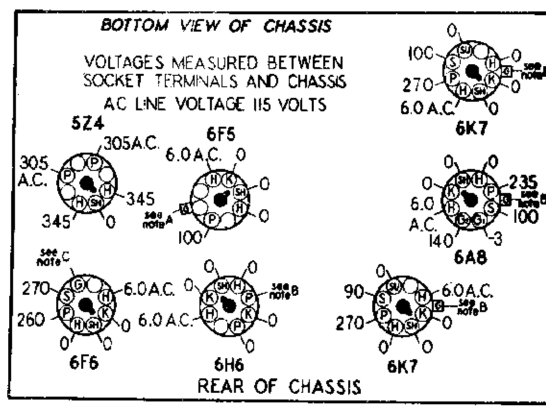
SOCKET VOLTAGES

RANGE SWITCH ON BROADCAST POSITION
VOLUME CONTROL ON FULL

DIAL TUNED TO 530 KC.
ANTENNA GROUNDED



IMPORTANT: Use a high resistance voltmeter of 1000 ohms per volt.

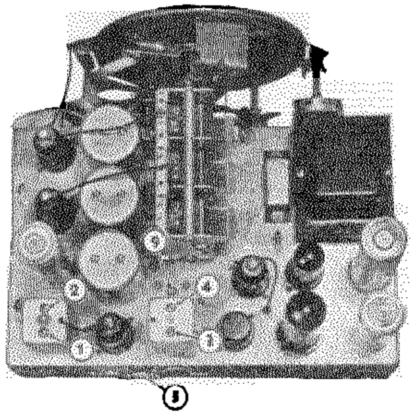
NOTE A: The grid bias for the 6F5 is −1.3 volts measured across resistor 60.

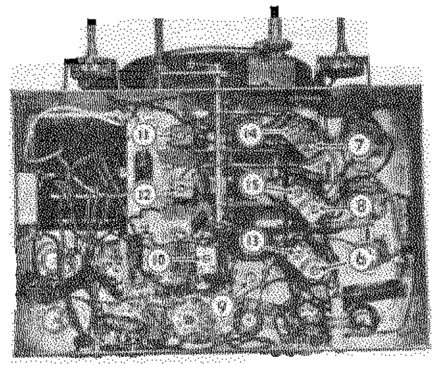
NOTE B: The grid bias for the 6A8, 6K7's, and the anode voltage of the A.V.C. section of the 6H6 is −3.0 volts measured across resistors 60 and 64.

NOTE C: The grid bias for the 6F6 output tube is −19.0 volts measured across resistor 59, 64 and 60.

MODEL R-146 CHASSIS (Receiver Models 1461 to 1469)

CALIBRATION AND ALIGNMENT





ALIGNING EQUIPMENT: For proper alignment, an output meter and an accurately calibrated oscillator with a tuning range from 456 KC. to 16 MC. are required.

Connect the output meter from the plate of the output tube to chassis. A convenient point to make the plate connection is to the yellow wire on speaker socket.

ALIGNING THE I. F. AMPLIFIER: Turn the volume control to maximum volume position and keep it in this position throughout the entire alignment procedure. Turn the range switch to the broadcast position (fully clockwise).

Connect the test oscillator output leads to the 6A8 control grid and chassis with a .1 mfd. condenser in series with the oscillator output. Set the oscillator to exactly 456 KC. Set the receiver dial at any point where it has no tuning effect on the oscillator signal.

Adjust the four I.F. trimmers, Nos. 1, 2, 3 and 4, for maximum output meter deflection, then repeat the trimmer adjustment.

WAVE-TRAP ADJUSTMENT: The wave-trap adjusting trimmer, No. 5, is located on the back of the chassis. Leave the test oscillator at 456 KC. Connect the oscillator output to the A and G terminals with a 400 ohm resistor in series with the A terminal and oscillator output. Then adjust the wave-trap trimmer No. 5 for minimum output. If some particular station with a frequency near 456 KC. causes code interference, it may be desirable to adjust the wave-trap on the actual frequency of the interfering station.

BROADCAST BAND CALIBRATION AND ALIGNMENT: With the gang condenser in full mesh, the dial pointer should be on the white horizontal line below 530 KC. on the dial scale. Leave the range switch in the extreme clockwise position, and leave the test oscillator connected to the A and G terminals of the receiver through a 400 ohm resistor.

Adjust the test oscillator to exactly 1500 KC. and turn the receiver dial pointer to 1500 KC. on the tuning dial. To calibrate the dial, adjust trimmer No. 6 for maximum output.

Carefully tune the receiver to the signal and adjust trimmers Nos. 7 and 8 for maximum output.

Adjust the test oscillator to 600 KC. and tune the receiver to the signal. Adjust trimmer No. 9 for maximum output. Then try to increase the output meter reading by detuning No. 9 slightly and retuning the receiver dial. If the output goes down, detune the trimmer in the opposite direction. Continue detuning the trimmer and retuning the receiver dial until maximum output meter deflection is secured. This operation is commonly known as "rocking" and when performed as described will give maximum selectivity and sensitivity even though the dial may be slightly off calibration at 600 KC.

BAND NO. 2 CALIBRATION AND ALIGNMENT: Turn the range switch to the center position.

Adjust the test oscillator to exactly 5.0 MC. and turn the receiver dial pointer to exactly 5.0 MC. on the tuning dial.

To calibrate the dial, adjust trimmer No. 10 for maximum output. If two peaks are found, the proper one is that with the trimmer screw farthest out.

Carefully tune the receiver to the signal and adjust trimmers Nos. 11 and 12 for maximum output. Then try to increase the output by detuning No. 12 slightly and retuning the receiver dial. Continue detuning No. 12 and retuning the dial until the output meter deflection is a maximum. Then readjust No. 11 for maximum output.

BAND NO. 3 CALIBRATION AND ALIGNMENT: Turn the range switch to the extreme counter-clockwise position. Be sure the D and G terminals on the antenna terminal strip are connected together.

Set the test oscillator to 16 MC. and turn the receiver dial pointer to exactly 16 MC. on the tuning dial.

To calibrate the dial, adjust trimmer No. 13 for maximum output. Check to see that it has been adjusted to the proper peak by tuning the receiver to approximately 15.1 MC. A repeat signal should be heard at this point. If none is present, even with greatly increased oscillator output, retune the receiver to 16 MC. and adjust trimmer No. 13 to the proper peak with the trimmer screw farther out.

Carefully tune the receiver to the signal and adjust trimmers Nos. 14 and 15 to a peak. Then try to increase the output by detuning No. 15 slightly and retuning the dial until a maximum output meter deflection is secured. Then readjust No. 14 for maximum output. Check the adjustment by tuning the receiver to the image at about 15.1 MC. The image should be much weaker than the 16 MC. signal. If the signal at 15.1 MC. dial setting is equal to or stronger than the 16 MC. signal, trimmer No. 15 is not set to the proper peak. Turn the trimmer in a turn or so, then readjust as above.

TRIMMER LOCATIONS

MODEL R-149 CHASSIS (Receiver Models 1491 to 149

CIRCUIT DESCRIPTION

The Stewart-Warner model R-149 chassis is a 12 tube, all-wave superheterodyne with an intermediate frequency of 456 kc. It has four tuning ranges which are 140 to 400 kc., 527 to 1750 kc., 1720 to 5600 kc., and 5.5 to 18.0 mc. Individual coils and trimmer condensers are provided for each band so that each circuit can be adjusted to give maximum efficiency on every frequency range.

The antenna coils are designed to give efficient reception with either a standard or doublet type antenna without the use of any additional coupling transformer. A small connector is provided on the antenna terminal strip to short the D and G terminals when a standard antenna is used. If a doublet antenna is used, the connector should be turned or removed to open the connection between the D and G terminals.

SELECTIVITY—SENSITIVITY SWITCH

Two degrees of selectivity are obtainable by means of the selectivity-sensitivity control operating on the first I. F. transformer. When the control is in the sharp position (counter-clockwise) the first I. F. transformer functions as a typical transformer with sharply tuned primary and secondary circuits. When it is in the broad position (clockwise) the resonant frequency of the primary is decreased and that of the secondary circuit increased. At the same time the selectivity curve of the secondary is broadened and the amplification reduced. The combined effect gives a broad flat top to the intermediate frequency amplifier selectivity curve.

AUTOMATIC VOLUME CONTROL

This chassis uses an amplified and dual A. V. C. action to keep the second detector signal more constant and still have sharp tuning. The diode of the 6H6 second detector tube which is capacity coupled to the second I. F. transformer, produces the A. V. C. voltage for the I. F. tube and the tuning eye only. The A. V. C. voltage for the R. F. and first detector tubes is secured by means of the 6J7 A. V. C. amplifier tube and the second 6H6 tube. The control grid of the 6J7 tube is capacity coupled to the control grid of the 6K7 first I. F. tube.

FIVE POINT TONE CONTROL

This control permits the following combinations of treble and bass response. No. 1 is with the switch in the extreme counter-clockwise position.

1. Minimum treble and emphasized bass.
2. Medium treble and emphasized bass.
3. Medium treble and normal bass.
4. Maximum treble and normal bass.
5. Maximum treble and emphasized bass.

CALIBRATION AND ALIGNMENT

Experience has definitely shown that a selective chassis such as the Stewart-Warner Model R-149 cannot be properly aligned by ear or "on the air." A high grade modulated service oscillator and an output meter are absolutely essential.

The oscillator should cover a frequency range extending from 175 KC. to 16,000 KC. It should have a wide range of signal output with a continuously variable output control. A very weak signal is needed for proper alignment without actuating the A. V. C. and a very strong one to align the A. V. C. channel and for use when the receiver is badly out of alignment.

PRECAUTIONS

During calibration and alignment, keep the receiver volume control in the maximum volume position if noise is not too great, and adjust the oscillator output so that the output meter reads near the center of its scale.

Use the lowest output meter scale that will provide a steady reading. For making trimmer adjustments, use a bakelite aligning tool which has only a small metal screwdriver tip.

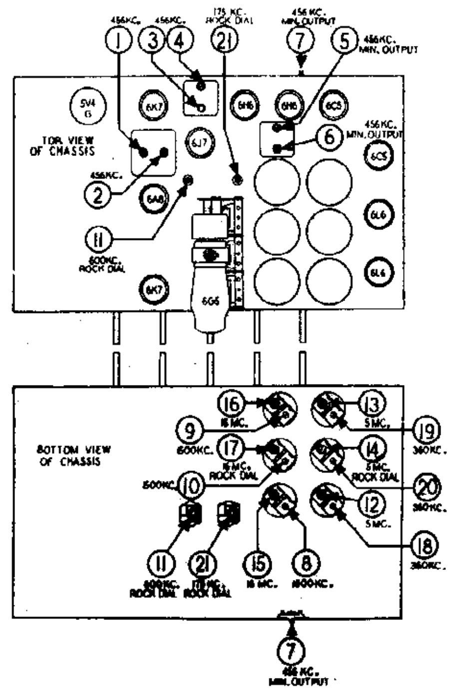
PRELIMINARY STEPS

Connect the output meter across the two plates of the two 6L6 power output tubes. **Important:** Do not connect from one 6L6 plate to chassis since this would unbalance the circuit and cause hum.

CALIBRATION AND ALIGNMENT

The following procedure on the proper adjustment of the various trimmers is divided into two classifications, calibration and alignment. Calibration is the adjustment of certain trimmers so that the radio signals can be received at the proper dial settings. Calibration of the R-149 is made at the high-frequency end of the dial. Alignment is the adjustment of trimmers so that the antenna and detector circuits are to give maximum sensitivity and selectivity.

The R. F. calibration and alignment of each band is pendent of all others, so that one band may be re-calib or re-aligned without affecting the trimmer adjustments of the other bands.



ALIGNMENT OF THE I. F. AMPLIFIER

1. (a) Turn the volume control to maximum volume tion and turn the sensitivity-selectivity control to the position (counter-clockwise).

(b) Turn the range switch to the broadcast position ond from the right) and set the tuning dial to any point v there is no tuning effect on the oscillator signal.

(c) Connect the test oscillator output leads to the 6A8 trol grid and the chassis with a .1 or .25 mfd. condens **series with the lead to the 6A8 grid. DO NOT OMIT CONDENSER OR ALIGNMENT WILL BE INCORRECT.**

(d) Set the test oscillator to exactly 456 KC. Adju output of the test oscillator to give about half scale defle on the output meter.

(e) Adjust the four I. F. transformer trimmers (trim No. 1, 2, 3 and 4) for maximum output meter deflectio

ALIGNMENT OF THE A. V. C. AMPLIFIER

2. (a) Leave the test oscillator set at 456 KC. and nected to the 6A8 control grid through a condenser.

(b) Turn the volume control down to protect the o meter and turn the output control of the oscillator up to enough signal so that the tuning eye closes more than way. If your oscillator cannot give this much 456 KC. ou the A. V. C. amplifier can be aligned immediately after pleting the Broadcast Alignment by means of a 1500 KC nal fed into the antenna terminal, with the receiver tun the signal.

(c) Readjust the volume control so that the output shows about half scale deflection.

(d) Adjust the two A. V. C. amplifier trimmers No. 6 for **minimum output meter deflection**. Readjust the vo control or oscillator output to the point necessary to a clearly defined point of minimum output when adjustin trimmers.

(e) Reduce the oscillator output to normal and turn volume control full on and repeat the adjustment of the trimmers as explained in 1 (a) to (e).

ADJUSTMENT OF WAVE TRAP

3. (a) Leave the test oscillator at 456 KC. but conne oscillator output to the A and G terminals of the receiver

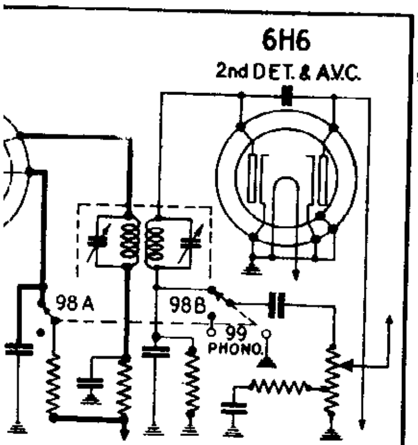
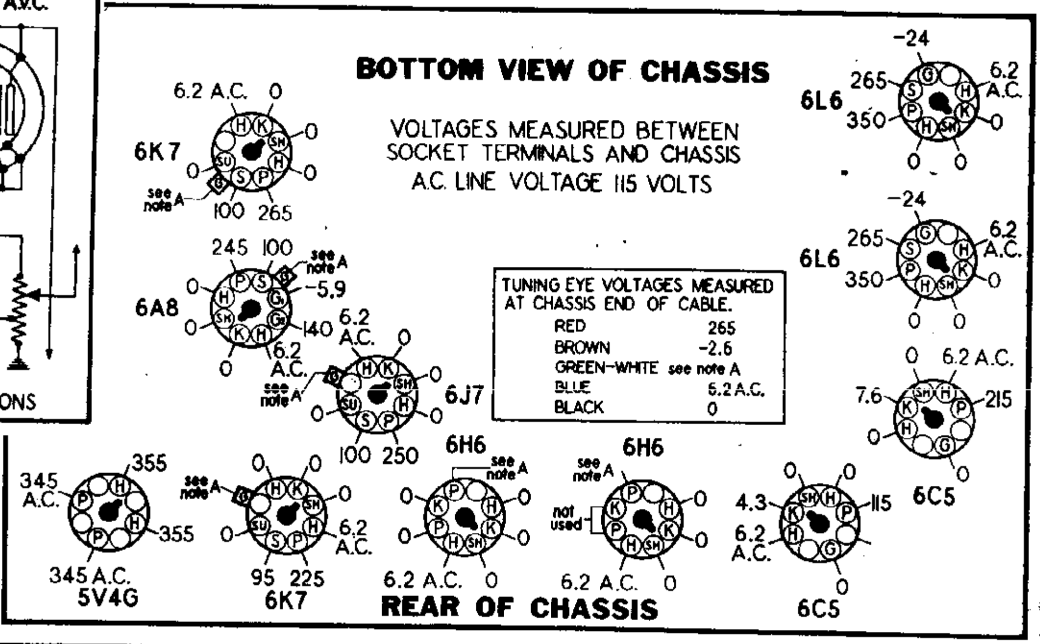
NOTE A: —2.6 volts measured across resistor 87.



149-X PHONOGRAPH CONNECTIONS



R-149 CHASSIS
1491 to 1499

a 400 or 500 ohm carbon resistor in series with the oscillator output and the A terminal.

(b) Adjust the wave trap trimmer No. 7 for **minimum** output. Increase the oscillator output as necessary to obtain a clearly defined point of minimum output. If some particular station with a frequency slightly different than 456 KC. causes code interference, it may be advisable to adjust trimmer No. 7 on the actual frequency of the interfering station.

BROADCAST BAND CALIBRATION

4. (a) Check the position of the dial pointer on its shaft by turning the tuning knob until the rotor plates of the gang condenser are in full mesh. The slow-moving dial pointer should then coincide with the low frequency end of the dial scale. If it does not, hold the dial gear and turn the pointer to the correct position.

(b) Turn the range switch control to the broadcast position (second from the right).

(c) Connect a 400 or 500 ohm carbon resistor in series with the test oscillator output and the receiver antenna terminal. Note: This resistor should remain connected for all subsequent adjustments.

(d) Ground the receiver.

(e) Adjust the test oscillator to exactly 1500 KC.

(f) Tune in the 1500 KC. oscillator signal or a station above 1300 KC. on the dial and determine whether the dial calibration is correct at the high frequency end of the dial. If the calibration is correct, do not adjust the broadcast oscillator shunt trimmer No. 8. If the calibration is incorrect, adjust trimmer No. 8 to give proper calibration.

BROADCAST BAND ALIGNMENT

5. (a) With the test oscillator set at 1500 KC. tune the receiver to the signal for maximum output and adjust the broadcast antenna and detector shunt trimmers No. 9 and 10 for maximum output. Do not touch the oscillator shunt trimmer No. 8 as this will change the calibration.

(b) Adjust the test oscillator to exactly 600 KC. and tune the receiver to the signal. Adjust the broadcast oscillator series padder No. 11 for maximum output. Then try to increase the output by detuning the padder and retuning the receiver dial. If this reduces the output, detune the padder on the opposite direction. Continue detuning the padder and retuning the dial until a maximum output meter deflection is secured. This operation is commonly known as "rocking." The object of this adjustment is to find the combination of padder adjustment and tuning condenser position which gives the maximum output. This adjustment should not be changed regardless of whether the dial reads exactly 600 KC. or slightly off 600 KC. for maximum output.

(c) Check the adjustment of trimmers No. 8, 9 and 10 at 1500 KC.

POLICE BAND CALIBRATION

6. (a) Turn the range switch to the Band No. 3 (green) position (second from the left).

(b) Adjust the test oscillator to exactly 5.0 megacycles.

(c) Tune in the 5 MC. oscillator signal at or near 5 MC. on the receiver dial to determine whether the receiver dial calibration is correct at 5 MC. If it is, do not adjust police band oscillator shunt trimmer No. 12. If the calibration is incorrect, set the dial pointer to 5 MC. on the dial, and adjust the oscillator shunt trimmer No. 12 until the oscillator signal comes in at this point. If there are two peaks, the proper one is that with the trimmer screw farthest out.

POLICE BAND ALIGNMENT

7. (a) With the test oscillator set at 5.0 MC. tune the receiver for maximum output.

(b) Adjust the police band antenna and detector trimmers No. 13 and 14 for maximum output. After this is done try to increase the output meter reading by detuning the detector trimmer No. 14 slightly and retuning the receiver dial. If the output goes down, detune the trimmer in the opposite direction. Continue detuning No. 14 and retuning the set until maximum output meter deflection is secured. Then readjust No. 13.

SHORT WAVE BAND CALIBRATION

8. (a) Turn the range switch to the extreme left (counter-clockwise).

(b) Be sure that the D and G terminals on the antenna terminal strip are connected together.

(c) Adjust the test oscillator to exactly 16 megacycles.

(d) Tune in the 16 MC. oscillator signal at or near 16 MC. on the receiver dial to determine whether the receiver dial calibration is correct at 16 MC. If it is, do not adjust the short wave band oscillator shunt trimmer No. 15. If the calibration is incorrect, set the receiver dial pointer exactly at 16 MC. and adjust the oscillator shunt trimmer No. 15 until the oscillator signal comes in at this point.

(e) Check to see that trimmer No. 15 is adjusted to the proper peak by tuning the receiver to approximately 15.1 MC. If a repeat signal is not heard at this point, even with greatly increased oscillator output, retune the receiver to 16.0 MC. and adjust trimmer No. 15 to the proper peak with the trimmer screw farther out.

SHORT WAVE BAND ALIGNMENT

9. (a) With the test oscillator set at 16 MC. tune the receiver for maximum output.

(b) Adjust the short wave antenna and detector trimmers No. 16 and 17 for maximum output. After this is done, try to increase the output meter deflection by detuning the detector trimmer No. 17 slightly and retuning the receiver dial. If this causes the output to drop, detune the trimmer in the opposite direction. Continue detuning No. 17 and retuning the set until the output is at a maximum. Then readjust No. 16.

(c) Check the adjustment of No. 17 by tuning the receiver to the image at 15.1 MC. and noting if the image is much weaker than the 16 MC. signal. If the signal at 15.1 MC. dial setting is equal to or stronger than the 16 MC. signal, trimmer No. 17 is not set to the proper peak. Turn the trimmer in a turn or so, then readjust as in 9 (b).

LONG WAVE BAND CALIBRATION

10. (a) Turn the range switch to the extreme right position (clockwise).

(b) Adjust the test oscillator to exactly 350 KC.

(c) Turn the receiver dial pointer to 350 KC. on the tuning dial and adjust the long wave band oscillator shunt trimmer No. 18 for maximum output.

LONG WAVE BAND ALIGNMENT

11. (a) With the test oscillator set at 350 KC., tune the receiver to the signal for maximum output.

(b) Adjust the antenna and detector trimmers No. 19 and 20 for maximum output. Do not touch the oscillator trimmer No. 18 as this will change the calibration.

(c) Adjust the test oscillator to exactly 175 KC. and tune the receiver to the signal. Adjust the long wave oscillator series padder No. 21 for maximum output, then try to increase the output by detuning the padder No. 21 and retuning the receiver dial.

(d) Repeat adjustments of trimmers No. 18, 19 and 20 a 350 KC.

MISCELLANEOUS PARTS

Part Number	DESCRIPTION	List Price
67667	Flat steel mtg. washer	$ .01
67977	No. 14 x 1¼ chassis mtg. screw	.02

APPARATUS SPECIFICATIONS

No. 80 Receiver........ 50-60 Cycles.................. P-25908 Chassis; P-25687 Loud Speaker

CIRCUIT DESCRIPTION

Nine tubes, A. C. operated, Superheterodyne receiver employing metal tubes and having three tuning ranges. These three tuning ranges cover all the important broadcasts and special service bands of both American and Foreign stations. These receivers are also equipped with a high fidelity control providing high fidelity reception by means of a special band widener device and a Carpinchoe high fidelity speaker. See P-25924 Installation and Operating Instructions, for properly installing and operating the No. 80 Receiver.

The various tubes in this receiver are used as follows: One of the No. 6K7 tubes functions as an R. F. Amplifier, another No. 6K7 tube is used in the I. F. Amplifier Stage, and the other No. 6K7 tube operates as an Audio Driver tube. The No. 6A8 tube is used as a Modulator. The No. 6J7 tube is used as the Oscillator tube. The No. 6H6 tube is used as a Demodulator-Automatic Volume Control tube. The audio power output stage uses the two No. 6F6 tubes, and the No. 5Z3 tube is used as the rectifier in the power supply unit.

P-25585	Transformer	Audio 2nd I. F.	1

Two dummy antennas are necessary. For most practical cases a 250-mmf. condenser connected in series with the high side of the signal generator can be used for the standard broadcast band. A suitable dummy antenna for the short-wave bands may consist of a small non-inductive carbon resistor of 400 ohms value; this latter dummy antenna replaces the former when making short-wave adjustments.

The locations of the various trimmers of the sets mentioned above will be found in the servicing data in Rider's Volume VI. *The i-f peak of each receiver is 465 kc.*

Always align either the r-f. or i-f. circuits (on those sets which are equipped with high-fidelity circuits and controls) with the high-fidelity control set at maximum counter-clockwise position (normal fidelity), unless the alignment is being checked at the high-fidelity setting as specified in the following instructions:

(The use of a cathode-ray oscillograph is recommended for alignment purposes by the manufacturer, although the instructions can be followed when a meter or glow type indicator is used.

Before proceeding with the alignment, connect the "high" terminal of the output indicator to the output of the demodulator circuit.

In Models 58 and 61, this connection should be made at the junction of R-15, R-18, and C-33.

In Models 62 and 63, this conneciton should be made at the junction of R-10, L-29, and C-37.

In Models 82 and 83, this connection should be made at the junction of R-12, L-29, and C-46.

In Model 84, this connection should be made at the junction of R-14, L-30, and C-47.

Connect the chassis to the other terminal of the indicator. Connect a 0.001-mf. condenser in series with the high side of the signal generator and the control grid of the 6K7 i-f. amplifier tube. Connect the other terminal of the signal generator to the chassis. Set the range switch of the set to the "A" band position and tune the set to highest frequency setting shown on the dial for this band. Tune the signal generator to 465 kc., the i-f. peak, and keep its output as low as consistent with proper output indications on either the oscillograph or meter.

Adjust the trimmers across the secondary and primary windings of the second i-f. transformer, in the order given, until maximum deflection is obtained on the output indicator.

Feed a frequency modulated signal to the same grid as stated above and adjust the trimmers for maximum output.

Change the input lead from the grid of the 6K7 tube to the control grid of the 6A8 modulator tube. Adjust the trimmers of the primary and secondary coils of the first i-f. transformer, adjusting the latter first for maximum output. Check the alignment of the second transformer and then recheck that of the first.

Check the alignment of the i-f. circuits with the fidelity control set at the maximum high fidelity position (maximum clockwise).

R-f. Circuits Alignment:

Have the On-Off switch set to "Off." (This switch is located in the rear of these chassis which have a "Q" circuit). On receivers equipped with a high-fidelity control, make sure that this is set for normal fidelity (maximum counter-clockwise). See that the tone control is at normal and that the volume control is set at maximum (maximum clockwise).

"A" Band Alignment:

Set range switch on chassis to "A" position. Set the receiver and the signal generator to the particular high-frequency setting called for in the table below, for this band, of the receiver being aligned. Adjust the shunt aligning condensers of the oscillator, r-f. amplifier, and antenna transformers in the order given until maximum output is obtained.

Set the receiver and signal generator to the particular low frequency called for in the table, and align only the oscillator by means of the oscillator series padder. *Align only the oscillator at this frequency.*

Recheck the adjustments of the shunt, trimmers of the oscillator, r-f. amplifier and antenna transformers.

"B" Band Alignment:

Operate the range switch on the chassis to the "B" position and align the oscillator, r-f. amplifier, and antenna transformers in the same manner as was done in the "A" band, using the frequencies listed in the table below under the "B" band.

"C" and "D" Bands Alignment:

Operate the range switch to the "C" band and follow the same procedure as in the "B" band. After this is completed, then change to the "D" band and follow the same procedure, using in each case the frequencies as set forth in the table below for the respective bands.

Models 58 and 61:

Band	High-Frequency Aligning Point	Aligning Frequency for Oscillator Series Padder
"A"	1400 kc.	600 kc.
"B"	3000 kc.	No Aligner
"C"	16 mc.	No Aligner

Align the bands in the following order: "C," "B" and then "A."

Models 62 and 63:

Band	High-Frequency Aligning Point	Aligning Frequency for Oscillator Series Padder
"A"	1500 kc.	600 kc.
"B"	5000 kc.	1800 kc.
"C"	16 mc.	No Aligner

Align the bands in the following order: "A," "B," and then "C."

CIRCUIT DESCRIPTION

Twelve tubes, A. C. operated, Deluxe High Fidelity, Superheterodyne receiver employing metal tubes and having four tuning ranges. These four tuning ranges cover all the important broadcasts and special service bands of both American and Foreign stations. High fidelity is obtained in this receiver by its design as a complete high quality reproducing system including the receiver chassis which has a special band widener device; a Carpinchoe high fidelity speaker and treatment of the enclosing cabinet by means of the new revolutionary Stromberg-Carlson development for a sound reproducing system. This new device, the Acoustical Labyrinth (patent applied for) extends the bass response, provides reproduction only from the front of the cabinet and eliminates all cabinet resonance. Audio reproduction is further improved by employing sound diffusing vanes in front of the loud speaker opening which breaks up the directional high frequencies, thereby providing excellent reproduction in all parts of the room by spreading out these directional frequencies. See P-25826 Installation and Operating Instructions, for properly installing and operating this receiver.

The tubes used in this receiver are as follows: One No. 6K7 tube functions as an R. F. Amplifier, another No. 6K7 tube is used in the I. F. Amplifier Stage and the other No. 6K7 tube operates in the First Audio Stage. The No. 6A8 tube is used as the Modulator tube. The No. 6C5 tube is used as the Oscillator tube. The No. 6H6 tube is used as a Demodulator-Automatic Volume Control tube. The No. 6J7 tube is used in the Interstation Noise Suppressing (Q) Circuit. Two of the No. 6F6 tubes are connected in parallel and operate as the Audio Drive tubes. The other two No. 6F6 tubes operate in push-pull in the audio power output stage. The No. 5Z3 tube is the rectifier tube of the power supply unit.

STROMBERG-CARLSON TEL. MFG. CO.

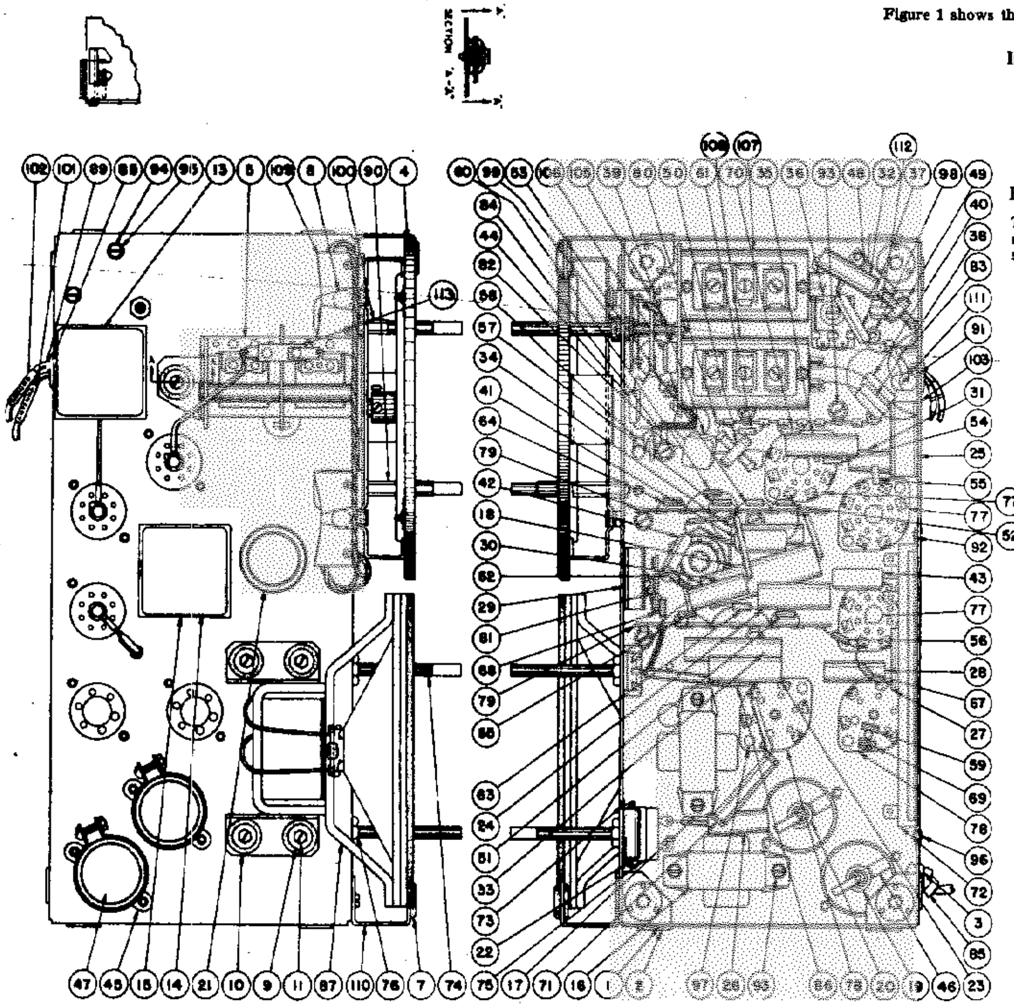
CIRCUIT DESCRIPTION

This triple range, superheterodyne receiver has five tubes and may be operated on a power supply circuit of either alternating or direct current at the voltages and frequency (for A. C. operation) specified above.

The various tubes are used in this receiver as follows: One No. 6A8 tube functions as both Oscillator and Modulator; one No. 6K7 tube is used in the I. F. Amplifier; the No. 6Q7 tube is used as the Demodulator, A. V. C. and Audio Amplifier tube. The No. 43 tube is used in the Audio Power Output stage, and the No. 25Z5 tube is used as the Rectifier tube for the receiver "B" voltage supply.



ALIGNMENT DATA

All alignment adjustments are accurately made at the factory on these receivers and ordinarily no re-adjustments are necessary. However, should it become necessary to make any readjustments, this alignment procedure should be carefully followed.

In making any alignment adjustments always adjust the signal generator's output to the minimum value where a good alignment may still be obtained. Never attempt to make any alignment adjustments using a strong signal.

Figure 1 shows the location of all the aligning capacitors used in this receiver.

Intermediate Frequency Adjustments

The intermediate frequency used in these receivers is 465 kilocycles. In making these I. F. circuit adjustments always align in the following order:

1. Secondary of 2nd I. F. Transformer (Capacitor C-10).
2. Primary of 2nd I. F. Transformer (Capacitor C-9).
3. Secondary of 1st I. F. Transformer (Capacitor C-8).
4. Primary of 1st I. F. Transformer (Capacitor C-7).

Radio Frequency Adjustments

The adjustments of the aligning capacitors used in the radio frequency circuits in this receiver should be very carefully made in the following order and at the frequencies specified below:

1. Oscillator's "C" Band Shunt Aligner at 17 Megacycles (Capacitor C-4).
2. Antenna "C" Band Shunt Aligner at 17 Megacycles (Capacitor C-1).
3. Oscillator's "B" Band Shunt Aligner at 3.4 Megacycles (Capacitor C-5).
4. Antenna "B" Band Shunt Aligner at 3.4 Megacycles (Capacitor C-2).
5. Oscillator's "A" Band Shunt Aligner at 1400 Kilocycles (Capacitor C-6).
6. Antenna "A" Band Shunt Aligner at 1400 Kilocycles (Capacitor C-3).
7. Oscillator's "A" Band Series Aligner at 600 Kilocycles (Capacitor (36)
8. Oscillator's "A" Band Shunt Aligner at 1400 Kilocycles (Capacitor C-6).
9. Antenna "A" Band Shunt Aligner at 1400 Kilocycles (Capacitor C-3).

ALIGNMENT DATA

All alignment adjustments are accurately made at the factory on these receivers and ordinarily no readjustments are necessary. However, should it become necessary to make any readjustments, this alignment procedure should be carefully followed.

In making any alignment adjustments always adjust the signal generator's output to the minimum value where a good alignment may still be obtained. Never attempt to make any alignment adjustments using a strong signal.

Figure 2 shows the location of all the aligning capacitors used in this receiver.

Intermediate Frequency Amplifier Adjustments

The intermediate frequency used in these receivers is 465 kilocycles. In making these I. F. circuit adjustments always align in the following order:

1. Secondary of 2nd I. F. Transformer (Capacitor C-13).
2. Primary of 2nd I. F. Transformer (Capacitor C-12).
3. Secondary of 1st I. F. Transformer (Capacitor C-11).
4. Primary of 1st I. F. Transformer (Capacitor C-10).

Radio Frequency Adjustments

The adjustments of the aligning capacitors used in the radio frequency circuits in this receiver should be very carefully made in the following order and at the frequencies specified below:

1. Oscillator's "C" Band Shunt Aligner at 17 Megacycles (Capacitor C-7).
2. R. F. Interstage "C" Band Shunt Aligner at 17 Megacycles (Capacitor C-6).
3. Antenna "C" Band Shunt Aligner at 17 Megacycles (Capacitor C-3).
4. Oscillator's "B" Band Shunt Aligner at 3.4 Megacycles (Capacitor C-8).
5. R. F. Interstage "B" Band Shunt Aligner at 3.4 Megacycles (Capacitor C-5).
6. Antenna "B" Band Shunt Aligner at 3.4 Megacycles (Capacitor C-2).
7. Oscillator's "A" Band Shunt Aligner at 1.4 Megacycles (Capacitor C-9).
8. R. F. Interstage "A" Band Shunt Aligner at 1.4 Megacycles (Capacitor C-4).
9. Antenna "A" Band Shunt Aligner at 1.4 Megacycles (Capacitor C-1).
10. Oscillator's "A" Band Series Aligner at 0.6 Megacycles (Capacitor (23)).
11. Oscillator's "A" Band Shunt Aligner at 1.4 Megacycles (Capacitor C-9).
12. R. F. Interstage "A" Band Shunt Aligner at 1.4 Megacycles (Capacitor C-4).
13. Antenna "A" Band Shunt Aligner at 1.4 Megacycles (Capacitor C-1).

CIRCUIT DESCRIPTION

The No. 130 Series of Radio Receivers are divided into two groups; the Nos. 130-U, 130-H, and 130-L are seven tube receivers and are not equipped with the "Tri-Focal Tuning System". The Nos. 130-M and 130-R are eight tube receivers and are equipped with the exclusive Stromberg-Carlson "Tri-Focal Tuning System". A socket is provided on the rear of the chassis for making connections between the tuning indicator and receiver circuits. The chassis used in these different models of No. 130 Receivers are identical.

These No. 130 Receivers are composed of a seven tube chassis employing metal tubes, and have three tuning ranges. In order to obtain maximum performance from these receivers, a sensitivity control is provided for use on the standard broadcast band only. Its control knob is located on the rear of the chassis base. When either the "B" or "C" ranges are in operation, this sensitivity control is automatically cut out of the circuit so that the receiver will function at its maximum sensitivity on these two ranges. In some localities it will be found that without the use of this control, it will be impossible to eliminate adjacent channel interference. When this condition is obtained, the receiver should be tuned accurately to the desired station, and this sensitivity control adjusted so that minimum interference is obtained from the interfering station. See Figure.1.

The various tubes are used in these receivers as follows: One No. 6K7 tube is used in the R. F. Amplifier, and the other No. 6K7 is used in the I. F. Amplifier. The No. 6A8 tube functions as both Oscillator and Modulator tube. The No. 6H6 tube is used as a Demodulator and Automatic Volume Control tube. The No. 6F5 tube is used in the Audio Frequency Amplifier Stage (Driver), and the No. 6F6 tube is used in the Audio Power Output Stage. The No. 80 tube is the Rectifier tube of the power supply unit. In the Nos. 130-M and 130-R Receivers the No. 6E5 tube is used as the indicator of the Tri-Focal Tuning System.

CIRCUIT DESCRIPTION

The No. 145 Radio Receiver is a ten tube, "Adjustable High Fidelity" receiver employing metal tubes including the new "Beam" power tubes. This receiver uses a Carpinchoe high fidelity dynamic speaker, and has incorporated in it the exclusive "Patent Applied For", Stromberg-Carlson "Tri-Focal" tuning system and the exclusive Stromberg-Carlson Acoustical Laboratories' revolutionary new development, the "Acoustical Labyrinth". This new device extends the bass response, provides reproduction only from the front of the cabinet, and eliminates all cabinet resonance. Audio reproduction is further improved in this receiver by employing sound diffusing vanes in front of the loud speaker opening which distribute the higher pitched tones, thereby providing excellent reproduction in all parts of the room by spreading out these directional frequencies.

Maximum selectivity between adjacent stations located in the standard broadcast band is obtained by the use of an additional tuned radio frequency ("Bi-resonator") circuit. When either the "X", "B", or "C" ranges are in operation, this additional tuned radio frequency circuit is automatically cut out of the receiver circuit. Adjustable high fidelity is obtained from this receiver by means of the variable band width, intermediate frequency transformers which are used in the two intermediate amplifier stages.

The various tubes are used in this receiver as follows: One No. 6K7 tube is used in the R. F. Amplifier, and the other two No. 6K7 tubes are used in the First and Second I. F. Amplifier Stages. The No. 6A8 tube is used as the Modulator tube, and the No. 6J7 tube is used as the Oscillator tube. The No. 6Q7 tube is used as the Demodulator, Automatic Volume Control, and Audio Amplifier tube. The two No. 6L6 tubes are used in the Audio Power Output Stage. The No. 6E5 tube is used as the Indicator of the "Tri-Focal Tuning System", and the No. 5Z3 tube is the Rectifier tube of the Power Supply Unit.

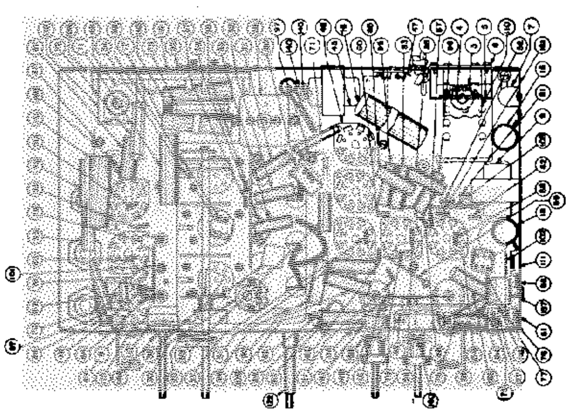
Voltage across vernier dial pilot lamp—*5.3* volts
Receiver tuned to 1000 Kc., no signal. A. C. voltages are indicated by italics.



ALIGNMENT DATA

All alignment-adjustments are accurately made at the factory on this receiver, and ordinarily no readjustments are necessary. However, should it become necessary to make any readjustments, this alignment procedure should be carefully followed.

In making any alignment adjustments always adjust the signal generator's output to the minimum value where a good alignment may still be obtained. Never attempt to make any alignment adjustments using a strong signal.

Figure 1 shows the location of all the aligning capacitors used in this receiver.

Intermediate Frequency Amplifier Adjustments

Because of the necessity of obtaining the proper shape of resonance curve of these stages in a high fidelity receiver, it is recommended that unless it is absolutely essential, these I. F. adjustments be untouched. In the factory these adjustments are made using a visual system which allows the operator to see the exact shape of the resonance curve. For this reason it is best to have these adjustments made at the factory. However, in the case where this cannot be done, the following procedure should be followed.

Operate the range switch of the receiver to the "A" range position. Set the tuning dial at its extreme low frequency position, and operate the "Tone-Fidelity" control knob so that the receiver is adjusted for the standard fidelity position as indicated by the fidelity indicator located on the front panel of the receiver. **Never attempt to align the I. F. circuits of this receiver with the "Tone-Fidelity" control set at any position other than the standard fidelity.** The I. F. circuits may then be checked for alignment by adjusting the aligning capacitors in the exact order as follows:

1. Secondary of 3rd I. F. Transformer (Capacitor C-18).
2. Primary of 3rd I. F. Transformer (Capacitor C-17).
3. Secondary of 2nd I. F. Transformer (Capacitor C-16).
4. Primary of 2nd I. F. Transformer (Capacitor C-15).
5. Secondary of 1st I. F. Transformer (Capacitor C-14).
6. Primary of 1st I. F. Transformer (Capacitor C-13).

Radio Frequency Adjustments

The alignment of the radio frequency circuits for the various ranges in this receiver should be very carefully made in the order and at the frequencies specified.

It will be noted that no instructions are given for aligning the receiver at other than two frequencies for any range. Each receiver is given an ex.cting check for "tracking" at various frequencies in each range before leaving the factory. It is felt by the manufacturers that should any receiver through accident require a check on the "tracking", it should be returned to the factory, where this may be easily and accurately done.

Alignment of Long-Wave-Weather Range (Also Referred to as "X" Band) Circuits

1. Oscillator's "X" Band Shunt Aligning Capacitor at 350 Kilocycles (Capacitor C-12).
2. R. F. Interstage "X" Band Shunt Aligning Capacitor at 350 Kilocycles (Capacitor C-8).
3. Antenna "X" Band Shunt Aligning Capacitor at 350 Kilocycles (Capacitor C-4).
4. Oscillator "X" Band Series Aligning Capacitor at 150 Kilocycles (Capacitor Item 112). When operation No. 4 has been completed repeat operations 1, 2, and 3 again and in the exact order given.

Alignment of Standard Broadcast Range (Also Referred to as "A" Band) Circuits

1. Oscillator's "A" Band Shunt Aligning Capacitor at 1500 Kilocycles (Capacitor C-11).
2. R. F. Interstage "A" Band Shunt Aligning Capacitor at 1500 Kilocycles (Capacitor C-7).
3. "A" Band, R. F. Bi-resonator Shunt Aligning Capacitor at 1500 Kilocycles (Capacitor C-19).
4. Antenna "A" Band Shunt Aligning Capacitor at 1500 Kilocycles (Capacitor C-3).
5. Oscillator "A" Band Series Aligning Capacitor at 600 Kilocycles (Capacitor C-20). When operation No. 4 has been completed repeat operations 1, 2, and 3 again and in the exact order given.

Alignment of Amateur, Police, and Aircraft Range (Also Referred to as "B" Band) Circuits

1. Oscillator's "B" Band Shunt Aligning Capacitor at 5 Megacycles (Capacitor C-10).
2. R. F. Interstage "B" Band Shunt Aligning Capacitor at 5 Megacycles (Capacitor C-6).
3. Antenna "B" Band Shunt Aligning Capacitor at 5 Megacycles (Capacitor C-2).
4. Oscillator "B" Band Series Aligning Capacitor at 1.8 Megacycles (Capacitor C-21). When operation No. 4 has been completed repeat operations 1, 2, and 3 again and in the exact order given.

Alignment of Short-Wave-Foreign Range (Also Referred to as "C" Band) Circuits

1. Oscillator's "C" Band Shunt Aligning Capacitor at 16 Megacycles (Capacitor C-9).
2. R. F. Interstage "C" Band Shunt Aligning Capacitor at 16 Megacycles (Capacitor C-5).
3. Antenna "C" Band Shunt Aligning Capacitor at 16 Megacycles (Capacitor C-1).

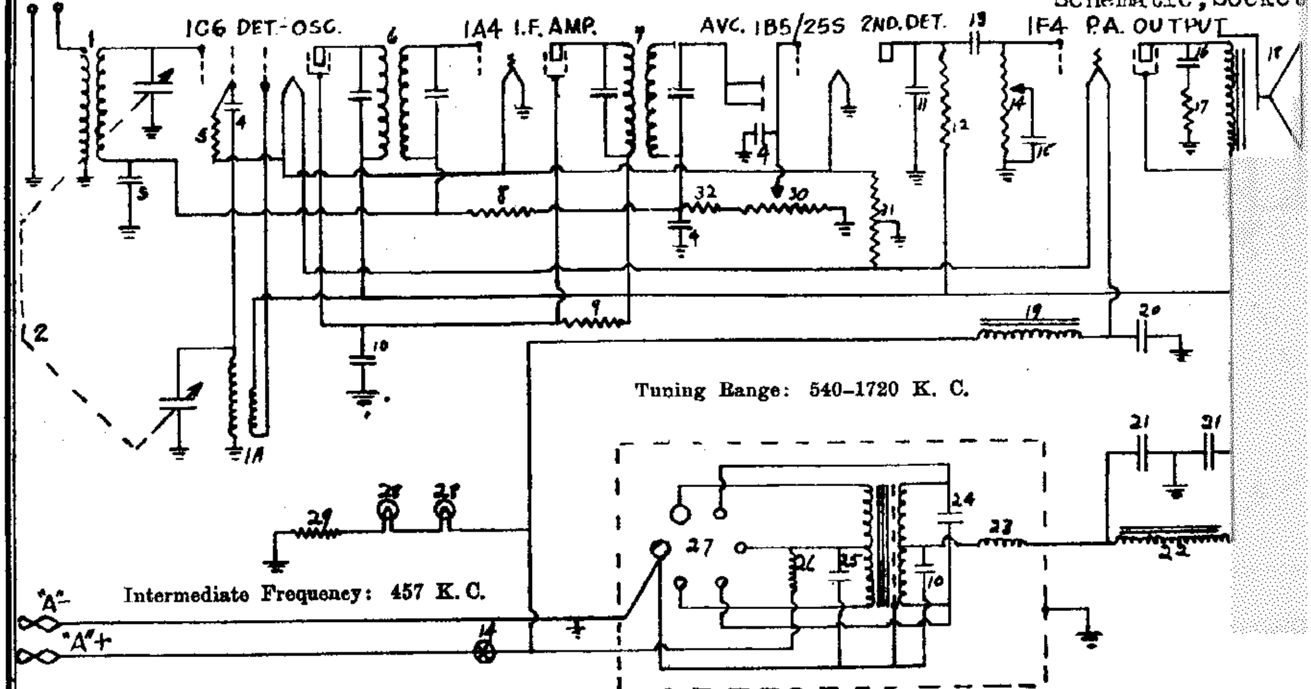
MODEL EN6-4
Schematic, Socket



I. F. Adjustments—A. Connect test oscillator output leads to control grid cap of 1C6 and to the chassis. Adjust oscillator to 457 K. C. and turn the receiver to a point where no interference is received from the heterodyne oscillator or from a local station. B. Adjust trimmers in top of I. F. coil shield cans for maximum output from the receiver as shown by an output meter.

R. F. Adjustments—Check dial calibration of dial scale by turning the variable condenser to the "full-in" position and make sure that the dial pointer registers the end of the scale. Then tune to 1400 K. C. on the dial, adjust test oscillator to 1400 K. C. and adjust trimmers on top of tuning condenser for maximum output as shown by an output meter.

Vibrator Unit—The vibrator power unit supplies the proper B and C voltages for the set's operation. It contains a plug-in vibrator, step-up transformer, and filter system. No adjustments should be undertaken on the vibrator unit, as it has been properly adjusted with precision equipment for a long service life.

Voltages—Proper voltage in 1F4 Screen and R. F. and I. F. tube plates on a fully charged battery is 125 to 130 volts. R. F. and I. F. Screen voltage is 55 to 60 volts.

Diagram Number	Part Number	Name
1.—1A	10N-1	Antenna Osc. Coil.
2.	9N-1	Variable Condenser.
3.	5N-1	.05 Mf. 400 V. Condenser.
4.	7N-1	.0001 Mf. Mica Condenser.
5.	4N-1	50 M. Ohm Resistor.

Power Source: 28 V to 36 V D.C.

Power Output: Undistorted 1.75 Watt, Maximum 2.25 Watts.

I. F. Adjustments—

(A) Connect test oscillator output leads to the control grid of 6A7 tube and chassis. Adjust oscillator to 457 K. C. and tune the receiver to a point where no interference is encountered from the heterodyne oscillator or from a local station.

(B) Adjust Trimmer Condensers in top of I. F. cans for maximum output as shown by an output meter.

R. F. Adjustments—

Check dial calibration by turning the variable condenser to the full-in position, and make sure that the dial pointer registers the end of the scale. Then tune to 1400 K. C. on the dial, adjust test oscillator to 1400 K. C. and adjust trimmer condensers on top of tuning condensers for maximum output as shown by an output meter.

Voltages—

Proper voltages at the rectifier cathode on a 33-volt line is from 190 to 210 volts.

Alignment

L. TATRO PRODUCTS CO.

GENERAL NOTES & ALIGNMENT PROCEDURE FOR L'TATRO MODELS Q-5636, R-5636, S-5636, W-6236, X-6236, Y-6236

The R.F. and I.F. circuits of these chassis are identical with the exception of the tube complements. Due to the combination of inductive and capacitive coupling employed in the antenna stage very uniform gain results in all three bands. IT IS TO BE NOTED HOWEVER THAT THIS COMBINATION REQUIRES SPECIAL CARE WHEN USING A SIGNAL GENERATOR FOR ALIGNMENT PURPOSES. The .002 MFD. mica condenser which provides the capacity coupling is also a part of the tuned grid circuit. If a signal generator is connected from the antenna lead to chassis without inserting the proper dummy antenna the .002 MFD. condenser will be short circuited, and will cause the R.F. input circuit to resonate at frequencies much lower than the dial reading.

For the high frequency band alignment (both H.F. bands) ALWAYS USE A 400 OHM CARBON RESISTOR BETWEEN THE SIGNAL GENERATOR AND THE ANTENNA LEAD. When aligning the BROADCAST BAND ALWAYS USE A .0002 MFD. CONDENSER BETWEEN THE SIGNAL GENERATOR AND THE ANTENNA LEAD.

DO NOT ATTEMPT TO ALIGN THESE RECEIVERS WITHOUT THE USE OF A CORRECTLY CALIBRATED SIGNAL GENERATOR OF RELIABLE MAKE HAVING GOOD ATTENUATOR CONSTRUCTION. On all models connect a high resistance output meter across the plate and screen terminals of the output tube, using a larger condenser in series with the meter to prevent D.C. plate current from flowing through the meter. KEEP THE SIGNAL GENERATOR INPUT LOW. It is preferable that the output of the receiver should not be allowed to exceed 200 milliwatts during the "peaking" operation on any trimmer. The volume and tone control knobs should be advanced to the full open position during alignment. Failure to observe this precaution will usually result in misalignment due to frequency shift caused by A.V.C. or due to overload of the I.F. amplifier tube.

I.F. ALIGNMENT - 456 K.C.

In order not to disturb the normal bias voltage applied to the tubes during alignment, it is advisable that the grid clips be left on the tubes, and that the signal be applied to the grid clips through a .005 MFD. condenser connected to the high side of the signal generator, and return the ground side of the signal generator to the receiver chassis. During alignment of 32 volt receivers it is advisable that a .5 MFD. condenser be connected between the ground side of the generator and the receiver chassis to allow the signal generator to be well grounded.

With the input connected to the I.F. tube grid, adjust the trimmer condenser on the second I.F. transformer for maximum output. Reduce the signal input and connect the signal source to the 6A7 grid and adjust the trimmers on the first I.F. transformer for maximum response.

H.F. BAND ALIGNMENT - USE 400 OHM DUMMY ANTENNA

Always use short leads from the dummy antenna (400 ohm resistor) to the generator and receiver. Also a short heavy lead (or .5 MFD. condenser with heavy leads) from the ground side of generator to receiver chassis.

Set the signal generator frequency at 16.0 megacycles. With the selector switch on point X-(clockwise position) and the receiver dial at 16 M.C. Adjust trimmer A in both directions. Two points should be found which will allow 16 M. C. signals to come through. Always set A at the lower capacity setting that gives 16 M.C. response. The center coil is the oscillator coil and the trimmer furthest from the selector switch is trimmer A.

Next vary the generator (or reciever dial) frequency very slowly back and forth and adjust trimmer B for maximum response on the output meter. The R. F. coil is the coil with the open side exposing the trimmer screws. Trimmer B is the trimmer furthest from the selector switch.

Next adjust the trimmer C, which is on the antenna coil and is the trimmer nearest to the selector switch, to give the greatest response on the output meter.

Now set the receiver dial and signal generator at 6.0 MEGACYCLES. Slowly tune the receiver dial both ways from 6 M.C. and slowly adjust trimmer "P" which is mounted on the receiver chassis. The setting giving greatest output is the desired setting. If considerable change from the original setting is required, peak the trimmer and realign at 16 and 6 M. C.

POLICE BAND ALIGNMENT: USE 400 OHM DUMMY ANTENNA

Set the selector switch in the center position (point Y), turn the dial to 3.0 megacycles and set the signal generator at 3.0 megacycles. Adjust the center oscillator trimmer D to bring in signal. Then adjust F & G, the center trimmers on the R. F. and antenna coils for maximum response.

BROADCAST BAND ALIGNMENT USE .0002 MFD. DUMMY ANTENNA

Set the selector switch on point Z-(Counter-clockwise position). Set the receiver dial at 1400 K.C. and feed a 1400 K.C. signal through the .0002 condenser to the antenna lead. Adjust trimmer H (oscillator trimmer nearest to the selector switch) to bring in signal. Adjust trimmer J (R.F. coil trimmer nearest to selector switch) for maximum response. Then adjust trimmer K (antenna coil trimmer furthest from selector switch) for maximum output.

Set receiver dial at 600 K. C. and tune signal generator to same frequency. Slowly turn tuning control back and forth and adjust trimmer M (mounted on the coil assembly plate) in both directions until the maximum response point is reached. If a large readjustment is required from the original adjustment, repeat BC band alignment.

If trouble is occasioned during alignment procedure due to broadcast signals interfering with the operation, the alignment may be made on the adjacent channel, that is 10 K.C. from the usual alignment frequency. For example if a strong station causes 600 K.C. interference set the dial and signal generator at either 590 or 610 K.C. The same applies to 1400 K.C. No appreciable error will result from aligning the trimmers at a point 10 K.C. from the recommended frequency.

The complete receiver after above procedure should be in correct adjustment, and may be checked on the air. Under normal conditions a single wire antenna 100 feet long with lead in at one end is recommended.

GENERAL NOTES AND ALIGNMENT PROCEDURE MODELS O4626, P4626

The R.F. and I.F. circuits on these receivers are identical with the exception of tube complements. Due to the combination inductive and capacitive coupling used in the antenna stage, very uniform gain result[illegible] IS TO BE NOTED H[illegible]HAT THIS COMBINATION REQUIRES SPECIAL CARE WHEN USING A SIGNAL GENERATOR FOR ALIGNMENT PURPOSES. The .0025 mica condenser which provides the capacity coupling is also a part of the tuned grid circuit. If a signal generator is connected from antenna to chassis without inserting the proper dummy antenna the .0025 MFD condenser will be short circuited and will cause the grid circuit of the 6A7 tube to resonate at a much too low frequency.

For the BROADCAST BAND ALIGNMENT ALWAYS USE A .0002 MFD CONDENSER BETWEEN THE SIGNAL GENERATOR AND THE ANTENNA LEAD. For the HIGH FREQUENCY BAND ALIGNMENT ALWAYS USE A 400 OHM CARBON RESISTOR BETWEEN THE SIGNAL GENERATOR AND THE ANTENNA LEAD.

DO NOT ATTEMPT TO ALIGN THESE RECEIVERS WITHOUT THE USE OF A CORRECTLY CALIBRATED SIGNAL GENERATOR OF RELIABLE MAKE. On all models connect a high resistance output meter across the plate and screen of the output tube, using a large condenser in series with the meter to prevent D.C. plate current from flowing through the meter. KEEP THE SIGNAL GENERATOR INPUT LOW and leave the volume control and tone control wide open to avoid misalignment which will result if high input is used (due to frequency shift with AVC or due to overload of the I.F. tube).

I.F. ALIGNMENT 456 K.C.

Connect signal generator through a .005 MFD condenser to the I.F. tube grid cap, and the ground side of the generator to the chassis. Adjust the trimmers on item 55 for maximum output. If high output or double peaks occur, reduce the input from the signal generator and readjust. Next reduce the input and connect the .005 MFD condenser to the grid cap of the 6A7 and adjust the trimmer condensers on ITEM 52 for maximum output. SLIGHTLY GREATER OUTPUT MAY BE OBTAINED BY READJUSTING THE TRIMMERS ON ITEM 55. THIS SHOULD NOT BE DONE UNLESS ABSOLUTELY NECESSARY AS IT INTRODUCES SOME REGENERATION AND MAY CAUSE EXCESSIVE HISS WHEN A CARRIER IS TUNED IN.

H.F. BAND ALIGNMENT: USE 400 OHM DUMMY ANTENNA.

First set signal generator and receiver dial at 16 MEGACYCLES, and receiver selector switch ON POINT (x). Turn trimmer (a) in and out--two points will be found that will allow 16 MC signals to come through. Always set (a) at the lower capacity setting that gives 16 MC response. (The H.F. trimmers (a) and (b) are color coded red for easy identification).

Next vary the generator frequency back and forth slowly and adjust trimmer (b) for maximum signal output, when this is obtained the H.F. band is properly aligned.

B.C. BAND ALIGNMENT: USE .0002 MFD DUMMY ANTENNA.

Set signal generator at 1400 K.C. Set selector switch on point (Y) and receiver dial to 1400 K.C. Adjust trimmer C to bring in signal.

Set generator near 600 K.C. (right on 600 K.C. if no local signal interfere), tune radio set to signal generator. "Rock" tuning condenser back and forth slowly and adjust item 37 simultaneously until maximum response is obtained. If considerable change from the original value of 37 adjustment is required--repeat the B.C. band alignment procedure.

The complete receiver should now be in correct adjustment, and may be checked on the air. Under normal conditions a single wire antenna 100 ft. long with lead in at one end is recommended.

If A.C. hum is experienced during alignment operations, try grounding the signal generator or the receiver chassis to a good ground.

If in a particular locality hum comes in with each station tuned in, this may be remedied by connecting a 10,000 ohm carbon resistor from the antenna side of item 20 to chassis. If hum still persists the antenna should be strung in a different direction so as not to pick up hum from power lines, etc.

MODEL 642

ASSEMBLY AND MOUNTING:

The set is mounted by means of a 3/8 inch machine bolt placed through a hole in the center of a space to clear 8¾ x 7¾ inches, and having no obstruction within 7½ inches from its surface which will then clear the auto chassis, and so located as to allow the insertion of the shafts without sharp bends. The rear of the set can then be joined to the head of this bolt, and the nut attached to the bolt and tightened against the opposite side of the partition, leaving the set in a rigid mounting.

The control unit is supplied with individual escutcheon plates to match your particular car. It is also possible to secure means for mounting the unit under the dash or on the steering column if the car is not equipped for dash mounting. Instructions for mounting the control unit in the dash of your car are enclosed with the proper escutcheon.

ALIGNMENT PROCEDURE

PRELIMINARY

Output Meter Connections (Copper Oxide Type Meter) . . Across voice coil
Output Meter reading to indicate 1 Watt output . . . . 1.73 Volts
Average sensitivity in microvolts for 1 Watt output . . See chart below

Generator ground lead connection . . . . Receiver Chassis
Dummy antenna value in series with generator output lead See chart below
Connection of generator output lead . . . . See chart below

Position of volume control . . . . Full on
Position of tone control . . . . OFF (or treble position)
Position of dial card at Maximum Capacity . . . . . . Max. Setting line

BAND RANGE	POSITION OF DIAL POINTER	GENERATOR FREQUENCY	DUMMY ANTENNA	GENERATOR CONNECTION	TRIMMERS ADJUSTED (in order shown)	MICRO-VOLTS
I.F. Stages	640 KC	465 KC	.1 Mfd.	Trans Grid	C31 C32 C33 C34	1200
Regular	1400 KC	1400 KC	.0002	Ant. Lead	C35 C36 C37	2
Regular	600 KC	600 KC	.0002	Ant. Lead	C4 C5	2

IMPORTANT ALIGNMENT NOTES

1. After adjusting the C4 oscillator padding condenser at 600 KC rotate dial back to 1400 KC and recheck the settings made on C35, C36, C37.

2. It will not be necessary to bend the plates of the variable condenser for alignment on other points on the dial.

3. It should be noted that after the receiver is installed in a car that it is not necessary, when preparing to align the set, to remove the control head and cables from the dash. There is a dial card on the variable condenser that will indicate the alignment frequencies and settings.

GENERAL INFORMATION

To examine this receiver for any reason first remove the two screws holding the cover. The speaker which is mounted on this cover will be removed at the same time allowing further inspection of the tubes and radio. The radio, being designed in two parts, having a pair of wire connectors from the chassis itself to the self contained power unit, can be removed from the case by first taking out the power unit.

The power unit has been very carefully designed to avoid any vibrator "Hash" from being picked up. Due to the exceptional sensitivity of the radio this interference must be kept at a minimum and it is advisable that the cover on the power unit be making good contact to the box. Tighten the cover by bending the flanges inward slightly. Also be sure that the .005 Mfd. 1600 Volt condenser across the vibrator is not open.

It is important that the chassis and power unit make contact to the inside of the receiver case. In addition it is advisable that the paint be removed from under the various bolt heads on the outside of the case that are holding power unit.

Harmonics of the I.F. may be noticed when the chassis is being serviced outside its case. This is a normal condition and will not be present when the set is in actual use.

NOTES ON THE ELIMINATION OF UNUSUAL NOISE CONDITIONS OCCURRING IN THE INSTALLATION IN CERTAIN CARS ARE GIVEN IN SECTION IX OF THE INSTRUCTIONS THAT WERE SENT WITH THE RECEIVER.

Car interference can be fed into the receiver through the flexible control cables, and it is suggested that these cables be bonded. Also see page 5 to this instruction book regarding the use of a shield bracket mounted over the tuning shaft coupling on the set.

In some types of installations (usually inverted mountings) some receivers may experience extreme loss of sensitivity. If the 2nd I.F. transformer (#6552 as shown on can) does not respond to alignment, it should be replaced with a new type. This condition in the I.F. transformer is caused by the position of the iron core being affected by heat generated within the chassis, and is usually indicated by the softening of the wax within the transformer. The new type I.F. transformer (Part #6542) eliminates this difficulty.

WHEN REPLACING THE 2ND. I.F. UNIT FOR THE REASON AS DESCRIBED ABOVE, IT IS OF COURSE NECESSARY TO READJUST THE TRIMMERS TO 465 KC. WHEN MAKING THE ADJUSTMENT ON THIS UNIT AND LIKEWISE WHEN RE-TRIMMING THE 1ST. I.F. STAGE BE SURE NOT TO PULL THE PLATES TOGETHER TOO TIGHT AS THIS MAY BEND THE PLATES PERMANENTLY OUT OF SHAPE AND THEY WILL NOT SPRING BACK WHEN THE SCREW IS TURNED IN THE OTHER DIRECTION. IN THIS EVENT PEAKING OF THE TRIMMERS WOULD NOT BE OBTAINED AND THE UNIT WOULD HAVE TO BE REPLACED.

ADDITION OF NEW SPECIAL TUNING CABLE SHIELD (5132) TO ELIMINATE EXCESSIVE IGNITION INTERFERENCE. IN MODEL HA6 SERIES 1.

In Ford 1936 V-8 and other automobiles where an excessive amount of ignition noise is present, the bracket described should be used in conjunction with a new type of shield (No. 5132). Both the bracket described and the new type shield described here are necessary for best noise elimination. The bracket and shield need not be ordered for models number above 5000 (series 2).

The new tuning cable shield (5132) will be supplied "No Charge" together with a screw used to fasten it over the tuning cable opening.

SERVICE FIRST AID
EVERY GOOD SERVICEMAN CHECKS TUBES AND THE ANTENNA SYSTEM FIRST.

DEFECT	GENERALLY CAUSED BY	REMEDY
QUALITY POOR	After Checking Voltage, Tubes and Vibrator; Check .02 Condenser in the plate circuit of the 75 tube which may be open	Change if necessary
	Speaker Cone off center	Adjust or change speaker
DEAD RECEIVER	Blown Fuse, Defective Off-On Switch, Open Voice Coil or Speaker Transformer	Check
	Defective Vibrator, Blown Condenser, Open Coil Winding	Check "B" Voltage
LOW VOLUME INSENSITIVE	Poor Antenna System, Receiver not aligned, Speaker Field Coil shorted	Check
	2nd. I.F. Transformer having lost its gain due to the heating of the wax and the shifting of the iron core coupling	Change to new type I.F. (# 6542 on can)
[illegible] OR HOWL	Possible open .1 in plate circuit of 42	Change if necessary
	Variable Condenser not floating freely in its rubber mountings	Free Condenser
RADIO FREQUENCY OSCILLATION	Open C8 bypass condenser .1 Mfd. 400 volt in B - circuit	Change
	The grid lead between the mixer tube 6L7 and the variable condenser may be too close to the antenna stage of the variable condenser (top section)	Push lead away
OFF CALIBRATION	Set not properly aligned	Check
	Dial hand not set to maximum line when condenser is at full capacity	Reset screw on back of drive head
SET NOT SELECTIVE	Check Alignment, especially the I.F. stages.	
SLIPPING OF THE VOLUME CONTROL SHAFT	Cable may not be meshed with slot in control shaft due to cable not going far enough in the coupling, or Volume control bracket may be bending back at an angle which does not allow the control to meet the shaft slot.	Correct as described

UNITED AMERICAN BOSCH CORP.

GENERAL DESCRIPTION

The Model 242 is an eight-tube superheterodyne receiver whose circuits comprise a first detector, an oscillator, two stages of intermediate frequency amplification, a combined second detector--automatic volume control, a stage of audio frequency amplification, an output stage and a rectifier.

This model is designed to operate over the standard broadcast band covering the frequencies from 550 to 1500 K.C.

LINE-UP CAPACITOR ADJUSTMENTS

To align the 242 chassis, it is essential to use a high grade modulated test oscillator and a sensitive output meter. The R.F. signal fed into the receiver must be very weak or it will cause the A.V.C. to function, making correct alignment difficult. The sensitivity of the output meter must be sufficient to give satisfactory reading with a low input signal.

Before attempting to align the receiver, the service man should familiarize himself with the general layout of the chassis, the location of the tubes and various alignment condensers. A top view of the chassis is shown in Fig. #1 and should be carefully studied before the actual work is started.

ADJUSTMENT OF I.F. (175 K.C.)

1. Set the volume control to maximum position.
2. Connect output meter across terminals of speaker voice coil.
3. Set the test oscillator to 175 K.C., and apply test signal to the grid of the second I.F. tube through a .25 mfd. blocking condenser.
4. Adjust alignment condenser "A" for maximum output.
5. Apply the test signal to the grid of the first detector tube.

NOTE: In the alignment of the 1st I.F. stage of this receiver it is necessary to use a "losser" so as to flatten out the top of the selectivity curve to give better tone quality. The "losser" consists merely of a .05 mfd. condenser and 1000 ohm resistor connected in series.

6. With the "losser" on the plate of the first detector tube to ground, adjust "B" (top) alignment condenser to maximum output.
7. With the "losser" on the grid of the 1st I.F. tube adjust "C" (bottom) alignment condenser to maximum output.
8. Do not recheck the first I.F. transformer without the "losser".

ADJUSTMENT OF OSCILLATOR AND R.F.

1. Set the test oscillator and pointer on scale to 1400 K.C.
2. Adjust the oscillator trimmer condenser "D" until the signal is received.

NOTE: When adjusting the oscillator trimmer condenser, the signal will be received at two different settings. Use the signal received with the alignment screws turned farthest out.

3. Apply the test signal to the antenna lead of the receiver through a .0002 mfd. series condenser and adjust the preselector alignment condenser "E" and antenna alignment condensers for maximum output.
4. Set the test oscillator and receiver to 600 K.C.
5. Adjust the oscillator lagging condenser "F" until the signal is received.
6. Return both the test oscillator and receiver to 1400 K.C.
7. Recheck the oscillator, preselector and antenna trimmer condensers.
8. Check calibration and sensitivity over scale.

GENERAL DESCRIPTION 250-251

This model is a ten-tube superheterodyne receiver whose circuit employs a type 58 tube as an R.F. amplifier, a type 58 tube as a first detector, a type 56 tube as an oscillator, two type 58 tubes as I.F. amplifiers, a type 56 as a combined second detector - A.V.C., a type 56 tube as a first A.F. amplifier, two type 45 tubes in a push-pull output stage, and a type 80 rectifier tube.

This receiver is designed to operate over the standard broadcast band on frequencies from 550 to 1500 K.C.

LINE-UP CAPACITOR ADJUSTMENTS

To align the Model 250 chassis, it is essential to use a high grade modulated test oscillator and a sensitive output meter. The R.F. signal fed into the receiver must be relatively weak or it will cause the A.V.C. to function, making correct alignment difficult. The sensitivity of the output meter must be sufficient to give satisfactory reading with a low signal.

Before attempting to align a receiver, the service man should familiarize himself with the general layout of the chassis, the location of the tubes and various alignment condensers. A top view of the chassis is shown in Figure #1 and should be carefully studied before the actual work is started.

ALIGNMENT OF I.F. (175 K.C.)

1. Connect the output meter across the terminals of the voice coil.
2. Turn the volume control to maximum position.
3. Set the test oscillator to 175 K.C. and apply signal to the grid of the type 58 second I.F. tube and adjust trimmer condenser "A" to maximum output.
4. Apply test signal to grid of type 58 first I.F. tube and adjust trimmers "B" and "C" to maximum output.
5. Apply test signal to grid of type 58 first detector tube and adjust trimmer condensers "D" and "E" to maximum output.

ALIGNMENT OF OSCILLATOR AND R.F.

1. Set test oscillator and dial indicator to 1400 K.C. and adjust alignment condenser "F" until the signal is received.
2. Set test oscillator and dial indicator to 600 K.C. and adjust alignment condenser "J" until the signal is received.
3. Set test oscillator and dial indicator to 1400 K.C. and apply signal to antenna lead of receiver.
4. Adjust trimmer condensers "G", "H" and "K" to maximum output.
5. Check sensitivity at several points over the scale.

GENERAL DESCRIPTION

The Models 501 and 502 are five-tube, A.C.-D.C., superheterodyne receivers whose circuits consist of a combined first detector-oscillator, a stage of intermediate frequency amplification, a combined second detector - automatic volume control - audio amplifier, a power output stage and a rectifier.

The Models 501 and 502 are designed to operate on frequencies from 540 to 1750 K.C. The Model 502 differs from the Model 501 in the cabinet only.

LINE-UP CAPACITOR ADJUSTMENTS

To align the Models 501 and 502 chassis, it is essential to use a high grade modulated oscillator and sensitive output meter. The R.F. signal fed into the receiver must be very weak or it will cause the A.V.C. to function, making correct alignment impossible. The sensitivity of the output meter must be sufficient to give satisfactory reading with a low signal.

Before attempting to align a receiver, the service man should familiarize himself with the general layout of the chassis, the location of the tubes and various alignment condensers. A top view of the chassis is shown in Fig. #1 and #2 and should be carefully studied before the actual work is started.

I.F. ADJUSTMENT (456 K.C.)

NOTE: The signal generator or alignment oscillator should have no external ground connection of the low potential side of its output either to ground or to the power line, and the low potential output terminal may be connected to the frame of the receiver. An external ground of the receiver frame will result in a loud hum making alignment impossible.

1. Connect output meter across the voice coil of speaker (speaker impedance is 4.5 ohms).
2. Set volume control at maximum.
3. Set the test oscillator to 456 K.C. and apply test signal to the grid of the 78 I.F. tube.
4. Adjust second I.F. alignment condenser "A" to maximum output.
5. Apply the test signal to the grid of the 6F7 first detector-oscillator tube.
6. Adjust alignment condensers "B" and "C" to maximum output.

OSCILLATOR AND R.F. ADJUSTMENT

1. Set dial scale to maximum mark beyond the 540 K.C. point with the gang condenser entirely closed.
2. Set the test oscillator and dial scale to 1500 K.C. and apply test signal to the antenna of the receiver.
3. Adjust the oscillator and antenna alignment condensers "D" and "E" to maximum output.
4. Check sensitivity over scale.

AMERICAN-BOSCH RADIO MODELS 305 Ed. 2-405

Five-Tube, Superheterodyne Receivers

SERVICE NOTES

GENERAL DESCRIPTION

The Models 305 Ed. 2 and 405 are five-tube superheterodyne receivers whose circuits comprise a combined first detector-oscillator, an intermediate frequency amplifier, a combined second detector-automatic volume control - first audio amplifier, an output stage and a rectifier.

The receiver is designed to operate over the broadcast band covering the frequencies from 550 to 1720 K.C.

The Model 305 Ed. 2 is a personal model with the speaker mounted on the chassis.

The Model 405 is a console model with a separate speaker.

LINE-UP CAPACITOR ADJUSTMENTS

To align the Model 305 Ed. 2 or 405 chassis, it is essential to use a high grade modulated oscillator and sensitive output meter. The R.F. signal fed into the receiver must be very weak or it will cause the A.V.C to function, making correct alignment impossible. The sensitivity of the output meter must be sufficient to give satisfactory reading with a low signal.

Before attempting to align a receiver, the service man should familiarize himself with the general layout of the chassis, the location of the tubes and various alignment condensers. A top view of the chassis is shown in Fig. #1 and should be carefully studied before the actual work is started.

I.F. ADJUSTMENT 456 K.C.

1. Connect output voltmeter to speaker.
2. Set volume control at maximum position.
3. Set signal generator at 456 K.C., and connect generator output lead to grid of I.F. tube.
4. Adjust condensers A & B on coil nearest back of set for maximum output as indicated on output voltmeter. Sensitivity at this point should be 300 microvolts.
5. Connect signal generator output lead to grid of first detector. Adjust condensers C & D on front coil to maximum output as indicated on output voltmeter.

OSCILLATOR ALIGNMENT

1. Switch generator to R.F. and set at 1400 K.C.
2. Connect generator lead to antenna.
3. Set scale to 100 with gang closed tightly.
4. Adjust condenser gang to a scale reading of 21 and peak oscillator trim condenser. (This condenser is the back alignment screw on gang condenser.)
5. To check I.F. alignment, connect I.F. signal generator to antenna; second harmonic should be at 912 K.C., third at 1368 K.C.
6. Adjust preselector trimmer condenser (on front section of gang condenser) to maximum output.

NOTE: If it is necessary to improve sensitivity at 600 or 1000 K.C., adjust plates until the set reaches the sensitivity limits. If bending plates does not help, change tubes. Oscillator condenser end plates should be bent out at 1700 K.C. end of condenser.

Alignment, Parts Voltage

LINE-UP CAPACITOR ADJUSTMENTS

To properly align the Model 360 chassis, it is essential to use a high grade modulated oscillator and a sensitive output meter. The R.F. signal fed into the receiver must be relatively weak or it will cause the A.V.C. to function making correct alignment impossible. The sensitivity of the output meter mustbe sufficient to give satisfactory reading with a low signal.

Before attempting to align a receiver, the service man shouldfamiliarize himself with the general layout of the chassis, the location of the tubes and the various alignment condensers. A top view of the chassis is shown in Fig.#1 and should be carefully studied before the actual work is started.

A- ADJUSTMENT OF I.F. (456 K.C.)

1. Set test oscillator to 456 K.C.
2. Apply test signal to grid of second I.F. tube #5 and adjust #14 and #15 to maximum output, reducing test oscillator as required.
3. Apply test signal to grid of first I.F. amplifier #6 and adjust #16 and #17 to maximum output.
4. Apply test signal to grid of first detector #11 and adjust #18 and #19 to maximum output.
5. Recheck the above four operations for accuracy.

B- ADJUSTMENT OF BLACK BAND & R.F.

1. Set test oscillator to 1500 K.C. and apply signal to grid of first detector tube #11. Place pointer of radio to 1.5 mark on dial. Adjust #20 until signal is tuned in. This adjusting screw is usually designated by a Red color dot. Having obtained tune at this point, set test oscillator to 600 K.C. and tune station selector to .6 mark on dial. Adjust #21 until the signal is tuned in.
2. Now return to 1500 K.C. point with set and test oscillator and make the resetting of #20 to obtain accurate adjustment to scale reading.
3. Apply test signal to antenna lead, making sure the equivalent (200 mmf.) is in the circuit and with test oscillator and dial indicator still set at 1500 kilocycles, adjust trimmer #22 and #23 for maximum output. Check sensitivity and calibration at several points on dial.
4. Set should come correctly to kilocycle settings of important broadcasting stations.

C- ADJUSTMENT OF GREEN BAND

1. Set test oscillator to 3600 K.C. and indicator of radio at 3.6 mark on dial.
2. Adjust trimmer #24 until signal is tuned in. This trim condenser is usually marked with a Red color dot.
3. Set test oscillator at 1600 K.C. and tune set to 1.6 mark. Adjust #25 to maximum output.
4. Return to 3600 K.C. and repeat adjustment. In adjusting the 3600 K.C. point it is possible to obtain two settings for different position of the trim condenser. This denotes merely the plus and minus frequency between oscillator and test oscillator which will give the correct I.F. frequency. The correct setting of the trim condenser is the one wherein the screw is turned furthest out. In any event, an incorrect setting will always be denoted by lack of sensitivity and calibration when the set and test oscillator are tuned to 2500 K.C. (mid-band).

D- ADJUSTMENT OF RED BAND

1. Set test oscillator to 8000 K.C. marking and tune receiver in region of 8.0 on dial scale. Note when signal is received. Next set test oscillator to 4000 K.C. setting and tune set to 4.0 on dial scale. Adjust #26 on right side of chassis until signal is heard.
2. Retune set and test oscillator to 8000 K.C. and observe pointer setting and sensitivity. Slight deviations from calibration can be compensated by manipulating the stiff wires connecting the oscillator coil to switch.

E- ALIGNING THE PURPLE BAND

1. Set test oscillator to 20,000 K.C. or if this is not available, then adjust to highest possible frequency, which preferably should be at least 15,000 K.C. Tune set to this frequency and note where set oscillator is received on dial scale. Then place test oscillator on 10,000 K.C. and adjust #27 on right of chassis until test oscillator is tuned at 10 on dial scale.
2. Now return both test oscillator and radio set to high frequency. Located underneath the base and adjacent to the switch and high frequency selector coils are two trim condensers #28 & #29 which are used for correct adjustment at this high frequency. Increase setting of test oscillator until signal generator can be tuned in at two points on dial (say 20 and 19). Then with pointer of set at 20 adjust #28 & #29 for maximum output decreasing test signal as signal becomes better tuned. At correct adjustment a very loud signal will be obtained at 20 on dial while a feeble signal or none at all is observed at 19.

The adjustment instructions just given apply to the Model 360 receiver which is in reasonable operating condition, but in some manner has been thrown out of adjustment. Obviously, before the radio service man can go through with the adjustments given here, he must assure himself that defective tubes, injured parts, such as punctured condensers, shorted variable condensers, open resistors, scratched high frequency coils, etc., are not such as to cause the set to be inoperative on one or more bands of frequencies.

SERVICE DATA

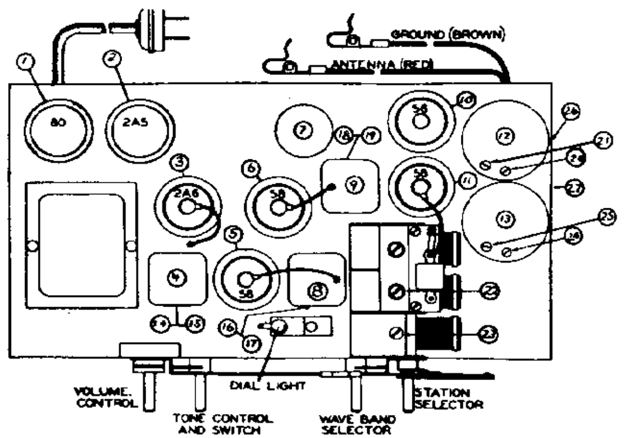
Noises when chassis is jarred, or sudden breaking into oscillations and whistling, are caused by poor contact between the bases of the tube shields and chassis. These bases are riveted to the chassis, but should oxide form on the aluminum it will cause poor contact.

This can be corrected by drilling small holes through the shield bases near the rivets and bolting the bases tightly to the chassis with Parker Kalon self-tapping screws.

GENERAL DESCRIPTION

The Model 360 is a seven tube, four band, all-wave, superheterodyne receiver whose circuits comprise an oscillator, a first detector, two stages of intermediate frequency amplification, a combined second detector, automatic volume control and first audio amplifier, an output stage and a rectifier.

This receiver has four bands with the following frequency coverage: On the broadcast band, printed in black, 540 to 1500 K.C. On the green band, 1500 to 4000 K.C. On the red band, 3500 to 9000 K.C. On the purple band, 8000 to 20,000 K.C.



PARTS LIST

MODEL 361

All parts the same as for Model 360 except for the following:

MAIN ASSEMBLIES

SA 106445	Chassis assembly (Models 361W, 361X, 361Y)

MISCELLANEOUS

SA 106098	Power transformer assembly

MODEL 364

The Model 364 has been designed to operate on power line voltage of from 90 to 250 volts, 50 to 60 cycles. In cases where the line voltage fluctuates considerably, it is recommended that the 80 rectifier tube be replaced with an 83 V. rectifier. This requires no change in the power transformer but a 400 ohm 8 watt resistor (part #SA 102177) should be connected in series with the B-plus lead at the rectifier socket.

All parts are the same as the Model 360 except:

MAIN ASSEMBLIES

SA 106442	Chassis assembly (Models 364W, 364X, 364Y)

SPEAKER PARTS (SA 105575)

SA 102819	Diaphragm & voice coil assy.
SA 102551	Output transformer
SA 101858	Field coil
FP 102270	Plate over core & frame assy.
SA 101733	Core and frame assembly

BRACKETS & CLAMPS

FP 79381	Clamp for speaker cable
FP 106819	Clamp for speaker (Model 360W
SA 105654	Dial scale bracket
SA 105655	Dial scale bracket

CABLES & CABLE ASSEMBLIES

SA 101711	Line cable assembly
KL 102064	Speaker cable

COILS

LINE-UP CAPACITOR ADJUSTMENTS

To properly align the Model 360 chassis, it is essential to use a high grade modulated oscillator and a sensitive output meter. The R.F. signal fed into the receiver must be relatively weak or it will cause the A.V.C. to function making correct alignment impossible. The sensitivity of the output meter must be sufficient to give satisfactory reading with a low signal.

Before attempting to align a receiver, the service man should familiarize himself with the general layout of the chassis, the location of the tubes and the various alignment condensers. A top view of the chassis is shown in Fig.#1 and should be carefully studied before the actual work is started.

A- ADJUSTMENT OF I.F. (456 K.C.)

1. Set test oscillator to 456 K.C.
2. Apply test signal to grid of second I.F. tube #5 and adjust #14 and #15 to maximum output, reducing test oscillator as required.
3. Apply test signal to grid of first I.F. amplifier #6 and adjust #16 and #17 to maximum output.
4. Apply test signal to grid of first detector #11 and adjust #18 and #19 to maximum output.
5. Recheck the above four operations for accuracy.

B- ADJUSTMENT OF BLACK BAND & R.F.

1. Set test oscillator to 1500 K.C. and apply signal to grid of first detector tube #11. Place pointer of radio to 1.5 mark on dial. Adjust #20 until signal is tuned in. This adjusting screw is usually designated by a Red color dot. Having obtained tune at this point, set test oscillator to 600 K.C. and tune station selector to .6 mark on dial. Adjust #21 until the signal is tuned in.
2. Now return to 1500 K.C. point with set and test oscillator and make the resetting of #20 to obtain accurate adjustment to scale reading.
3. Apply test signal to antenna lead, making sure the equivalent (200 mmf.) is in the circuit and with test oscillator and dial indicator still set at 1500 kilocycles, adjust trimmer #22 and #23 for maximum output. Check sensitivity and calibration at several points on dial.
4. Set should come correctly to kilocycle settings of important broadcasting stations.

C- ADJUSTMENT OF GREEN BAND

1. Set test oscillator to 3600 K.C. and indicator of radio at 3.6 mark on dial.
2. Adjust trimmer #24 until signal is tuned in. This trim condenser is usually marked with a Red color dot.
3. Set test oscillator at 1600 K.C. and tune set to 1.6 mark. Adjust #25 to maximum output.
4. Return to 3600 K.C. and repeat adjustment. In adjusting the 3600 K.C. point it is possible to obtain two settings for different position of the trim condenser. This denotes merely the plus and minus frequency between oscillator and test oscillator which will give the correct I.F. frequency. The correct setting of the trim condenser is the one wherein the screw is turned furthest out. In any event, an incorrect setting will always be denoted by lack of sensitivity and calibration when the set and test oscillator are tuned to 2500 K.C. (mid-band).

D- ADJUSTMENT OF RED BAND

1. Set test oscillator to 8000 K.C. marking and tune receiver in region of 8.0 on dial scale. Note when signal is received. Next set test oscillator to 4000 K.C. setting and tune set to 4.0 on dial scale. Adjust #26 on right side of chassis until signal is heard.
2. Retune set and test oscillator to 8000 K.C. and observe pointer setting and sensitivity. Slight deviations from calibration can be compensated by manipulating the stiff wires connecting the oscillator coil to switch.

E- ALIGNING THE PURPLE BAND

1. Set test oscillator to 20,000 K.C. or if this is not available, then adjust to highest possible frequency, which preferably should be at least 15,000 K.C. Tune set to this frequency and note where set oscillator is received on dial scale. Then place test oscillator on 10,000 K.C. and adjust #27 on right of chassis until test oscillator is tuned at 10 on dial scale.
2. Now return both test oscillator and radio set to high frequency. Located underneath the base and adjacent to the switch and high frequency selector coils are two trim condensers #28 & #29 which are used for correct adjustment at this high frequency. Increase setting of test oscillator until signal generator can be tuned in at two points on dial (say 20 and 19). Then with pointer of set at 20 adjust #28 & #29 for maximum output decreasing test signal as signal becomes better tuned. At correct adjustment a very loud signal will be obtained at 20 on dial while a feeble signal or none at all is observed at 19.

The adjustment instructions just given apply to the Model 360 receiver which is in reasonable operating condition, but in some manner has been thrown out of adjustment. Obviously, before the radio service man can go through with the adjustments given here, he must assure himself that defective tubes, injured parts, such as punctured condensers, shorted variable condensers, open resistors, scratched high frequency coils, etc., are not such as to cause the set to be inoperative on one or more bands of frequencies.

SERVICE DATA

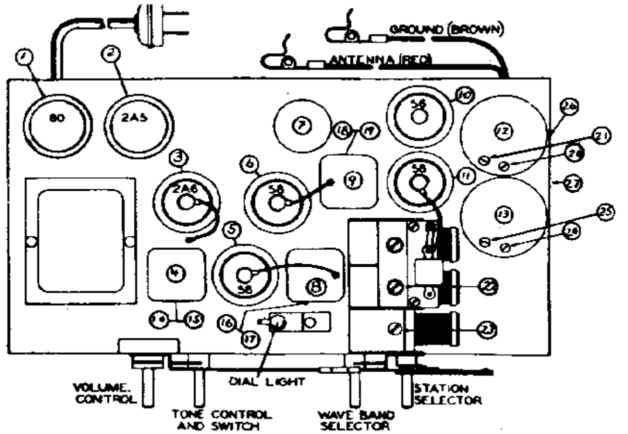
Noises when chassis is jarred, or sudden breaking into oscillations and whistling, are caused by poor contact between the bases of the tube shields and chassis. These bases are riveted to the chassis, but should oxide form on the aluminum it will cause poor contact.

This can be corrected by drilling small holes through the shield bases near the rivets and bolting the bases tightly to the chassis with Parker Kalon self-tapping screws.

GENERAL DESCRIPTION

The Model 360 is a seven tube, four band, all-wave, superheterodyne receiver whose circuits comprise an oscillator, a first detector, two stages of intermediate frequency amplification, a combined second detector, automatic volume control and first audio amplifier, an output stage and a rectifier.

This receiver has four bands with the following frequency coverage: On the broadcast band, printed in black, 540 to 1600 K.C. On the green band, 1500 to 4000 K.C. On the red band, 3500 to 9000 K.C. On the purple band, 8000 to 20,000 K.C.



PARTS LIST

MODEL 361

All parts the same as for Model 360 except for the following:

MAIN ASSEMBLIES

SA 106445	Chassis assembly (Models 361W, 361X, 361Y)

MISCELLANEOUS

SA 106098	Power transformer assembly

MODEL 364

The Model 364 has been designed to operate on power line voltage of from 90 to 250 volts, 50 to 60 cycles. In cases where the line voltage fluctuates considerably, it is recommended that the 80 rectifier tube be replaced with an 83 V. rectifier. This requires no change in the power transformer but a 400 ohm 8 watt resistor (part #SA 102177) should be connected in series with the B-plus lead at the rectifier socket.

All parts are the same as the Model 360 except:

MAIN ASSEMBLIES

SA 106442	Chassis assembly (Models 364W, 364X, 364Y)

SPEAKER PARTS (SA 105575)

SA 102819	Diaphragm & voice coil assy.
SA 102551	Output transformer
SA 101858	Field coil
FP 102270	Plate over core & frame assy.
SA 101733	Core and frame assembly

BRACKETS & CLAMPS

FP 79381	Clamp for speaker cable
FP 106819	Clamp for speaker (Model 360W
SA 105654	Dial scale bracket
SA 105655	Dial scale bracket

CABLES & CABLE ASSEMBLIES

SA 101711	Line cable assembly
KL 102064	Speaker cable

COILS

SA 105684	Oscillator coil (Black Band)
SA 105683	Oscillator coil (Green Band)
SA 105689	Oscillator coil (Red Band)
SA 105687	Oscillator coil (Blue Band)
SA 105690	Preselector coil (Black Band)
SA 105691	Preselector coil (Black Band)

Power Supply Characteristics ---------- 105 to 125 volts, 50 to 60 cycle, A.C.
Power Consumption ---------- 65 Watts
Tuning Range ---------- 540 to 1600 K.C.
Maximum Undistorted Output ---------- 3 Watts
Line-Up Frequencies ---------- 175 K.C., 1400 K.C., 600 K.C.

GENERAL DESCRIPTION

The Model 307 is a seven-tube superheterodyne receiver whose circuits comprise a stage of radio frequency amplification, a combined first detector-oscillator, two stages of intermediate frequency amplification, a combined second detector-automatic volume control and first audio amplifier, an audio output stage and a rectifier.

The Model 307 is designed to operate on the broadcast band extending from 540 to 1600 kilocycles.

LINE-UP CAPACITOR ADJUSTMENTS

To align the Model 307 chassis, it is essential to use a high grade modulated oscillator and sensitive output meter. The R.F. signal fed into the receiver must be very weak or it will cause the A.V.C. to function, making correct alignment difficult. The sensitivity of the output meter must be sufficient to give satisfactory reading with a low signal.

Before attempting to align a receiver, the service man should familiarize himself with the general layout of the chassis, the location of the tubes and various alignment condensers. A top view of the chassis is shown in Fig. #1 and should be carefully studied before the actual work is started.

I.F. ADJUSTMENT (175 K.C.)

1. Set the volume control on maximum.
2. Set the test oscillator on 175 K.C. and connect to the grid of the second I.F. tube.
3. Adjust alignment condenser #4 on top of third I.F. coil for maximum output.
4. Connect the test oscillator to the grid of the first I.F. tube and adjust the alignment condensers #2 and #3 on top of the second I.F. coil.
5. Connect the test oscillator to the grid of the first detector tube and adjust the alignment condenser #1 on top of the first I.F. coil for maximum output. With the tuning condenser closed, adjust the pointer 1/8" past the second line from the left.

ADJUSTMENT OF OSCILLATOR AND R.F.

1. Set the test oscillator and pointer to 1400 kilocycles.
2. Adjust the oscillator trimmer condenser #5 on the second signal heard when turning the alignment screw out.
3. Connect the test oscillator to the antenna lead of the receiver through a 200 mmfd. condenser.
4. Adjust the antenna and R.F. alignment condensers #6 and #7 for maximum output.
5. Check the receiver over scale for sensitivity and calibration.
6. If the oscillator does not track at 600 kilocycles bend the oscillator tuning condenser plates (rear section of tuning condenser) until the receiver reaches its maximum sensitivity.

GENERAL DESCRIPTION

This model is a ten-tube superheterodyne receiver designed to operate over the broadcast band on frequencies from 550 K.C. to 1500 K.C.

The circuit employs a type 58 tube as a first detector, a type 56 tube as an oscillator, two type 58 tubes as intermediate frequency amplifiers, a type 27 as a second detector, a type 27 as an automatic volume control tube, a type 27 tube as a first audio amplifier, two type 45 tubes in push-pull output and a type 80 tube as a rectifier.

LINE-UP CAPACITOR ADJUSTMENTS

To properly align the chassis, it is essential to use a high grade modulated test oscillator and a sensitive output meter. The R.F. signal fed into the receiver must be very weak or it will cause the A.V.C. to function making correct alignment difficult. The sensitivity of the output meter must be sufficient to give satisfactory reading with a low signal.

Before attempting to align the chassis, the service man should familiarize himself with the general layout of the chassis, the location of the tubes and the various alignment condensers. A top view of the chassis is shown in Fig. #1 and should be carefully studied before the actual work is started.

ALIGNMENT OF I.F. (175 K.C.)

1. Set the volume control and noise delay to maximum position, and tone control to treble position.

2. Set the test oscillator to 175 K.C. and apply test signal to grid of the type 58 second I.F. tube.

3. Adjust trimmer "A" to maximum output.

4. Apply test signal to grid of type 58 first detector tube and adjust trimmers "B" and "C" to maximum output.

ALIGNMENT OF OSCILLATOR AND PRESELECTOR

1. Set dial scale and test oscillator to 1400 K.C.

2. Adjust trimmer "D" to maximum output.

3. Apply test signal to antenna lead through a .0002 mfd. condenser

4. Adjust trimmers "E" and "F" to maximum output.

5. Check sensitivity at various points on the dial scale.

MAIN ASSEMBLIES

Part #	Description
107078	Chassis assembly - Mdls 462A & Y
107721	Cabinet - Model 462A
106304	Cabinet - Model 462Y
107102	Speaker assembly - Model 462A
107942	Speaker assembly - Model 462Y

BRACKETS, CLIPS & CLAMPS

Part #	Description
107113	Chassis mounting bracket- Mdl 462A
79381	Speaker cable clamp
105703	Insulation strip bracket on variable condenser
105358	Bracket with bearing on variable condenser assembly
105655	Dial scale indicator bracket
107321	Dial lamp bracket assembly
101785	Bracket for iron cored filter choke
105368	Dial scale clip
103601	Speaker diaphragm bracket

A - ALIGNING THE I.F. (456 K.C.)

1. Set test oscillator to 456 K.C.
2. Connect test oscillator to grid of 2nd I. F. tube and adjust #90 and #91 to maximum output, reducing test oscillator output as required.
3. Connect test oscillator to grid of 1st I. F. tube and adjust #92 and #93 to maximum output.
4. Connect test oscillator to grid of 1st detector and adjust #94 and #95 to maximum output.

B - R.F. ADJUSTMENT BROADCAST BAND

1. Set test oscillator to 1500 K.C. and connect to grid of first detector.
2. Set station indicator to 1.5 on dial scale.
3. Adjust #12 until signal is tuned in. This adjustment screw is usually color coded. Having obtained tune at this point, set test oscillator to 600 K.C. and tune station selector to .6 mark on dial.
4. Adjust #14 until signal is tuned in.
5. Return to 1500 K. C. setting with set and test oscillator, and readjust #12 to obtain accurate adjustment to scale reading.
6. Connect test oscillator to antenna lead of the chassis making sure that the equivalent (200 mmf.) is in the circuit.
7. Continue setting of 1500 K.C.
8. Adjust #96 and #97 for maximum output. Check sensitivity and calibration at several points on dial. Set should come correctly to kilocycle settings of important broadcast stations.

C - ALIGNING THE GREEN BAND

1. Set test oscillator to 3600 K.C. and station indicator to 3.6, and dial.
2. Adjust #13 until signal is tuned in. This adjustment screw is usually color coded.
3. Set test oscillator to 1600 K.C. and station indicator to 1.6 on dial.
4. Adjust #16 until signal is tuned in.
5. Return to 3600 K. C. setting and repeat adjustment of #13. In adjusting #13, it is possible to obtain two peaks. This denotes merely the plus and minus frequency between oscillator and test oscillator which will give the correct I.F. frequency. The correct setting of the trim condenser is the one wherein the screw is turned farthest out. In any event, an incorrect setting will always be denoted by lack of sensitivity when the set and test oscillator are tuned to 2500 K.C. (mid-band).

D - ALIGNING THE RED BAND

1. Set test oscillator to 8000 K. C. and tune receiver in region of 8.0 on dial. Note where signal is received.
2. Next, set test oscillator to 4000 K.C. and tune set to 4.0 on dial.
3. Adjust #18 on right side of chassis (see Figure #2) until signal is tuned in.
4. Retune set and test oscillator to 8000 K.C. and observe pointer setting and sensitivity. Slight deviations from calibration can be compensated by manipulating the stiff wires connecting the oscillator coil to switch.

E - ALIGNING THE PURPLE BAND

1. Set test oscillator to 20,000 K. C. or if this is not available, then adjust to highest possible frequency, which should at least be 15,000 K.C. Tune set to this frequency and note where signal is received on dial.
2. Then set test oscillator to 10,000 K.C. and station indicator to 10. on dial. Adjust #20 on right side of chassis (Fig. #2) until signal is tuned in at 10. on dial scale.
3. Now retune both test oscillator and set to highest frequency. Located underneath the chassis and mounted on the wave change switch are two trim condensers (see Figure #2) which are used for correct adjustment at this high frequency.
4. Increase output of test oscillator until signal can be tuned in at two points on dial (say 19. and 20.). Then with pointer set at 20., adjust #23 and #28 for maximum output, decreasing test signal as signal becomes better tuned. At correct adjustment a very loud signal will be obtained at 20. on the dial while a feeble signal or none at all will be observed at 19. This is a practical illustration of the effectiveness of preselection as outlined in the first part of this description.

The adjustment instructions just given apply to a Model 462 which is in reasonable operating condition, but in some manner has been thrown out of adjustment. Before the radio service man can go through with the adjustment just given here, he must assure himself that defective tubes, injured parts; such as punctured condensers, shorted variable condensers, open resistors, open by-pass condensers, scratched high frequency coils, etc., are not such as to cause the set to be inoperative on one or more bands of frequencies.

KITS

The following kits are available for adapting the control head furnished with this set to panel mounting:

Part #	Description
KT 951	Under-dash mounting
KT 952	1934 Plymouth, Chrysler, Dodge
KT 953	1934 Ford
KT 954	1935 Plymouth, Chrysler, Dodge, Hupmobile
KT 955	1935 Ford

Type and Number of Tubes ---------- 1 #6A7, 1 #78, 1 #75, 1 #42, 1 #84 - Total 5
Battery Current (6.3 Volt Battery) ---------- 6.5 Amperes
Tuning Range ---------- 540 to 1500 K.C.
Maximum Undistorted Output ---------- 3.0 Watts
Maximum Output ---------- 4.0 Watts
Line-up Frequencies ---------- I.F. 456 K.C., 1400 K.C., 1500 K.C.

MODEL 536
Socket, Trimmers
Chassis, Alignment
Vibrator Data, Notes

UNITED AMERICAN BOSCH CORP.

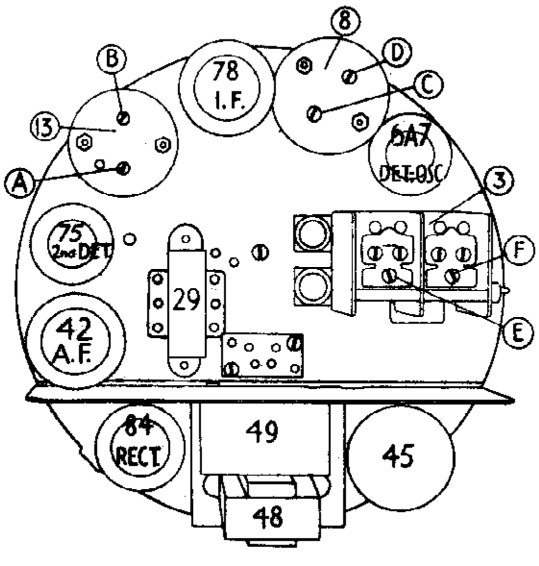

Figure No. 2

GENERAL DESCRIPTION

The Model 536 Car Radio has been designed, manufactured and tested with special regard for the requirements of automobile radio. The electrical, mechanical and acoustical features of the set have been decided upon after extensive tests in automobiles to determine the proper requirements for satisfaction. This Car Radio is a single unit compact radio chassis, power pack, and speaker with a separate remote control. The set is contained in a cylindrical housing and is provided with many features which result in improved tone quality, attractive appearance, mechanical stability and desirable service features.

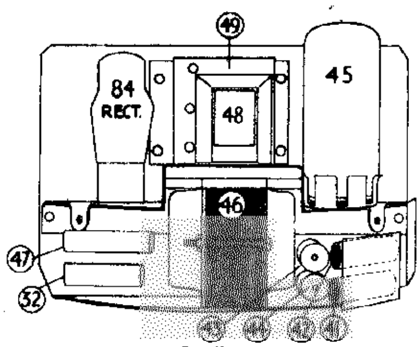

Figure No. 3

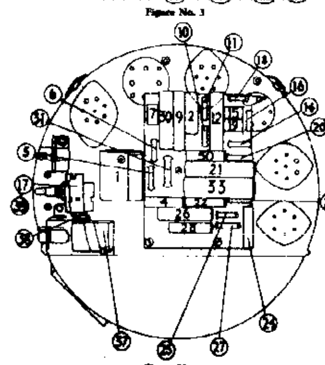

Figure No. 4

CIRCUIT DESCRIPTION

The circuit is of the superheterodyne type employing five tubes as follows: A type 6A7 as a combined first detector-oscillator, a type 78 as an intermediate frequency amplifier, a type 75 as a combination second detector-A.V.C.-and first audio amplifier, a type 42 as an output tube and a type 84 as a rectifier in the power supply.

As the Model 536 is equipped with both an external spark trap (connected in the battery cable) and an internal, tuned spark trap, the use of spark-plug suppressors is unnecessary in many installations.

SERVICE DATA

COMMON TROUBLES THAT CAN BE EASILY LOCATED AND REMEDIED WITHOUT REMOVING RECEIVER FROM CAR OR FROM ITS HOUSING

DIAL LIGHT DOES NOT LIGHT

Dial light may be loose in socket, broken or burned out.

Socket on end of lead in rear of control head pulls straight out.

SET INOPERATIVE AND TUBES DO NOT LIGHT

Check fuse in container on receiver ammeter lead. Remove speaker cover and disconnect speaker plug. Remove vibrator, all tubes and disconnect dial-light cable from set. Check with ohmmeter from "Hot A" side of battery cable (male bayonet connector inside the fuse-container housing) to ground. Should ohmmeter show an open circuit when line switch is closed, obviously a tube or the vibrator is shorted and these parts can be checked separately to determine which is defective. On the other hand, if ohmmeter shows a short circuit, the chassis should be removed from its housing and checked.

INSENSITIVE OR WEAK

Check car antenna for poor connections and grounds. Also check tubes and the receiver alignment.

INTERMITTENT RECEPTION

This is usually caused by a poor connection from the set antenna lead to the car antenna lead-in, and this point should always be checked when intermittent reception occurs.

MICROPHONIC OR INTERMITTENT

Tap each tube lightly with a small piece of wood or an insulated screw driver handle. The offending tube, when tapped, will usually howl very loudly if microphonic, or will give intermittent results if defective.

LOW POWER OUTPUT

Check tubes and vibrator. Usually caused by the latter.

RECEPTION CUTS OFF AT CERTAIN SETTINGS OF DIAL-SCALE POINTER

Usually caused by some foreign metallic substance shorting a section of the condenser gang. These particles are often too small to be seen but can be removed by blowing them out with an air pressure hose or an ordinary hand pump. Great care must be exercised not to destroy the thin mica insulators assembled under the trimmers on top of condenser gang.

POOR TONE QUALITY

Foreign material is apt to become lodged between the speaker voice coil and the field core. This hampers the movement of the speaker diaphragm. As the rear of the speaker diaphragm is open, this space can be blown out clean with an air hose.

BUZZING SOUND IN SPEAKER

This can be remedied in many cases by the method described above. It can also be caused by a loose winding on the voice coil, in which case the turns of this winding should be pushed together, and a thin coat of collodion or coil cement should be applied to hold the windings in place.

RATTLES

Check receiver for loose cover thumb screws, tube shield, and housing screws. Rattles, seemingly in the radio receiver, are often traced to loose parts on the bulkhead or dashboard of the car.

SET INOPERATIVE
TUBES LIGHT AND VIBRATOR BUZZES

A. Check B voltage (approximately 240 volts) from middle terminal of electrolytic filter condenser #49 to ground. This point is easily reached with the speaker cover removed. If no voltage or low voltage is obtained, test the vibrator and 84 tube. If voltage is still incorrect, the receiver should be removed from its housing for further checking.

B. With the speaker plugged in, remove the clip from the grid of the 75 tube and touch the clip to the grid cap of the tube several times in succession. A clicking noise should be heard in the speaker. This is a practical test for the audio amplifier and speaker. If this clicking noise is not heard, the 75 and 42 tubes should be tested and the voltages checked at the plates of these tubes. The speaker should be also checked with an ohmmeter by testing across the prongs of the sp[illegible] plug for continuity. While making [illegible] test, the cable should be moved bac[illegible] forth to show up any possible intermi[illegible] open circuit in the speaker cable. Check the voice coil and the field coil for continuity.

If the audio and speaker are still dead, the chassis should be removed from its housing.

If the audio and speaker are working correctly, test the remaining tubes and check the voltages at each socket.

In the event that the chassis has to be removed from the car for repairs, this can easily be done as follows:

Disconnect all chassis cables and the flexible control shafts from the receiver. Remove the speaker cover and pull out the speaker plug. Remove the screws around the outside of the housing and pull the chassis straight out. The chassis can be removed in many cars in this manner without unbolting the chassis housing from the car.

LOCATING TROUBLE IN CHASSES

To locate a shorted, open, or defective unit, causing low or no B voltage, disconnect the power pack from the receiver section by unsoldering the red lead (coming from coil #32, Fig. 3) from the terminal at the end of resistor #23, Fig. 4. Check the voltage at the free end of this Red lead (should be approximately 250 volts.) If the voltage is incorrect, the trouble is definitely in the power pack and all component parts should [illegible] be checked.

Conversely, if the voltage reading proves to be correct, the trouble is in the receiver section and all parts should be checked. In locating a short or open in the filament circuit, the power pack can be disconnected from the filament supply of the receiver section by removing the red wire on the top term[illegible] "off" and "on" switch which is [illegible] 42 tube. This will conne[illegible] pack in the file[illegible] short or open is [illegible] that the troub[illegible] tion.

WEAK OR INSENSITIVE AFTER REALIGNMENT

Check coils and associated circuits in the deficient "stage" of the set for proper resistance values.

LOW POWER OUTPUT WITH B VOLTAGE CORRECT

Check speaker field coil, voice coil and associated audio circuit for resistance continuity and defective condensers. All riveted component parts can be removed by merely punching out the rivets with a small diameter straight side punch. Replacement parts can be secured with small machine screws and nuts.

In changing the power transformer, it is necessary only to remove the four drive screws, two located directly over the resistor and condenser strip, and the other two in back of the condenser gang on the power pack shield. In replacing the power transformer be sure to tighten the screws securely and replace the shield braid bond or vibrator noise will be present.

INSTRUCTIONS FOR ADJUSTING VIBRATOR

After the vibrator has been in use for some time, it may refuse to start operating. This is an indication of "worn" tungsten contact points; but, as a reserve supply of tungsten has been provided, a simple adjustment can be made to prolong the life of the vibrator.

1. Remove the vibrator unit from its housing by removing the tension spring with a pair of round-nose pliers.

2. Remove the rubber sock, being careful not to bend the wires at the soldered connection.

3. Lay the vibrator on a piece of white paper so that when viewed from above it appears exactly as shown in Fig. 1.

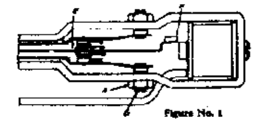

Figure No. 1

4. Loosen lock nut [illegible] clockwise until .005" [illegible] between contacts C and [illegible] points are somewhat r[illegible] not be seen across the[illegible] even though they are [illegible] that is, within .005" of touching each other.

5. A simple check on the correctness of the spacing adjustment is obtained by pressing lightly against the center of the reed with a small nail in the direction and location shown by arrow E. When the reed is thus moved so as to close contacts C and D, the weight F on the free end of the reed should move 1/64" from its "at rest" position. This check should be made [illegible] nut A has been firmly re-[illegible]

6. [illegible] readjust the spacing between contacts G and H unless the tungsten is nearly all worn away. In this case, readjustment may be made in the same manner as for contacts C and D.

7. In re-inserting the vibrator into its rubber sock, be very careful to turn the "flats" of the sock hole so that they are parallel to the flat side of the vibrator frame. This provides ample space in the sock for the free movement of the reed. Make certain that the slot in the prong terminal plate engages the small projection on the inside edge of the housing. Then replace the tension spring. THESE INSTRUCTIONS DO NOT APPLY TO ANY OTHER TYPES OF VIBRATORS.

LINE-UP CAPACITOR ADJUSTMENTS

All the adjustable capacitors, commonly called trimmer condensers, are very accurately adjusted at the factory and will not need any further adjustment unless a coil or I.F. transformer is changed, or the adjustments tampered with in the field. Therefore, DO NOT attempt to change the setting of any of the trimmer condensers unless it is definitely known that adjustment is necessary and a high grade modulated oscillator is available. In such a case, proceed as follows, referring to Fig. #2:

1. Set test oscillator to 456 K.C.

2. Set condenser gang to approximately 600 K.C. This will be at a point where the condenser plates are nearly all in mesh.

3. Connect output meter across voice coil of speaker. This may be done by connecting one lead of the output meter to the blue lead of the speaker terminal strip and the other lead to any metal part of the chassis. (The impedance of the voice coil is 3.0 ohms.)

4. Apply test signal to grid of 78 I.F. tube through a .5 mfd. blocking condenser and adjust trimmers A and B to maximum output reducing output of test oscillator as required.

5. Apply test signal to grid of 6A7 detector-oscillator tube and adjust trimmers C and D to maximum output.

6. Set test oscillator to 1500 K.C. and turn condenser gang until the rotor plates are wide open. Then place a piece of thin paper (approximately .015 thick) between the rotor and stator at the bottom of the gang, and then close the rotor down to this spacing. This is the exact setting of the condenser gang for the receiver oscillator at 1500 K.C. and should be carefully set as the resultant alignment of the receiver is directly dependent upon it.

7. Adjust trimmer E to maximum output and then remove the paper gauge.

8. Set test oscillator and condenser gang to 1400 K.C.

9. Apply test signal to antenna lead through a .0002 mfd. condenser and adjust trimmer F to maximum output. This completes the adjustment of the receiver.

GENERAL DESCRIPTION

The Model 565 is a six-tube, three-band superheterodyne receiver, designed for world-wide reception and employing the new all-metal tubes.

The circuit of the chassis employs a type 6L7 as a first detector, a type 6C5 as a separate oscillator or mixer tube, a type 6K7 as an intermediate frequency amplifier, a type 75 as a combination second detector, A.V.C. and first audio amplifier, a type 6F6 pentode power amplifier and a type 80 rectifier with its associated filter system.

LINE-UP CAPACITOR ADJUSTMENTS

To align the circuits of this receiver, it is essential to use a high-grade modulated test oscillator, the output of which can be continuously varied and reduced sufficiently to prevent the action of the A.V.C. of the receiver from occuring when the individual circuits are brought into alignment. A conventional output meter can be connected across the terminals of the speaker voice coil to indicate when the circuits are correctly aligned. The sensitivity of this meter must be sufficient to give satisfactory reading with a low input signal.

Before attempting to align the receiver, the service man should familiarize himself with the general layout of the chassis, location of the tubes and various alignment condensers. Top and bottom views are shown in Figures #1 and #2 and should be carefully studied before the actual work is started.

ADJUSTMENT OF I.F. (465 K.C.)

1. Set volume control on full and adjust tone control to center position.
2. Connect output meter across speaker voice coil terminals.
3. Set test oscillator to 465 K.C. and adjust its output to produce a measurable reading on the output meter when the test signal is applied to the grid of the 6K7 I.F. tube thru a .5 mfd. blocking condenser.
4. Adjust trimmers #25 and #26 to maximum output.
5. Apply test signal to grid of 6L7 first detector tube and adjust trimmers #20 and #21 to maximum output.

ADJUSTMENT OF RED BAND

NOTE: Before proceeding with the following adjustments, it is important that trimmer #11 located on top of the condenser gang, be carefully adjusted. This trimmer has been correctly adjusted prior to its shipment at the factory and no further adjustment should be necessary, unless it has been tampered with. In this event, turn the adjustment screw of this trimmer to maximum capacity (screw turned to extreme clockwise position—all the way in), then turn screw about a half-turn in a counter-clockwise direction.

1. Set wave change switch to the red-band position (lower center control turned to its extreme left-hand setting).
2. Set dial indicator and test oscillator to 16,000 K.C. and apply test signal to the "A" and "G" terminals of the chassis thru a .0002 mfd. condenser and a 400 ohm resistor in series. This condenser-resistor combination is the approximate equivalent of a short-wave antenna.
3. Adjust trimmer #50 to maximum output.

NOTE: When adjusting the oscillator trimming condensers, it is possible to obtain two different peaks. Correct adjustment is obtained by trimming to the second peak from maximum capacity of the trim condenser. Adjustment to the wrong peak will result in a lack of sensitivity and poor calibration at mid-band positions.

4. Adjust trimmer #7 by the "max-max" method. This is accomplished as follows: With dial indicator and test oscillator still set at 16,000 K.C., adjust trimmer #7 to maximum output and note reading of the output meter. Then, change the setting of #7 trimmer slightly in either direction and then without changing trimmer screw, tune receiver by means of tuning knob thru a maximum and note reading of output meter. If second reading is lower, reverse the direction of the adjustment of #7 trimmer. Proceed with this adjustment in progressive steps, each time tuning receiver thru a maximum, until no further improvement can be obtained by tuning receiver, the #7 trimmer screw, or both together. Although this procedure may at first appear a bit complicated, facility is easily acquired with practice; and after a few trials the operation can be completed in a few minutes.
5. Set dial indicator and test oscillator to 6000 K.C. and "max-max" the lagging condenser #59 to maximum output.

ADJUSTMENT OF GREEN BAND

1. Set wave-change switch to the green-band position (middle setting).
2. Set dial indicator and test oscillator to 4000 K.C. and adjust trimmers #61 and #8 to maximum output.
3. Set dial indicator and test oscillator to 1800 K.C. and "max-max" lagging condenser #52 to maximum output.

ADJUSTMENT OF WHITE BAND

1. Set wave-change switch to the white or broadcast-band position (right-hand setting).
2. Set dial indicator and test oscillator to 1400 K.C. and adjust trimmers #57 and #9 to maximum output.
3. Set dial indicator and test oscillator to 560 K.C. and "max-max" lagging condenser #58 to maximum output.

GENERAL DESCRIPTION

This model is a seven-tube, three-band superheterodyne receiver designed for world wide reception and employs the new all-metal tubes.

The circuit employs a high frequency amplifier using the new type 6K7 tube. This is followed by a combined first detector-oscillator circuit employing a 6A8 tube. These tubes with their associated circuits, (coils, variable condensers, trim condensers for R.F. and detector stages, and trim and lag condensers for the oscillators) comprise a complete assembly in compact form separately cushioned from the main chassis. This assembly is known as the "Centr-O-matic" unit. From the high frequency assembly the energy passes thru an I.F. selective transformer and to an I.F. amplifier tube (type 6K7). From here further selection takes place and the energy is sent to the diode (type 6H6) where second detection takes place and voltages are provided for automatic volume control. A first audio amplifier tube (type 6F5) follows the diode and this is further followed by a pentode power amplifier tube (type 6F6). A type 80 rectifier supplies the direct current for energizing the tubes.

REMOVING INDIVIDUAL COIL AND SWITCH SECTIONS OF CENTR-O-MATIC UNIT

If a component part located underneath the switch and coil assemblies of the "Centr-O-matic" unit has to be replaced or a section of the unit has to be removed for inspection, each section can easily be removed separately. To do this proceed with care as follows:

1. Remove the three coil shields.
2. Remove the two self-tapping screws which fasten the mounting plate of the wave-change switch shaft to the chassis. Pull switch shaft out straight.
3. Unsolder the stator and rotor leads from the gang condenser.
4. The fastening screws for the switch sections are located on top of the "Centr-O-matic" unit and are indicated by X,Y and Z in figure #3. Remove the corresponding screw.
5. Each individual section can then be pulled out straight.

NOTE: On the R.F. section the plate lead from the 6K7 socket will have to be unsoldered from the socket before the section can be removed. On the oscillator section one blue lead from the 6A8 detector-oscillator socket will have to be unsoldered at the switch terminal.

6. After repairs have been made resolder the leads mentioned above and replace the section being careful to observe that the slotted holes in the switch bracket line up with the round guide pins on the base plate of the "Centr-O-matic" unit. This is IMPORTANT as the switch shaft cannot be inserted if the switch brackets do not line up.
7. Replace the section fastening screw.
8. Resolder the stator and rotor leads on the gang condenser.
9. Replace the switch shaft and the mounting plate fastening screws. When inserting the switch shaft, be careful that all the switch discs are in the same position, otherwise the switch shaft will not slide in. NEVER force the shaft into the switch discs. If shaft does not slide in freely, examine the position of the slots in each switch disc.
10. Before replacing the coil shields, it might be advisable to bend the shields slightly to assure that positive contact is made. To do this hold the shield with your two hands using the thumbs and the first two fingers as shown in figure #1. Pull out the ends of the shields slightly and at the same time apply a little pressure on the sides of the shield as indicated by the arrows in the drawing. Then replace the shields and observe that they fit tightly. In addition to assuring positive contacts, this will also prevent the shields from rattling.

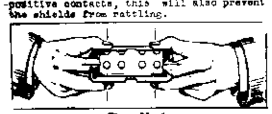

Figure No. 1

LINE-UP CAPACITOR ADJUSTMENTS

To align the circuits of this receiver it is essential to use a high grade modulated test oscillator, the output of which can be continuously varied with absence from overload when the individual circuits of the receiver are brought into alignment. A conventional output meter can be connected across the terminals of the speaker voice coil to indicate when the circuits are aligned. The sensitivity of the output meter must be sufficient to give satisfactory reading with a low input signal. Before attempting to align the receiver, the service man should familiarize himself with the general layout of the chassis, the location of the tubes and various alignment condensers. Top and bottom views of the chassis are shown in figures #2, #3 and #4 and should be carefully studied before the actual work is started.

ADJUSTMENT OF I.F. (465 K.C.)

1. Set volume control on full and turn tone control to the bass position.
2. Connect output meter across voice coil of speaker.
3. Set test oscillator to 465 K.C. and adjust its output to produce a measurable reading on output meter when test signal is applied to the grid of the 6K7 I.F. tube through a .5 mfd. blocking condenser.
4. Adjust trimmer #52 for maximum output, reducing output of test oscillator as required.
5. Apply test signal to grid of 6A8 detector-oscillator and adjust #44 and #45 for maximum output.

ADJUSTMENT OF BROADCAST BAND

1. Set wave-change switch to the Black or Broadcast Band position.
2. Set test oscillator and dial indicator to 1600 K.C.
3. Apply test signal to antenna terminal of chassis through a .0002 mfd. series condenser and adjust #31, #19 and #8 for maximum output.
4. Set test oscillator and dial indicator to 570 K.C. and adjust #37 for maximum output.
5. Return to 1600 K.C. setting with both test oscillator and dial indicator and readjust #31, #19 and #8 for accuracy.

ADJUSTMENT OF GREEN BAND

NOTE: In adjusting the two short-wave Bands (Green and Red) a .0002 mfd. condenser and a 400 ohm resistor connected in series should be inserted in the high side of the test oscillator leads. This condenser-resistor combination is the approximate equivalent of a short wave antenna.

1. Set wave change switch to the Green Band position.
2. Set test oscillator and dial indicator to 5500 K.C. and adjust #30, #18 and #7 for maximum output.
3. Set test oscillator and dial indicator to 1900 K.C. and adjust #36 for maximum output.
4. Return to 5500 K.C. setting and make readjustment of #30, #18 and #7.

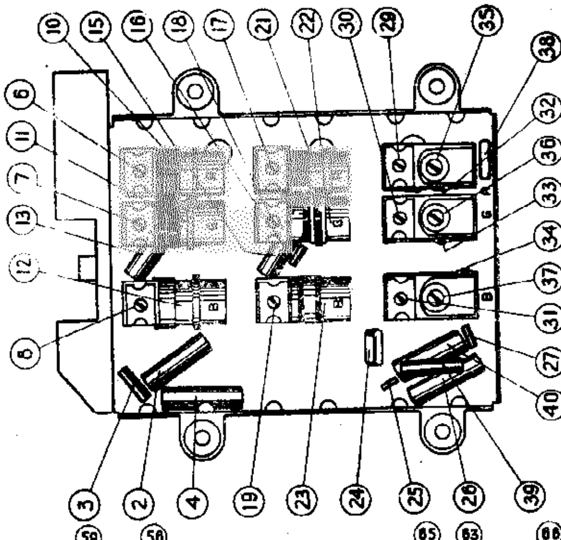
ADJUSTMENT OF RED BAND

1. Set wave change switch to the Red Band position.
2. Set test oscillator and dial indicator to 17000 K.C. and adjust #29, #17 and #6 for maximum output.
3. Set test oscillator and dial indicator to 6000 K.C. and adjust #35 for maximum output.
4. Return to 17000 K.C. setting and make readjustment of #29, #17 and #6.

NOTE: The adjustment of the two short-wave oscillator lag condensers (#35 and #36) is best made by the max-max. method.

This is done as follows:

Tune the receiver with the left hand by means of the tuning knob and adjust the lag condenser in either direction and then without changing it, tune the receiver thru a maximum, noting reading on the output meter. Change the lag condenser further in the same direction, retune receiver and note reading. If the output drops with the second adjustment, reverse direction of the adjustment of lag condenser. Continue this type of trial and error adjustment until no further improvement can be made when either the tuning control or the lagging condenser are changed. While this procedure may appear to be difficult, facility can easily be acquired by practise and the operation requires only a few minutes.



IMPORTANT: While testing or making repairs on this receiver, the chassis should not be turned upside down or on its side for any long period of time while the set is turned on as the chemicals in the electrolytic filter condenser will come out thru the air vents making the condenser appear to be defective. If the set is left in this position too long the condenser may be injured.

MODELS 355 & 357

ELECTRICAL SPECIFICATIONS

Type and Number of Tubes ---------------- 1 #6A7, 1 #78, 1 #75, 1 #43, 1 #2525 - Total 5
Power Supply Characteristics ------------ 105 to 125 volts D.C. or A.C. 50 to 60 cycles
Power Consumption -- 45 Watts
Tuning Range -- 540 to 4200 K.C.
Maximum Undistorted Power -- 3 Watts
Line-Up Frequencies -------------------------- 175 K.C., 1400 K.C., 600 K.C., 1800 K.C.

GENERAL DESCRIPTION

The Model 357 is a five tube, two band, A.C. - D.C., superheterodyne receiver whose circuits consist of a combined first detector - oscillator, and intermediate frequency amplifier stage, a combined second detector-automatic volume control and first audio amplifier, an output stage and a rectifier.

The receiver is of the two band type and is designed to work on the following frequencies:

On the Black band from 540 to 1600 kilocycles and on the Red band from 1600 to 4200 kilocycles.

LINE-UP CAPACITOR ADJUSTMENTS

To align the 357 chassis, it is essential to use a high grade modulated oscillator and sensitive output meter. The R.F. signal fed into the receiver must be weak or it will cause the A.V.C. to function, making correct alignment difficult. The sensitivity of the output meter mustbe sufficient to give satisfactory reading with a low signal.

Before attempting to align a receiver, the serviceman should familiarize himself with the general layout of the chassis, the location of the tubes and various alignment condensers. A top view of the chassis is shown in Figure #1 and should be carefully studied before the actual work is started.

ADJUSTMENT OF I.F. (175 K.C.)

1. Set volume control on full.
2. Tone control should be on bass position.
3. Connect output meter across voice coil of loud speaker (speaker impedance is 3.5 ohms).
4. Set test oscillator to 175 K.C. and adjust its output to produce measurable reading on output meter when test oscillator is connected between frame of the chassis and the grid of 78 I.F. tube #4.
5. Adjust #8 and #9 to maximum output, reducing signal oscillator outputas stage is brought into resonance.
6. Connect test oscillator to grid of 6A7 (#5) and adjust #10 and #11 to maximum output.

ADJUSTMENT OF B.C. OSC. & R.F.

1. Set wave change switch to broadcast or BLACK scale position.
2. Connect test oscillator to grid of first detector tube 6A7 (#5) and adjust test oscillator to 1400 K.C.
3. Check dial scale by observing maximum mark beyond 550 K.C. calibration point when gang is entirely closed.
4. Set scale at 1400 K.C. and adjust #12 to maximum output. NOTE: Two peaks will be heard as trimmer condenser is tuned. The second peak from maximum capacity of trim condenser should be used.
5. Connect test oscillator to antenna through 100. mmf. condenser and with scale still setat 1400 K.C. adjust condensers #12, 13 and 14 to maximum output.
6. Set scale and test oscillator to 600 K.C. and adjust #16 simultaneously changing this adjustment and the tuning control of chassis for maximum output. This type of adjustment is known as "max-max" and is obtained in the following manner:

Tune receiver with left hand by means of tuning knob and adjust #16 in either direction, and then without changing it, tune the receiver through a maximum, noting the value of output meter reading. Change #16 further in same direction, retune receiver and note reading. If output drops with second adjustment, reverse direction of the adjustment of #16, continue this type of trial and error adjustment until no further improvement can be made when either tuning control or #16 are changed. While this procedure may appear difficult, facility can be easily acquiredby practice and the operation requires only a few moments.

7. With test oscillator and scale set at 1400 K.C. readjust #12,13 and 14, since previous operation may have altered oscillator trimmer setting.
8. Check sensitivity across band.

ADJUSTMENT OF S.W. OSCILLATOR

1. Set wave change switch to short wave or RED band position.
2. Set test oscillator to 1800 K.C. and adjust #15 and tuning control to a "max-max" as per instructions given under Broadcast Band Alignment.
3. Check sensitivity across band.

MODEL 350

ELECTRICAL SPECIFICATIONS

Type and Number of tubes ---------------- 1 #2A7, 1 #58, 1 #2A6, 1 #2A5, 1 #80 - Total 5
Power Supply Characteristics ------------------------ 105 to 125 volt, 50 to 60 cycle
Power Consumption -- 50 Watts
Tuning Ranges -- 540 to 4200 K.C.
Maximum Undistorted Output -- 3 Watts
Line-Up Frequencies -------------------------- 175 K.C., 1400 K.C., 600 K.C., 1800 K.C.

GENERAL DESCRIPTION

The Model 350 is a five tube, two band, superheterodyne receiver. Its circuit comprises a combined first detector-oscillator, a stage of intermediate frequency amplification, a combined second detector-automatic volume control and first audio amplifier, a power output amplifier and a rectifier.

This receiver is designed to work over two bands; the broadcast band (black band) extending from 540 to 1600 kilocycles and the red band extending from 1600 to 4200 kilocycles.

LINE UP CAPACITOR ADJUSTMENTS

To properly align the Model 350 chassis, it is essential to use a high grade modulated oscillator and a sensitive output meter. The R.F. signal fed into the receiver must be very weak or it will cause the A.V.C. to function making correct alignment impossible. The sensitivity of the output meter mustbe sufficient to give satisfactory reading with a low signal.

Before attempting to align a receiver, the service man should familiarise himself with the general layout of the chassis, the location of the tubes and the various alignment condensers. A top view of the chassis is shown in Fig. #2 and should be carefully studied before the actual work is started.

1. Set volume control on full.
2. Tone control shouldbe on bass position.
3. Short circuit antenna and ground leads to prevent local stations from interfering with subsequent alignment operations.
4. Connect output meter across voice coil of loud speaker (speaker impedance is 3.5 ohms).
5. Set test oscillator to 175 K.C. and adjust its output to produce measurable readings on output meter when test oscillator is connected between frame of the chassis and the grid of 58 I.F. tube #6.
6. Adjust #4 and #5 to maximum output, reducing signal oscillator output as stage is brought into resonance.
7. Connect test oscillator to grid of 2A7 (#9) and adjust #7 and #8 to maximum output.

ADJUSTMENT OF B.C. OSC. & R.F.

1. Set wave change switch to broadcast or BLACK scale position.
2. Connect test oscillator to grid of first detector tube 2A7 (#9) and adjust test oscillator to 1400 K.C.
3. Set dial scale to maximum mark beyond 550 K.C. calibration point when gang is entirely closed.
4. Set scale at 1400 K.C. and adjust #10 to maximum output. NOTE: Two peaks will be heard as trimmer condenser is tuned. The second peak from maximum capacity should be used.
5. Connect test oscillator to antenna through 100. mmf. condenser and with scale still set at 1400 K.C. adjust condensers #10, 11 and 12 to maximum output.
6. Set scale and test oscillator to 600 K.C. and adjust #14 simultaneously changing this adjustment and the tuning control of chassis for maximum output. This type of adjustment is known as "max-max" and is obtained in the following manner:

Tune receiver with left hand by means of tuning knob and adjust #14 in either direction and then without changing it, tune the receiver through a maximum, noting the value of output meter reading. Change #14 further in same direction, retune receiver and note reading. If output drops with second adjustment, reverse direction of the adjustment of #14, continue this type of trial and error adjustment until no further improvement can be made when either tuning control or #14 are changed. While this procedure may appear difficult, facility can be easily acquired by practice and the operation requires only a few moments.

7. With test oscillator and scale set at 1400 K.C. readjust #10, 11 and 12, since previous operation may have altered oscillator trimmer setting.
8. Check sensitivity across band.

ADJUSTMENT OF S.W. OSC.

1. Set wave change switch to short wave on RED band position.
2. Set test oscillator to 1800 K.C. and adjust #13 and tuning control to a "max-max" as per instructions given under Broadcast Band Alignment.
3. Check sensitivity across band.

TROUBLE NOTES

INTERMITTENT RECEPTION

Intermittent reception occurring in the early Model 350 is caused by variations in characteristics in the 2A7 tube. The following circuit changes will stabilize the action of the 2A7 oscillator tube.

1. Replace R5 and R2 (2A7 and 58 bias resistors) with 750 ohm resistors.
2. Remove #19 which is connected between the 2A7 oscillator plate terminal and R6.
3. Connect a 20,000 ohm resistor to the 2A7 oscillator plate terminal and the 250 volt terminal of the electrolytic condenser.

NOTE: This 250 volt terminal may be located by turning chassis upside down and looking at the chassis from the back. The 250 volt point is the upper right hand terminal of the electrolytic condenser.

4. Replace C26 (2A5 bypass condenser) with a .01-600 volt condenser. Parts required for above changes:

2 SA 105965 - 750 ohm resistors
1 SA 105874 - 20,000 ohm resistor
1 SA 103895 - .01 mfd. 600 V. condenser

Should a loud hum develop in the Model 350, it is probably caused by a poor ground between the riveted connection from the filament of the 2A6 socket to ground. This can be corrected by soldering a short lead from the filament lug on the socket to the body of the chassis.

GENERAL DESCRIPTION

This model is a four-tube (plus a ballast tube), two-band superheterodyne receiver, designed to operate over the standard broadcast band extending from 530 to 1525 K.C., and a short-wave band extending from 1500 to 3000 K.C.

The receiver uses a type 6A7 tube as a first detector-oscillator, a type 6C6 as a second detector, a type 43 as a power output tube, a type 2525 as a rectifier and a type K55C as a ballast tube.

LINE-UP CAPACITOR ADJUSTMENTS

To properly align the circuits of this receiver it is essential to use a high grade modulated test oscillator, the output of which can be continuously varied and reduced sufficiently to prevent overload as the individual circuits of the receiver are brought into alignment. A conventional output meter should be connected across the terminals of the speaker voice coil to indicate when the individual circuits are correctly aligned. The sensitivity of this meter must be sufficient to give satisfactory readings with low input signals.

Before attempting to align the receiver, the service man should familiarize himself with the general layout of the chassis, location of the various tubes and alignment condensers. Top and bottom views of the chassis are shown in Figures #1 and #2 and should be carefully studied before actual work is started.

ALIGNMENT OF I.F. (465 K.C.)

1. Set the volume control to maximum position and wave change switch to standard broadcast band.
2. Connect the output meter across the voice coil terminals of the speaker.
3. Set the test oscillator to 465 K.C. and adjust its output to produce a measureable reading on the output meter when the test signal is applied to the grid of the type 6A7 first detector-oscillator tube through a 0.5 mfd. blocking condenser.
4. Adjust trimmers #9 and #11 to maximum output.

ALIGNMENT OF OSCILLATOR AND R. F.

1. Check the pointer setting to be sure that is is exactly horizontal when the tuning condenser is completely closed.
2. Set the test oscillator and dial indicator to 1400 K.C. and adjust the oscillator trimmer condenser #17 to maximum output.
3. Apply the test signal to the antenna of the receiver through a .0001 mfd. blocking condenser and adjust trimmer condenser #6 to maximum output.
4. Check sensitivity over the band.
5. Turn wave change switch to the shortwave band and check the sensitivity over scale.

ELECTRICAL SPECIFICATIONS

Type and Number of Tubes .... 1 #6A8, 1 #6K7, 1 #75, 1 #6F6, 1 #5Y3 - Total 5
Power Supply Characteristics .... 105 to 125 volts, 50 to 60 cycle A.C.
Power Consumption .... 46 Watts
Power Output .... 3.0 Watts
Undistorted Power Output .... 1.5 Watts
Tuning Range .... 545 to 1725 KC., and 2100 to 7200 KC.
Line-Up Frequencies .... 465 KC., 1700 KC., 600 KC., 6000 KC.

GENERAL DESCRIPTION

These models are five-tube, two-band superheterodyne receivers employing a type 6A8 tube as a combination first detector-oscillator, a type 6K7 tube as a first I.F. amplifier, a type 75 tube as a combination second detector - A.V.C. - first audio amplifier, a type 6F6 tube as an output amplifier and a type 5Y3 tube as a rectifier.

These models are designed to operate over two bands on frequencies from 545 to 1725 KC. and 2100 to 7200 KC.

The model 605 is a table model while the model 605C is a console model using a larger speaker.

LINE-UP CAPACITOR ADJUSTMENTS

To align the circuits of this receiver it is essential to use a high grade modulated test oscillator, the output of which can be continuously varied with absence from overload when the individual circuits of the receiver are brought into alignment.

A conventional output meter can be connected across the terminals of the speaker voice coil to indicate when the circuits are aligned. The sensitivity of the output meter must be sufficient to give satisfactory reading with a low input signal.

Before attempting to align the receiver, the service man should familiarize himself with the general layout of the chassis, the location of the tubes and various alignment condensers. Top and bottom views of the chassis are shown in Figs. #1 and #2 and should be carefully studied before the actual work is started.

ADJUSTMENT OF I.F. (465 KC.)

1. Connect the output meter to the terminals of the speaker voice coil.
2. Set the volume control to maximum position and tone control to treble.
3. Apply the test signal to the grid of the type 6K7 I.F. tube through a .1 mfd. blocking condenser.
4. Adjust trimmer condenser #25 to maximum output.
5. Apply the test signal to the grid of the type 6A8 first detector-oscillator tube and adjust trimmer condensers #17 and #18 to maximum output.

ADJUSTMENT OF BROADCAST BAND

1. Apply test signal to antenna lead and with a strong input signal adjust wave trap trimmer condenser #4 to minimum output.
2. Apply test signal to the antenna lead through a .0002 mfd. condenser.
3. Set test oscillator and dial indicator to 1700 KC. and adjust oscillator trimmer condenser #11 until the signal is received.
4. Adjust preselector trimmer #3 to maximum output.
5. Set test oscillator and dial indicator to 600 KC. and adjust oscillator series condenser #12 to maximum output.
6. Return both test oscillator and dial indicator to 1700 KC. and check adjustment of oscillator and preselector trimmer condensers.

ADJUSTMENT OF S. W. BAND

1. Turn the wave change switch to the short-wave position.
2. Set the test oscillator and dial indicator to 6000 KC. and adjust oscillator trimmer condenser #10 until the signal is received.
3. Adjust the preselector trimmer condenser #2 to maximum output.
4. Check the receiver over scale for sensitivity and calibration.

ELECTRICAL SPECIFICATIONS

Type and Number of Tubes	1 #6A8, 1 #6K7, 1 #6H6, 1 #6F5, 1 #25A6, 1 #25Z6, 1 #K42C (Ballast) in Model 620, 1 #K42B (Ballast) in Model 625 - Total 7
Power Supply Characteristics	105-125 volts D.C. or 105-125 volts, 50-60 cycle A.C.
Power Consumption	52 Watts
Maximum Output	1.0 Watts
Maximum Undistorted Output	0.75 Watts
Tuning Ranges	(Black Band - 540 to 1550 K.C. (Green Band - 1500 to 4500 K.C. (Red Band - - 5500 to 15500 K.C.
Line-Up Frequencies	I.F. 465 K.C., 1400 K.C., 600 K.C., 4000 K.C., 15000 K.C.

GENERAL DESCRIPTION

These models are seven-tube, three-band, A.C.-D.C. superheterodyne receivers whose circuits employ all metal tubes. A type 6A8 tube is used as a combined first detector-oscillator, a type 6K7 tube as an intermediate frequency amplifier, a type 6H6 tube as a second detector and automatic volume control, a type 6F5 as a first audio frequency amplifier, a type 25A6 as an output amplifier, a type 25Z6 as a rectifier, and a type K42C as a ballast tube in the Model 620 or a type K42B in the Model 625.

The Model 620 is a personal model with the speaker mounted on the chassis while the Model 625 is a console model using a larger separate speaker.

LINE-UP CAPACITOR ADJUSTMENTS

To align the circuits of this receiver it is essential to use a high grade modulated test oscillator, the output of which can be continuously varied with absence from overload when the individual circuits of the receiver are brought into alignment.

A conventional output meter can be connected across the terminals of the speaker voice coil to indicate when the circuits are aligned. The sensitivity of the output meter must be sufficient to give satisfactory reading with a low input signal.

Before attempting to align the receiver, the service man should familiarize himself with the general layout of the chassis, the location of the tubes and various alignment condensers. Top and bottom views of the chassis are shown in Figs. #1 and #2 and should be carefully studied before the actual work is started.

ADJUSTMENT OF I.F. (465 K.C.)

1. Set the volume control to maximum position and tone control to treble position.
2. Connect the output meter to the terminals of the voice coil.
3. Set the test oscillator to 465 K.C. and apply the test signal to the grid of the type 6K7 I.F. tube through a .1 mfd. blocking condenser.
4. Adjust trimmer condensers #36 and #37 to maximum output.
5. Apply the test signal to the grid of the type 6A8 first detector-oscillator tube and adjust trimmer condensers #22 and #23 to maximum output.
6. Connect the test oscillator to the antenna of the receiver and with a strong input signal adjust wave trap trimmer condenser #6 to minimum output.

BROADCAST BAND ADJUSTMENT

1. Set the test oscillator and dial indicator to 1400 K.C.
2. Apply the test signal to the antenna of the receiver through a .0002 mfd. condenser.
3. Adjust oscillator trimmer condenser #14 until the signal is received.
4. Adjust the preselector trimmer condenser #5 to maximum output.
5. Set test oscillator and dial indicator to 600 K.C. and adjust the oscillator series condenser #16 until the signal is received. Tune the receiver to a slightly lower frequency and readjust trimmer #16 to maximum output. If the sensitivity increases, continue this procedure in the same direction until maximum sensitivity is reached. If the sensitivity decreases, try this procedure at slightly higher frequencies until maximum sensitivity is reached.
6. Return test oscillator and dial indicator to 1400 K.C. and check adjustment of the oscillator and preselector trimmer condensers.

ADJUSTMENT OF GREEN BAND

1. Set the wave change switch to the green band position.
2. Set the test oscillator and dial indicator to 4000 K.C. and adjust the oscillator trimmer condenser #13 until the signal is received.
3. Adjust the preselector trimmer condenser #4 to maximum output.
4. Check the sensitivity and calibration over scale.

ADJUSTMENT OF RED BAND

1. Set the wave change switch to the red band position.
2. Set the test oscillator and dial indicator to 15000 K.C. and adjust the oscillator trimmer condenser #12 until the signal is received. Two positions may be found at which the signal may be tuned in. Use the position with the lower capacity trimmer setting or with the alignment screw turned farther out.
3. Adjust the preselector trimmer #3 to maximum output.
4. Check the receiver over scale for calibration and sensitivity.

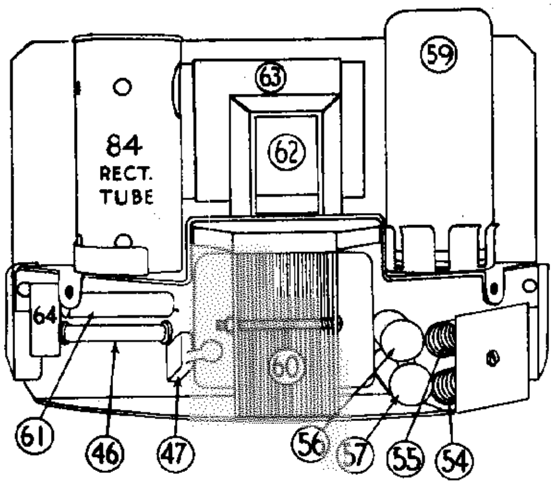
Vibrator Adjustment

UNITED AMERICAN BOSCH CORP.



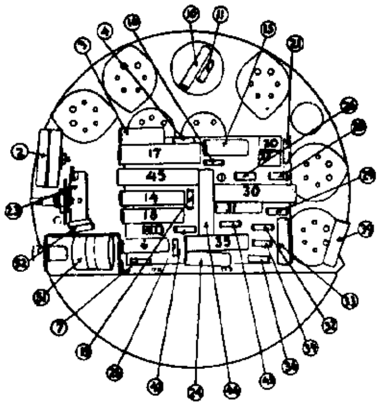


Figure No. 3

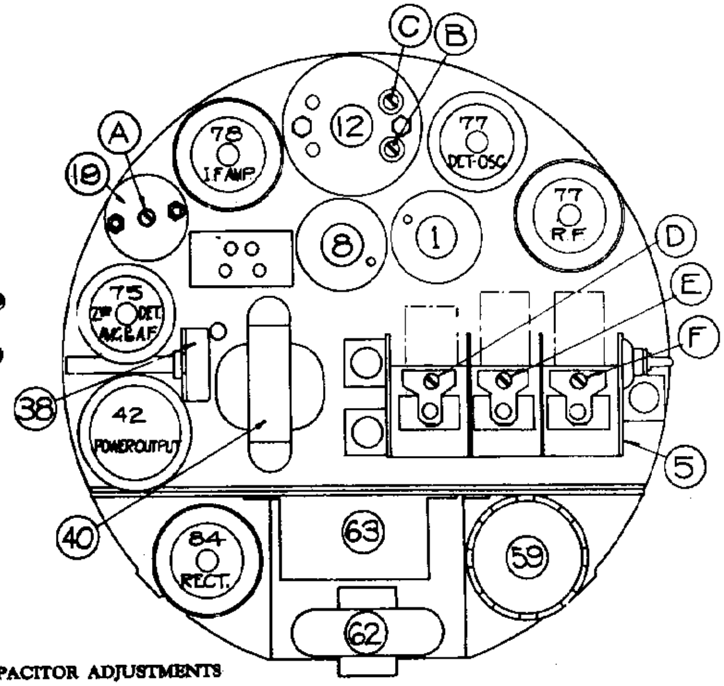

Figure No. 2

INSTRUCTIONS FOR ADJUSTING VIBRATOR

After the vibrator has been in use for some time, it may refuse to start operating. This indicates worn tungsten contact points. Since a reserve supply of tungsten is available, a simple adjustment can be made to prolong the life of the vibrator.

1. Remove the vibrator unit from its housing by removing the tension spring with a pair of round nosed pliers.

2. Remove the rubber sock, being careful not to bend the wires at the soldered connections.

3. Lay the vibrator on a piece of white paper so that when viewed from above it appears exactly as shown in Fig. 1.

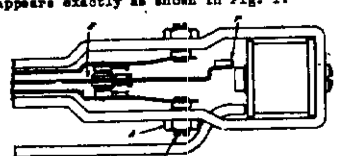

Figure No. 1

4. Loosen lock nut "A" and turn screw "B" clockwise until .005" of light can be seen between contacts "C" and "D". If the contact points are somewhat roughened, light cannot be seen across their entire diameter, even though they are correctly replaced, that is within .005" of touching each other.

5. A simple check on the correctness of the spacing adjustment is obtained by pressing lightly against the center of the reed with a small nail in the direction and location shown by arrow "E". When the reed is thus moved so as to close contacts "C" and "D", the weight "F" on the free end of the reed should move 1/64" from its "at rest" position. This check should be made after lock nut "A" has been firmly retightened.

6. Do not readjust the spacing between contacts "G" and "H" unless the tungsten is nearly all worn away. In this case, re-adjustment may be made the same as for contacts "C" and "D".

7. In re-inserting the vibrator into its rubber sock, be very careful to turn the "flats" of the sock hole so that they are parallel to the flat side of the vibrator frame. This provides ample space in the sock for the free movement of the reed. Make certain that the slot in the prong terminal plate engages the small projection on the inside edge of the housing. Then replace the tension spring. THESE INSTRUCTIONS DO NOT APPLY TO ANY OTHER TYPES OF VIBRATORS.

LINE-UP CAPACITOR ADJUSTMENTS

All the adjustable capacitors, commonly called trimmer condensers, are very accurately adjusted at the factory and will not need any further adjustment unless a coil or I.F. transformer is changed or the adjustments are tampered within the field. Therefore, DO NOT attempt to change the setting of any of the trimmer condensers unless it is definitely known that adjustment is necessary, and a high grade modulated test oscillator is available. In such a case, proceed as follows, referring to Fig. #2.

1. Set test oscillator to 175 K.C.

2. Set condenser gang to approximately 600 K.C. This will be at a point where the condenser plates are nearly all in mesh.

3. Connect output meter across voice coil of speaker. This may be done by connecting one lead of the output meter to the blue lead of the speaker terminal strip and the other lead to the frame of the chassis. The impedance of the voice coil is 3. ohms.

4. Apply test signal to grid of 78 I.F. tube thru a .5 mfd. blocking condenser and adjust trimmer "A" to maximum output reducing output of test oscillator as required.

5. Apply test signal to grid of 77 first detector-oscillator and adjust trimmers "B" and "C" to maximum output.

6. Set test oscillator to 1500 K.C. and rotate condenser gang until the plates are wide open. Place a piece of paper (approx. .015 thick) between the rotor and stator plates at the bottom of the gang and close the rotor down to this spacing. This is the exact setting of the condenser gang for the receiver oscillator at 1500 K.C. and should be carefully set as the resultant alignment of the receiver is directly dependent upon it.

7. Adjust trimmer "D" to maximum output and then remove the paper gauge.

8. Set test oscillator and condenser gang to 1400 K.C.

9. Apply test signal to grid of 77 R.F. tube and adjust trimmer "E" to maximum output.

10. Apply test signal to antenna lead thru a .0002 mfd. condenser and adjust trimmer "F" to maximum output.

11. Check sensitivity at several points.

Power Supply Characteristics	105-125 volts, 50-60 cycle A.C.
Power Consumption	47 Watts
Maximum Output	3 Watts
Maximum Undistorted Output	2.4 Watts
Tuning Ranges	(Black Band - 540 to 1650 K.C. (Green Band - 1500 to 4500 K.C. (Red Band - - 5500 to 16500 K.C.
Line-Up Frequencies	I.F. 465 K.C., 1400 K.C., 600 K.C., 4000 K.C.

GENERAL DESCRIPTION

This model is a six-tube, three-band, superheterodyne receiver whose circuits employ all-metal tubes. The circuit employs a type 6A8 tube as a combined first detector-oscillator, a type 6K7 tube as an intermediate frequency amplifier, a type 5H6 tube as a second detector and automatic volume control, a type 6F5 tube as a first audio frequency amplifier, a type 6F6 as an output amplifier, and a type 5Y3 tube as a rectifier.

LINE-UP CAPACITOR ADJUSTMENTS

To align the circuits of this receiver it is essential to use a high grade modulated test oscillator, the output of which can be continuously varied with absence from overload, when the individual circuits of the receiver are brought into alignment. A conventional output meter should be connected across the terminals of the speaker voice coil to indicate when the circuits are aligned. The sensitivity of the output meter must be sufficient to give satisfactory reading with a low input signal.

Before attempting to align the receiver, the service man should familiarize himself with the general layout of the chassis, the location of the tubes and various alignment condensers. Top and bottom views of the chassis are shown in Figures #1 and #2 and should be carefully studied before the actual work is started.

ADJUSTMENT OF I.F. (456 K.C.)

1. Set volume control to maximum position.
2. Connect output meter across voice coil of speaker.
3. Set test oscillator to 465 K.C., and apply signal to grid of 6K7 I.F. tube through a 0.5 mfd. blocking condenser.
4. Adjust trimmers #25 and #26 to maximum output, reducing output of test oscillator as required.
5. Apply test signal to grid of 6A8 first detector-oscillator tube and adjust trimmers #21 and #22 to maximum output.
6. Apply test signal to antenna of receiver.
7. Adjust trap coil trimmer #5 to minimum output.

ADJUSTMENT OF BROADCAST BAND (540 to 1550 K.C.)

1. Set wave change switch to standard broadcast band position.
2. Set test oscillator and dial indicator to 1400 K.C.
3. Apply the test signal to the antenna of the receiver through a .0002 mfd. blocking condenser and adjust the oscillator trimmer condenser #14 until the signal is received.
4. Adjust the preselector trimmer #4 to maximum output.
5. Set the test oscillator and dial indicator to 600 K.C. and adjust the oscillator series condenser #17 until the signal is received. Tune the variable condenser to a slightly lower frequency and readjust trimmer #17 to maximum output. If the sensitivity increases, continue this trial and error method in the same direction until no further improvement in sensitivity can be made. If the sensitivity decreases, try this adjustment at slightly higher frequencies.

ADJUSTMENT OF GREEN BAND

1. Set the wave change switch to the green band position.
2. Set the test oscillator and dial indicator to 4000 K.C. and adjust the oscillator trimmer condenser #13 until the signal is tuned in.
3. Adjust the preselector trimmer condenser #3 to maximum output.
4. Check the sensitivity and calibration over scale.

ADJUSTMENT OF RED BAND

1. Set the wave change switch to the red band position.
2. Set the test oscillator and dial indicator to 15000 K.C. and adjust the oscillator trimmer condenser #12 until the signal is received. Two positions may be found at which the signal may be tuned in. Use the position with the lower capacity trimmer setting or with the alignment screw turned farther out.
3. Adjust the preselector trimmer #2 to maximum output.
4. Check the receiver over scale for calibration and sensitivity.

GENERAL DESCRIPTION

This model is a six-tube, three-band, superheterodyne receiver whose circuits employ all-metal tubes. The circuit employs a type 6A8 tube as a combined first detector-oscillator, a type 6K7 tube as an intermediate frequency amplifier, a type 6H6 tube as a second detector and automatic volume control, a type 6F5 tube as a first audio frequency amplifier, a type 6F6 as an output amplifier, and a type 5Y3 tube as a rectifier.

LINE UP CAPACITOR ADJUSTMENTS

To align the circuits of this receiver it is essential to use a high grade modulated test oscillator, the output of which can be continuously varied with absence from overload, when the individual circuits of the receiver are brought into alignment. A conventional output meter should be connected across the terminals of the speaker voice coil to indicate when the circuits are aligned. The sensitivity of the output meter must be sufficient to give satisfactory reading with a low input signal.

Before attempting to align the receiver, the service man should familiarize himself with the general layout of the chassis, the location of the tubes and various alignment condensers. Top and bottom views of the chassis are shown in Figures #1 and #2 and should be carefully studied before the actual work is started.

ADJUSTMENT OF I.F. (456 K.C.)

1. Set volume control to maximum position.
2. Connect output meter across voice coil of speaker.
3. Set test oscillator to 456 K.C., and apply signal to grid of 6K7 I.F. tube through a 0.2 mfd. blocking condenser.
4. Adjust trimmers #25 and #26 to maximum output, reducing output of test oscillator as required.
5. Apply test signal to grid of 6A8 first detector-oscillator tube and adjust trimmers #21 and #22 to maximum output.
6. Apply test signal to antenna of receiver.
7. Adjust trap coil trimmer #5 to minimum output.

ADJUSTMENT OF BROADCAST BAND
(540 to 1550 K.C.)

1. Set wave change switch to standard broadcast band position.
2. Set test oscillator and dial indicator to 1400 K.C.
3. Apply the test signal to the antenna of the receiver through a .0002 mfd. blocking condenser and adjust the oscillator trimmer condenser #14 until the signal is received.
4. Adjust the preselector trimmer #4 to maximum output.
5. Set the test oscillator and dial indicator to 600 K.C. and adjust the oscillator series condenser #17 until the signal is received. Tune the variable condenser to a slightly lower frequency and readjust trimmer #17 to maximum output. If the sensitivity increases, continue this trial and error method in the same direction until no further improvement in sensitivity can be made. If the sensitivity decreases, try this adjustment at slightly higher frequencies.

ADJUSTMENT OF GREEN BAND

1. Set the wave change switch to the green band position.
2. Set the test oscillator and dial indicator to 4000 K.C. and adjust the oscillator trimmer condenser #13 until the signal is tuned in.
3. Adjust the preselector trimmer condenser #3 to maximum output.
4. Check the sensitivity and calibration over scale.

ADJUSTMENT OF RED BAND

1. Set the wave change switch to the red band position.
2. Set the test oscillator and dial indicator to 15000 K.C. and adjust the oscillator trimmer condenser #12 until the signal is received. Two positions may be found at which the signal may be tuned in. Use the position with the lower capacity trimmer setting or with the alignment screw turned farther out.
3. Adjust the preselector trimmer #2 to maximum output.
4. Check the receiver over scale for calibration and sensitivity.

AMERICAN-BOSCH CentrOmatic RADIO MODELS 660T-660C

Seven-Tube, Three-Band, Superheterodyne Receivers.

SERVICE NOTES

ELECTRICAL SPECIFICATIONS

Type and Number of Tubes ..... 2 #6K7, 1 #6A8, 1 #6H6, 1 #6F5, 1 #6F6, 1 #5Y3 - Total 7
Power Supply .... 105 to 125 volts, 50 to 60 cycles A.C.
Power Consumption .... 60 Watts
Maximum Undistorted Output .... 2.5 Watts
Maximum Output .... 3.5 Watts
Tuning Ranges .... (White Band - 525 to 1800 KC. (Green Band - 1756 to 6000 KC. (Red Band - - 5800 to 18500 KC.
Line-Up Frequencies . I.F.465 KC.,1600 KC.,570 KC.,5500 KC.,1900 KC.,17000 KC.,&6000 KC.

GENERAL DESCRIPTION

This model is a seven-tube, three-band, superheterodyne receiver designed for world-wide reception and employs the new all-metal tubes.

The circuit employs a high frequency amplifier using the new type 6K7 tube. This is followed by a combined first detector-oscillator circuit employing a 6A8 tube. These tubes with their associated circuits, (coils, variable condensers, trim condensers for R.F. and detector stages, and trim and lag condensers for the oscillators) comprise a complete assembly in compact form seperately cushioned from the main chassis. This assembly is known as the "CentrOmatic" unit. From the high frequency assembly the energy passes thru an I.F. selective transformer and to an I.F. amplifier tube (type 6K7). From here further selection takes place and the energy is sent to the diode (type 6H6) where second detection takes place and voltages are provided for automatic volume control. A first audio amplifier tube (type 6F5) follows the diode and this is further followed by a pentode power amplifier tube (type 6F6). A type 5Y3 rectifier supplies the direct current for energizing the tubes.

REMOVING INDIVIDUAL COIL AND SWITCH SECTIONS OF CENTROMATIC UNIT

If a component part located underneath the switch and coil assemblies of the "CentrOmatic" unit has to be replaced or a section of the unit has to be removed for inspection, each section can easily be removed separately. To do this proceed with care as follows:

1. Remove the two screws which fasten the mounting plate of the wave change switch shaft to the chassis. Pull switch shaft out straight.
2. Unsolder the stator and rotor leads from the gang condenser.
3. The fastening screws for the switch sections are located on top of the "CentrOmatic" unit and are indicated by X, Y and Z in Figure #1. Remove the corresponding screws.
4. Each individual section can then be pulled out straight.

NOTE: On the R.F. section the plate lead from the 6K7 socket will have to be unsoldered from the socket before the section can be removed. On the oscillator section the blue lead from the 6A8 detector-oscillator socket and the yellow plate supply lead to the switch will have to be unsoldered from the switch.

5. After repairs have been made, resolder the leads mentioned above and replace the section, being careful to observe that the slotted holes in the switch bracket line up with the round guide pins on the base plate of the "CentrOmatic" unit. This is IMPORTANT as the switch shaft cannot be inserted if the switch brackets do not line up.
6. Replace the section fastening screws.
7. Resolder the stator and rotor leads on the gang condenser.
8. Replace the switch shaft and the mounting plate fastening screws. When inserting the switch shaft, be careful that all the switch discs are in the same position. Otherwise the switch shaft will not slide in. NEVER force the shaft into the switch discs. If shaft does not slide in freely, examine the position of the slots in each switch disc.

LINE-UP CAPACITOR ADJUSTMENTS

To align the circuits of this receiver it is essential to use a high grade modulated test oscillator, the output of which can be continuously varied with absence from overload when the individual circuits of the receiver are brought into alignment. A conventional output meter can be connected across the terminals of the speaker voice coil to indicate when the circuits are aligned. The sensitivity of the output meter must be sufficient to give satisfactory reading with a low input signal. Before attempting to align the receiver, the service man should familiarize himself with the general layout of the chassis, the location of the tubes and various alignment condensers. Top and bottom views of the chassis are shown in Figures #1 and #2 and should be carefully studied before the actual work is started.

ADJUSTMENT OF I.F. (465 KC.)

1. Set volume control on full and turn tone control to the bass position.
2. Connect output meter across voice coil of speaker.
3. Set test oscillator to 465 KC. and adjust its output to produce a measureable reading on output meter when test signal is applied to the grid of the 6K7 I.F. tube through a .5 mfd. blocking condenser.
4. Adjust trimmers #44 and #51 to maximum output, reducing output of test oscillator as required.
5. Apply test signal to grid of 6A8 detector-oscillator and adjust #38 and #40 to maximum output.

ADJUSTMENT OF BROADCAST BAND

1. Set wave change switch to the White or Broadcast Band position.
2. Set test oscillator and dial indicator to 1600 KC.
3. Apply test signal to antenna terminal of chassis through a .0002 mfd. series condenser and adjust #26, #13 and #3 to maximum output.
4. Set test oscillator and dial indicator to 570 KC. and adjust #28 to maximum output, at the same time rocking the variable tuning condenser.
5. Return to 1600 KC. setting with both test oscillator and dial indicator and readjust #26, #13 and #3 for accuracy.

ADJUSTMENT OF GREEN BAND

NOTE: In adjusting the two short-wave bands (Green and Red) a .0002 mfd. condenser and a 400 ohm resistor connected in series should be inserted in the high side of the test oscillator leads. This condenser-resistor combination is the approximate equivalent of a short-wave antenna.

1. Set wave change switch to the Green Band position.
2. Set test oscillator and dial indicator to 5500 KC. and adjust #31, #15 and #7 to maximum output.
3. Set test oscillator and dial indicator to 1900 KC. and adjust #34 to maximum output, at the same time rocking the variable tuning condenser.
4. Return to 5500 KC. setting and make readjustment of #31, #15 and #7.

ADJUSTMENT OF RED BAND

1. Set wave change switch to the Red Band position.
2. Set test oscillator and dial indicator to 17000 KC. and adjust #30, #14 and #6 to maximum output.
3. Set test oscillator and dial indicator to 6000 KC. and adjust #35 to maximum output, at the same time rocking the variable tuning condenser.
4. Return to 17000 KC. setting and make readjustment of #30, #14 and #6.

IMPORTANT: While testing or making repairs on this receiver, the chassis should not be turned upside down or on its side for any long period of time while the set is turned on as the chemicals in the electrolytic filter condenser will come out through the air vents making the condenser appear to be defective. If left in this position too long the condenser may be injured.

MODEL 660C

All service parts for Model 660C are the same as for Model 660T except for the following parts:

Dia. #	Part #	Description of Parts
84	SK 9513	Speaker assembly ....

Bosch 207-A Ed. 5. D.C.

The schematic diagram shown in the accompanying illustration is a t-r-f. receiver, operating from the 110-volt, d-c. line. The diagram shown has incorporated in it all the changes that were made in production runs, but in case you should have to repair an early type, we are giving below the changes as they have been made.

Edition 2. C-21 was changed from 8 mf., 200 volts, to 25 mf., 10 volts, Part No. SA-104487.

Edition 3. C-18 was connected to ground and changed to one end of R-11. R-3 was formerly connected to the junction of R-6 and R-8. This was changed to the junction of R-4 and R-6. C-19 was changed from 0.1 mf. to 0.08 mf.

Edition 4. R-12, Part No. 99864, and C-22, Part No. SA-100880, were added. C-7 and C-8 were also added, Part No. SA-102243.

Power Supply .... 105 to 125 volts, 50 to 60 cycles
Power Consumption .... 80 Watts
Maximum Undistorted Output .... 4.5 Watts
Maximum Output .... 6.5 Watts
Tuning Ranges .... (Green Band - 150 to 390 KC.
(White Band - 525 to 1600 KC.
(Blue Band - 1750 to 6000 KC.
(Red Band - 5800 to 18500 KC.
Line-Up Frequencies .. I.F. 465 KC., 350 KC., 130 KC., 1600 KC., 570 KC., 5500 KC., 1900 KC., 17000 KC., and 6000 KC.

GENERAL DESCRIPTION

This model is a nine-tube, four-band, superheterodyne receiver designed for world-wide reception including the U.S. Weather Band and employs the new all-metal tubes. The circuit employs a high frequency amplifier using the new type 6K7 tube. This is followed by the first detector circuit employing a 6A8 tube and a separate oscillator (type 6C5). These tubes with their associated circuits, (coils, variable condensers, trim condensers for R.F. and detector stages, and trim and lag condensers for the oscillators) comprise a complete assembly in compact form separately cushioned from the main chassis. This assembly is known as the "CentrOmatic" unit. From the high frequency assembly the energy passes through an I.F. selective transformer and to an I.F. amplifier tube (type 6K7). From here further selection takes place and the energy is sent to the diode (type 6H6) where second detection takes place and voltages are provided for automatic volume control. A first audio amplifier tube (type 6F5) follows the diode and this is further followed by a push-pull output stage employing two type 6F6 tubes. A type 5Y3 rectifier supplies the direct current for energizing the tubes.

REMOVING INDIVIDUAL COIL AND SWITCH SECTIONS OF CENTROMATIC UNIT

If a component part located underneath the switch and coil assemblies of the "CentrOmatic" unit has to be replaced or a section of the unit has to be removed for inspection, each section can easily be removed separately. To do this proceed with care as follows:

1. Remove the two screws which fasten the mounting plate of the wave change switch shaft to the chassis frame. Pull switch shaft straight out.
2. Unsolder the stator and rotor leads from the gang condenser.
3. The fastening screws for the switch sections are located on top of the "CentrOmatic" unit and are indicated by X, Y, and Z in Figure #1. Remove the corresponding screws.
4. Each individual section can then be pulled out straight.

NOTE: On the R.F. section, the plate lead from the 6K7 socket will have to be unsoldered from the switch terminal before the section can be removed.

On the oscillator section, the plate lead to the 6C5 socket and the plate supply lead will have to be unsoldered from the switch terminal before the section can be removed.

5. After repairs have been made, resolder the plate leads mentioned above and replace the section being careful to observe that the slotted holes in the switch bracket line up with the round guide pins on the base plate of the "CentrOmatic" unit. This is IMPORTANT as the switch shaft cannot be inserted if the switch brackets do not line up.
6. Replace the section fastening screws.
7. Resolder the stator and rotor leads on gang condenser.
8. Replace the switch shaft and the mounting fastening screws. When inserting the switch shaft, be careful that all the switch discs are in the same position. Otherwise the switch shaft will not slide in. NEVER force the shaft into the switch discs. If shaft does not slide in freely, examine the position of the slot in each switch disc.

LINE-UP CAPACITOR ADJUSTMENTS

To align the circuits of this receiver it is essential to use a high grade modulated test oscillator, the output of which can be contiguously varied with absence from overload when the individual circuits of the receiver are brought into alignment. A conventional output meter can be connected across the terminals of the speaker voice coil to indicate when the circuits are aligned. The sensitivity of the output meter must be sufficient to give satisfactory reading with a low input signal.

Before attempting to align the receiver, the service man should familiarize himself with the general layout of the chassis, the location of the tubes and various alignment condensers. Top and bottom views of the chassis are shown in Figures #1 and #2 and should be carefully studied before the actual work is started.

ADJUSTMENT OF I.F. (465 KC.)

1. Set volume control on full and turn tone control to bass position.
2. Connect output meter across voice coil of speaker.
3. Set test oscillator to 465 KC. and adjust its output to produce a measurable reading on output meter when test signal is applied to the grid of 6K7 I.F. tube through a .5 mfd. blocking condenser.
4. Adjust trimmers #63 and #66 for maximum output reducing output of test oscillator as required.
5. Apply test signal to grid of 6A8 first detector and adjust #47 and #48 for maximum output.

ADJUSTMENT OF GREEN BAND

1. Set wave change switch to Green Band position.
2. Set test oscillator and dial indicator to 350 KC.
3. Apply test signal to antenna terminal of the chassis through a .0002 mfd. series condenser and adjust #44, #23, and #12 for maximum output.
4. Set test oscillator and dial indicator to 130 KC. and adjust #45 for maximum output, at the same time rocking the variable tuning condenser.
5. Return to 350 KC. setting with both test oscillator and dial indicator and repeat adjustment of #44, #23 and #12 for accuracy.

ADJUSTMENT OF BROADCAST BAND

1. Set wave change switch to the White or Broadcast Band position.
2. Set test oscillator and dial indicator to 1600 KC. and adjust #42, #21 and #10 for maximum output.
3. Set test oscillator and dial indicator to 570 KC., and adjust #41 for maximum output, at the same time rocking the variable tuning condenser.
4. Return to 1600 KC. setting and make readjustment of #42, #21 and #10.

ADJUSTMENT OF BLUE BAND

NOTE: In adjusting the Blue and Red Bands, a .0002 mfd. condenser and a 400 ohm resistor connected in series should be inserted in the high side of the test oscillator leads. This condenser-resistor combination is the approximate equivalent of a short-wave antenna.

1. Set wave change switch to Blue Band position.
2. Set test oscillator and dial indicator to 5500 KC. and adjust #38, #19 and #8 for maximum output.
3. Set test oscillator and dial indicator to 1900 KC. and adjust #39 for maximum output, at the same time rocking the variable tuning condenser.

ADJUSTMENT OF RED BAND

1. Set wave change switch to Red Band position.
2. Set test oscillator and dial indicator to 17000 KC. and adjust #34, #16 and #5 for maximum output.
3. Set test oscillator and dial indicator to 6000 KC. and adjust #36 for maximum output, at the same time rocking the variable tuning condenser.
4. Return to 17000 KC. setting and make readjustment of #34, #16 and #5.

IMPORTANT: While testing or making repairs on this receiver, the chassis should not be turned upside down or on its side for any long period of time while the set is turned on as the chemicals in the electrolytic filter condenser will come out through the air vents making the condenser appear to be defective. If left in this position too long the condenser may

Nine-Tube, Four-Band, Superheterodyne Receivers

GENERAL DESCRIPTION

This model is a nine-tube, four-band, superheterodyne receiver designed for world-wide reception including the U.S. Weather Band and employs the new all-metal tubes. The circuit employs a high frequency amplifier using the new type 6K7 tube. This is followed by the first detector circuit employing a 6A8 tube and a separate oscillator (type 6C5). These tubes with their associated circuits, (coils, variable condensers, trim condensers for R.F. and detector stages, and trim and lag condensers for the oscillators) comprise a complete assembly in compact form separately cushioned from the main chassis. This assembly is known as the "CentrOmatic" unit. From the high frequency assembly the energy passes through an I.F. selective transformer and to an I.F. amplifier tube (type 6K7). From here further selection takes place and the energy is sent to the diode (type 6H6) where second detection takes place and voltages are provided for automatic volume control. A first audio amplifier tube (type 6F5) follows the diode and this is further followed by a push-pull output stage employing two type 6F6 tubes. A type 5Y3 rectifier supplies the direct current for energizing the tubes.

REMOVING INDIVIDUAL COIL AND SWITCH SECTIONS OF CENTROMATIC UNIT

If a component part located underneath the switch and coil assemblies of the "CentrOmatic" unit has to be replaced or a section of the unit has to be removed for inspection, each section can easily be removed separately. To do this proceed with care as follows:

1. Remove the two screws which fasten the mounting plate of the wave change switch shaft to the chassis frame. Pull switch shaft straight out.
2. Unsolder the stator and rotor leads from the gang condenser.
3. The fastening screws for the switch sections are located on top of the "CentrOmatic" unit and are indicated by X, Y, and Z in Figure #1. Remove the corresponding screws.
4. Each individual section can then be pulled out straight.

NOTE: On the R.F. section, the plate lead from the 6K7 socket will have to be unsoldered from the switch terminal before the section can be removed.

On the oscillator section, the plate lead to the 6C5 socket and the plate supply lead will have to be unsoldered from the switch terminal before the section can be removed.

5. After repairs have been made, resolder the plate leads mentioned above and replace the section being careful to observe that the slotted holes in the switch bracket line up with the round guide pins on the base plate of the "CentrOmatic" unit. This is IMPORTANT as the switch shaft cannot be inserted if the switch brackets do not line up.
6. Replace the section fastening screws.
7. Resolder the stator and rotor leads on gang condenser.
8. Replace the switch shaft and the mounting fastening screws. When inserting the switch shaft, be careful that all the switch discs are in the same position. Otherwise the switch shaft will not slide in. NEVER force the shaft into the switch discs. If shaft does not slide in freely, examine the position of the slot in each switch disc.

LINE-UP CAPACITOR ADJUSTMENTS

To align the circuits of this receiver it is essential to use a high grade modulated test oscillator, the output of which can be contiguously varied with absence from overload when the individual circuits of the receiver are brought into alignment. A conventional output meter can be connected across the terminals of the speaker voice coil to indicate when the circuits are aligned. The sensitivity of the output meter must be sufficient to give satisfactory reading with a low input signal.

Before attempting to align the receiver, the service man should familiarize himself with the general layout of the chassis, the location of the tubes and various alignment condensers. Top and bottom views of the chassis are shown in Figures #1 and #2 and should be carefully studied before the actual work is started.

ADJUSTMENT OF I.F. (465 KC.)

1. Set volume control on full and turn tone control to bass position.
2. Connect output meter across voice coil of speaker.
3. Set test oscillator to 465 KC. and adjust its output to produce a measurable reading on output meter when test signal is applied to the grid of 6K7 I.F. tube through a .5 mfd. blocking condenser.
4. Adjust trimmers #53 and #55 for maximum output reducing output of test oscillator as required.
5. Apply test signal to grid of 6A8 first detector and adjust #47 and #48 for maximum output.

ADJUSTMENT OF GREEN BAND

1. Set wave change switch to Green Band position.
2. Set test oscillator and dial indicator to 350 KC.
3. Apply test signal to antenna terminal of the chassis through a .0002 mfd. series condenser and adjust #44, #23, and #12 for maximum output.
4. Set test oscillator and dial indicator to 150 KC. and adjust #45 for maximum output, at the same time rocking the variable tuning condenser.
5. Return to 350 KC. setting with both test oscillator and dial indicator and repeat adjustment of #44, #23 and #12 for accuracy.

ADJUSTMENT OF BROADCAST BAND

1. Set wave change switch to the White or Broadcast Band position.
2. Set test oscillator and dial indicator to 1600 KC. and adjust #42, #21 and #10 for maximum output.
3. Set test oscillator and dial indicator to 570 KC., and adjust #41 for maximum output, at the same time rocking the variable tuning condenser.
4. Return to 1600 KC. setting and make readjustment of #42, #21 and #10.

ADJUSTMENT OF BLUE BAND

NOTE: In adjusting the Blue and Red Bands, a .0002 mfd. condenser and a 400 ohm resistor connected in series should be inserted in the high side of the test oscillator leads. This condenser-resistor combination is the approximate equivalent of a short-wave antenna.

1. Set wave change switch to Blue Band position.
2. Set test oscillator and dial indicator to 5500 KC. and adjust #38, #19 and #8 for maximum output.
3. Set test oscillator and dial indicator to 1900 KC. and adjust #39 for maximum output, at the same time rocking the variable tuning condenser.

ADJUSTMENT OF RED BAND

1. Set wave change switch to Red Band position.
2. Set test oscillator and dial indicator to 17000 KC. and adjust #34, #16 and #5 for maximum output.
3. Set test oscillator and dial indicator to 6000 KC. and adjust #36 for maximum output, at the same time rocking the variable tuning condenser.
4. Return to 17000 KC. setting and make readjustment of #34, #16 and #5.

IMPORTANT: While testing or making repairs on this receiver, the chassis should not be turned upside down or on its side for any long period of time while the set is turned on as the chemicals in the electrolytic filter condenser will come out through the air vents making the condenser appear to be defective. If left in this position too long the condenser may

ALIGNMENT INSTRUCTIONS FOR MODEL 812

I. F. ADJUSTMENT

1. Connect the five leads to the loud speaker.
2. Set volume control at maximu, tone control on base, and fround antenna lead.
3. Connect the 175 KC oscillator to the grid of the 2nd I. F. tube.
   a) Align the second I. F. transformer, for max. sensitivity. 20,000 u.v.
4. Connect the 175 KC oscillator to the grid of the 1st I.F. tube.
   a) Align the first and second I.F. coils for max. sens. Limit: 500 u.v.
5. Check the I. F. stability.

OSCILLATOR ADJUSTMENT

1. Adjust scale so that the indicator will be on the second line from the left, when the gang is entirely closed.
2. Connect ant. lead of the R. F. Oscillator to the grid of the 1st Detector.
3. Set the oscillator and set scale at 1400 Kilocycles.
   a) Peak the oscillator condenser on the second signal heard, when turning the condenser out. The osc. condenser is the front align. cond. on the variable condenser gang.
4. Connect ant. lead of the R. F. oscillator to the antennae lead of the set.
   a) Without touching the oscillator condenser, align the R. F. and ant. alignment condensers to the 1400 Kilocycle signal, until maximum sensitivity is obtained.
5. Check sensitivity at 1400 Kilocycles.
   Check sensitivity at 1000 Kilocycles.
   Check sensitivity at 550 Kilocycles.
6. If set lacks sensitivity at 600 or 550, the plates of the condenser gang should be adjusted until the set will reach the sensitivity limits.
7. If set does not track at 600, readjust plates of osc. section of gang condenser.

Part #	Description
	MAIN ASSEMBLIES
CH 9575	Chassis assembly
SK 955	Speaker
CU 9517	Control unit - less shafts
	BRACKETS & CLAMPS
FP 79381	Clamp (Battery, antenna & speaker cables)
BK 95176	Bracket for loading coil
	CABLES & CABLE ASSEMBLIES
CB 9570	Battery cable assembly
TU 1014	Shielded loom
	SOCKETS
SO 956	Speaker socket
SO 953	Tube socket (4 prong)
SO 9511	Tube socket (metal tube)
	WASHERS, BUSHINGS & SPACERS
WA 1046	Washers for mounting studs
WA 8-8 CA	Lock washer for mtg. studs
SR 955	Spacer for variable cond. rubber bushing
IS 1002	Rubber bushing for variable condenser mounting
WA 7-10 CA	Washer for loading-coil mtg.
	SCREWS & STUDS
SD 957	Mounting studs
FP 104892	Thumb screw
	MISCELLANEOUS
NT 103475	Mtg. nuts for loading coil
SH 9533	Flexible drive shaft (2 used)

UNITED AMERICAN BOSCH CORP.

LOCATING TROUBLE IN CHASSIS

To locate a short, open or defective unit which causes low or no "B" voltage, disconnect the power pack from the receiver section by disconnecting the two red leads at each end of the 4000 ohm resistor #58 in the power pack that pass into the receiver section. Check the voltage at the input side of the resistor, which should be approximately 250 volts. If the voltage is incorrect, the trouble is definitely in the power pack and all component parts should be checked.

Conversely, if the voltage reading proves to be correct, the trouble is in the receiver section and all its parts should be checked.

In locating a "short" or "open" in the filament circuit, the power pack can be disconnected from the filament supply of the receiver section by removing the red wire from the lower terminal of the RF battery choke #55. This will connect only the power pack in the filament circuit; and if the short or open is corrected, it will prove that the trouble is in the receiver section.

WEAK OR INSENSITIVE AFTER REALIGNMENT

Check coils and associated circuits in the different "stages" of the receiver for proper resistance values.

LOW POWER OUTPUT WITH "B" VOLTAGE CORRECT

Check the speaker field coil, voice coil and associated audio circuit for resistance continuity and defective 6F6 plate by-pass condenser.

All riveted component parts can be removed merely by punching out the rivets with a small-diameter straight side punch. Replacement parts can be secured with small machine screws and nuts.

In changing the power transformer, it is necessary only to remove the four machine screws. When replacing the power transformer, be sure to tighten these screws securely.

GENERAL DESCRIPTION

The Models 736, 737 and 738 American-Bosch All-Metal Tube Car-Radios have been designed, manufactured and tested with special consideration for the requirements of automobile radio. The electrical, mechanical and acoustical features of these sets have been developed only after extensive tests in automobiles to determine the proper requirements for greatest satisfaction.

The Models 736, 737 and 738 are seven-tube superheterodyne car-radios, differing only in the type of loud speaker equipment used. In the Model 736, a self-contained speaker is incorporated within the receiver housing. The Model 736 uses a separate header-type speaker, for mounting on the header bar directly above the windshield. A separate bulkhead-mounted speaker is used with the Model 738 receiver.

The Models 736, 737 and 738 are equipped with three spark traps: an internal, tuned spark trap in the battery circuit to assist in the suppression of ignition interference; an external spark trap connected in series with the battery cable; and an antenna spark trap provided in the antenna circuit. The use of these spark traps makes the installation of additional suppression equipment unnecessary in most cars.

LINE-UP CAPACITOR ADJUSTMENTS

All the adjustable capacitors, commonly called trimmer condensers, are very accurately adjusted at the factory, and will not need any further adjustment unless a coil or I.F. transformer is changed or the adjustments tampered with in the field. Therefore, DO NOT attempt to change the setting of any of the trimmer condensers unless it is definitely known that adjustment is necessary, and a high grade modulated test oscillator and an output meter are available. Then proceed as follows, referring to Figs. 1 and 2:

NOTE: Before aligning the gang-condenser trimmers on the bottom of the gang condenser, it will be necessary to remove the three rubber plugs from the bottom of the receiver housing. The setting of the trimmer on the TOP of the condenser gang should UNDER NO CIRCUMSTANCES BE DISTURBED.

1. Set test oscillator to 175 K.C.
2. Set condenser gang to approximately 600 K.C. This will be at a point where the condenser plates are nearly all in mesh.
3. Connect output meter across voice coil of speaker. This may be done by connecting one lead of the output meter to the blue lead of the speaker terminal strip and the other lead to the frame of the chassis. The impedance of the voice coil is 3.0 ohms.
4. Apply test signal to grid cap of 6K7 I.F. tube through a .5 mfd. blocking condenser and adjust trimmers #26 and #27 to maximum output reducing output of test oscillator as required.
5. Apply test signal to grid cap of 6A8 first detector-oscillator and adjust trimmers #19 and #20 to maximum output.
6. Set test oscillator to 1600 K.C. and rotate condenser gang until the plates are wide open. Place a piece of paper (approximately .015" thick) between the rotor and stator plates at the top of the gang and close the rotor down to this spacing. This is the exact setting of the condenser gang for the receiver oscillator at 1600 K.C. and should be carefully set as the resultant alignment of the receiver is directly dependant upon it.
7. Adjust trimmer "A" to maximum output and then remove the paper gauge.
8. Set test oscillator and condenser gang to 1400 K.C.
9. Apply test signal to grid cap of 6K7 R.F. tube and adjust trimmer "B" to maximum output.
10. Apply test signal to antenna lead thru a .0002 mfd. condenser and adjust trimmer "C" to maximum output.
11. Check sensitivity at several points.

ENGINEERING CHANGES

On early Models 736, 737 and 738 the following changes were made to make these Models 736 A2, 737 A2 and 738 A2:

1. The type 6J7 R.F. tube was changed to a type 6K7.
2. The .005 mfd., 600 volt condenser (CW 952) from the plate of the type 6F6 output tube to ground was changed to a .008 mfd., 600 volt condenser (CW 9524).
3. A .0005 mfd. mica condenser (CM 9519) was added from the grid of the type 6F5 audio tube to ground.
4. The type 6A8 detector-oscillator tube was placed on A.V.C. This change was made by removing the jumper from terminal on R.F. coil to ground and connecting this terminal by a jumper to the terminal on the antenna coil to which the red and yellow lead and the 100,000 ohm resistor are connected.

MODEL 601662 Chevrolet
Alignment, Voltage

GENERAL: The Chevrolet Model 601662 is a four tube, superheterodyne auto radio with a header speaker. It is designed specifically for the 1935 Model Chevrolet automobiles and can be installed on either the "Standard" or "Master" Models. Two types of tuning controls are used. One type mounts on the bottom flange of the instrument panel of "Standard" Chevrolets and the other mounts in the instrument panel of "Master" Chevrolets.

TUBE COMPLEMENT

Type	Function
6F7	R.F.--1st Audio Amplifier
6A7	Detector--Oscillator
6B7	I.F. Amplifier--2nd Det.--A.V.C.
42	Power Output

CIRCUIT DESCRIPTION

This receiver requires the use of four tubes, three of which are the dual purpose type. The circuit is the conventional superheterodyne type that does not involve the use of any regeneration which might affect its stability.

The antenna circuit of this receiver is an improved type designed for use with undercar antenna systems. An exceptionally high gain is obtained in this circuit by resonating it with the car antenna. This results in higher sensitivity and a lower station hiss level. A separate adjustment is provided on the receiver to permit accurate alignment of this circuit to the car antenna.

The output transformer is mounted on the receiver chassis because of the space limitation in the Header type speaker.

PEAKING PROCEDURE

The only way the circuits of this receiver can be peaked properly is with the use of a calibrated oscillator and an output meter. The circuits are very carefully adjusted at the factory and do not need any further adjustment unless tampered with in the field or a coil has been replaced. It is, therefore, advisable not to attempt any adjustments unless it is definitely known that an adjustment is necessary.

Connecting Output Meter

Connect the output meter leads to the chassis frame and to the plate prong of the type 42 output tube. The plate prong can be located by looking at the bottom of the tube with the filament prongs toward you. The first prong to the right of the filaments is the plate prong. Make sure that the meter is protected with a series D.C. blocking condenser.

IMPORTANT

Due to the high sensitivity of these receivers, the receiver chassis must be in its case before making any adjustments. This is necessary in order to obtain accurate adjustments and to prevent oscillation due to lack of the shielding effect of the receiver case.

Peaking I.F. Stages at 262 K.C.

(a) Connect the ground lead of the test oscillator to the chassis frame. Connect a .5 mfd. condenser in series with the other lead and connect this lead to the grid cap of the 6A7 tube, leaving the tube's grid clip in place.

(b) Set the test oscillator on 262 kilocycles.

(c) Turn the volume control of the receiver on full.

(d) Peak the I.F. trimmers P-4 and P-3 on the 2nd I.F. coil, Illus. #9 on Fig. 2.

(e) Then peak each of the trimmers P-2 and P-1 on the 1st I.F. coil, Illus. #8 on Fig. 2.

NOTE: In order to insure accurate settings of the I.F. trimmers the above adjustments should be repeated using the lowest oscillator output that will give a reasonable output meter scale deflection. Make all adjustments for maximum output.

Peaking Gang Condenser at 1530 K.C.

(a) Connect the output of the test oscillator to the antenna connection of the receiver and to the chassis ground. (Do not use the .5 mfd. condenser that was required in aligning the I.F. stages.)

(b) Turn the rotor plates of the gang condenser until they are COMPLETELY OUT OF MESH.

(c) Set the test oscillator on 1530 kilocycles.

(d) Adjust the trimmer for the oscillator section of the gang condenser (middle section) CAREFULLY for maximum output. Then adjust the trimmers for the "R.F." and "ANT." sections of the gang condenser also for maximum output.

Peaking Gang Condenser at 1400 K.C. and Compensating Condenser at 600 K.C.

(a) Set the test oscillator at 1400 kilocycles.

(b) Turn the condenser rotor plates until the 1400 K.C. signal from the test oscillator is tuned in with maximum output.

(c) Readjust the parallel trimmers for the "R.F." and "ANT." sections of the gang condenser (shown on Fig. 2) for maximum output. DO NOT DISTURB the setting of the "OSC." section of the gang condenser as this is adjusted at 1530 K.C. only, and any further adjustments at this point will affect both the tuning range of the receiver and the tracking of its circuits.

(d) Set the test oscillator on 600 kilocycles.

(e) Turn the condenser rotor plates until the 600 K.C. signal from the test oscillator is tuned in with maximum output.

(f) Peak the antenna compensating condenser (Illus. #21 on Fig. 3) for maximum output. Re-tune the condenser plates for maximum output. Repeat these operations alternately until no further improvement in output can be noted.

(g) Reset the test oscillator on 1400 kilocycles.

(h) Turn the condenser rotor plates until the 1400 K.C. signal is tuned in with the maximum output.

(i) Readjust the trimmer for the "ANT." section of the gang condenser CAREFULLY for maximum output.

Adjusting the Compensating Condenser to Car Antenna

After the "ANT." trimmer of the gang condenser has been correctly set according to preceding information, it will require no further adjustment. It will be necessary, however, to reset the "antenna compensating condenser" (Illus. #21 on Fig. 3) to the car antenna when installing the receiver in a car in order to compensate for the wide range of antenna capacities being used. This is done in the following manner:

(a) Tune the receiver to a weak broadcast station between 570 to 640 K.C.

(b) Peak the "antenna compensating condenser" for maximum output, rocking the receiver dial and adjusting the compensating condenser alternately until no further improvement in output can be obtained.

CAUTION: Do not touch the adjustment of the parallel trimmer for the "ANT." section of the gang condenser after the receiver is installed on a car.

VOLTAGE CHART

The voltages shown below are average readings taken from the tube socket contacts to the chassis frame, and will vary ± 10% when the set is tested on a 6 volt battery due to differences in characteristics of vibrators and tubes. All readings were taken with a 1000 ohm per volt meter.

NOTE: Ampere drain of set at 6 volts is 6 amperes.
Milliampere drain from B supply is 55 M.A.

VOLTAGE CHART

The voltages shown below are average readings taken from the tube socket contacts to the chassis frame, and may vary plus or minus 10% when the set is tested on a 6 volt battery. This is due to variations in characteristics of vibrators and tubes. All readings taken with a 1000 ohm per volt meter.

PEAKING PROCEDURE

Connecting Output Meter

Connect the terminals of the output meter to the two plate prongs of the type 6E6 output tube which can be determined by looking at the bottom of the tube with the filament prongs toward you. The prongs located on each side of the filaments are the plate prongs--make sure that the meter is protected with a series condenser.

IMPORTANT

Due to the high sensitivity of these receivers, the receiver chassis must be in its case before making any adjustments. This is necessary in order to obtain accurate adjustments and to prevent oscillation due to lack of the shielding effect of the receiver case. Also, the following procedure should be followed closely if the "Syncro-Tuning" Circuit is to function properly.

1. Peaking I.F. Stages at 262 K.C.

(a) Connect the ground lead of the test oscillator to the chassis frame. Connect a .5 mfd. condenser in series with the other lead and connect this lead to the grid cap of the 6A7 tube, leaving the tube's grid clip in place. (The .5 mfd. condenser is necessary to prevent the oscillator circuit of the receiver from affecting the I.F. adjustments.)

(b) Set the test oscillator on 262 kilocycles.

(c) Turn the volume control of the receiver on full.

(d) Peak each of the I.F. trimmers P3 and P4 on the 2nd I.F. coil, (Illus. #9 on Fig. 3).

(e) Then peak each of the trimmers P1 and P2 on the 1st I.F. coil, (Illus. #8 on Fig. 3).

(f) In order to insure accurate settings of the I.F. trimmers, the above adjustments should be repeated using the lowest oscillator output that will give a reasonable output meter scale deflection. Make all adjustments for maximum output.

2. Peaking Oscillator Section of Gang Condenser at 1540 K.C.

(a) Connect the output of the test oscillator to the antenna connection of the receiver and to the chassis ground. (Do not use the .5 mfd. condenser that was required in aligning the I.F. stages.)

(b) Turn the rotor plates of the gang condenser until they are COMPLETELY OUT OF MESH.

(c) Set the test oscillator on exactly 1540 kilocyles.

(d) Adjust the parallel trimmer for the "OSC". section (middle section) CAREFULLY for maximum output. Then adjust the trimmers for the other two sections of the gang condenser, also for maximum output.

3. Tracking "Syncro-Tuning" Circuit

(a) Set the test oscillator on 1400 kilocycles. (Leave test oscillator connected to ant. and gnd. of receiver.)

(b) Turn the condenser rotor plates until the 1400 K.C. signal from the test oscillator is tuned in with maximum output.

(c) Readjust the parallel trimmers for the "ANT." and "R.F." sections of the gang condenser (shown on Fig. 2) for maximum output. DO NOT DISTURB the setting of the oscillator trimmer as this is adjusted at 1540 K.C. only and any adjustment at this point will affect both the tuning range of the receiver and the tracking of its circuits.

NOTE: In order to accurately set the "ANT." trimmer of the condenser gang at 1400 K.C. it will be necessary to make a preliminary adjustment of the "antenna compensating condenser" (Illus. #21 on Fig. 3) before installing the receiver on a car.

(d) Set the test oscillator on 600 kilocycles.

(e) Turn the condenser rotor plates until the 600 K.C. signal from the test oscillator is tuned in with maximum output.

(f) Peak the antenna compensating condenser (Illus. #21 on Fig. 3) for maximum output. Re-tune the gang condenser for maximum output. Repeat these operations alternately until no further improvement in output can be obtained.

(g) Reset the test oscillator on 1400 kilocycles.

(h) Turn the condenser rotor plates until the 1400 K.C. signal is tuned in with maximum output.

(i) Readjust the trimmer for the "ANT." section of the gang condenser CAREFULLY for maximum output.

4. Adjusting Compensating Condenser to Car Antenna

After the "ANT." trimmer of the gang condenser has been correctly set according to preceding information, it will require no further adjustment. It will be necessary, however, to reset the "antenna capacity compensating condenser" (Illus. #21 on Fig. 3) to the car antenna when installing the receiver in a car in order to compensate for the wide range of antenna capacities being used. This is done in the following manner:

(a) Tune the receiver to a weak broadcast station between 570 to 640 K.C.

(b) Peak the "antenna capacity compensating condenser" for maximum output, rocking the receiver dial and adjusting the compensating condenser alternately until no further improvement in output can be obtained.

CAUTION: Do not touch the adjustment of the parallel trimmer for the "ANT." section of the gang condenser after the receiver is installed on a car.

PEAKING PROCEDURE

Connecting Output Meter

Connect the terminals of the output meter to the two plate prongs of the type 6A6 output tube which can be determined by looking at the bottom of the tube with the filament prongs toward you. The prongs located on each side of the filaments are the plate prongs--make sure that the meter is protected with a series condenser.

IMPORTANT

Due to the high sensitivity of these receivers, the receiver chassis must be in its case before making any adjustments. This is necessary in order to obtain accurate adjustments and to prevent oscillation due to lack of the shielding effect of the receiver case. Also, the following procedure should be followed closely if the "Snycro-Tuning" circuit is to function properly.

1. Peaking I.F. Stages at 262 K.C.

(a) Connect the ground lead of the test oscillator to the chassis frame. Connect a .5 mfd. condenser in series with the other lead and connect this lead to the grid cap of the 6A7 tube, leaving the tube's grid clip in place. (The .5 mfd. condenser is necessary to prevent the oscillator circuit of the receiver from affecting the I.F. adjustments.)

(b) Set the test oscillator on 262 kilocycles.

(c) Turn the volume control of the receiver on full.

(d) Peak each of the I.F. trimmers on the 2nd I.F. coil, Illustration #9 on Fig. 3.

(e) Then peak each of the trimmers on the 1st I.F. coil, Illustration #8 on Fig. 3.

(f) In order to insure accurate settings of the I.F. trimmers the above adjustments should be repeated using the lowest oscillator output that will give a reasonable output meter scale deflection. Make all adjustments for maximum output.

2. Peaking Oscillator Section of Gang Condenser at 1540 K.C.

(a) Connect the output of the test oscillator to the antenna connection of the receiver and to the chassis ground. (Do not use the .5 mfd. condenser that was required in aligning the I.F. stages.)

(b) Turn the rotor plates of the gang condenser until they are COMPLETELY OUT OF MESH.

(c) Set the test oscillator on exactly 1540 kilocycles.

(d) Adjust the parallel trimmer for the "OSC." section (middle section) CAREFULLY for maximum output. Then adjust the trimmers for the other two sections of the gang condenser, also for maximum output.

3. Tracking "Syncro-Tuning" Circuit

(a) Set the test oscillator on 1400 kilocycles. (Leave test oscillator connected to ant. and gnd. of receiver.)

(b) Turn the condenser rotor plates until the 1400 K.C. signal from the test oscillator is tuned in with maximum output.

(c) Readjust the parallel trimmers for the "ANT." and "R.F." sections of the gang condenser (shown on Fig. 2) for maximum output. DO NOT DISTURB the setting of the oscillator trimmer as this is adjusted at 1540 K.C. only and any adjustment at this point will affect both the tuning range of the receiver and the tracking of its circuits.

NOTE: In order to accurately set the "ANT." trimmer of the condenser gang at 1400 K.C. it will be necessary to make a preliminary adjustment of the "antenna compensating condenser" (Illustration #21 on Fig. 3) before installing the receiver on a car.

(d) Set the test oscillator on 600 kilocycles.

(e) Turn the condenser rotor plates until the 600 K.C. signal from the test oscilaltor is tuned in with maximum output.

(f) Peak the "antenna compensating condenser," (Illustration #21 on Fig. 3) for maximum output, rocking the rotor plates of the condenser gang back and forth and adjusting the "antenna compensating condenser" alternately until no further improvement in output can be obtained. (This trimmer is not critical in its adjustment, however, it should be adjusted carefully using a very low test osc. output.)

(g) Reset the test oscillator on 1400 kilocycles.

(h) Turn the condenser rotor plates until the 1400 K.C. signal is tuned in with maximum output.

(i) Readjust the trimmer for the "ANT." section of the gang condenser CAREFULLY for maximum output.

4. Adjusting Compensating Condenser to Car Antenna

After the "ANT." trimmer of the gang condenser has been correctly set according to preceding information, it will require no further adjustment. It will be necessary, however, to reset the "antenna capacity compensating condenser" (Illus. #21 on Fig. 3) to the car antenna when installing the receiver in a car in order to compensate for the wide range of antenna capacities being used. This is done in the following manner:

(a) Tune the receiver to a weak broadcast station between 570 to 640 K.C.

(b) Peak the "antenna capacity compensating condenser" for maximum output, rocking the receiver dial and adjusting the compensating condenser alternately until no further improvement in output can be obtained.

CAUTION: Do not touch the adjustment of the parallel trimmer for the "ANT." section of the gang condenser after the receiver is installed on a car.

4. Adjusting Compensating Condenser to Car Antenna---Cont'd.

according to the preceding information, it will require no further adjustment. It will be necessary, however, to reset the 'antenna capacity compensating condenser' (Bottom View of chassis) to the car antenna when installing the receiver in a car in order to compensate for the wide range of antenna capacities being used. This is done in the following manner:

(a) Tune the receiver to a weak broadcast station between 570 to 640 K.C.

(b) Peak the compensating condenser for maximum output, rocking the receiver dial and adjusting the compensating condenser alternately until no further improvement in output can be obtained.

CAUTION: Do not touch the adjustment of the parallel trimmer for the "ANT" section of the gang condenser after the receiver is installed on a car.

PEAKING PROCEDURE

The only way the circuits of this receiver can be peaked properly is with the use of a calibrated test oscillator and an output meter. The circuits are very carefully adjusted at the factory and do not need any further adjustment unless tampered with in the field or a defective coil has been replaced. It is, therefore, advisable not to attempt any adjustments unless it is definitely known that an adjustment is necessary. This is especially important in connection with the "Syncro-Tuning" circuit.

Connecting Output Meter

Connect one of the output meter leads to the plate prong of the type 42 output tube. (The plate prong is the first prong to the left of the filament when looking at the bottom of the tube with the filament prongs toward you.) Connect the other lead to the receiver chassis, making sure that the output meter is protected with a D.C. blocking condenser connected 3. in series to prevent damage to the meter.

IMPORTANT

Due to the high sensitivity of these receivers, the receiver chassis must be in its case before making any adjustments. This is necessary in order to obtain accurate adjustments and to prevent oscillation due to lack of the shielding effect of the receiver case. Also, DO NOT DISTURB the placement of the capacity wire located on top of the gang condenser. This wire should lay flat across the top of the condenser gang, extending from the "OSC." section to the "R.F." section.

1. Peaking I.F. Stages at 262 K.C.

(a) Connect the ground lead of the test oscillator to the chassis frame. Connect a .5 mfd. condenser in series with the other lead and connect this lead to the grid cap of the 6B7 tube, leaving the tube's grid clip in place. (The .5 mfd. condenser is necessary to prevent the oscillator circuit of the receiver from affecting the I.F. adjustments.)

(b) Set the test oscillator on 262 kilocycles.

(c) Turn the volume control of the receiver on full.

(d) Peak each of the I.F. trimmers on the 2nd I.F. coil, Illus. #8 on Fig. 3.

(e) Remove the test oscillator lead from the grid clip of the 6B7 tube and connect it to the grid clip of the 6A7 tube, leaving the tube's grid clip in place.

(f) Then peak each of the trimmers on the 1st I.F. coil, Illus. #7, Fig. 3.

(g) In order to insure accurate settings of the I.F. trimmers the above adjustments should be repeated using the lowest oscillator output that will give a reasonable output meter scale deflection. Make all adjustments for maximum output.

2. Peaking Oscillator Section of Gang Condenser at 1540 K.C.

(a) Connect the output of the test oscillator to the antenna connection of the receiver and to the chassis ground. (Do not use the .5 mfd. condenser that was required in aligning the I.F. stages.)

(b) Turn the rotor plates of the gang condenser until they are COMPLETELY OUT OF MESH.

(c) Set the test oscillator on exactly 1540 kilocycles.

(d) Adjust the parallel trimmer for the "OSC." section (middle section) CAREFULLY for maximum output. Then adjust the trimmers for the other two sections of the gang condenser also for maximum output.

Tracking "Syncro-Tuning" Circuit

(a) Set the test oscillator on 1400 kilocycles. (Leave test oscillator connected to ant. and gnd. of receiver.)

(b) Turn the condenser rotor plates until the 1400 K.C. signal from the test oscillator is tuned in with maximum output.

(c) Readjust the parallel trimmers for the "ANT." and "R.F." sections of the gang condenser (shown on Fig. 2) for maximum output. DO NOT DISTURB the setting of the oscillator trimmer as this is adjusted at the 1540 K.C. only and adjustment at this point will affect both the tuning range of the receiver and the tracking of its circuits.

NOTE: In order to accurately set the "ANT." trimmer of the condenser gang at 1400 K.C. it will be necessary to make a preliminary adjustment of the "antenna compensating condenser" (Illus. #15 on Fig. 3) before installing the receiver on a car.

(d) Then set the test oscillator on 600 kilocycles.

(e) Turn the condenser rotor plates until the 600 K.C. signal from the test oscillator is tuned in with maximum output.

(f) Peak the antenna compensating condenser (Illus. #15 on Fig. 3) for maximum output. Re-tune the gang condenser for maximum output. Repeat this operation alternately until no further improvement in output can be obtained.

(g) Reset the test oscillator on 1400 kilocycles.

(h) Turn the condenser rotor plates until the 1400 K.C. signal is tuned in with maximum output.

(i) Adjust the trimmer for the "ANT." section of the gang condenser CAREFULLY for maximum output.

4. Adjusting Compensating Condenser to Car Antenna

After the "ANT." trimmer of the gang condenser has been correctly set

All readings (except filaments) taken on 115 volt line with 1000 ohms per volt meter from tube socket contacts to chassis using the 250 volt scale. Filament readings were taken with a low range A-C voltmeter.

MODEL 1105 Delco
Alignment

UNITED MOTORS SERVICE

GENERAL: The Delco Model 1105 is a five tube, two band, A.C., receiver. The tubes used are: 6D6 Oscillator-Modulator, 6D6 I-F Amplifier, 76 Detector, 6B5 Output and type 80 Rectifier.

The frequency range is from 540 to 1570 kilocycles on the Broadcast Band and from 1570 to 4000 kilocycles on the short wave band (Police and Amateur).

CIRCUIT ALIGNMENT

All of the adjustable condensers are very accurately adjusted at the factory and should need no further adjustment unless tampered with in the field or a defective coil has been replaced. If realignment is found necessary the circuits can be properly adjusted only with the use of a calibrated test oscillator and an output meter.

1. Peaking I-F Stages at 450 Kilocycles

   (a) Connect the output of the test oscillator through a .02 mfd. series condenser to the top cap of the 6D6 Osc.-Mod. tube. DO NOT REMOVE THE GRID CLIP.

   (b) Connect the ground lead of the test oscillator to the chassis frame or ground terminal of the receiver.

   (c) Set the test oscillator to 450 kilocycles.

   (d) Rotate the receiver tuning condenser until the rotor plates are completely out of mesh.

   (e) Turn the band selector switch to the right hand position. (Short Wave Band)

   (f) Turn the volume control of the receiver on full.

   (g) With the test oscillator set to the lowest usable output level adjust the I-F trimmer condensers located on top of the I-F coils, Fig. 2, for maximum output.

   NOTE: Make the adjustments very carefully, going over them several times to insure that the final setting is at resonant frequency. Also, an insulated screw driver should be used to insure accurate adjustments.

2. Aligning R-F Circuits

   (a) Turn the band selector switch to the left hand position. (Broadcast Band)

   (b) Leave the receiver tuning condenser rotor plates completely out of mesh.

   (c) Connect the output lead from the test oscillator through a .00025 mfd., series condenser to the antenna terminal of the receiver.

   (d) Set the test oscillator to exactly 1570 kilocycles.

   (e) Adjust the trimmer on the "Osc." section of the tuning condenser gang for maximum output. (Fig. 3)

   (f) Set the test oscillator to 1400 kilocycles.

   (g) Tune in the 1400 kilocycle signal with the station selector for maximum output.
   Note: Do not disturb the setting of the "Osc." trimmer as this is adjusted at 1570 kilocycles only and any further adjustment at this point would affect both the tuning range of the receiver and the tracking of its circuits.

   (h) Adjust the trimmer on the "Ant" section of the tuning condenser gang for maximum output.

NOTE: There are no adjustments on this receiver for the Police Band.

MODEL 1106 Delco
Alignment
Voltage

UNITED MOTORS SERVICE

GENERAL: The Delco Model 1106 is a 5 tube, 110 volt, 60 cycle operated, two band receiver with A.V.C. The type tubes used are: 6A7 Oscillator-Modulator, 6D6 I-F Amplifier, 75 Detector, A.V.C., and 1st Audio Amplifier, 42 Power Output and an 80 Rectifier.

The frequency range is from 540 to 1720 kilocycles on the Broadcast Band and from 2300 to 6200 kilocycles on the Short Wave Band.

CIRCUIT ALIGNMENT

All of the adjustable condensers are very accurately adjusted at the factory and should need no further adjustment unless tampered with in the field or a defective coil has been replaced. If realignment is found necessary, the circuits can be properly adjusted only with the use of a calibrated test oscillator or signal generator and an output meter.

1. Peaking I-F Stages at 465 Kilocycles

(a) Connect the ground lead of the test oscillator to the chassis frame. Connect the other lead to the grid cap of the 6A7 tube through a .02 mfd. series condenser. DO NOT REMOVE THE GRID CLIP.

(b) Set the test oscillator to exactly 465 kilocycles.

(c) Turn the volume control of the receiver on full.

(d) Peak each of the trimmers on the 2nd I-F coil., Illus. #11 on Fig. 2.

(e) Peak each of the trimmers on the 1st I-F coil., Illus. #10 on Fig. 2.

(f) In order to insure accurate settings of the I-F trimmers, the above adjustments should be repeated using the lowest test oscillator output that will give a reasonable output meter scale deflection.

2. Aligning R-F Circuits -- Broadcast Band (540-1720 K.C.)

(a) Remove the test oscillator lead from the grid of the 6A7 tube and connect it to the receiver antenna terminal through a .00025 mfd. series condenser.

(b) Check to see the tuning dial has not slipped on the condenser gang shaft by turning the rotor plates of the condenser gang until they are completely out of mesh, at which point the dial pointer should be at the high frequency end of the dial calibration.

(c) Turn the band selector switch to the right for operation on the Broadcast Band (540-1720 K.C.)

(d) Set the test oscillator frequency to exactly 1720 K.C.

(e) Turn the gang condenser until the plates are completely out of mesh.

(f) Adjust the broadcast padding condenser for the oscillator section of the condenser gang, shown as Illus. #18 on Fig. 3, to bring in the 1720 kilocycle signal from the test oscillator with maximum output.

(g) Set the test oscillator frequency and the receiver dial to exactly 1400 kilocycles.

(h) Adjust the broadcast padding condenser, Illus. #60 Fig. 3, for the antenna section of the condenser gang for maximum output.

(i) Set test oscillator on 600 kilocycles.

2. Aligning R-F Circuits--Broadcast Band (540-1720 K.C.)--Cont'd.

(j) Set receiver dial at approximately 600 kilocycles, leaving the test oscillator connected to the ANT and GND terminal of the receiver and the band change switch in the Broadcast position.

(k) Adjust the oscillator tracking condenser Illus. #16 Fig. 3, rocking the tuning condenser gang back and forth until no further increase in output can be obtained.

3. Aligning R-F Circuits--Short Wave Band (2.3 to 6.2 meg.)

(a) Leave test oscillator connected to ANT and GND of receiver and turn the band selector switch to the left for operation on the Short Wave Band.

(b) Set test oscillator frequency and receiver dial to exactly 5.8 megacycles.

(c) Adjust the short wave padding condenser, Illus. #61 Fig. 3, for the oscillator section of the condenser gang until the 5.8 megacycle signal from the test oscillator is tuned in with maximum output.

(d) Adjust the short wave padding condenser, Illus. #62. Fig. 3 for maximum output.

(e) Turn the receiver dial and set test oscillator to approximately 2.5 megacycles.

(f) Adjust the Oscillator tracking condenser, Illus. #17 Fig. 3, rocking the tuning condenser gang back and forth until no further improvement in output can be obtained.

4. Adjustment of 465 K.C. Wave Trap

Some code and aircraft signals are broadcast on a frequency exactly the same or near the I.F. frequency of the receiver. To eliminate interference from these signals, a 465 K.C. antenna filter is incorporated in the set. To adjust:

(a) Leave test oscillator output leads connected to the set ANT and GND.

(b) Set the test oscillator frequency to exactly 465 K.C. and adjust the 465 K.C. wave trap trimmer, Illus. #5, Fig. 3 for MINIMUM 465 K.C. SIGNAL RESPONSE.

*TUBE SOCKET VOLTAGES

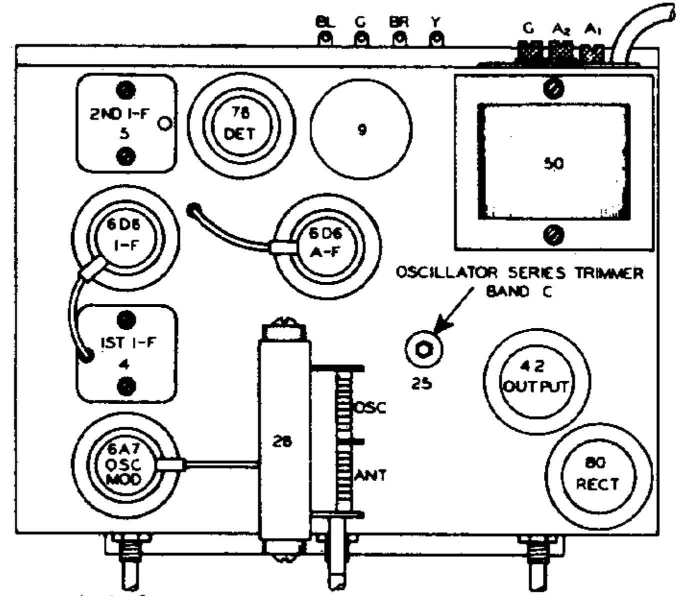
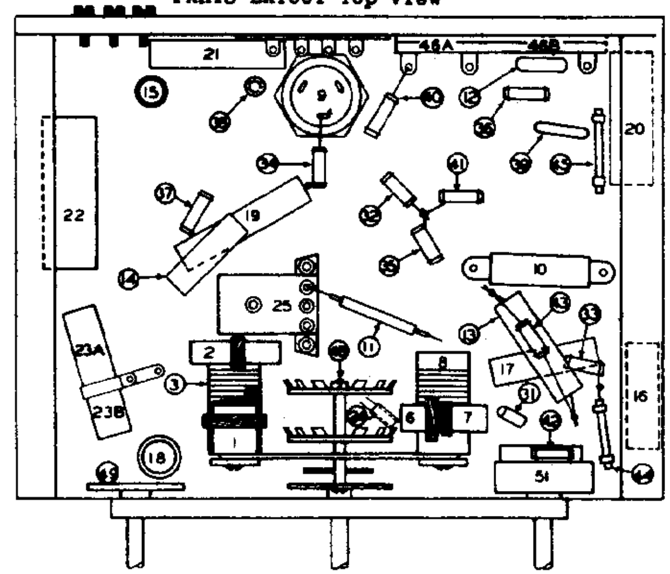
*Readings taken from the tube socket contacts to ground (except heaters) with a meter having a resistance of 1000 ohms per volt using a 250 volt scale and a line voltage of 115 volts A.C.

NOTE: On the wave band switch Illus. #48 there is a small eyelet soldered to one of the switch connecting lugs. This eyelet, Illus. #24 is used as a small condenser the capacity of which is formed by inserting an insulated wire into the sleeve of the eyelet. In replacing any defective wave band switches, care should be taken to see that the "capacity wire" is inserted in the sleeve of the eyelet. This insulated wire should be passed through the eyelet and a slight hook made in the end to prevent it from pulling out.

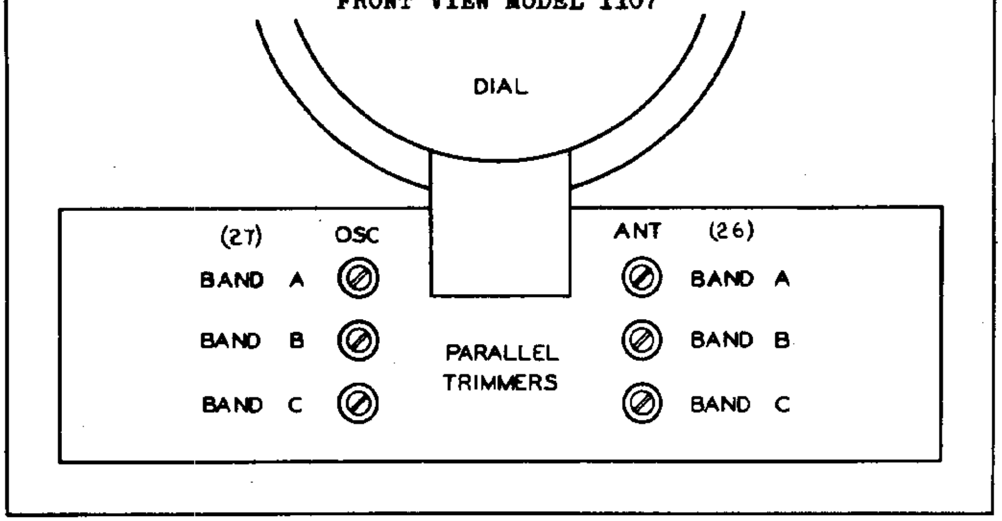


PARTS LAYOUT-Top View



PARTS LAYOUT--Bottom View

FRONT VIEW MODEL 1107



MODEL 1107 Delco
Alignment

UNITED MOTORS SERVICE

GENERAL: The Delco Model 1107 is a 6 tube, 110 volt A.C., three band receiver with A.V.C. The tubes used are a 6A7 Oscillator-Modulator, 6D6 I-F Amplifier, 75 Detector and A.V.C., 6D6 A-F Amplifier, 42 Output and type 80 Rectifier.

The frequency ranges on bands covered are: American Broadcast Band (C) 540 to 1700 kilocycles, Police and Amateur Band (B) 1700 to 5000 kilocycles and the Foreign Short Wave Band (A) 5.4 to 15 megacycles.

ALIGNMENT PROCEDURE

1. **Peaking I-F Stages at 450 Kilocycles**

(a) Connect the output of the test oscillator through a .02 mfd. condenser to the grid cap of the 6A7 tube, leaving the tube's grid clip in place. Connect the ground lead from the test oscillator to the receiver chassis.

(b) Turn the tuning condenser rotor plates until they are completely meshed. (540 K.C. end)

(c) Turn the band selector switch to Band A (extreme left hand position).

(d) Set the test oscillator to 450 kilocycles.

(e) Adjust both trimmers located on top of the 2nd. I-F coil for maximum output. (Illus. #5, Fig. 3)

(f) Adjust both trimmers located on top of the 1st. I-F coil for maximum output. (Illus. #4, Fig. 3)

(g) Using the lowest test oscillator output that will give a reasonable scale deflection on the output meter repeat operations (e) and (f) as many times as necessary to obtain the maximum output.

2. **Peaking R-F Circuits--Band "C" (540 to 1700 K.C.)**

(a) Connect the output of the test oscillator through a .00025 mfd. condenser to the "Ant" terminal of the receiver.

(b) Turn the tuning condenser rotor plates until they are COMPLETELY OUT OF MESH.

(c) Turn the band selector switch to Band C (extreme right hand position).

(d) Set the test oscillator to 1720 kilocycles.

(e) Peak the Band "C" oscillator parallel trimmer shown on Fig. 1.

(f) Set the test oscillator to 1400 kilocycles.

(g) Tune-in the 1400 kilocycle signal with the station selector.

(h) Peak the Band "C" antenna parallel trimmer shown on Fig. 1.

(i) Using the lowest test oscillator output that will give a reasonable output meter reading, repeat operations (g) and (h) until no further increase in output can be obtained.

(j) Set the test oscillator to 600 kilocycles.

(k) Tune-in the 600 kilocycle signal with the station selector in the region of 60 on the dial, for maximum reading on the output meter.

(l) Adjust the oscillator series trimmer, (Illus. #25, Fig. 4) while rocking the condenser gang plates back and forth slightly, until no further increase in output can be obtained.

(m) Repeat operations (g) and (h) for more accurate adjustments.

Peaking R-F Circuits--Band "B" (1700 to 5000 K.C.)

(a) Turn the band selector switch to Band "B" (Middle position).

(b) Set the test oscillator to 5000 kilocycles. (5.0 megacycles)

(c) Turn the station selector to 5 on Band "B".

(d) Peak the Band "B" oscillator parallel trimmer shown on Fig. 1.

(e) Peak the Band "B" antenna parallel trimmer (Fig. 1).

4. **Peaking R-F Circuits--Band "A" (5.4 to 15 Meg.)**

(a) Replace the .00025 mfd. condenser which is being used in series with the output lead of the test oscillator with a 400 ohm carbon resistor.

(b) Turn the band selector switch to Band "A".

(c) Set the test oscillator to 15 megacycles.

(d) Close the Band "A" Oscillator parallel trimmer (Fig. 1) and then open three turns.

(e) Close the Band "A" Antenna parallel trimmer (Fig. 1) and then open 1/2 turn.

(f) Turn the station selector to 15 on the dial (Band "A").

(g) Peak the Band "A" oscillator parallel trimmer (Fig. 1) on the FIRST test oscillator signal heard when closing the condenser. In making this adjustment care should be taken not to use too much output from the test oscillator to avoid setting the oscillator circuit on the wrong frequency.

NOTE: Check on the adjustment of the Band "A" oscillator parallel trimmer as follows:

1. Increase the test oscillator output not more than ten times.
2. Try to tune-in the 15 megacycle test oscillator signal with the station selector at approximately 14 on the dial.
3. If the 15 megacycle signal can be heard at approximately 14 and 15 both on the dial the oscillator parallel trimmer has been aligned on the correct frequency. It should be noted, however, that the signal tuned in at 15 on the dial should be much stronger than the signal heard at 14. If this condition is not found it will be necessary to repeat the operation (g).

(h) Reduce the output of the test oscillator to the previous output and re-tune the station selector to 15 megacycles at 15 on the dial.

(i) Peak the Band "A" antenna parallel trimmer (Fig. 1) for maximum output, then re-tune the station selector for maximum output.

(j) Repeat the two operations in (i) as many times as necessary to obtain the maximum output.

MODEL 1108 Delco
Glass Tubes
Alignment

UNITED MOTORS SERVICE

GENERAL: The Delco Models 1108 is a six tube, 115 volt, 50-60 cycles A.C., three band receiver with A.V.C., Tone Control and a "Band Spread" dial. The tubes used are 6A7 Detector-Oscillator, 6D6 1st I-F Amplifier, 6D6 2nd I-F Amplifier, 75 Detector, A.V.C. and 1st Audio amplifier, 42 Power Output and an 80 Rectifier tube.

The frequency ranges on bands covered are: American Broadcast Band (A) 550 to 1750 kilocycles, Police and Amateur Band (B) 1700 to 5680 kilocycles and the Foreign Short Wave Band (C) 5.4 to 18 megacycles.

CIRCUIT ALIGNMENT

All of the adjustable condensers are very accurately adjusted at the factory and should need no further adjustment unless tampered with in the field or a defective coil has been replaced. If realignment is found necessary the circuits can be properly adjusted only with the use of a calibrated test oscillator and an output meter.

The receiver should be aligned in a location free from local interference (interference caused by motors, flashers, automobile ignition, etc.) as high frequency disturbances will cause difficulties when adjusting the short wave circuits.

1. Peaking I-F Stages at 490 Kilocycles

(a) Connect the signal lead of the test oscillator to the grid cap of the 6A7 tube through a .25 mfd. condenser. DO NOT REMOVE THE GRID CLIP FROM THE TUBE.

(b) Connect the ground lead of the test oscillator to the receiver chassis.

(c) Set receiver dial pointer to 1400 K.C. and band change switch on position "A".

(d) Place test oscillator in operation at 490 K.C.

(e) Turn receiver volume control to the maximum position.

(f) Adjust the six I-F trimmers located on top of the I-F coils, (Fig. 2) until maximum output is obtained. During alignment, maintain as low a value of signal from the test oscillator as is consistant with obtaining a readable indication on the output meter.

Aligning at 1400 Kilocycles

(a) Connect the signal lead of the test oscillator to the antenna binding post through a .00025 mfd. condenser. (Leave test oscillator ground lead connected to the chassis ground.)

(b) Turn dial knob until condensers are fully MESHED. The dial pointer (hour hand) should be on the horizontal line of the dial, pointing to 9 and 3 o'clock. The minute hand should be at 12 o'clock or in the vertical position.

(c) Set test oscillator to 1400 K.C.

(d) Turn dial pointer 1400 K.C. and leave band change switch on position "A" (extreme left hand position).

(e) Adjust the Band "A" oscillator parallel trimmer, Illus. 46A (Fig. 2) to maximum output.

(f) Adjust the Band "A" R-F parallel trimmer, Illus. 45A (Fig. 2) to maximum output.

3. Aligning at 600 K.C.

(a) Set the test oscillator to 600 Kilocycles.

(b) Tune in the 600 K.C. signal with the receiver dial in the region of 600 K.C. for maximum output. (This point does not have to be exactly at the 600 K.C. dial setting.)

(c) Adjust the Band "A" oscillator tracking condenser, Illus. #38 (Fig. 2) while rocking the tuning condenser back and forth through resonance until no further increase in output can be obtained.

(d) Repeat operations (c), (d), (e) and (f) under "Aligning at 1400 K.C." for accurate adjustments.

4. Aligning at 5 Megacycles (5000 K.C.)

(a) Turn band change switch to Band "B" (middle position)

(b) Set the test oscillator to 5 megacycles.

(c) Turn receiver dial pointer to 5 megacycles.

(d) Adjust the Band "B" oscillator parallel trimmer Illus. #46B (Fig.2) to maximum output.

(e) Adjust the Band "B" R-F parallel trimmer, Illus. #45B (Fig. 2) to maximum output.

(f) Check dial setting at 1800 K.C.

5. Aligning at 18 Megacycles (18,000 K.C.)

(a) Replace the .00025 mfd. series condenser in the signal lead from the test oscillator with a 400 ohm carbon resistor.

(b) Turn the band change switch to Band "C" (extreme right hand position).

(c) Turn receiver dial pointer to 18 megacycles.

(d) Set the test oscillator to 18 megacycles.

(e) Adjust the Band "C" oscillator parallel trimmer, Illus. #46C (Fig. 2) to maximum output.

NOTE: On the 18 Megacycle Alignment of trimmer Illus. #46C, it will be noted that there are two settings at which the signal will be received. Use the signal received with oscillator parallel trimmer setting having the most capacity or the point at which the trimmer screw is farthest in.

(f) Adjust the Band "D" R-F parallel trimmer, Illus. 45C (Fig. 2) to maximum output.

MODEL 1108 Delco

(e) Adjust the Band "A" oscillator parallel trimmer, Illus. 46A (Fig. 2) to maximum output.

(f) Adjust the Band "A" R-F parallel trimmer, Illus. 45A (Fig. 2) to maximum output.

3. **Aligning at 600 K.C.**

(a) Set the test oscillator to 600 Kilocycles.

(b) Tune in the 600 K.C. signal with the receiver dial in the region of 600 K.C. for maximum output. (This point does not have to be exactly at the 600 K.C. dial setting.)

(c) Adjust the Band "A" oscillator tracking condenser, Illus. #38 (Fig. 2) while rocking the tuning condenser back and forth through resonance until no further increase in output can be obtained.

(d) Repeat operations (c), (d), (e) and (f) under "Aligning at 1400 K.C." for accurate adjustments.

4. **Aligning at 5 Megacycles (5000 K.C.)**

(a) Turn band change switch to Band "B" (middle position)

(b) Set the test oscillator to 5 megacycles.

(c) Turn receiver dial pointer to 5 megacycles.

(d) Adjust the Band "B" oscillator parallel trimmer Illus. #46B (Fig.2) to maximum output.

(e) Adjust the Band "B" R-F parallel trimmer, Illus. #45B (Fig. 2) to maximum output.

(f) Check dial setting at 1800 K.C.

5. **Aligning at 18 Megacycles (18,000 K.C.)**

(a) Replace the .00025 mfd. series condenser in the signal lead from the test oscillator with a 400 ohm carbon resistor.

(b) Turn the band change switch to Band "C" (extreme right hand position).

(c) Turn receiver dial pointer to 18 megacycles.

(d) Set the test oscillator to 18 megacycles.

(e) Adjust the Band "C" oscillator parallel trimmer, Illus. #46C (Fig. 2) to maximum output.

NOTE: On the 18 Megacycle Alignment of trimmer Illus. #46C, it will be noted that there are two settings at which the signal will be received. Use the signal received with oscillator parallel trimmer setting having the most capacity or the point at which the trimmer screw is farthest in.

(f) Adjust the Band "D" R-F parallel trimmer, Illus. 45C (Fig. 2) to maximum output.

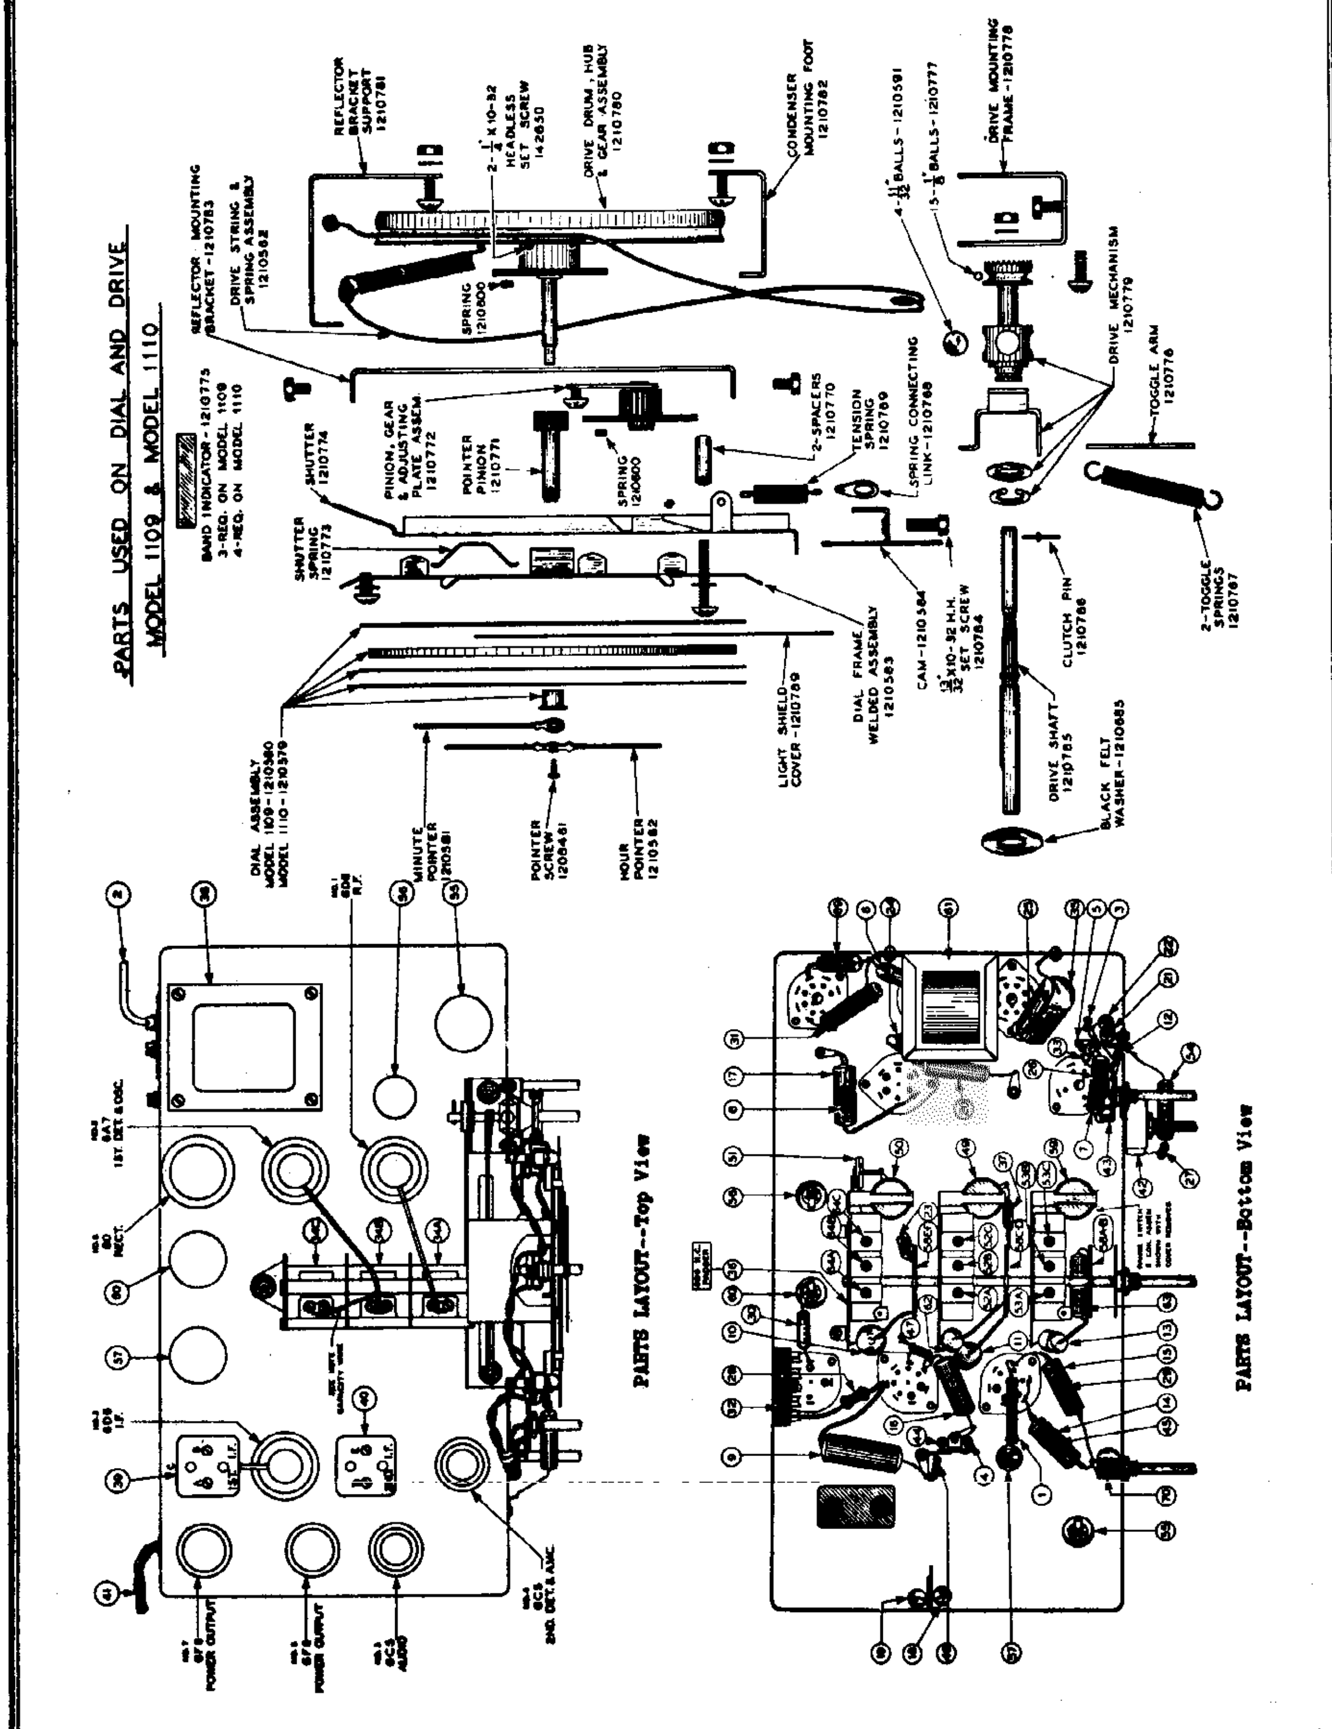
Chassis, Dial Parts

UNITED MOTORS SERVICE



UNITED MOTORS SERVICE

GENERAL: The Delco Model 1109 is an eight tube, 110 volt A.C., 50-60 cycle, three band receiver with A.V.C., Tone Control, "Band Spread" dial, and a full 10" dynamic speaker. This receiver has incorporated in its chassis, four of the new metal type tubes. The complete tube complement is as follows: 6D6 R-F Amplifier, 6A7 Detector-Oscillator, 6D6 I-F Amplifier, 6C5 (Metal) 2nd Detector - A.V.C., 6C5 (Metal) 1st A-F Amplifier, two type 6F6 (Metal) tubes in the output stage, connected for push-pull operation and an 80 type Rectifier.

The frequency ranges on the three bands covered are: American Broadcast Band (A) 540 to 1800 K.C., Police and Amateur Band (B) 1800 to 5600 K.C., and the Foreign Short Wave Band (C) 5.6 to 18 Megacycles.

CIRCUIT ALIGNMENT

All of the adjustable trimmer condensers are very accurately adjusted at the factory and should need no further adjustment unless tampered with in the field or a defective coil has been replaced. If realignment is found necessary the circuits can be properly adjusted only with the use of a calibrated test oscillator and an output meter.

The receiver should be aligned in a location free from local interference (interference caused by motors, flashers, automobile ignition, etc.) as high frequency disturbances will cause difficulties when adjusting the short wave circuits.

1. **Peaking I-F Stages at 455 Kilocycles**

(a) Connect the signal lead of the test oscillator to the grid cap of the 6A7 tube through a .25 mfd. condenser. DO NOT REMOVE THE GRID CLIP FROM THE TUBE.

(b) Connect the ground lead of the test oscillator to the receiver chassis.

(c) Set receiver dial pointer to 1400 K.C. and band change switch on position "A".

(d) Place test oscillator in operation at 455 K.C.

(e) Turn receiver volume control to the maximum position.

(f) Adjust the five I-F trimmers on the two I-F coils (Illus. 39 & 40) carefully for maximum output in the following sequence -- A-B-C-D-E. During alignment, maintain as low a signal output from the test oscillator as is consistent with obtaining a readable indication on the output meter.

2. **Aligning at 1400 Kilocycles**

(a) Connect the signal lead of the test oscillator to the antenna binding post through a .0002 mfd. condenser. (Leave test oscillator ground lead connected to the chassis ground).

(b) Turn dial knob until condensers are fully MESHED. The dial pointer (hour hand) should be on the horizontal line of the dial, pointing to 9 and 3 o'clock. The minute hand should be at 12 o'clock or in the vertical position.

(c) Set test oscillator to 1400 K.C.

(d) Turn dial pointer 1400 K.C. and leave band change switch on position "A" (extreme left hand position).

(e) Adjust the Band "A" oscillator parallel trimmer, Illus. 64A (Fig. 3) to maximum output.

(f) Adjust the Band "A" R-F parallel trimmer, Illus. 52A (Fig. 3) to maximum output.

(g) Adjust the Band "A" Antenna parallel trimmer, Illus. 53A to maximum output.

3. **Aligning at 600 K.C.**

(a) Set the test oscillator to 600 Kilocycles.

(b) Tune in the 600 K.C. signal with the receiver dial in the region of 600 K.C. for maximum output. (This point does not have to be exactly at the 600 K.C. dial setting.)

(c) Adjust the Band "A" oscillator padding condenser, Illus. #56 (Fig. 3) while rocking the tuning condenser back and forth through resonance until no further increase in output can be obtained.

(d) Repeat operations (c), (d), (e), (f), and (g) under "Aligning at 1400 K.C." for accurate adjustments.

4. **Aligning at 5 Megacycles (5000 K.C.)**

(a) Turn band change switch to Band "B" (middle position).

(b) Set the test oscillator to 5 megacycles.

(c) Turn receiver dial pointer to 5 megacycles.

(d) Adjust the Band "B" oscillator parallel trimmer, Illus. #64B (Fig. 3) to maximum output.

(e) Adjust the Band "B" R-F parallel trimmer, Illus. #52B (Fig. 3) to maximum output.

(f) Adjust the Band "B" Antenna parallel trimmer, Illus. 53B (Fig. 3) to maximum output.

(g) Check dial setting at 1800 K.C.

5. **Aligning at 18 Megacycles (18,000 K.C.)**

(a) Replace the .0002 mfd. series condenser in the signal lead from the test oscillator with a 400 ohm carbon resistor.

(b) Turn the band change switch to Band "C" (extreme right hand position).

(c) Turn receiver dial pointer to 18 megacycles.

(d) Set the test oscillator to 18 megacycles.

(e) Adjust the Band "C" oscillator parallel trimmer, Illus. #64C (Fig. 3) to maximum output.

NOTE: On the 18 Megacycle Alignment of trimmer Illus. #64C, it will be noted that there are two settings at which the signal will be received. Use the signal received with oscillator parallel trimmer setting having the most capacity or the point at which the trimmer screw is farthest in.

(f) Adjust the Band "C" R-F parallel trimmer, Illus. 52C (Fig. 3) to maximum output.

(g) Adjust the Band "C" Antenna parallel trimmer, Illus. 53C (Fig. 3) to maximum output.

*A.C. voltage readings.

Above readings taken from tube socket contacts to ground (except filaments) using a line voltage of 115 volts A.C. and a meter having a resistance of 1000 ohms per volt.

NOTE

A neutralizing capacity is used in this receiver, in the form of a small wire soldered to the stator of the oscillator section of the condenser gang, (see Fig. 2) and capacity coupled to the 6A7 tube grid lead.

GENERAL: The Delco Model 1110 is a ten tube, 110 volt AC, 50-60 cycle, four band receiver with A.V.C., Tone Control, "Band Spread" dial and equipped with two dynamic speakers. This receiver has incorporated in its chassis five of the new metal type tubes. The complete tube complement is as follows: 6D6 R-F Amplifier, 6A7 Detector-Oscillator, 6K7 (Metal) I-F Amplifier, 6C5 (Metal) 2nd Detector-A.V.C., 6F5 (Metal) Driver, 6F6 High Frequency A-F Amplifier, two type 45 tubes in the Output Stage, and a type 5Z3 Rectifier.

The frequency ranges on the four bands covered are: Weather Band (A) 150 to 410 K.C. American Broadcast Band (B) 550 to 1750 K.C., Police and Amateur Band (C) 1700 to 5500 K.C., and the Foreign Short Wave Band (d) 5.4 to 18 Megacycles.

AUDIO SYSTEM

A two channel audio system is used in the Delco Model 1110 receiver--one channel, comprising a 6F6 tube coupled into a small speaker reproduces the high notes of the musical range and the other channel comprising two type 45 tubes connected in push-pull reproduces the low and middle register of the musical range. From a service viewpoint this audio system should be considered as dual audio amplifier. Care should be taken when changing any part of the speaker system, to see that the polarity of all transformers and voice coils remain as originally connected in order that the speakers will be in "phase." If this is not done, one speaker will have a tendency to cancel out certain frequency responses of the other. Particular attention should be given to the wire colors shown on the Circuit Diagram in replacing any parts. To determine whether the speakers are in phase--short out the voice coil on the large speaker to see that the small speaker is reproducing the "highs" and then reverse the voice coil leads on the large speaker, leaving them in the position of the strongest and best reception.

CIRCUIT ALIGNMENT

All of the adjustable condensers are very accurately adjusted at the factory and should need no further adjustment unless tampered with in the field or a defective coil has been replaced. If realignment is found necessary the circuits can be properly adjusted only with the use of a calibrated test oscillator and an output meter.

The receiver should be aligned in a location free from local interference (interference caused by motors, flashers, automobile ignition, etc.) as high frequency disturbances will cause difficulties when adjusting the short wave circuits.

DIAL SETTING CHECK: Turn dial knob until rotor plates of condenser gang are fully meshed. The "hour" hand should be on the horizontal line of the dial pointer to 9 and 3 o'clock. The "minute" hand should be in a vertical position or at 12 o'clock. This check should be made before attempting any adjustments.

CAUTION: Do not attempt to make any adjustments of the trimmer condensers with the band change switch cover removed.

1. Peaking I-F Stages at 455 Kilocycles
   - (a) Connect the signal lead of the test oscillator to the grid cap of the 6A7 tube through a .25 mfd. condenser. DO NOT REMOVE THE GRID CLIP FROM THE TUBE.
   - (b) Connect the ground lead of the test oscillator to the receiver chassis.
   - (c) Set receiver dial pointer to 1400 K.C. and band change switch on position "B".
   - (d) Place test oscillator in operation at 455 K.C.
   - (e) Turn receiver volume control to the maximum position.
   - (f) Adjust the five I-F trimmers on the two I-F coils Illus. 52 & 53 (Fig. 2) carefully for maximum output in the following sequence--A-B-C-D-E. During alignment, maintain as low a signal output from the test oscillator as is consistant with obtaining a readable indication on the output meter.

2. Aligning at 175 Kilocycles (Band "A")
   - (a) Connect the signal lead of the test oscillator to the antenna binding post on the chassis through at .0002 mfd. condenser. Leave test oscillator ground lead connected to the receiver chassis.
   - (b) Place test oscillator in operation at 175 K.C.
   - (c) Turn band change switch to Band "A" (extreme left).
   - (d) Tune in the 175 K.C. signal from the test oscillator with the receiver dial for maximum output. (This point does not have to be exactly at the 175 K.C. dial setting).
   - (e) Adjust the Band "A" oscillator tracking condenser, Illus. #45 (Fig. 3) while rocking the tuning condenser plates back and forth through resonance until no further increase in output can be obtained.

3. Aligning at 350 Kilocycles (Band "A")
   - (a) Place test oscillator in operation at 350 K.C., leaving the leads connected the same as before.
   - (b) Turn dial pointer to 350 K.C.
   - (c) Adjust the Band "A" oscillator parallel condenser, Illus. 51A (Fig. 3) to maximum output.
   - (d) Adjust the Band "A" R-F parallel trimmer, Illus. 51A (Fig. 3) to maximum output.
   - (e) Adjust the Band "A" Antenna parallel trimmer, Illus. 48A (Fig. 3) to maximum output.
   - (f) Repeat operations under paragraph #2 "Aligning at 175 Kilocycles" for accurate adjustments.

4. Aligning at 1400 Kilocycles (Band "B")
   - (a) Place test oscillator in operation at 1400 K.C.
   - (b) Turn dial pointer to 1400 K.C. setting and band change switch to Band "B".
   - (c) Adjust the Band "B" oscillator parallel condenser, Illus. 51B (Fig. 3) to maximum output.
   - (d) Adjust the Band "B" R-F parallel trimmer, Illus. 51B (Fig. 3) to maximum output.
   - (e) Adjust the Band "B" Antenna parallel trimmer Illus. 48B (Fig. 3) to maximum output.

5. Aligning at 600 Kilocycles (Band "B")
   - (a) Place test oscillator in operation at 600 K.C.
   - (b) Tune in the 600 K.C. test oscillator signal with the receiver dial for maximum output. (This point does not have to be exactly at the 600 K.C. dial setting).
   - (c) Adjust the Band "B" oscillator tracking condenser, Illus. 46 while rocking the tuning condenser plates back and forth through resonance until no further increase in output can be obtained.
   - (d) Repeat operations under paragraph #4 "Aligning at 1400 Kilocycles" for accurate adjustments.

6. Aligning at 5 Megacycles (5000 K.C. Band "C")
   - (a) Place test oscillator in operation at 5 megacycles.
   - (b) Turn dial pointer to 5 megacycles and band change switch to Band "C".
   - (c) Adjust the Band "C" oscillator parallel trimmer, Illus. #51C to maximum output.
   - (d) Adjust the Band "C" R-F Parallel trimmer Illus. #51C to maximum output.
   - (e) Adjust the Band "C" Antenna parallel trimmer Illus. #48C (Fig. 3) to maximum output.

7. Aligning at 18 Megacycles (18,000 K.C. Band "D")
   - (a) Replace the .0002 mfd. condenser in the signal lead from the test oscillator with a 400 ohm carbon resistor, leaving the test oscillator leads connected the same as before.
   - (b) Turn the band change switch to Band "D" (extreme right hand position).
   - (c) Turn the receiver dial pointer to 18 Megacycles.
   - (d) Place test oscillator in operation at 18 Megacycles.
   - (e) Adjust the Band "D" oscillator parallel trimmer, Illus. 51D (Fig. 3) to maximum output.

     NOTE: On the 18 Megacycle Alignment of trimmer Illus. 51D, it will be noted that there are two settings at which the signal will be received. Use the signal received with the trimmer setting having the most capacity or the point at which the trimmer screw is the farthest in.
   - (f) Adjust the Band "D" R-F parallel trimmer Illus. 51D to maximum output.
   - (g) Adjust the Band "D" Antenna parallel trimmer, Illus. 48D to maximum output.

PARTS LAYOUT--Bottom View

MODEL 3205 Delco
Alignment

UNITED MOTORS SERVICE

GENERAL: The Delco Model 3205 is a six tube, 32 volt, two band receiver with A.V.C. and sensitivity control. The tubes used are: 6D6 R-F Amplifier, 6A7 Oscillator-Modulator, 6D6 I-F Amplifier, 85 Detector and 1st Audio Amplifier and two type 48 Output Tubes.

The frequency range is from 540 to 1570 kilocycles on the Broadcast Band and from 1570 to 4000 kilocycles on the Short Wave Band.

SENSITIVITY CONTROL

The sensitivity control is a low resistance potentiometer, (Illus. #33) One end is connected to the antenna lead and the other end is connected to the cathodes of the R-F and Osc.-Mod. tubes. The moving arm is connected to the chassis. When the knob is turned toward the left (counter-clockwise) it simultaneously decreases the resistance across the primary of the antenna coil and increases the grid bias on the R-F and Osc.-Mod. tubes. This has the effect of decreasing the sensitivity of the receiver and increasing the selectivity. Since the sensitivity of the R-F and I-F amplifiers is simultaneously decreased, it serves as a control of overall oscillations which sometimes develop with abnormally high line voltage.

GROUND CIRCUIT

DO NOT ground the chassis except through the use of the "GND" terminal on the terminal strip located on the rear of the chassis. This terminal connects to the chassis frame through a series condenser in order to prevent a short circuit when operating the receiver on a 32 volt system with the positive side grounded.

CIRCUIT ALIGNMENT

All of the adjustable condensers are very accurately adjusted at the factory and should need no further adjustment unless tampered with in the field or a defective coil has been replaced. If realignment is found necessary, the circuits can be properly adjusted only with the use of a test oscillator and an output meter.

1. Peaking I-F Stages at 450 Kilocycles

(a) Connect the antenna of the signal generator to the control grid connection on top of the 6A7 tube through a .02 mfd. series condenser. DO NOT REMOVE THE GRID CLIP.

(b) Connect the ground terminal of the signal generator to the ground terminal of the receiver.

(c) Set the signal generator to exactly 450 kilocycles.

(d) Rotate the receiver tuning condenser until the rotor plates are completely meshed.

(e) Turn the band selector switch to the left. (Short Wave)

(f) Adjust the line voltage to 32 volts.

(g) Turn the volume control and the sensitivity control all the way to the right.

(h) With the signal generator set to the lowest usable output level adjust the I-F trimmer condensers for maximum signal output.

NOTE: The I-F trimmers are located on top of the I-F coils, Fig. 2 and may be adjusted with an insulated screw driver. Always make the adjustments very carefully, going over them several times to insure that the final setting is at resonant frequency.

2. Aligning R-F Circuits--Broadcast Band (540-1570 K.C.)

(a) Turn the band selector switch to the right hand position. (Broadcast Band)

(b) Rotate the tuning condenser until the rotor plates are completely out of mesh.

(c) Connect the antenna terminal of the signal generator to the receiver antenna terminal through a .00025 mfd., mica, series condenser.

(d) Connect the ground terminal of the signal generator to the ground terminal of the receiver.

(e) Set the signal generator to exactly 1575 kilocycles.

(f) Adjust the "Osc." section (rear section) of the tuning condenser gang for maximum signal output.

(g) Set the signal generator to 1400 kilocycles.

NOTE: If electrical interference causes an excessive reading on the output meter, making alignment difficult, it can be reduced by connecting a 5 to 10 mfd., paper, condenser between the ground terminal of the receiver and the chassis frame.

(h) Tune in the 1400 kilocycle signal with tuning condenser for maximum output.

NOTE: Do not disturb the setting of the oscillator trimmer (rear section) as this is adjusted at 1575 kilocycles only and any further adjustment at this point would affect both the tuning range of the receiver and the tracking of its circuits.

(i) Adjust the "R-F" parallel trimmer of the condenser gang for maximum output.

(j) Adjust the "Ant." parallel trimmer of the condenser gang for maximum output.

(k) Repeat operations (h), (i) and (j) until no further improvement in output can be made.

3. Aligning R-F Circuits--Short Wave (1570-4000 K.C.)

(a) Set the signal generator to 2500 kilocycles.

(b) Turn the band selector switch to the left. (Short Wave)

(c) Tune in the 2500 kilocycle signal with the tuning condenser for maximum output.

(d) Adjust the R-F short wave padding condenser, Illus. #18B for maximum output.

(e) Adjust the Ant. short wave padding condenser, Illus. #18A for maximum output.

MODELS 3206,3207 Delco
Alignment,Voltage

UNITED MOTORS SERVICE

GENERAL: The Delco Models 3206 (table model) and 3207 (console model) employ the same chassis which is a nine tube, 32 volt, four band receiver. The tubes used are 6D6 R-F amplifier, 6A7 Oscillator-Modulator, 6D6 I-F Amplifier, 85 Detector and A-F Amplifier and four type 48 output tubes in push-pull parallel.

The frequency ranges on the four bands covered are: Foreign Short Wave Band (A) 5.9 to 15.3 megacycles, Police and Amateur Band (B) 1590 to 4500 kilocycles, American Broadcast Band (C) 540 to 1600 kilocycles and the Weather Band (D) 148 to 400 kilocycles.

SENSITIVITY CONTROL

The sensitivity control is a potentiometer connected across the A1 and A2 terminals on the antenna and ground terminal strip on the rear of the chassis. The movable arm is connected to the antenna coil. It is used to vary the strength of the signal in order to prevent overloading the R-F amplifier because of the low plate voltage used.

GROUND CIRCUIT

DO NOT ground the chassis except through the use of the "GND" terminal on the terminal strip located on the rear of the chassis. This terminal connects to the chassis frame through a series condenser in order to prevent a short circuit when operating the receiver on a 32 volt system with the positive side grounded.

CIRCUIT ALIGNMENT

All of the condensers are very accurately adjusted at the factory and should need no further adjustment unless tampered with in the field or a defective coil has been replaced. If realignment is found necessary, the circuits can be properly adjusted only with the use of a signal generator and an output meter.

1. Peaking I-F Stages at 450 Kilocycles

(a) Connect the antenna of the signal generator to the control grid connection on top of the 6A7 tube through a .02 mfd. series condenser. DO NOT REMOVE THE GRID CLIP.

(b) Connect the ground terminal of the signal generator to the ground terminal of the receiver.

(c) Set the signal generator to exactly 450 kilocycles.

(d) Rotate the receiver tuning condenser until the rotor plates are completely out of mesh.

(e) Turn the band selector switch to Band A. (First position on left)

(f) Adjust the line voltage to 32 volts.

(g) Turn the volume control and sensitivity control knobs all the way to the right.

(h) With the signal generator set to the lowest usable output level, adjust the I-F trimmer condensers for maximum signal output.

NOTE: The I-F trimmers are located on top of the I-F coils, Fig. 2, and may be adjusted with an insulated screw driver. Always make the adjustments very carefully, going over them several times to insure that the final setting is at resonant frequency.

2. Aligning R-F Circuits Band "D" (148-400 K.C.)

(a) Turn the band selector switch to the first position on the right. (Band D)

(b) Rotate the receiver tuning condenser until the rotor plates are completely IN MESH and adjust the dial pointer, if necessary, so that it is exactly horizontal.

(c) Connect the antenna terminal of the signal generator to terminal "A1" on the rear of the receiver through a .00025 mfd. mica series condenser.

(d) Set the signal generator to 400 kilocycles.

(e) Rotate the station selector until the rotor plates are completely OUT OF MESH.

(f) Adjust the Band D "Osc." parallel trimmer (Fig. 2), for maximum output.

NOTE: If electrical interference causes an excessive reading on the output meter, making alignment difficult, it can be reduced by connecting a 5 to 10 mfd. paper condenser between the ground terminal of the receiver and the chassis frame.

(g) Adjust the Band D "R-F" parallel trimmer, (Fig. 2), for maximum output.

(h) Adjust the Band D "Ant" parallel trimmer, (Fig. 2), for maximum output.

(i) Repeat operations (f), (g) and (h) until no further improvement in output can be obtained.

(j) Set the signal generator to 150 kilocycles.

(k) Tune-in the 150 kilocycle signal with the station selector in the region of 15 on the dial (Band D), for maximum reading on the output meter.

(l) Adjust the Band D oscillator series trimmer, (Illus. #31B, Fig. 2) while rocking the condenser gang plates back and forth slightly, until no further increase in output can be obtained.

(m) Repeat operations (f), (g) and (h) for more accurate adjustments.

3. Aligning R-F Circuits - Band C (540-1600 K.C.)

(a) Turn the band selector switch to the second position from the right. (Band C)

(b) Set the signal generator to 1400 kilocycles.

(c) Rotate the station selector until the pointer points to 140. (Band C)

(d) Adjust the Band C "Osc." parallel trimmer (Fig. 2), for maximum signal output.

(e) Adjust the Band C "R-F" parallel trimmer, (Fig. 2), for maximum signal output.

(f) Adjust the Band C "Ant" parallel trimmer (Fig. 2), for maximum signal output.

(g) Repeat operations (d), (e) and (f).

(h) Set the signal generator to 600 kilocycles.

(i) Tune-in the 600 kilocycle signal with the station selector in the region of 60 on the dial (Band C), for maximum reading on the output meter.

(j) Adjust the Band C oscillator series trimmer, (Illus. #31A, Fig. 2) while rocking the condenser gang plates back and forth slightly, until no further increase in output can be obtained.

(k) Repeat operations (d), (e) and (f) for more accurate adjustments.

4. Aligning R-F Circuits - Band B (1590-4500 K.C.)

(a) Turn the band selector switch to the second position from the left. (Band B)

(b) Set the signal generator to 4000 kilocycles.

(c) Rotate the station selector until the pointer points to 4.0. (Band B)

(d) Adjust the Band B "Osc." parallel trimmer, (Fig. 2), for maximum signal output.

(e) Adjust the Band B "R-F" parallel trimmer, (Fig. 2), for maximum signal output.

(f) Adjust the Band B "Ant." parallel trimmer, (Fig. 2), for maximum signal output.

(g) Repeat operations (d), (e) and (f).

(h) Set the signal generator to 1700 kilocycles.

(i) Tune-in the 1700 kilocycle signal with the station selector in the region of 1.7 on the dial (Band B), for maximum reading on the output meter.

(j) Adjust the Band B oscillator series trimmer (Illus. #30B, Fig. 2) while rocking the condenser gang plates back and forth slightly, until no further increase in output can be obtained.

(k) Repeat operations (d), (e) and (f) for more accurate adjustments.

5. Aligning R-F Circuits - Band A (5,900-15,300 K.C.)

(a) Replace the .00025 series condenser in the output lead from the signal generator with a 400 ohm, carbon resistor.

(b) Turn the band selector switch to the first position on the left. (Band A)

(c) Set the signal generator to 15 megacycles. (15,000 K.C.)

(d) Rotate the station selector until the pointer points to 15. (Band A)

(e) Adjust the Band A "Osc." parallel trimmer, (Fig. 2), for maximum signal output.

(f) Adjust the Band A "R-F" parallel trimmer, (Fig. 2), for maximum signal output.

(g) Adjust the Band A "Ant." parallel trimmer, (Fig. 2), for maximum signal output.

(h) Repeat operations (e), (f) and (g).

(i) Set the signal generator to 6 megacycles. (6000 K.C.)

(j) Tune-in the 6 megacycle signal with the station selector in the region of 6.0 on the dial (Band A) for maximum reading on the output meter.

(k) Adjust the Band A oscillator series trimmer (Illus. #30A, Fig. 2) while rocking the condenser gang plates back and forth slightly, until no further increase in output can be obtained.

(l) Repeat operations (e), (f) and (g) for more accurate adjustments.

*TUBE SOCKET VOLTAGES

Tube	Function	H	P	Gs	Su	G	Go	Ga	K
6D6	R-F Amplifier	6.4	30.5	30.5	0	0	-	-	0
6A7	Osc-Mod	6.4	30.5	17.4	-	0	**	30.5	0
6D6	I-F Amplifier	6.4	30.5	30.5	0	0	-	-	0
85	Det. & 1st A-F	6.4	9.0	-	-	0	-	-	0
76	A-F Amplifier	6.4	30.0	-	-	0	-	-	0
48	(4) Output	25.2	30.0	30.5	-	1.4	-	-	6.2

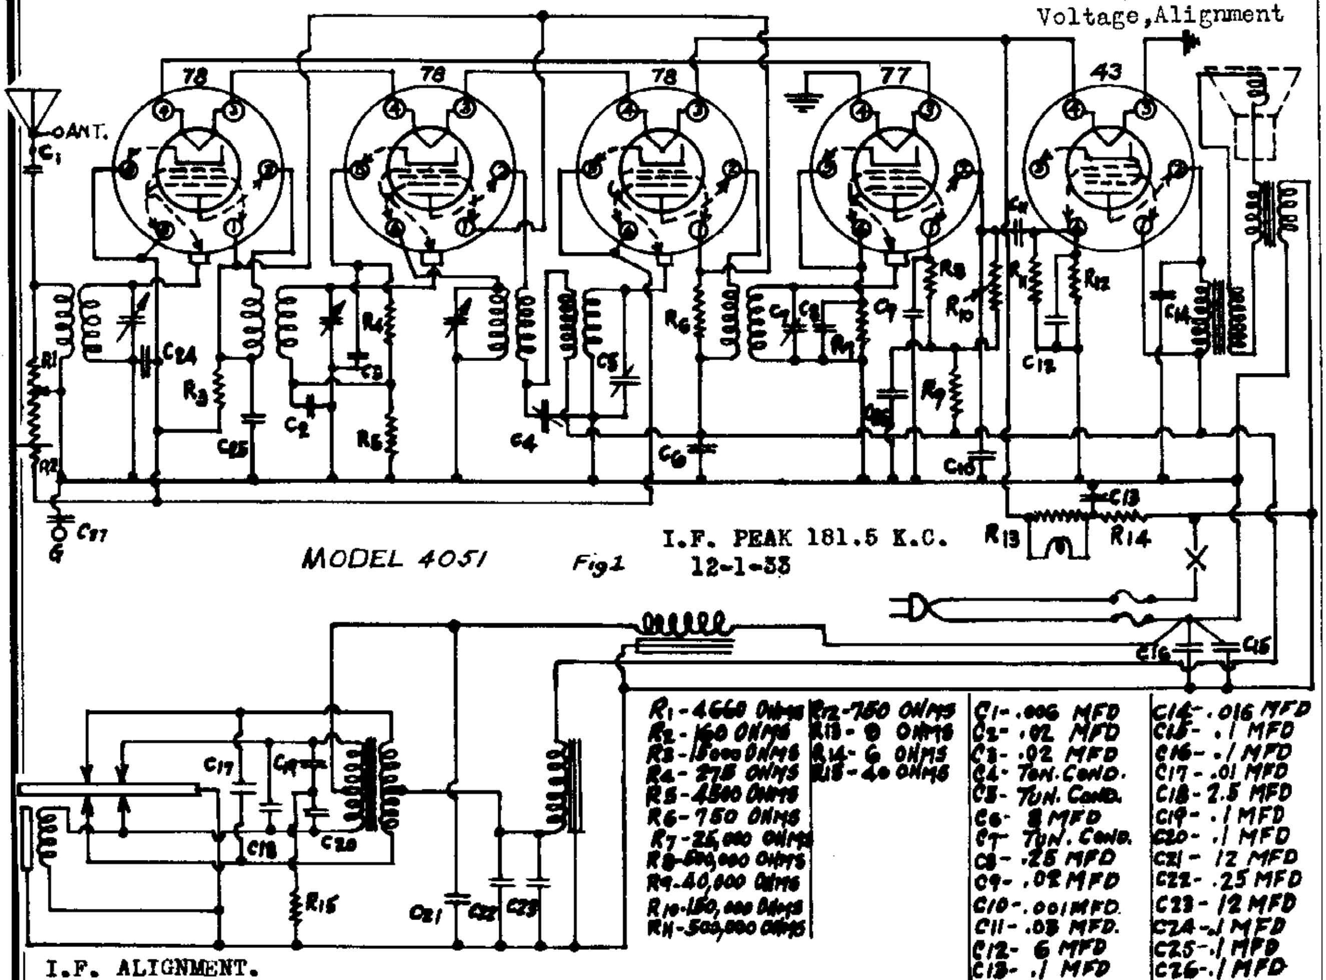
Current drain 8.0 amperes at 32 volts.

**Oscillator grid (Go) voltage varies from - 1 at the low frequency end of the dial to - 5 at the high frequency end of the dial.

* Readings taken on 32 volt power supply with 1000 ohms per volt voltmeter from tube socket contacts (except filaments) to chassis.

UNITED MOTORS SERVICE

MODEL 4051, 32 volts
Schematic
Voltage, Alignment



I.F. ALIGNMENT.

1. Connect the Oscillator to the grid cap of the 1st. Detector (78 Tube)
2. Set the Oscillator for 181.5 K.C.
3. Peak the I.F. trimmer condensers, peaking the secondary of the second I.F. Transformer first and working forward to the primary of the first I.F. Transformer.

R.F. ALIGNMENT.

1. Connect the Oscillator to the antenna and ground posts of the receiver.
2. Tune the receiver to 1400 K.C.; operate the Oscillator at 1400 K.C.
3. Peak the parallel trimmers on the tuning condenser; peak the oscillator section (small plates) first.

CAUTION.

Do NOT connect the chassis of the receiver to the chassis of the vibrator as they are 32 Volts apart electrically. Connecting the two chassis together will cause the fuses to blow.

VOLTAGE CHART

TUBE	Tube prong numbers. #1	#2	#3 & #4 Filament	#5	#6
78	135	135	6.4	5.0	5.0
78	135	154	6.4	35.0	.0
78	135	154	6.4	5.0	5.0
77	50	77	6.4	5.5	5.5
43	154	148	25.0	22.5	

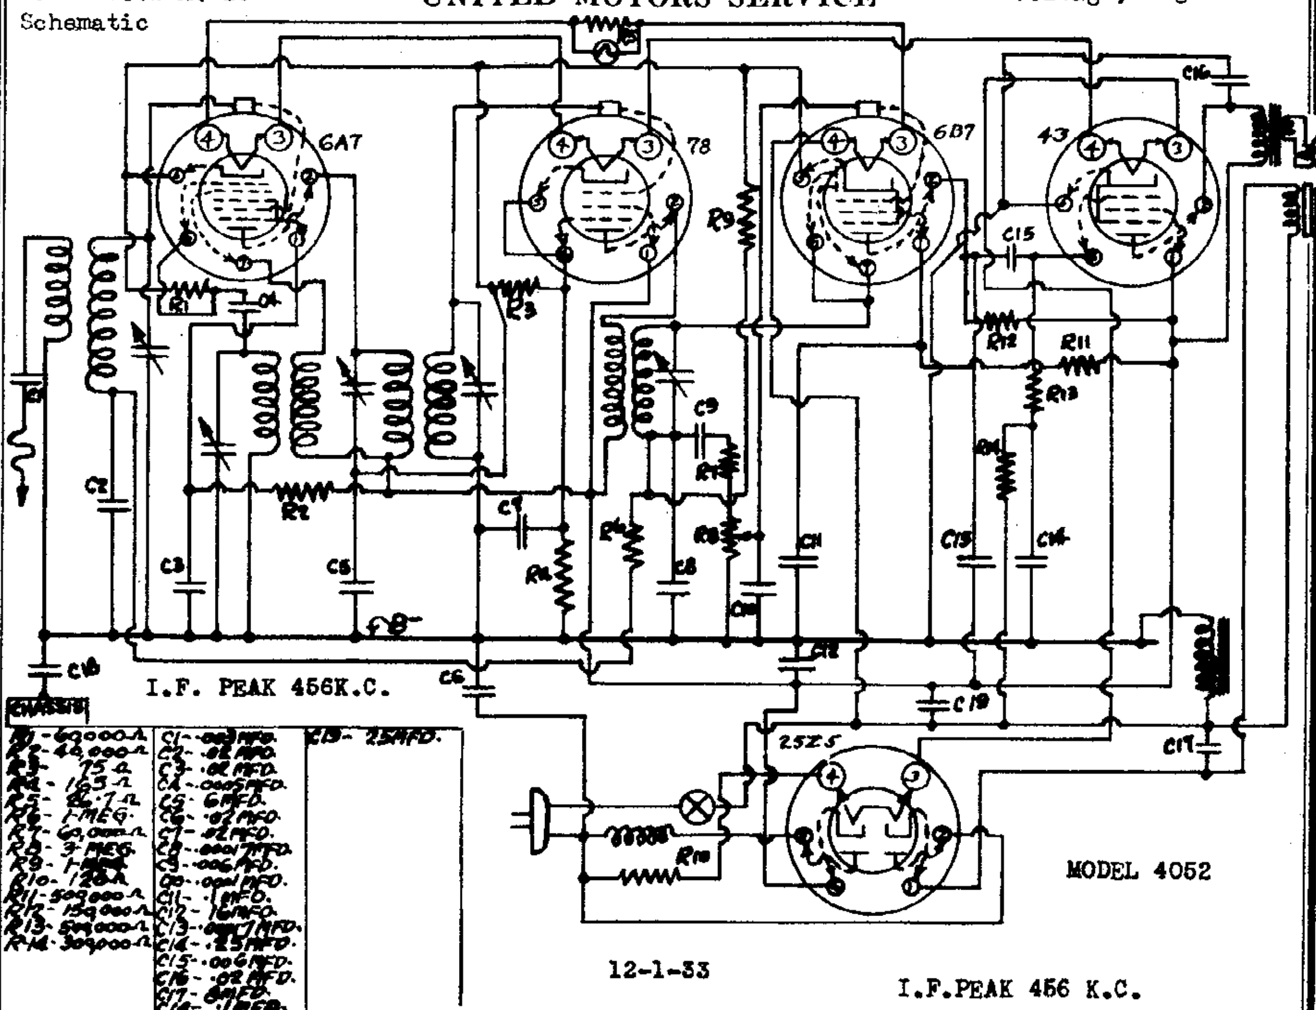
NOTE:

All readings are taken from indicated tube socket prong to frame except filament voltages. Volume Control on full. Supply Voltage at 32 Volts. Any increase or decrease in the power supply will vary these readings proportionately.

MODEL 4052 AC-DC
Schematic

UNITED MOTORS SERVICE

Voltage, Alignment



I.F. ALIGNMENT.
Peak the I.F. circuits of this receiver at 456 K.C. Use a fibre wrench for aligning the I.F. circuits, DO NOT attempt to use a metal wrench for this purpose.

R.F. & OSCILLATOR ALIGNMENT.
Peak the trimmer condensers on the tuning condenser at exactly 1400 K.C. Variation of this frequency will prevent tuning in both 550 and 1712 K.C. satisfactoily.

*NOTE:
The I.F. frequency of this receiver falls in the Government Coast Guard communications band. In certain locations code may be heard between stations over the entire dial as a nearby Coast Guard station may ride through on the I.F. circuits are repeaked at a slightly lower , or a slightly higher, frequency the code signal will be rejected by the I.F. circuits.

VOLTAGE CHART
"B" MINUS for this receiver will be found on the tuning condenser frame. All D.C. Voltages are measured between the indicated tube prong and the frame of the tuning condenser. The A.C. Voltages of the tube filaments are measured directly across the tube filament prongs with an A.C. meter.

TUBE	TUBE PRONG NUMBERS					
	#1	#2	#3 & #4(Fil)	#5	#6	#7

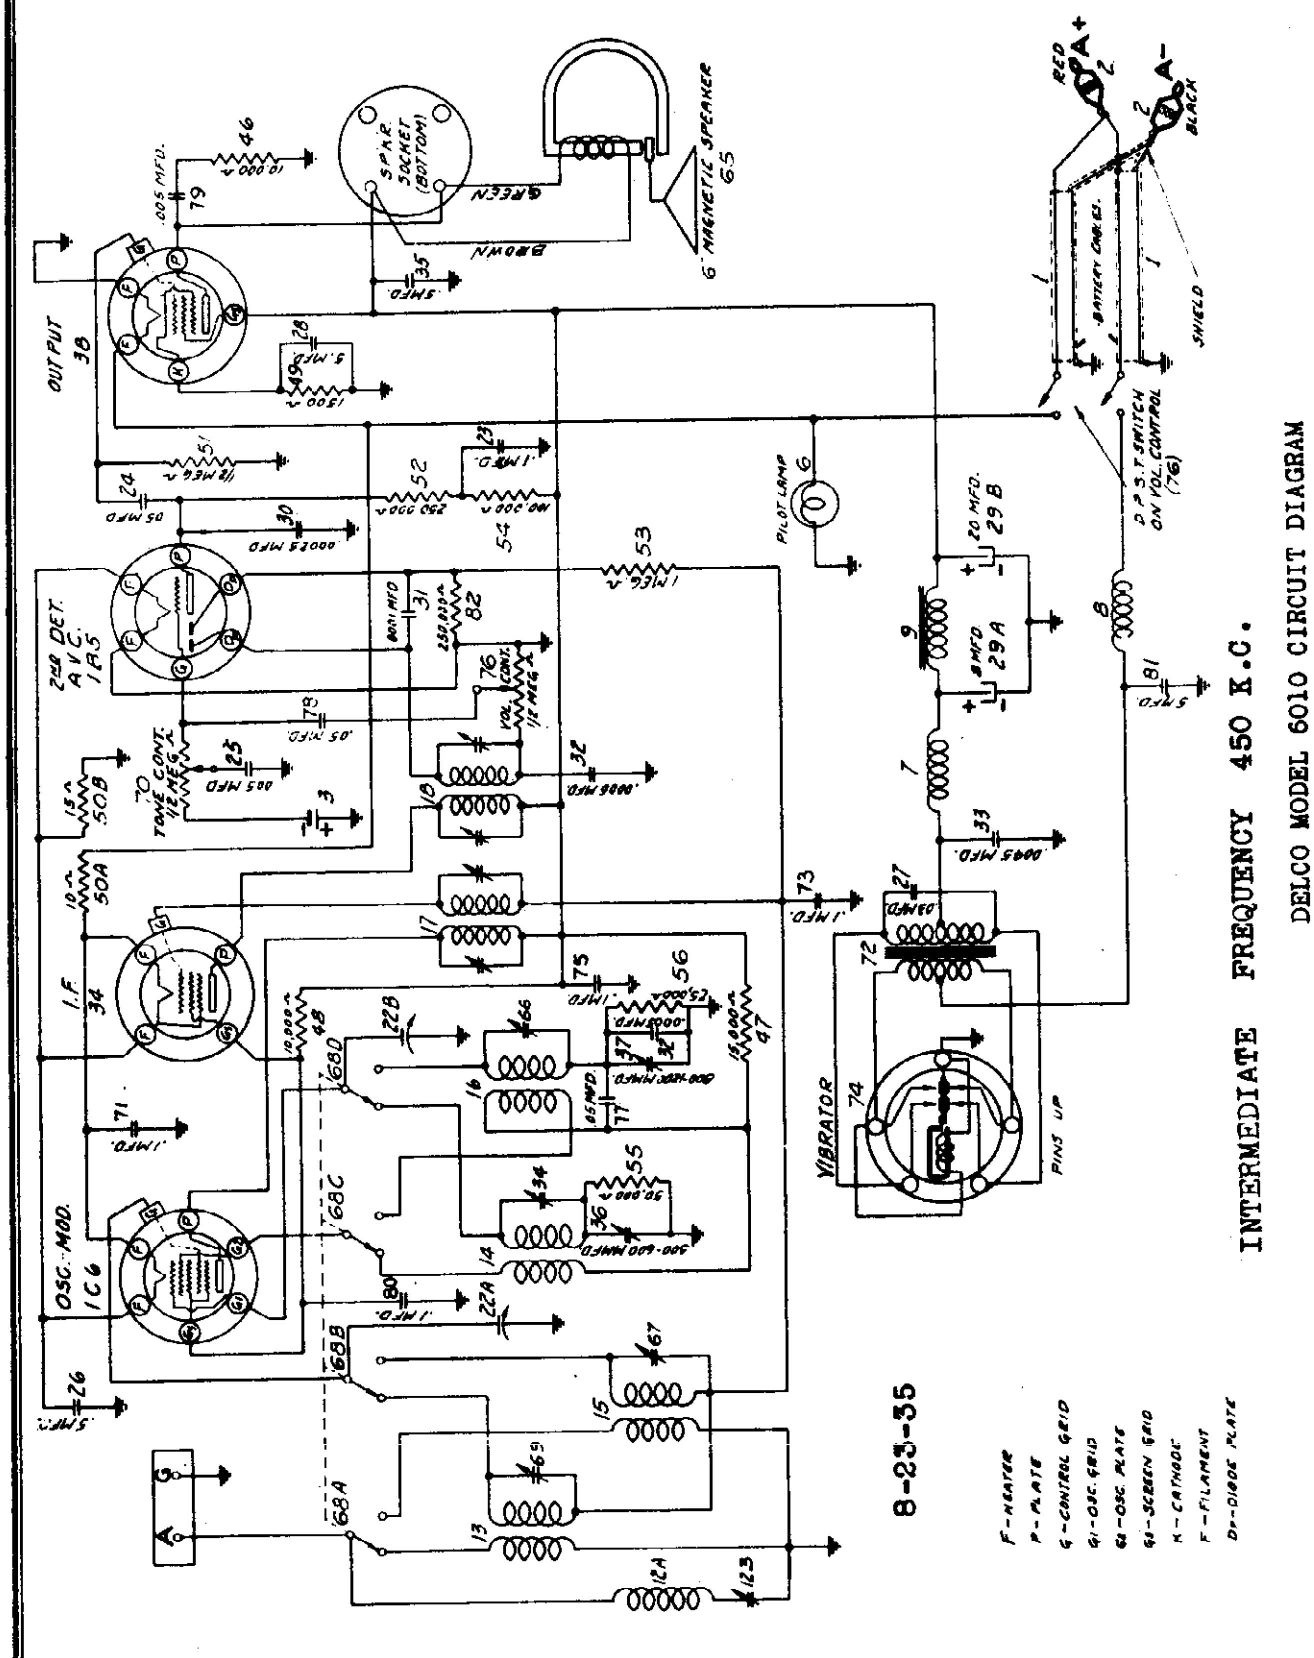
UNITED MOTORS SERVICE



MODEL 6010 Delco
Alignment,Voltage

GENERAL: The Delco Model 6010 is a 5 tube, 6 volt battery operated receiver with A.V.C. The type tubes used are: 1C6 Oscillator-Modulator, 34 I-F Amplifier, 1B5 Detector, A.V.C., and 1st A-F Amplifier and a type 38 Output tube.

The frequency range is from 540 to 1720 kilocycles on the Broadcast Band and from 2300 to 6200 kilocycles on the Short Wave Band.

CIRCUIT ALIGNMENT

All of the adjustable condensers are very accurately adjusted at the factory and should need no further adjustment unless tampered with in the field or a defective coil has been replaced. If realignment is found necessary, the circuits can be properly adjusted only with the use of a calibrated test oscillator or signal generator and an output meter.

1. Peaking I-F Stages at 465 Kilocycles

(a) Connect the ground lead of the test oscillator to the chassis frame. Connect the other lead to the grid cap of the 1C6 tube through a .02 mfd. series condenser. DO NOT REMOVE THE GRID CLIP.

(b) Set the test oscillator to exactly 465 kilocycles.

(c) Turn the volume control of the receiver on full.

(d) Peak each of the trimmers on the 2nd I-F coil., Illus. #18 on Fig. 2.

(e) Peak each of the trimmers on the 1st I-F coil., Illus. #17 on Fig. 2.

(f) In order to insure accurate settings of the I-F trimmers, the above adjustments should be repeated using the lowest test oscillator output that will give a reasonable output meter scale deflection.

2. Aligning R-F Circuits -- Broadcast Band (540-1720 K.C.)

(a) Remove the test oscillator lead from the grid of the 1C6 tube and connect it to the receiver antenna terminal through a .00025 mfd. series condenser.

(b) Check to see the tuning dial has not slipped on the condenser gang shaft by turning the rotor plates of the condenser gang until they are completely out of mesh, at which point the dial pointer should be at the high frequency end of the dial calibration.

(c) Turn the band selector switch to the right for operation on the Broadcast Band (540-1720 K.C.)

(d) Set the test oscillator frequency to exactly 1720 K.C.

(e) Turn the gang condenser until the plates are completely out of mesh.

(f) Adjust the broadcast padding condenser for the oscillator section of the condenser gang, shown as Illus. #34 on Fig. 3, to bring in the 1720 kilocycle signal from the test oscillator with maximum output.

(g) Set the test oscillator frequency and the receiver dial to exactly 1400 kilocycles.

(h) Adjust the broadcast padding condenser, Illus. #59 Fig. 5, for the antenna section of the condenser gang for maximum output.

(i) Set test oscillator on 600 kilocycles.

2. Aligning R-F Circuits--Broadcast Band (540-1720 K.C.)--Cont'd.

(j) Set receiver dial at approximately 600 kilocycles, leaving the test oscillator connected to the ANT and GND terminal of the receiver and the band change switch in the Broadcast position.

(k) Adjust the oscillator tracking condenser Illus. #36 Fig. 3, rocking the tuning condenser gang back and forth until no further increase in output can be obtained.

3. Aligning R-F Circuits--Short Wave Band (2.3 to 6.2 meg.)

(a) Leave test oscillator connected to ANT and GND of receiver and turn the band selector switch to the left for operation on the Short Wave Band.

(b) Set test oscillator frequency and receiver dial to exactly 5.8 megacycles.

(c) Adjust the short wave padding condenser, Illus. #66 Fig. 3, for the oscillator section of the condenser gang until the 5.8 megacycle signal from the test oscillator is tuned in with maximum output.

(d) Adjust the short wave padding condenser, Illus. #67 Fig. 3 for maximum output.

(e) Turn the receiver dial and set test oscillator to approximately 2.5 megacycles.

(f) Adjust the Oscillator tracking condenser, Illus. #57 Fig. 3, rocking the tuning condenser gang back and forth until no further improvement in output can be obtained.

4. Adjustment of 465 K.C. Wave Trap

Some code and aircraft signals are broadcast on a frequency exactly the same or near the I.F. frequency of the receiver. To eliminate interference from these signals, a 465 K.C. antenna filter is incorporated in the set. To adjust:

(a) Leave test oscillator output leads connected to the set ANT and GND.

(b) Set the test oscillator frequency to exactly 465 K.C. and adjust the 465 K.C. wave trap trimmer, Illus. #12B Fig. 3 for MINIMUM 465 K.C. SIGNAL RESPONSE.

*TUBE SOCKET VOLTAGES

Tube	Function	F	P	Gs	G2	G1	K
1C6	Osc.-Mod.	2.1	135	85	-2.8	100	-
34	I-F Amp.	2.1	135	85	-	-	-

PEAKING PROCEDURE

Peaking I.F. Stages at 262 K.C.

(a) Connect the ground lead of the test oscillator to the chassis frame. Connect a .5 mfd. condenser in series with the other lead and connect this lead to the grid cap of the 6A7 tube, leaving the grid clip in place. The .5 mfd. condenser is necessary to prevent the oscillator circuit of the receiver from affecting the I.F. adjustments.

(b) Set the test oscillator on 262 kilocycles.

(c) Turn the volume control of the receiver on full.

(d) Peak the I.F. trimmer P-4 and P-3 located on the 2nd I.F. coil shown on Figure 3.

(e) Then peak trimmers P-2 and P-1 located on the first I.F. coil also shown on Figure 3.

(f) In order to insure accurate settings of the I.F. trimmers the above adjustments should be repeated using the lowest oscillator output that will give a reasonable deflection of the output meter pointer. Make all adjustments for maximum output.

Peaking Gang Condenser at 1530 and 1400 K.C.

(a) Connect the output of the test oscillator to the antenna connection of the receiver and to the chassis ground. Do not use the .5 mfd. condenser that was required in aligning the I.F. stages.

(b) Turn the rotor plates of the gang condenser until they are COMPLETELY OUT OF MESH.

(c) Set the test oscillator on 1530 kilocycles.

(d) Adjust the trimmer condenser for the oscillator section (middle section) of the gang condenser CAREFULLY for maximum output. Then adjust the trimmers for the "R.F." and "ANT" sections of the gang condenser. (See Fig. 2)

(e) Set the test oscillator on 1400 kilocycles.

(f) Turn the condenser rotor plates until the 1400 K.C. signal from the test oscillator is tuned in with maximum output. (No calibration blocks should be used as the oscillator circuit is adjusted at 1530 K.C. on this set.)

Peaking Gang Condenser at 1530 and 1400 K.C.--Cont'd.

(g) Readjust the parallel trimmers for the "R.F." and "ANT" sections of the gang condenser for maximum output. DO NOT disturb the oscillator trimmer (middle section) as this is adjusted at 1530 K.C. only, and any further adjustments at this point will affect both the tuning range of the receiver and the tracking of its circuits.

(h) The capacity of the output circuit of the test oscillator may be slightly different than that of the under car antenna the receiver is to be used on. Therefore, it is advisable to readjust the "ANT" trimmer to the car antenna when reinstalling the receiver. This may be done by tuning the receiver to a broadcast station around 1400 K.C. and adjusting for maximum volume.

CIRCUIT CHANGES

A number of .05 mfd. tubular condensers were used at the factory in place of the .06 mfd. condenser part #1209213 condenser shown on figure 2 as illustration #33. For Service Replacement purposes of any defective .05 mfd. condensers--use part #1209213 condenser.

VOLTAGE CHART

The voltages shown below are average readings taken from the tube socket contacts to the chassis frame, and will vary ±10% when the set is tested on a 6 volt battery due to differences in characteristics of vibrators and tubes.

TUBE BASE DIAGRAM SYMBOLS*

Type	Function	H	Pp	S	Tp	Gt	G	G1	G2	K
78	R.F.	6	240	130	-	-	0	-	-	8.0

41 A.F.	215	210	6	0	16.3	0	

PEAKING

All of the adjustable condensers, commonly called "trimmer" condensers, are very accurately adjusted at the factory and will not need any further adjustment unless a coil or I.F. transformer is changed or the adjustments are tampered with in the field.
DO NOT attempt to change the setting of any of the trimmer condensers unless it is definitely known that the adjustment is necessary. If re-alignment is found necessary a test oscillator, fibre screw driver and output meter will be necessary to accurately align the circuits.

PEAKING I.F. STAGES AT 262 K.C.

The only way the I.F. stages can be peaked properly is with the use of an oscillator and output meter. Connect the output meter to the plate prong of the 41 output tube and to the chassis frame. Make sure that the output meter is protected with a series condenser internally, if not, connect a 1/10 mfd. condenser in series with the ground lead to the chassis. The Dayrad #875 Universal Test Meter and Series #51 Volt-Ohmeter have this protective condenser included in them.

(a) Connect the output of the oscillator to the grid cap of the 6F7 tube (leave grid cap in place) and to the chassis ground.

(b) Turn the condenser gang until the plates are entirely out of mesh.

(c) Set the oscillator on 262 K.C. and feed this signal through the I.F. stages of the set.

(d) Peak the I.F. trimmer which is in the I.F. coil having only one adjusting screw first. Then peak the two condensers of the 2nd I.F. coil.

(e) Set the oscillator output at the lowest level that will give a reasonable scale deflection on the output meter. This should be less than half the maximum output available.

(f) Make all trimmer adjustments for maximum deflection on the output meter scale.

PEAKING GANG CONDENSER AT 1400 K.C.

(a) Connect the output of the oscillator to the antenna connection of the set and to the chassis ground.

(b) In order that the position of the condenser plates for 1400 K.C. may be accurately determined, a wood calibration block (painted red, part number 1208073) should be used. This block may be used also in peaking all of the U.M.S., B-O-P, and Chevrolet radios that use the "tubeless rectifier".

(c) Insert the RED block under the middle section of the gang condenser, so that the largest flat side rests on the chassis base and the square notch stops solidly against the stationary plate support bracket.

(d) Open the condenser plates until they stop solidly against the beveled edge of the block as shown in Fig. (1).

(e) Peak the parallel trimmers on top of the condenser gang, the oscillator section first at 1400 K.C. for maximum deflection on the output meter.

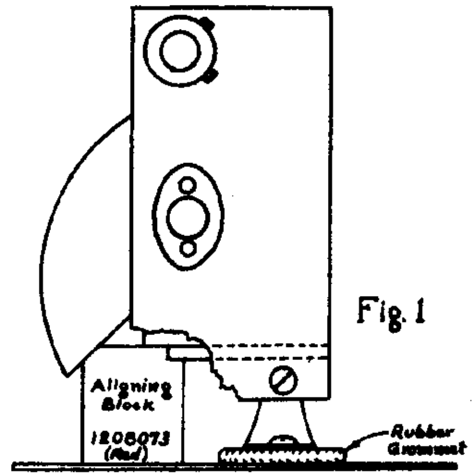

Fig. 1

(f) To insure sharp peaking of all trimmers reduce the oscillator output to the lowest level that will give a reasonable deflection on the output meter scale.

NOTE: Always use the red calibration block when aligning the parallel trimmers on the gang condenser. Do not rely on the logging of the dial to determine the 1400 K.C. setting. When the aligning procedure is completed, the logging of the dial may be slightly off and should be re-set.

UNIVERSAL BATTERY CO.

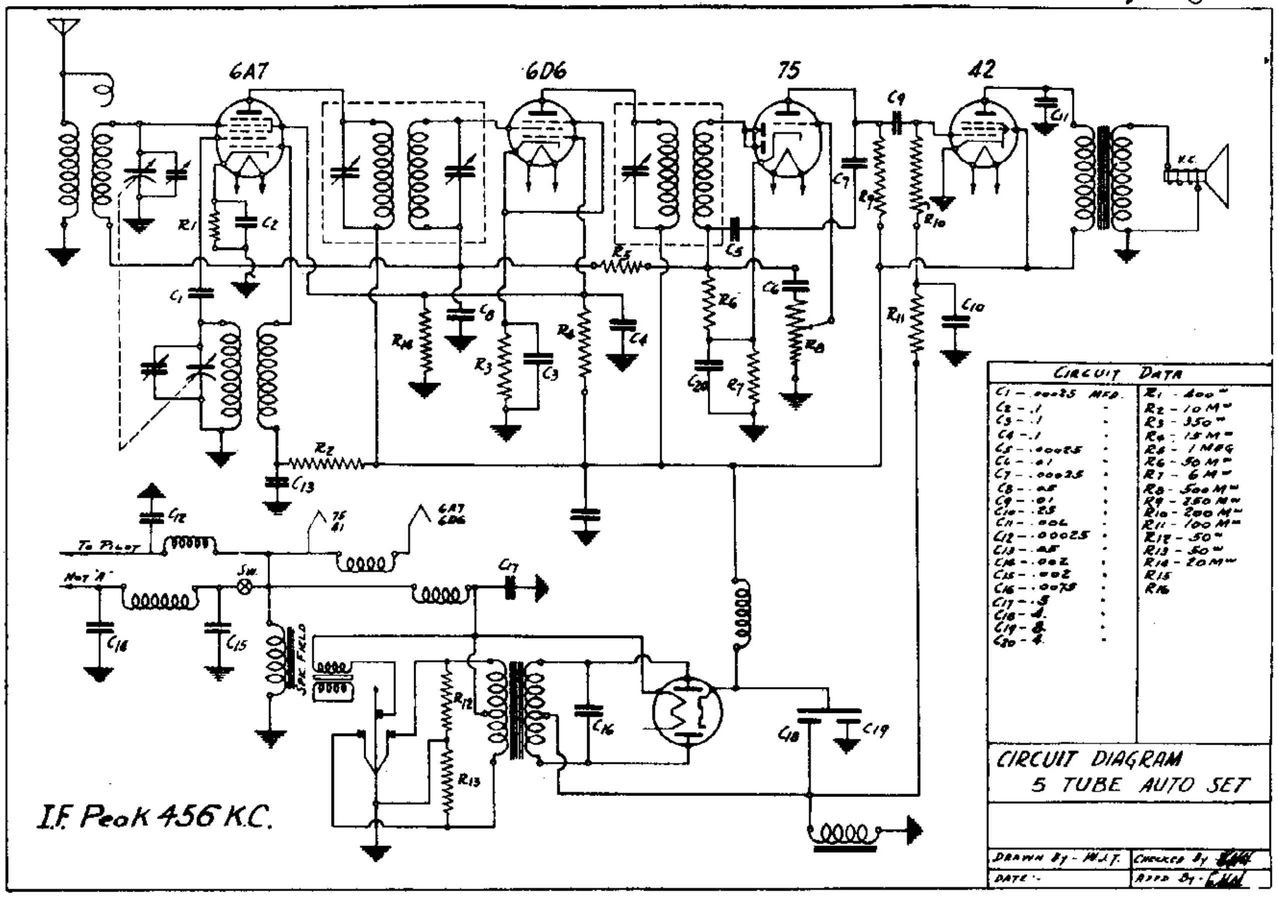
WARWICK MFG. CO.

MODEL 5-Tube Auto
Schematic, Alignmen



I. F. ALIGNMENT:

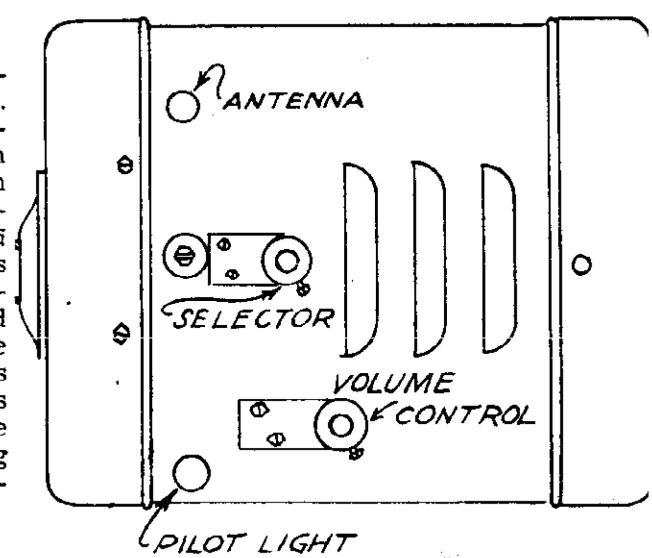
With volume control turned on full and variable gang condenser at maximum capacity, attach test oscillator lead in series with a .1 mfd. condenser to grid of 6A7 tube. Set test oscillator 456 KC and adjust I.F. trimmers for maximum output as indicated on an output meter connected across voice coil of speaker or from plate and screen of 41 tube.

R. F. ALIGNMENT:

Set test oscillator at 1500 KC and connect to antenna of receiver through a 150 mmf. condenser. Rotate variable gang condenser to minimum capacity and back off slightly. Adjust trimmer on oscillator section of gang condenser (first section from shaft end) to resonance indicated by maximum output. Re-set test oscillator at 1400 KC and rotate variable condenser until oscillator signal is picked up. Adjust antenna (rear section) to resonance. Check alignment at 1400, 1000, 600 and 550 kilocycles by setting test oscillator to these frequencies and rotate condenser until signal is picked up. Off tracking at 1000 and 600 kilocycles may be compensated for by slightly bending the slotted plates of the antenna section of gang condenser. DO NOT BEND PLATES OF OSCILLATOR SECTION.

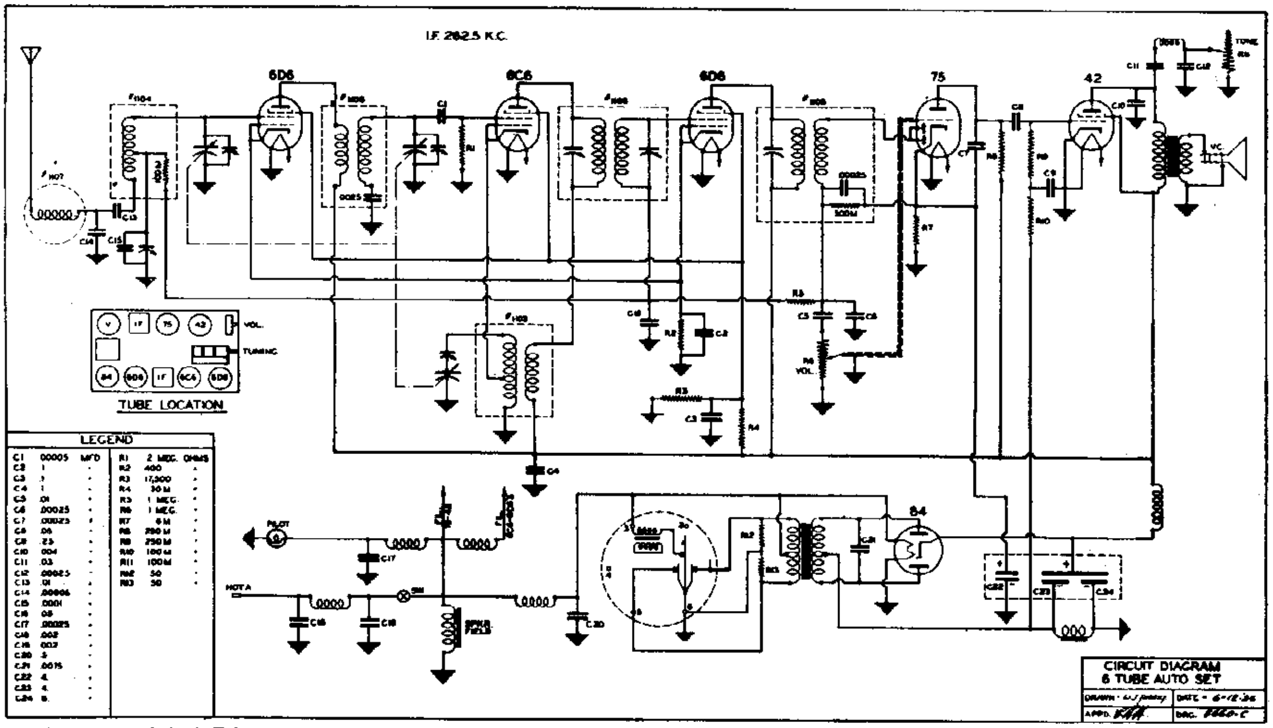
DIAL ADJUSTMENT

To correctly adjust dial pointer, tune the set to a station of known frequency or turn selector knob to end of tuning range in either direction and adjust slotted shaft in back of remote head until dial pointer reaches correct frequency setting. The dial is calibrated in kilocycles. Add one cipher to dial reading to determine frequency of station tuned.



MODEL 6-Tube Auto
Schematic, Alignment

WARWICK MFG. CO.



I. F. ALIGNMENT:

With volume control on full and variable gang condenser at maximum capacity, attach test oscillator lead in series with a .1 mfd. condenser tc stator of R. F. section of gang condenser (center section). Set test oscillator at 262.5 KC and adjust I.F. trimmers for maximum output as indicated on an output meter connected across voice coil of speakers or from plate and screen of 42 tube.

Set test oscillator to 600 KC and adjust oscillator padding (located on bakelite strip, 2nd from front). Also adjust 600 KC antenna padding condenser (located on bakelite strip, 1st condenser) Reset test oscillator to 1400 KC and readjust antenna and R. F. trimmers.

R. F. ALIGNMENT:

Set test oscillator at 1550 KC and connect through a 150 mmf. condenser to antenna of reciever. Rotate variable gang condenser to minimum capacity and back off slightly. Adjust trimmer on oscillator section of gang condenser (third section from shaft end) to resonance indicated by maximum output. Re-set test oscillator of 1400 KC and rotate variable condenser until oscillator signal is picked up. Adjust antenna trimmer (front section) and R. F. trimmer (center section) to resonance.

DIAL ADJUSTMENT:

To correctly adjust dial pointer, tune set to a station of known frequency or turn selector knob to end of tuning range in either direction and adjust slotted shaft in back of remote head until dial pointer reaches correct frequency setting. The dial is calibrated in kilocycles. Add one cipher to dial reading to determine frequency at station tuned.

ANTENNA ADJUSTMENT:

When set is in operation, tune to a station on or about 1400 KC and adjust antenna trimmer to maximum volume. This trimmer is accessable by removing the plug button on the front cover of the receiver.

Proper adjustment of this trimmer matches the particular antenna used in the auto to the receiver which increases the sensitivity of the receiver.

Alignment and Calibration

Correct alignment is extremely important in connection with all wave receivers. The receivers are all properly aligned at the factory with precision instruments and realignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment.

A signal generator that will provide an accurately calibrated signal at 456, 1730, 1500, 600, 5800, 5000, 18,300, 15,000 and 6000 KC and an output indicating meter are required. It will be practically impossible to align the receiver if unsatisfactory apparatus is used. If a station is tuned in with the selectivity control in the broad position and this control is then turned to the sharp position, the station may disappear. This is not an indication that the receiver is out of alignment.

Use a non-metallic screwdriver for the adjustments. The complete procedure is as follows:

I. F. Adjustment

Set the signal generator for a signal of 456 KC.

Connect the output of the signal generator through a 0.1 mf. condenser to the grid of the 1st detector.

Connect the ground lead of the receiver to the ground post of the signal generator.

Turn the band selector to the Range B position (standard wave band—purple dial color).

Turn the selectivity control to the sharp position and keep it in this position for all adjustments.

Turn the volume control to the maximum position.

Attenuate the signal from the signal generator to prevent the levelling-off action of the A.V.C.

Then adjust the five I.F trimmers until maximum output is obtained. The adjusting screws for these condensers are reached from the top of the chassis, and the location is shown in Fig. 5.

Range B Alignment

1730 KC Adjustment

Set the signal generator for 1730 KC.

Turn the rotor of the tuning condenser to the full open position.

Keep the band selector in the standard wave position.

Connect the antenna lead of the receiver through a 200 mmf. condenser to the output of the signal generator.

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the oscillator Range B trimmer (C32) until maximum output is obtained. The location of this trimmer is shown in Fig. 3.

1500 KC Adjustment

Set the signal generator for 1500 KC.

Turn the rotor of the tuning condenser carefully until maximum output

Loosen the pointer set screw and set the large pointer at the 1500 KC mark on the standard wave band scale. Retighten the set screw.

Adjust the interstage Range B trimmer (C7) and antenna Range B trimmer (C2) to maximum.

Do not change the setting of the oscillator Range B trimmer.

600 KC Adjustment

Set the signal generator for 600 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 600 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

Range C Alignment

5800 KC Adjustment

Set the signal generator for 5800 KC.

Connect the antenna lead of the receiver through a 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band selector to the Range C position (1st short wave band—green dial color).

Adjust the oscillator Range C trimmer (C30) until maximum output is obtained. See Fig. 3 for location of this trimmer.

5000 KC Adjustment

Set the signal generator for 5000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the interstage Range C trimmer (C8) and antenna Range C trimmer (C3) to maximum.

Do not change the setting of the oscillator Range C trimmer.

Range D Alignment

18,300 KC Adjustment

Set the signal generator for 18,300 KC.

Keep the antenna lead of the receiver connected through the 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band selector to the Range D position (2nd short wave band—red dial color).

Adjust the oscillator Range D trimmer (C29) until maximum output is obtained. See Fig. 3 for location of this trimmer.

15,000 KC Adjustment

Set the signal generator for 15,000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the interstage Range D trimmer (C9) and antenna Range D trimmer (C4) to maximum.

When adjusting the interstage Range D trimmer, it will be necessary at the same time to turn the tuning condenser rotor slowly back and forth until the peak of greatest intensity is obtained.

Then go back and repeat the procedure as given for the 18,300 KC adjustment. If it is found necessary to make any appreciable change in the setting of the oscillator Range D trimmer, the 15,000 KC adjustment must be repeated.

Do not make any further change in the setting of the oscillator Range D trimmer.

6000 KC Adjustment

Set the signal generator for 6000 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 6000 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

D. C. Resistance of Windings

Twenty-five Cycle Receivers

The twenty-five cycle receiver differs from the sixty cycle receiver only in the fact that a different power transformer is used. The correct power transformer is shown in the parts list.

The twenty-five cycle receiver can be operated satisfactorily from a sixty cycle power supply. However, the reverse is not true, the sixty cycle receiver cannot be operated from a twenty-five cycle power supply.

A 115-230 Volt, 40 to 60 cycle as well as other power transformers with special power ratings are also available for this model.

Changes in Early Models

In the early models of this receiver the tone control resistor (R11) was connected as a series variable resistor connecting in series through the condenser C23 between the grids of the 45 tubes in the audio output stage. In the later models it is employed as a potentiometer in the manner shown in Fig. 2.

The 100,000 ohm resistor (R18) was not used in the early models. Condenser C21 was connected directly to resistor R7.

The type 6K7 metal tubes replace the type 6D6 glass tubes which were used in the early models.

Condenser C35 was added to the oscillator coil standard wave section in later models. It is not, however, used in all cases but only when this capacity is required in this circuit.

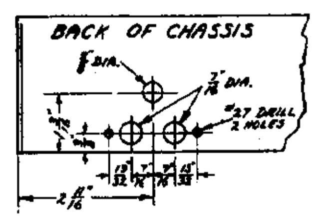

Fig. 8—Details of Panel Drilling for Phono Assembly

Phonograph Connections

Phonograph connections can be made as shown in Fig. 7. The parts required to make this installation are shown in the parts list.

To mount the phono switch and phono jack, drill holes of a size and in the position shown in Fig. 8 at the left hand side (from back) of the rear panel of the chassis.

Alignment and Calibration

Correct alignment is extremely important in connection with all wave receivers. The receivers are all properly aligned at the factory with precision instruments and realignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment.

A signal generator that will provide an accurately calibrated signal at 456, 1730, 1500, 600, 5800, 5000, 18,300, 15,000 and 6000 KC and an output indicating meter are required. It will be practically impossible to align the receiver if unsatisfactory apparatus is used. If a station is tuned in with the selectivity control in the broad position and this control is then turned to the sharp position, the station may disappear. This is not an indication that the receiver is out of alignment.

Use a non-metallic screwdriver for the adjustments.

The complete procedure is as follows:

I. F. Adjustment

Set the signal generator for a signal of 456 KC.

Connect the output of the signal generator to the grid of the 1st detector through a 0.1 MF condenser.

Connect the ground lead of the receiver to the ground post of the signal generator.

Turn the band selector to the Range B position (standard wave band—purple dial color).

Turn the selectivity control to the sharp position and keep it in this position for all adjustments.

Turn the volume control to the maximum position.

Attenuate the signal from the signal generator to prevent the levelling-off action of the A.V.C.

Then adjust the five I.F. trimmers until maximum output is obtained. The adjusting screws for these condensers are reached from the top of the chassis, and the location is shown in Fig. 5.

Range B Alignment

1730 KC Adjustment

Set the signal generator for 1730 KC.

Turn the rotor of the tuning condenser to the full open position.

Keep the band selector in the standard wave position.

Connect the antenna lead of the receiver through a 200 mmf. condenser to the output of the signal generator.

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the oscillator Range B trimmer (C38) until maximum output is obtained. The location of this trimmer is shown in Fig. 3.

1500 KC Adjustment

Set the signal generator for 1500 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Loosen the pointer set screw and set the large pointer at the 1500 KC mark on the standard wave band scale. Retighten the set screw.

Adjust the 1st and 2nd interstage Range B trimmers (C8 and C13) and antenna Range B trimmer (C2) to maximum.

Do not change the setting of the oscillator Range B trimmer.

600 KC Adjustment

Set the signal generator for 600 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 600 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

Be sure to use a non-metallic screwdriver for this adjustment.

Range C Alignment

5800 KC Adjustment

Set the signal generator for 5800 KC.

Connect the antenna lead of the receiver through a 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band selector to the Range C position (1st short wave band—green dial color).

As mentioned above, keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the oscillator Range C trimmer (C40) until maximum output is obtained. See Fig. 3 for location of this trimmer.

5000 KC Adjustment

Set the signal generator for 5000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the 1st and 2nd interstage Range C trimmers (C9 and C12) and antenna Range C trimmer (C3) to maximum.

Do not change the setting of the oscillator Range C trimmer.

Range D Alignment

18,300 KC Adjustment

Set the signal generator for 18,300 KC.

Keep the antenna lead of the receiver connected through the 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band selector to the Range D position (2nd short wave band—red dial color).

As mentioned above, keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the oscillator Range D trimmer (C41) until maximum output is obtained. See Fig. 3 for location of this trimmer.

15,000 KC Adjustment

Set the signal generator for 15,000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the 1st and 2nd interstage Range D trimmers (C10 and C11) and antenna Range D trimmer (C4) to maximum.

When adjusting the 2nd interstage Range D trimmer, it will be necessary at the same time to turn the tuning condenser rotor slowly back and forth until the peak of greatest intensity is obtained.

Then go back and repeat the procedure as given for the 18,300 KC adjustment. If it is found necessary to make any appreciable change in the setting of the oscillator Range D trimmer, the 15,000 KC adjustment must be repeated.

Do not make any further change in the setting of the oscillator Range D trimmer.

6000 KC Adjustment

Set the signal generator for 6000 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 6000 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

Use a non-metallic screwdriver for this adjustment.

Twenty-five Cycle Receivers

The twenty-five cycle receiver differs from the sixty cycle receiver only in the fact that a different power transformer is used. The correct power transformer is shown in the parts list.

The twenty-five cycle receiver can be operated satisfactorily from a sixty cycle power supply. However, the reverse is not true, the sixty cycle receiver cannot be operated from a twenty-five cycle power supply.

A 115-230 Volt, 40 to 60 cycle as well as other power transformers with special power ratings are also available for this model.

MODEL 2 DL Series
Alignment, Voltage
Drive, Phono. Notes

WELLS-GARDNER & CO., INC.

I. F. Adjustment

Set the signal generator for a signal of 456 KC.

Connect the output of the signal generator through a .1 mf. condenser to the grid of the 1st detector.

Connect the ground lead of the receiver to the ground post of the signal generator.

Turn the band switch to the Range B position (standard wave band).

Turn the selectivity control to the sharp position and keep it in this position for all adjustments.

Turn the volume control to the maximum position.

Attenuate the signal from the signal generator to prevent the levelling-off action of the AVC.

Then adjust the five I.F. trimmers until maximum output is obtained. The adjusting screws for these condensers are reached from the top of the chassis and the location is shown in Fig. 3.

Range B Alignment

After the procedure for the alignment of each range, as explained below, is completed, it is advisable to repeat the procedure as a final check.

1730 KC Adjustment

Set the signal generator for 1730 KC.

Turn the rotor of the tuning condenser to the full open position.

Keep the band switch in the standard wave position.

Connect the antenna lead of the receiver through a 200 mmf. condenser to the output of the signal generator.

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent AVC action.

Adjust the oscillator Range B trimmer (C19) until maximum output is obtained. The location of this trimmer is shown in Fig. 3.

1500 KC Adjustment

Set the signal generator for 1500 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

In sets using pointers, loosen the screw of the large pointer and set the pointer at the 1500 KC mark on the standard wave band scale. Retighten the screw.

In sets using the moving beam of light, there is moving light assembly held to the front of the drive drum by means of a screw. Loosen this screw and move the light assembly until it is at the 1500 KC mark on the dial. Retighten the screw.

Adjust the 1st and 2nd interstage Range B trimmers (C8 and C11) and antenna Range B trimmer (3) to maximum.

Do not change the setting of the oscillator Range B trimmer.

600 KC Adjustment

Set the signal generator for 600 KC

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 600 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

Range C Alignment

CAUTION—When aligning the short wave bands be sure NOT to adjust at the image frequency. This can be checked as follows: Let us say the signal generator is set for 5000 KC. The signal will then be heard at 5000 KC on the dial of the radio. The image signal, which is much weaker, will be heard at 5000 less 912 KC, or 4088 KC. It may be necessary to increase the input signal to hear the image.

5800 KC Adjustment

Set the signal generator for 5800 KC.

Connect the antenna lead of the receiver through a 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band switch to the Range C position (first short wave band).

Adjust the oscillator Range C trimmer (C18) until maximum output is obtained. See Fig. 3 for location of this trimmer.

5000 KC Adjustment

Set the signal generator for 5000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the 1st and 2nd interstage Range C trimmers (C7 and C10) and antenna Range C trimmer (C2) to maximum.

Do not change the setting of the oscillator Range C trimmer.

1800 KC Adjustment

Set the signal generator for 1800 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 1800 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

Range D Alignment

18,300 KC Adjustment

Set the signal generator for 18,300 KC.

Keep the antenna lead of the receiver connected through the 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band switch to the Range D position (second short wave band).

Adjust the oscillator Range D trimmer (C17) until maximum output is obtained. See Fig. 3 for location of this trimmer.

15,000 KC Adjustment

Set the signal generator for 15,000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the 1st and 2nd interstage Range D trimmers (C6 and C9) and antenna Range D trimmer (C1) to maximum.

When adjusting the 2nd interstage Range D trimmer, it will be necessary at the same time to turn the tuning condenser rotor slowly back and forth until the peak of greatest intensity is obtained.

Do not change the setting of the oscillator Range D trimmer.

6000 KC Adjustment

Set the signal generator for 6000 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 6000 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

Trimmer Replacement

If one trimmer of the gang trimmer strip should become defective, it is not necessary to replace the entire strip. A single trimmer P-17A36, as shown in the replacement parts list, may be used. Disconnect the lead from the coil side (side not grounded) of the defective trimmer in the strip. This connection is then made to the single trimmer. Connect it to the side of the trimmer not in contact with the adjusting screw. The other side of the single trimmer is then connected to a good ground, using a piece of heavy wire in order to support the trimmer adequately. In replacing a trimmer, be sure to keep both leads as short as possible and keep the ungrounded lead as far from ground as possible.

Planetary Drive Assembly

The planetary assembly is the unit that is integral with the tuning shaft.

If the nut on the back end of this assembly is too tight, the drive will be jerky and will turn hard in high speed. If this condition exists, back off this nut one or two turns and note the effect.

If this nut is too loose, the drive will slip in slow speed. The remedy in this case, of course, is to tighten the nut.

Should the condenser drive cord slip when the planetary pulley is turning, inspect the tuning condenser, drive drum and gears to see if they are turning properly or if they are being obstructed in some way.

If the drive turns unevenly (rough in spots), this may mean that the planetary assembly is defective or damaged internally and a new unit will be required.

Phonograph Connections

Phonograph connections can be made as shown in Fig. 7. The parts required as shown in the parts list. Knockouts are provided in the back of the chassis for mounting the phono jack and phono switch—See Fig. 8.

The phono switch should be mounted with one set of terminals nearest the bottom of the chassis base.

The connections are made by opening the diode return circuit at the volume control. This is done by removing the wire connecting condenser C42 to resistors R15, R19 and R22, at the terminal strip located near the back of the planetary drive. Cut this wire to correct length and solder it to the proper terminal on the phono switch—See Fig. 7, keeping the wire close to the back of the chassis base.

A wire is then connected from the lug on the above mentioned terminal strip to which C42 was connected, to the correct terminal on the phono switch—See Fig. 7. This wire should be brought directly to the back of the chassis at a point close to the phono jack pin tip nearest the channel provided for a chassis mounting bolt, and then routed over to the switch.

Complete the other connections as illustrated in Fig. 7.

It will be necessary to re-route the AC line cord away from the 6C5 1st audio grid lead by running it between the volume control and the filter choke and then straight back to the hole provided for it in the chassis base.

If a hum is heard when the phono pickup is touched, reverse the two pickup leads.

Twenty-five Cycle Models

The twenty-five cycle receiver differs from the sixty cycle receiver only in the fact that a different power transformer is used. The correct power transformer is shown in the parts list.

The twenty-five cycle receiver can be operated satisfactorily from a sixty cycle power supply. However, the reverse is not true, the sixty cycle receiver cannot be operated from a twenty-five cycle power supply.

A 115-230 volt, 40 to 60 cycle as well as other power transformers with special power ratings are also available for this model.

Replacing Drive Cord

Take off the station pointer by removing the screw at the center of the dial.

Remove the pilot lamp assembly by pulling the socket clips upward off the dial assembly.

Loosen the dial assembly by removing the two screws which secure this assembly to the chassis brackets.

Then lay the complete dial assembly face down in front of the chassis. It is not necessary to remove the volume control and tone control collars which hold the indicator cords of these two controls in position.

Turn the drive drum until the opening in this drum is approximately vertical and with the hole at the top as shown in Fig. 6.

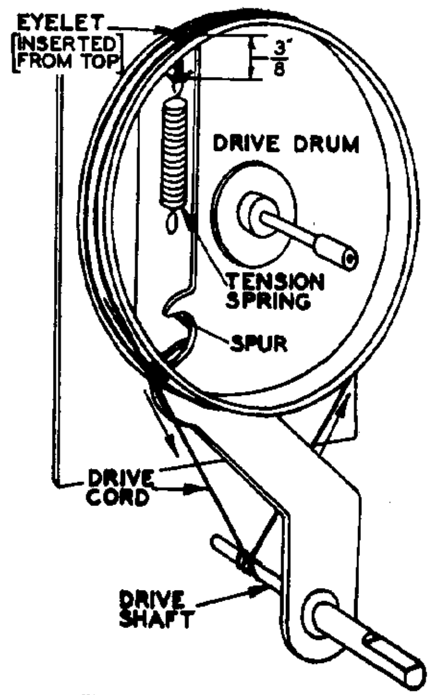

Fig. 6—Replacing Drive Cord

Remove the tension spring and the old drive cord.

See that the eyelet is in the hole in the drive drum as shown in Fig. 6. Insert one end of the new drive cord from the outside through this eyelet in the drive drum.

Tie the end of the cord which has been inserted through the eyelet to one end of the tension spring.

Wrap the cord in a counter clockwise direction (facing front of chassis) around the drive drum approximately one and one-quarter turns progressing toward the front.

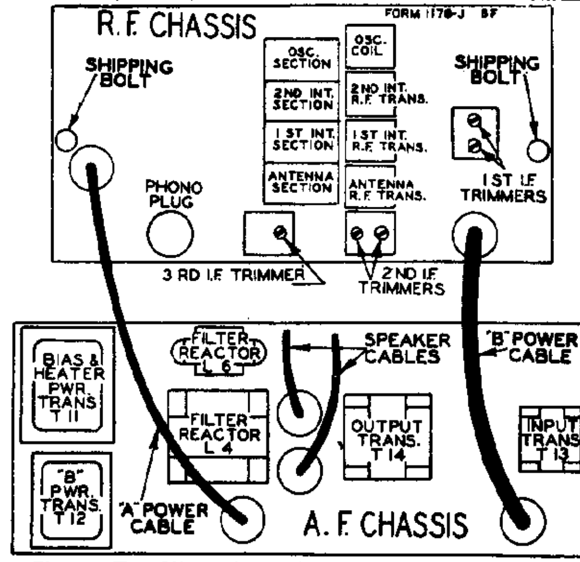

Fig. 4—Top View of Chassis Showing Location of Units

Changes in Early Models

In the early models condenser C65, shown in the R.F. Schematic Fig. 2, was not used. A 20 mmf. condenser, also designated as C65, was connected in parallel with condenser C14.

Condenser C10 from B+ to ground was not used in early models. Another condenser in the early models, also designated as C10 and 250 mmf. in value, was connected from the A.V.C. amplifier plate to ground.

Resistor R38 was not used in early models.

On the A.F. chassis the speaker sockets were wired with ground to the opposite side of voice coil.

WELLS-GARDNER & CO., INC.

Circuit

This model is a four band receiver with a tuning range in each band as shown in the specifications above. Four band coverage is accomplished by means of four sets of antenna, interstage and oscillator coils and a six section four position switch.

Among the many features incorporated in this receiver are—Improved Automatic Volume Control, Adjustable Selectivity Control, Dual Volume and Sensitivity Control, Bass Compensator and a 30 Watt High Fidelity Audio Amplifier. These are discussed in the following circuit description.

Referring to the R.F. Schematic Fig. 2, the following are the code numbers of the R.F. and Oscillator Assemblies:

T1 —Antenna R.F. Transformer
T2 —B Range Antenna R.F. Transformer
T3 —1st Interstage R.F. Transformer
T4 —E Range Interstage R.F. Transformer
T5 —2nd Interstage R.F. Transformer
T9 —Oscillator Inductors
T10—E Range Oscillator Inductors

The standard wave, 1st, 2nd and 3rd short wave coils in each assembly are indicated by the letters B, C, D and E, respectively. The six sections of the band switch are designated in the R.F. schematic Fig. 2 and in Fig. 5 as the antenna section, interstage primary section 2, interstage primary section 1, interstage secondary section, oscillator section 2 and oscillator section 1.

The band switch completes connections to the coils in use. It also short circuits the antenna R.F. transformer secondaries, the interstage transformer primaries and secondaries and the oscillator coils of lower frequency, not in use.

The antenna transformer with tuned secondary feeds into a type 6K7 R.F. amplifier tube. The output of this tube is fed into a double tuned R.F. stage. The output of the latter actuates the control grid of a 6K7 tube which functions as the 1st detector.

A separate type 76 tube is employed in the oscillator circuit. The oscillating circuit is always resonant at a frequency which is 456 KC above the frequency to which the R.F. amplifier is tuned.

The oscillator potential is fed into the cathode circuit of the 6K7 first detector tube. As a result of the beating of the two frequencies, the intermediate or beat frequency of 456 KC is present in the plate circuit of this tube.

Two stages of I.F. amplification are employed using 6K7 tubes. The primaries and secondaries of the first and second I.F. transformers and the primary of the 3rd I.F. transformer are tuned by small trimmer condensers.

Referring to the 1st and 2nd I.F. transformers T6 and T7 in Fig. 2, it will be noted that there are coupling windings below the primaries.

When the selectivity control is in the sharp position, the coupling winding is open circuited and the loose coupling which exists between the primary and secondary of this transformer results in high selectivity. When the selectivity control is in the broad position, the coupling winding which is wound under the primary is connected in series with the secondary. This provides overcoupling which results in a greatly widened resonance curve. Passage of a wide range of audio frequencies is thus obtained.

A dual manual volume control is employed. In one section the audio voltage applied to the 1st audio tube is varied (R8). In the other section the R.F. and 1st I.F. bias is varied (R2). The purpose of the latter section is to reduce the sensitivity of the receiver at low volume settings in order to cut down noise pick-up between stations. The variable section R2 is shorted out by the band selector switch when it is in the Range D and E positions.

The 3rd I.F. transformer has 2 secondary windings. One of these windings works into the diode section of the 6B7 signal diode. The other winding works into the 76 A.V.C. diode.

The audio voltage developed by the signal diode across volume control resistor R8 is transmitted through the movable arm to the control grid of the pentode section of the 6B7 tube, which acts as a one stage audio amplifier. The pentode plate of this tube is connected through the "B" power cable to one side of the primary of the push-pull input transformer in the power stage.

The audio voltage developed across volume control resistor R8 is also applied through the movable arm to the control grid of the triode section of the 6F7 bass amplifier. A resistance capacity filter composed of condensers C36 and C37 and resistor R14 in the triode plate circuit of this tube bypasses the higher audio frequencies. The lower audio frequencies which pass through this filter develop a voltage across resistors R38, R17 and R18.

R17 is the bass note control and is connected mechanically to the manual volume control. The movable arm is connected to and applies the bass audio voltage to the control grid of the pentode section of the 6F7 bass amplifier. At high volume settings the movable arm is at the low potential end of R17 (near R18). At low volume settings it is at the other end of this resistor in order to increase the bass note response. The reason for the increase in low note response is that the characteristics of the ear are such that the low notes are not heard as well as the middle register notes at lower volume levels.

The plate of the pentode section of the 6F7 tube is connected through the "B" power cable to the other side of the primary of the push-pull input transformer.

The A.V.C. system used in this receiver is one which has a flat characteristic over an extremely wide input range. As mentioned above, it will be seen in Fig. 2 that one of the 3rd I.F. transformer secondary windings works into the 76 A.V.C. diode tube. A signal passing through this transformer will result in a voltage across diode resistor R19. This voltage is applied to the control grid of the 76 A.V.C. amplifier.

Referring now to Figs. 2 and 3, there is a diode circuit consisting of the A.V.C. amplifier voltage winding of power transformer T11 (sixth winding from top) the plate and cathode elements of the 45 bias rectifier tube and resistors R22, R23 and R24. The diode current flowing in this circuit establishes a drop across these resistors. This voltage is below ground and furnishes operating voltages for the 76 A.V.C. amplifier tube which functions as a DC amplifier. Under no signal conditions, the plate of this tube is at ground potential. The grid is at the voltage of the maximum negative voltage end of resistor R23 while the cathode is at the minimum negative voltage end of this resistor. The resulting bias voltage brings this tube below the cut-off point and no plate current flows.

When a signal of a predetermined value or greater flows in the 3rd I.F. transformer, the voltage established across diode resistor R19 reduces the bias voltage of the A.V.C. amplifier to the point at which plate current flows in this tube. The plate current establishes a drop in resistor R25, lowering the plate voltage by the amount of this drop. The plate of the A.V.C. amplifier tube is connected to the control grid circuits of the R.F. and 1st I.F. tubes, resulting in A.V.C. action.

The output stage employs four type 2A3 tubes arranged in push-pull parallel. Fixed bias voltage for these tubes is obtained from a diode circuit in which are the output bias winding of power transformer T11 (fifth winding from top) and the grid and cathode elements of the type 45 bias rectifier tube. 30 watts of undistorted output may be obtained. Two 12" auditorium type dynamic speakers are used. Each speaker is provided with deflecting vanes for the purpose of spreading the directional higher audio notes through the entire room.

Two type 5Z3 tubes connected in parallel are used as "B" power rectifiers in the power unit. There are 2 power transformer assemblies, T11 and T12. In assembly T11 the top 4 windings illustrated in Fig. 3 supply the tube heater and filament voltages and the pilot lamp voltages. As mentioned, the fifth winding supplies the output stage bias voltage and the sixth winding supplies the A.V.C. amplifier tube voltages. Assembly T12 supplies the "B" voltage.

To reduce hum, DC is used in the heater circuits of the 6F7 and 6B7 tubes. The 2 heaters are connected in series in the negative "B" line.

The 45 bias rectifier tube, mention of which has already been made, has two functions. The cathode and grid elements act as a diode supplying bias voltage for the output tubes. The cathode and plate elements act as a diode supplying operating voltages for the A.V.C. amplifier. The two associated transformer windings must be in phase and wired as per the color code in the A.F. Schematic, Fig. 3.

The phono short circuiting plug, which is in the phono socket completes the signal diode circuit connections. Phonograph circuit connections are explained in the article under that name in this manual.

Metal Tubes

One type of the new metal tubes is used in this receiver, namely the 6K7. This replaces the type 6D6 glass tube. This metal tube operates at the same voltages and is nearly identical in characteristics to the corresponding glass tube which it replaces. In Fig. 7 are shown the metal tube pin positions from a bottom socket view.

The shells of metal tubes get quite hot and users should be cautioned against touching them.

Phonograph Connections

A phonograph socket is provided on the R.F. chassis by means of which phonograph connections can be made without electrical changes in the chassis. The receiver is shipped from the factory with a plug in this socket. If no phonograph is used this plug must be inserted as it completes the signal diode circuit for radio reception.

Two sets of accessories are supplied for phonograph connections for this model. One set is used when the phonograph is contained in a separate cabinet, and the other set is used when the phonograph and radio are in a combination cabinet. The electrical connections are the same in both cases and are illustrated in Fig. 13 (A). Parts required in either case are shown in the parts list in this manual.

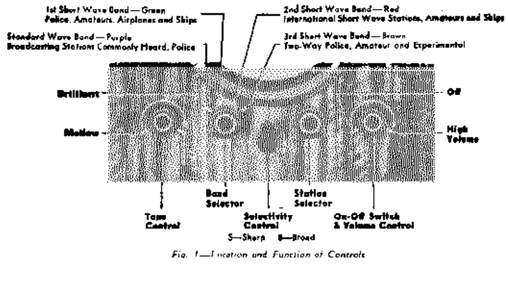

Fig. 1—Location and Function of Controls

Phonograph in Seperate Cabinet

For this assembly, a 5 conductor cable and a small metal panel assembly are supplied. This assembly has the radio-phono switch, tip jacks for pick-up leads and terminal plate for phono cable.

The phono panel is mounted at the most convenient place in the cabinet at which connections can be completed. The switch is secured to the motor board as illustrated in Fig. 14.

The socket at the end of the cable is secured to the terminal plate on the panel and the plug at the other end of the cable is inserted into the phono socket on the R.F. chassis.

When the switch is thrown to the radio side, the phono pick-up is excluded from the signal diode circuit. When it is thrown to the phono side, the signal diode circuit is opened and the phonograph connections completed to this circuit. Resistor R23 is short circuited. This brings the grid and cathode of the 76 A.V.C. amplifier to the same potential and causes a plate current in this tube of sufficient intensity to bring the R.F. and 1st I.F. tubes to the point of cut off (See article on circuit for further information regarding operation of A.V.C. system).

Phonograph and Radio in Combination Cabinet

For this assembly, a number of separate items as shown in the parts list are supplied. The phono short circuiting plug supplied with the receiver is used after certain changes have been made.

First take off the shell of this plug by twisting the shell in either direction. The shell is then drilled and equipped with a rubber grommet as shown in Fig. 13 (B). Next unsolder and remove the jumper wire from the plug as shown in Fig. 13 (A). Extend the leads through the hole in the shell and solder the leads to the prongs on the plug as illustrated. Complete the connections to the switch and tip jacks as shown. The switch is mounted on the motor board and the tip jacks at the nearest convenient place.

The description of the connections as given for the separate phonograph cabinet also applies to the combination.

Alignment and Calibration

Correct alignment is extremely important in connection with all-wave receivers. The receivers are all properly aligned at the factory with precision instruments and realignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment.

A signal generator that will provide an accurately calibrated signal at 456, 1730, 1500, 600, 5800, 5000, 18,300, 15,000, 6000, 48,000 and 40,000 KC and an output indicating meter are required. It will be practically impossible to align the receiver if unsatisfactory apparatus is used. If a station is tuned in with the selectivity control in the broad position and this control is then turned to the sharp position, the station may disappear. This is not an indication that the receiver is out of alignment.

Use a non-metallic screwdriver for the adjustments. The complete procedure is as follows:

I. F. Adjustment

Set the signal generator for a signal of 456 KC.

Connect the output of the signal generator to the grid of the 1st detector through a 0.1 mf. condenser.

Connect the ground lead of the receiver to the ground post of the signal generator.

Turn the band selector to the Range B position (standard wave band- purple dial color).

Turn the selectivity control to the sharp position and keep it in this position for all adjustments.

Turn the volume control to the maximum position.

Attenuate the signal from the signal generator to prevent the levelling-off action of the A.V.C.

Then adjust the five I.F. trimmers until maximum output is obtained. The adjusting screws for these condensers are reached from the top of the chassis, and the location is shown in Fig. 4.

Range B Alignment

1730 KC Adjustment

Set the signal generator for 1730 KC.

Turn the rotor of the tuning condenser to the full open position.

Keep the band selector in the standard wave position.

Connect the antenna lead of the receiver through a 200 mmf. condenser to the output of the signal generator.

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the oscillator Range B trimmer (C54) until maximum output is obtained. The location of this trimmer is shown in Fig. 6.

1500 KC Adjustment

Set the signal generator for 1500 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Loosen the pointer set screw and set the large pointer at the 1500 KC mark on the standard wave band scale. Re-tighten the set screw.

Adjust the 1st and 2nd interstage Range B trimmers (C17 and C18) and antenna Range B trimmer (C3) to maximum.

Do not change the setting of the oscillator Range B trimmer.

600 KC Adjustment

Set the signal generator for 600 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 600 KC trimmer until the peak of greatest intensity is obtained. See Fig. 6 for location of this trimmer.

Be sure to use a non-metallic screwdriver for this adjustment.

Range C Alignment

5800 KC Adjustment

Set the signal generator for 5800 KC.

Connect the antenna lead of the receiver through a 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band selector to the Range C position (1st short wave band—green dial color).

As mentioned above, keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the oscillator Range C trimmer (C56) until maximum output is obtained. See Fig. 6 for location of this trimmer.

5000 KC Adjustment

Set the signal generator for 5000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the 1st and 2nd interstage Range C trimmers (C16 and C19) and antenna Range C trimmer (C4) to maximum.

Do not change the setting of the oscillator Range C trimmer.

Range D Alignment

18,300 KC Adjustment

Set the signal generator for 18,300 KC.

Keep the antenna lead of the receiver connected through the 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band selector to the Range D position (2nd short wave band—red dial color).

As mentioned above, keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the oscillator Range D trimmer (C57) until maximum output is obtained. See Fig. 6 for location of this trimmer.

15,000 KC Adjustment

Set the signal generator for 15,000 KC. Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the 1st and 2nd interstage Range D trimmers (C15 and C20) and antenna Range D trimmer (C5) to maximum.

When adjusting the 2nd interstage Range D trimmer, it will be necessary at the same time to turn the tuning condenser rotor slowly back and forth until the peak of greatest intensity is obtained.

Then go back and repeat the procedure as given for the 18,300 KC adjustment. If it is found necessary to make any appreciable change in the setting of the oscillator Range D trimmer, the 15,000 KC adjustment must be repeated.

Do not make any further change in the setting of the oscillator Range D trimmer.

6000 KC Adjustment

Set the signal generator for 6000 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 6000 KC trimmer until the peak of greatest intensity is obtained. See Fig. 6 for location of this trimmer.

Use a non-metallic screwdriver for this adjustment.

Range E Alignment

48,000 KC Adjustment

Set the signal generator for 48,000 KC.

Keep the antenna lead of the receiver connected through the 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band selector to the Range E position (3rd short wave band—brown dial color).

Adjust the oscillator Range E trimmer (C50) until maximum output is obtained. See Fig. 6 for location of this trimmer.

40,000 KC Adjustment

Set the signal generator for 40,000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the interstage Range E trimmer (C14) and antenna Range E trimmer (C6) to maximum.

Do not change the setting of the oscillator Range E trimmer.

Switch Contact Location Numbering

A standard arrangement for switch contact location numbering has been adopted. This numbering is illustrated in Fig. 9. In contact locations not used, the number applying to that particular location is not employed.

Twenty-five Cycle Receivers

The twenty-five cycle receiver differs from the sixty cycle receiver in the fact that special twenty-five cycle filament and "B" power transformers must be used. It also has two additional condensers in the power unit—C67 and C68 as illustrated in Fig. 3. The twenty-five cycle transformers and the condensers are shown in the parts list.

The twenty-five cycle receiver can be operated satisfactorily from a sixty cycle power supply if the two condensers C67 and C68 are removed. However, the reverse is not true, that is, a sixty cycle receiver cannot be operated from a twenty-five cycle power supply.

115-230 Volt, 40 to 60 cycle filament and "B" power transformers are also available for this model

Standard and Short Wave Battery Radio July 1936

Series 6G

6 Tube - 2 Band

Tubes

The tubes used in this receiver are of the 2 volt series. All of them are of the filament or directly heated types. All of them have a 2 volt filament and should not be connected to a power supply not intended for this type of tube. **Maximum filament voltage range is 1.8 to 2.0 volts. Operation of the tubes at under or over this value will be injurious to the tubes and may affect operation of the receiver.**

VOLTAGES AT SOCKETS
Volume Control at Maximum — Antenna Shorted to Ground — Band Switch in Standard Wave Position

Type of Tube	Function	Across Filament	Plate to Ground	Screen to Ground	Grid to Ground
1C6	1st Det.-Osc.	2.0	90 90(1)	60	6(2)
34	I.F.	2.0	90	60	6(2)

(5) As read from negative end of R10 to ground.

Alignment Procedure

Correct alignment is extremely important in connection with all wave receivers. The receivers are all properly aligned at the factory with precision instruments and re-alignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment.

A signal generator that will provide an accurately calibrated signal at 456, 1730, 1500, 600, 16,000, 15,000 and 6000 KC and an output indicating meter are required. It will be practically impossible to align the receiver if unsatisfactory apparatus is used.

Use a non-metallic screwdriver for the adjustments. The complete procedure is as follows:

I. F. Adjustment

Set the signal generator for a signal of 456 KC.

Connect the output of the signal generator through a .1 mf. condenser to the grid of the 1st detector.

Connect the ground lead of the radio to the ground post of the signal generator.

Turn the band switch to the Range B position (standard wave band).

Turn the volume control to the maximum position.

Attenuate the signal from the signal generator to prevent the levelling-off action of the AVC.

Then adjust the four I.F. trimmers until maximum output is obtained. The adjusting screws for these condensers are reached from the top of the chassis, and the location is shown in Fig. 7.

Range B Alignment

After the procedure for the alignment of each range, as explained below, is completed, it is advisable to repeat the procedure as a final check.

1730 KC Adjustment

Set the signal generator for 1730 KC.

Turn the rotor of the tuning condenser to the full open position.

Keep the band switch in the standard wave position.

Connect the antenna lead of the radio through a 200 mmf. condenser to the output of the signal generator.

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent AVC action.

Adjust the oscillator Range B trimmer (C8) until maximum output is obtained. The location of this trimmer is shown in Fig. 7.

1500 KC Adjustment

Set the signal generator for the 1500 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Loosen the pointer screw and set the pointer at the 1500 KC mark on the standard wave band scale. Retighten the screw.

Adjust the antenna Range B trimmer (C2) to maximum.

Do not change the setting of the oscillator Range B trimmer.

600 KC Adjustment

Set the signal generator for 600 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 600 KC trimmer (C9) until the peak of greatest intensity is obtained. See Fig. 7 for location of this trimmer.

Range D Alignment

CAUTION—When aligning the short wave band be sure NOT to adjust at the image frequency. This can be checked as follows: Let us say the signal generator is set for 15,000 KC. The signal will then be heard at 15,000 on the dial of the radio. The image signal, which is much weaker, will be heard at 15,000 less 912 KC, or 14,088 KC. It may be necessary to increase the input signal to hear the image.

16,000 KC Adjustment

Set the signal generator for 16,000 KC.

Connect the antenna lead of the radio through a 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band switch to the Range D position (short wave band).

Adjust the oscillator Range D trimmer (C7) until maximum output is obtained. See Fig. 7 for location of this trimmer.

15,000 KC Adjustment

Set the signal generator for 15,000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the antenna Range D trimmer (C1) to maximum. When adjusting this trimmer, it will be necessary at the same time to turn the tuning condenser rotor slowly back and forth until the peak of greatest intensity is obtained.

Do not change the setting of the oscillator Range D trimmer.

6000 KC Adjustment

Set the signal generator for 6000 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 6000 KC (C6) trimmer until the peak of greatest intensity is obtained. See Fig. 7 for location of this trimmer.

I. F. Adjustment

Set the signal generator for a signal of 175 KC.

Connect the output of the signal generator through a .05 mf. condenser to the stator of the R.F. inter-stage section of the tuning condenser. (See Fig. 2 for location of this section.)

Connect the ground lead of the signal generator to the chassis ground.

Turn the Local-Distance switch to the Distance position and keep it in this position for all adjustments.

Set the volume control at the maximum position.

Attenuate the signal from the signal generator to prevent the levelling-off action of the AVC.

Then adjust the three I.F. trimmers until maximum output is obtained. The location of these trimmers is shown in Fig. 2.

1575 KC Adjustment

Set the signal generator for 1575 KC.

Turn the rotor of the tuning condenser to the full open position.

If a low capacity antenna is used, connect the shielded antenna lead from the chassis through a 150 mmf. condenser to the antenna post of the signal generator. (If high capacity, use 1500 mmf.) The antenna plug must be correctly inserted, dependent on the capacity of the antenna used.

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent AVC action.

Adjust the trimmer of the oscillator section of the three gang condenser until maximum output is obtained—see Fig. 2 for location of this trimmer.

1400 KC Adjustment

Set the signal generator for 1400 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the R.F. interstage and antenna 1400 KC trimmers for maximum output.

Do not change the setting of the oscillator trimmer.

600 KC Adjustment

Set the signal generator for 600 KC.

Connect the output of the signal generator through a .05 mf. condenser to the control grid of the 6K7 R.F. tube.

Turn the tuning condenser rotor until maximum output is obtained. Then turn the tuning condenser rotor back and forth, at the same time adjusting the 600 KC padder (see Fig. 2) until the peak of greatest intensity is obtained.

Re-connect the output of the signal generator to the shielded antenna lead through a 150 mmf. condenser (1500 mmf. if antenna is high capacity).

Adjust the 600 KC antenna trimmer to maximum. This trimmer is reached from the outside of the case

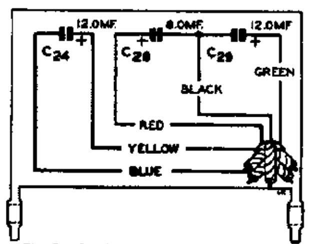

Fig. 5—Condenser Block—Internal Wiring

Adjusting Antenna 600 KC Trimmer

After the receiver is installed and the car antenna is connected, it will be necessary to adjust the antenna trimmer. Tune in a weak signal at approximately 600 KC with the volume control about three-fourths on. Turn the adjusting screw of the antenna 600 KC trimmer up or down until maximum output is obtained. See Fig. 3 for location of this trimmer.

As shown in this illustration, the antenna plug is inserted in one of two ways, depending on whether the car has a high or low capacity antenna. Full instructions are in the installation manual packed with each radio.

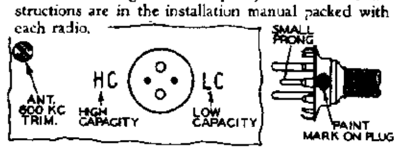

Fig. 3—Antenna Plug Insertion

Calibrating the Radio

To calibrate the radio, tune in a station of known frequency. At the back of the control head is the calibration screw. Remove the pilot lamp assembly. Insert a fine blade screwdriver and turn this screw until the pointer on the dial scale is at the frequency of the station being received. The knob must be held during this adjustment.

If the control head is inaccessible it may be calibrated by setting the pointer from the front. Remove the crystal by inserting a knife blade under the lower edge. Loosen the pointer screw, set the pointer and retighten.

Replacement Parts

There is a large letter on the chassis which identifies the set as to major part changes. When ordering parts please be sure to mention the series number and this large letter.

I. F. Adjustment

Set the signal generator for a signal of 175 KC.

Connect the output of the signal generator through a .05 mf. condenser to the stator of the R. F. inter-stage section of the tuning condenser. (See Fig. 2 for location of this section.)

Connect the ground lead of the signal generator to the chassis ground.

Set the volume control at the maximum position.

Attenuate the signal from the signal generator to prevent the levelling-off action of the AVC.

Then adjust the three I.F. trimmers until maximum output is obtained. The location of these trimmers is shown in Fig. 2.

1575 KC Adjustment

Set the signal generator for 1575 KC.

Turn the rotor of the tuning condenser to the full open position.

If a low capacity antenna is used, connect the shielded antenna lead from the chassis through a 150 mmf. condenser to the antenna post of the signal generator. (If high capacity, use 1500 mmf.)

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent AVC action.

Adjust the trimmer of the oscillator section of the three gang condenser until maximum output is obtained—see Fig. 2 for location of this trimmer.

1400 KC Adjustment

Set the signal generator for 1400 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the R.F. interstage and antenna 1400 KC trimmers for maximum output.

Do not change the setting of the oscillator trimmer.

600 KC Adjustment

Set the signal generator for 600 KC.

Connect the output of the signal generator through a .05 mf. condenser to the control grid of the 6D6 R.F. tube.

Turn the tuning condenser rotor until maximum output is obtained. Then turn the tuning condenser rotor back and forth, at the same time adjusting the 600 KC padder (see Fig. 2) until the peak of greatest intensity is obtained.

Re-connect the output of the signal generator to the shielded antenna lead.

Adjust the 600 KC antenna trimmer to maximum. This trimmer is reached from the outside of the case—see Fig. 3.

Adjusting Antenna 600 KC Trimmer

After the receiver is installed and the car antenna is connected, it will be necessary to adjust the antenna trimmer. Tune in a weak signal at approximately 600 KC with the volume control about three-fourths on. Turn the adjusting screw of the antenna 600 KC trimmer up or down until maximum output is obtained. See Fig. 3 for location of this trimmer.

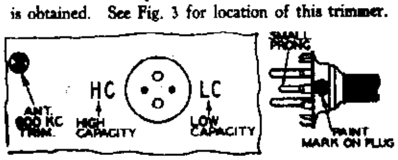

Fig. 3—Antenna Plug Insertion

Antenna Disconnected — Battery 6 Volts Under Load

Type of Tube	Function	Across Heater	Plate to Ground	Screen to Ground	Cathode to Ground
6D6	R.F.	6	233	103	4.0

(1) Grid bias read across filter choke L6
(2) Plate to Plate A.C. voltage

Calibrating the Receiver

To calibrate the receiver, tune in a station of known frequency. At the back of the control head is the calibration screw. Remove the pilot lamp assembly. Insert a fine blade screwdriver and turn this screw until the pointer on the dial scale is at the frequency of the station being received. The knob must be held during this adjustment.

If the control head is inaccessible it may be calibrated by setting the pointer from the front. Remove the crystal by inserting a knife blade under the lower edge. Loosen the pointer screw, set the pointer and retighten.

Antenna

IMPORTANT—If the car antenna is of high capacity (600 mmf. or higher) insert the antenna plug with the mark on the HC side—See Fig. 10. If it is a low capacity antenna, insert the plug with the mark on the LC side

The General Motors cars have steel roofs, and a running board or other under car antenna must be used. These are low capacity antennas. The Chrysler motor cars (except Plymouth) have a steel roof separated from the body proper, which is used as an antenna. These are high capacity antennas. Other cars without steel roofs such as Ford and Plymouth have a built-in roof antenna which is of low capacity.

If a running board or under-car antenna is used, it must be one which is covered with a suitable insulation, to prevent short circuiting in wet weather.

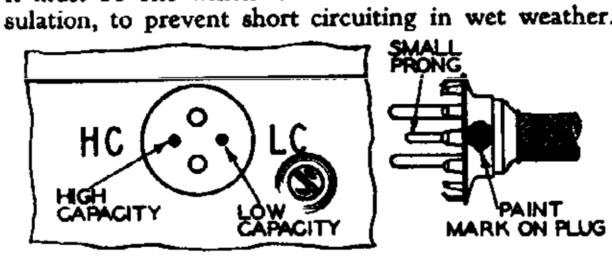

Fig. 10—Antenna Plug Insertion

MODEL 6N Series
Alignment, Notes

WELLS-GARDNER & CO.

Alignment and Calibration

Misalignment or mistracking of condensers generally manifests itself as broad tuning and lack of volume at portions or all of the standard wave band. The receivers are all properly aligned at the factory with precision instruments and realignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment.

A signal generator that will provide accurately calibrated signals over the standard wave band and at the intermediate frequency, and an output meter are required for indicating the effect of adjustments.

Use a non-metallic screwdriver for the adjustments. The complete procedure is as follows:

I. F. Adjustment

Set the signal generator for a signal of 175 KC.

Connect the antenna lead of the signal generator thru a .05 mf. condenser to the stator of the 1st detector section of the tuning condenser. (See Fig. 2 for location of this section.) This can be done by pushing a wire or conductor between the stator plates or by extending an insulated wire thru the hole in the shield over the stator and pushing the wire thru the hole in the lug which extends up from the insulated stator assembly.

Connect the ground lead of the signal generator to the chassis ground.

Short out the oscillator section of the tuning condenser.

Set the volume control at the maximum position.

Attenuate the signal from the signal generator to prevent the levelling-off action of the AVC.

Then adjust the three I.F. trimmers until maximum output is obtained. The location of these trimmers is shown in Fig. 2.

1650 KC Adjustment

Set the signal generator for 1650 KC.

Turn the rotor of the tuning condenser to the full open position.

If a low capacity antenna is used connect the shielded antenna lead from the chassis through a 150 mmf. condenser to the antenna post of the signal generator. (If high capacity, use 1500 mmf.)

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent AVC action.

Adjust the trimmer of the oscillator section of the three gang condenser until maximum output is obtained—see Fig. 2 for location of this trimmer.

1400 KC Adjustment

Set the signal generator for 1400 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the 1st detector and antenna trimmers for maximum output.

Do not change the setting of the oscillator trimmer.

Adjusting Antenna Trimmer

After the receiver is installed and the car antenna is connected it will be necessary to adjust the antenna trimmer. Tune in a weak signal between 1200 and 1400 KC with the volume control about three-fourths on. Remove the cover of the chassis case. The antenna trimmer is on the center tuning condenser section—see Fig. 2. Turn the adjusting screw of this condenser up or down until maximum output is obtained. CAUTION—Do not turn any of the other trimmer adjusting screws for this adjustment.

Calibrating the Receiver

To calibrate the receiver, tune in a station of known frequency. At the back of the control head is the calibration screw. Remove the pilot lamp assembly. Insert a fine blade screwdriver and turn this screw until the pointer on the dial scale is at the frequency of the station being received. The knob must be held during this adjustment.

If the control head is inaccessible it may be calibrated by setting the pointer from the front. Remove the crystal by inserting a knife blade under the lower edge. Loosen the pointer screw, set the pointer and retighten.

Suppression of Ignition and Generator Noise

The two units mentioned below must be used in every case:

Distributor Suppressor—Remove the high tension lead to the distributor. Insert a distributor suppressor and connect the wire to the other end of the suppressor (see Fig. 13). If this is not practical, cut the high tension lead *close to the distributor* and use a wood screw end type distributor suppressor in this line.

Generator Condenser—The generator condenser is installed at the cut-out as shown in Fig. 13. The lead from the condenser goes to the terminal on the cut-out.

In some of the new cars the cut-out relay is on the front of the dash or in some other location. It will be most convenient to mount this generator condenser at the relay.

Withdraw Antenna Cable Plug

Turn on the receiver and start the engine.

If motor noise is heard, proceed as follows:

Shielding High Tension Lead—In some cars when the coil is mounted on the dash, the high tension lead from the coil to within about four inches of the distributor must be covered with braided shielding and the shield grounded to the motor block or frame.

Bypass Condenser—Try a .25 or .5 mfd. condenser from the ammeter to ground. Try a condenser from the car fuse to ground, switch to ground, windshield wiper connections and various other 6 volt connections to ground noting what effect these condensers have on the noise pick-up.

Try a .25 or .5 mfd. condenser from the "Hot" side of the coil primary to ground. In some cases this condenser may not help. It can be tried out, however, experimentally.

Spark Plug Suppressors—If motor noise persists, spark plug suppressors must be installed. One suppressor is put on each plug as shown in Fig. 13. These are not regularly supplied with the receiver and must be purchased extra. Seventy percent of all cars will not require spark plug suppressors.

Care should be taken that a good mechanical and electrical connection is made between the spark plugs, suppressors and plug wires.

Then Reinsert Antenna Cable Plug

If motor noise is heard when the antenna cable is reconnected, proceed as follows until the noise is satisfactorily reduced:

Dome Light Lead—To determine the amount of noise due to the dome light lead, disconnect this lead at the ammeter, block, or where it is connected, coil it up, and tuck it as far as possible up in the column at which it comes down. Then, with the engine running, ground the end of this wire. If this is found to reduce the noise noticeably, interference is being radiated by the dome light lead. Reconnect the dome light lead and try a .25 or .5 mfd. condenser from the connecting point of the lead to ground. If this does not cure the noise, disconnect the lead and encase it in braided copper shield from the point where it leaves the column post to the point of connection. Keep the lead as far away as possible from car ignition wires and ground the shield.

If the noise due to the dome light lead still persists, disconnect this lead and remove it from the front corner post, at which point it is generally run down. Run the lead down one of the side posts in back of the door and direct to the storage battery. If done in this manner this lead should be fused.

Bonding Cables—Try grounding to the dash all cables and tubing which pass through it, such as oil lines, gas lines, etc. By means of a file, contact can be established between any of the lines and the dash, in order to determine whether such a ground will reduce the noise. To bond the cables to the dash, clean the point of contact, wrap a length of braided shielding around the cable and solder the connection. Then solder the end of the shielding to the dash or ground it under a screw head if one is convenient.

Sufficient play should be left in the bonding shielding so that movement of the cables or tubing will not loosen this shielding from the dash.

High and Low Tension Leads—In some cases, the high and low tension leads between the coil and distributor are run close together. In some cars they are in the same conduit. If this is the case, remove the low tension lead from this conduit. In any event, keep the high and low tension leads as far apart from each other as possible. Shield and ground the shield of the low tension lead, if separating the two leads is not sufficient.

Steering Column, Etc.—It is possible for the steering column, foot pedals and brake lever to carry interference to the back of the dash at which point it may affect the radio receiver. See if each of these items are well grounded to the frame of the car. By means of a file or a braided shielding jumper, contact can be established between any of these items and the frame in order to determine whether such a ground will reduce the noise. A piece of one inch braided shielding should be used if such a ground is necessary and this shielding may be grounded under a screw head, nut or may be soldered in position.

Grounding Engine and Other Parts—The engine must, in every case, be well grounded to the frame of the car. If it is not, use a very heavy braided lead for this purpose, similar to a storage battery ground lead. In like manner it may be necessary to check the grounding of the metal dash, instrument panel, radiator and hood to the frame of the automobile.

Weak Pick-up—Noise, on occasion, may be due to weak pick-up caused by the automobile being in a shielded location or by a faulty antenna system. The action of the automatic volume control, due to the low pick-up, causes the set to operate at its maximum sensitivity, thereby increasing noisy reception, due both to external pick-up and internal conditions.

Loose Parts in Car—Noisy operation is also caused in some instances by loose parts in the car body or frame. These loose parts rubbing together affect the grounding and cause noises, due to the rubbing or wiping action. Tightening up the frame and body at all points and in some cases, the use of a copper jumper will eliminate noise of this nature.

Making Final Adjustments and Bolting Chassis in Place

Battery Cable

The battery connection is made at the ammeter. The end of the battery cable with the connecting lug is secured to one of the posts at the back of the ammeter in the instrument panel.

The other end of the battery cable has a fuse receptacle with bayonet fitting. Insert the fuse shield and fuse into the receptacle and connect it to the bayonet pin connector in the end of the battery lead coming from the chassis case as shown in Fig. 11.

Fuse

A 20 ampere automobile fuse is used in the battery cable. This fuse is placed in an insulating shield and is in the receptacle provided for it at the chassis end of the battery cable. **CAUTION—Be sure the fuse shield is on the fuse before the latter is inserted in the receptacle.** ***If a fuse blows, do not replace it without first investigating the cause.***

Bolting Chassis in Place

Place the nuts and flat washers on the mounting bolts and put the chassis in place on the dash, extending the mounting bolts through the drilled holes in the dash.

On one of the mounting bolts assemble the extra shakeproof lockwasher as shown in Fig. 9. Then complete the assembly to the dash as illustrated.

After the chassis is in place, secure the flexible shafts and electrical cables into position at the nearest convenient point.

Advancing Generator Charging Rate

The installation of the automobile radio imposes an additional drain on the car storage battery. This can be compensated for by advancing the charging rate of the car generator. Check the state of charge of the storage battery about a week after the installation of the automobile radio is made and have the charging rate adjusted accordingly.

Readjusting Flexible Shafts

When the receiver is in position on the dash, loosen the flexible shaft casing set screws on the chassis. Allow the casing to position itself so that it does not bind. Then retighten the set screws.

WELLS-GARDNER & CO.

Alignment and Calibration

Correct alignment is extremely important in connection with all wave receivers. The receivers are all properly aligned at the factory with precision instruments and realignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment.

A signal generator that will provide an accurately calibrated signal at 456, 380, 350, 165, 1730, 1500, 600, 18,300, 15,000 and 6000 KC and an output indicating meter are required. It will be practically impossible to align the receiver if unsatisfactory apparatus is used. If a station is tuned in with the selectivity control in the broad position and this control is then turned to the sharp position, the station may disappear. This is not an indication that the receiver is out of alignment.

Use a non-metallic screwdriver for the adjustments. The complete procedure is as follows:

I. F. Adjustment

Set the signal generator for a signal of 456 KC.

Connect the output of the signal generator through a .1 mf. condenser to the grid of the 1st detector.

Connect the ground lead of the receiver to the ground post of the signal generator.

Turn the band selector to the Range B position (medium wave band—green dial color).

Turn the selectivity control to the sharp position and keep it in this position for all adjustments.

Turn the volume control to the maximum position.

Attenuate the signal from the signal generator to prevent the levelling-off action of the A. V. C.

Then adjust the four I.F. trimmers until maximum output is obtained. The adjusting screws for these condensers are reached from the top of the chassis, and the location is shown in Fig. 5.

Range A Alignment

380 KC Adjustment

Set the signal generator for 380 KC.

Turn the rotor of the tuning condenser to the full open position.

Turn the band selector to the Range A position (long wave band—purple dial color).

Connect the antenna lead of the receiver through a 200 mmf. condenser to the output of the signal generator.

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the oscillator Range A trimmer (C30) until maximum output is obtained. The location of this trimmer is shown in Fig. 3

350 KC Adjustment

Set the signal generator for 350 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the interstage Range A trimmer (C10) and antenna Range A trimmer (C3) to maximum.

Do not change the setting of the oscillator Range A trimmer.

165 KC Adjustment

Set the signal generator for 165 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 165 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

Range B Alignment

1730 KC Adjustment

Set the signal generator for 1730 KC.

Turn the rotor of the tuning condenser to the full open position.

Turn the band selector to the Range B position (medium wave band—green dial color).

Keep the antenna lead of the receiver connected through the 200 mmf. condenser to the output of the signal generator.

Adjust the oscillator Range B trimmer (C34) until maximum output is obtained. The location of this trimmer is shown in Fig. 3.

1500 KC Adjustment

Set the signal generator for 1500 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Loosen the pointer set screw and set the large pointer at the 1500 KC mark on the medium wave band scale. Retighten the set screw.

Adjust the interstage Range B trimmer (C11) and antenna Range B trimmer (C5) to maximum.

Do not change the setting of the oscillator Range B trimmer.

600 KC Adjustment

Set the signal generator for 600 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 600 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

Range D Alignment

18,300 KC Adjustment

Set the signal generator for 18,300 KC.

Connect the antenna lead of the receiver through a 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band selector to the Range D position (short wave band—red dial color).

Adjust the oscillator Range D trimmer (C35) until maximum output is obtained. See Fig. 3 for location of this trimmer.

15,000 KC Adjustment

Set the signal generator for 15,000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the interstage Range D trimmer (C12) and antenna Range D trimmer (C6) to maximum.

When adjusting the interstage Range D trimmer, it will be necessary at the same time to turn the tuning condenser rotor slowly back and forth until the peak of greatest intensity is obtained.

Then go back and repeat the procedure as given for the 18,300 KC adjustment. If it is found necessary to make any appreciable change in the setting of the oscillator Range D trimmer, the 15,000 KC adjustment must be repeated.

Do not make any further change in the setting of the oscillator Range D trimmer.

6000 KC Adjustment

Set the signal generator for 6000 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 6000 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

Servicing R. F. Coil Assemblies

The R. F. transformers and oscillator coil assemblies in this receiver are sold complete with can. This is due to the fact that the trimmers are soldered to the can, and cannot be easily disassembled.

The lead colors and resistances of the various windings in each assembly are shown in Fig. 4.

If it is ever necessary to remove one of coil assemblies from the can, proceed as follows: First remove the nuts from the screws at the top of the can. The outside lug on the trimmer condenser is inserted in a slot in the coil can, and this lug is soldered into position.

Apply a soldering iron to the can at the point of the soldered connection. Then with a screw driver lift up on the outside edge of the trimmer (edge soldered to can) until the trimmer is clear of the can. After the trimmers are all unsoldered, the coil can be taken out.

Twenty-five Cycle Receivers

The twenty-five cycle receiver can be operated satisfactorily from a sixty cycle power supply. However, the reverse is not true, the sixty cycle receiver cannot be operated from a twenty-five cycle power supply.

A 115-230 Volt, 40 to 60 cycle as well as other power transformers with special power ratings are also available for this model.

Phonograph Connections

Phonograph connections can be made as shown in Fig. 7. The parts required are shown in the parts list. Knockouts are provided in the back panel of the chassis for mounting the phono jack and phono switch—See Fig. 8.

For mounting the 12 mfd. 25 volt dry electrolytic condenser, two No. 27 drill holes should be drilled in the side of the chassis directly below the wet electrolytic condensers. These holes are 1¼" from the bottom, ¾" and 3¾" from the front of chassis. The ground lug which extends out from the side of the chassis should be bent back into the chassis wall.

Mount the single lug insulated terminal strip (P-4A49) on the mounting bolt of the double lug insulated terminal strip (located on the rear panel, directly in back of the band selector switch).

The connections are made by opening the diode return circuit at the volume control. Unsolder the 50,000 ohm resistor R9 from the lug at the volume control and the terminal strip. Also unsolder from this terminal strip the shielded lead which runs to the 2nd I.F. transformer. Cut this shielded lead to length and connect it to the lug on the new terminal strip (P-4A49). Connect one side of the 50,000 ohm resistor R-9 to the same lug and the other side to the phono switch — see Fig. 7.

The extra shielded lead which is provided should be connected from the volume control to the phono switch as shown in Fig. 7. Be sure to remove the shielding from the portion of this lead that passes over the volume control.

Remove the ground from the cathode terminal of the 6B7 2nd detector tube socket by bending the chassis ground lug away from this terminal. Be sure to solder back to this lug any leads that were connected to it (not including the cathode connection).

Connect one side of the 12 mfd. 25 volt electrolytic condenser to ground and the other side of this condenser to the cathode of the 6B7 2nd detector tube socket and to the phono switch as shown in Fig. 7. To this same terminal on the phono switch connect the 900 ohm resistor. The other side of the resistor is connected to ground. Complete the other connections as illustrated in Fig. 7.

A high impedance pickup should be used. If a low impedance pickup is used a step-up transformer will be required for sufficient volume. The volume control and tone control of the set will regulate the phono volume and tone.

D. C. Resistance of Windings

MODEL 9C Series
Alignment, Resistance

WELLS - GARDNER & CO.

Alignment and Calibration

A signal generator that will provide an accurately calibrated signal at 456, 1730, 1500, 600, 4800, 4200, 16,000, 15,000 and 6000 KC and an output indicating meter are required. It will be practically impossible to align the receiver if unsatisfactory apparatus is used. If a station is tuned in with the selectivity control in the broad position and this control is then turned to the sharp position, the station may disappear. This is not an indication that the receiver is out of alignment.

Use a non-metallic screwdriver for the adjustments. The complete procedure is as follows:

I. F. Adjustment

Set the signal generator for a signal of 456 KC.

Connect the output of the signal generator through a 0.1 mf. condenser to the switch end of condenser C11—see Fig. 2. There is a lead which goes to the lug on top of the center stator section of the tuning condenser—see Fig. 11. The connection can be made at this lug.

Connect the ground lead of the receiver to the ground post of the signal generator.

Turn the band selector to the Range B position (standard wave band—purple dial color).

Turn the selectivity control to the sharp position and keep it in this position for all adjustments.

Turn the volume control to the maximum position.

Attenuate the signal from the signal generator to prevent the levelling-off action of the A.V.C.

Then adjust the five I.F. trimmers until maximum output is obtained. The adjusting screws for these condensers are reached from the top of the chassis, and the location is shown in Fig. 11.

Range B Alignment

1730 KC Adjustment

Set the signal generator for 1730 KC.

Turn the rotor of the tuning condenser to the full open position.

Keep the band selector in the standard wave position.

Connect the antenna lead of the receiver through a 200 mmf. condenser to the output of the signal generator.

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the oscillator Range B trimmer (C32) until maximum output is obtained. The location of this trimmer is shown in Fig. 9.

1500 KC Adjustment

Set the signal generator for 1500 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Loosen the pointer set screw and set the large pointer at the 1500 KC mark on the standard wave band scale. Retighten the set screw.

Adjust the interstage Range B trimmer (C8) and antenna Range B trimmer (C2) to maximum.

Do not change the setting of the oscillator Range B trimmer.

600 KC Adjustment

Set the signal generator for 600 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 600 KC trimmer until the peak of greatest intensity is obtained. See Fig. 9 for location of this trimmer.

Be sure to use a non-metallic screwdriver for this adjustment.

Range C Alignment

4800 KC Adjustment

Set the signal generator for 4800 KC.

Connect the antenna lead of the receiver through a 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band selector in the Range C position (1st short wave band—green dial color).

As mentioned above, keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the oscillator Range C trimmer (C30) until maximum output is obtained. See Fig. 9 for location of this trimmer.

4200 KC Adjustment

Set the signal generator for 4200 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the interstage Range C trimmer (C9) and antenna Range C trimmer (C3) to maximum.

Do not change the setting of the oscillator Range C trimmer.

Range D Alignment

16,000 KC Adjustment

Set the signal generator for 16,000 KC.

Keep the antenna lead of the receiver connected through the 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band selector to the Range D position (2nd short wave band—red dial color).

As mentioned above, keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the oscillator Range D trimmer (C29) until maximum output is obtained. See Fig. 9 for location of this trimmer.

15,000 KC Adjustment

Set the signal generator for 15,000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the interstage Range D trimmer (C10) and antenna Range D trimmer (C4) to maximum.

When adjusting the interstage Range D trimmer, it will be necessary at the same time to turn the tuning condenser rotor slowly back and forth until the peak of greatest intensity is obtained.

Then go back and repeat the procedure as given for the 16,000 KC adjustment. If it is found necessary to make any appreciable change in the setting of the oscillator Range D trimmer, the 15,000 KC adjustment must be repeated.

Do not make any further change in the setting of the oscillator Range D trimmer.

6000 KC Adjustment

Set the signal generator for 6000 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 6000 KC trimmer until the peak of greatest intensity is obtained. See Fig. 9 for location of this trimmer.

Use a non-metallic screwdriver for this adjustment.

Testing Batteries

If the receiver does not operate satisfactorily test the batteries under load. A high resistance meter is required for the "B" and "C" voltages. If any of the batteries are considerably below their rated voltage, new ones should be used. When the "B" batteries are replaced the "C" batteries should also be replaced. The reason for this is that the "C" drain is such that the "C" batteries are run down in about the same time as the "B" batteries.

"A" Battery and Regulator

This receiver is designed to operate with a 2 volt storage cell, but may be operated with a 3 volt dry "A" battery if used with a voltage regulator. The receiver may also be used with an air cell "A" battery provided a series resistor is used to reduce the voltage to the proper level of 2 volts for the tube filaments. Although the voltage regulator mentioned above can be used, the series resistor is cheaper and is satisfactory as the voltage of one of these batteries drops very little during the useful life of the battery.

D. C. Resistance of Windings
Refer to Figs. 10 & 2

Following are the D. C. resistances of the various coil windings in the chassis. The values given below will vary slightly in different sets.

Part No.	Item	Code	D. C. Resistance in Ohms

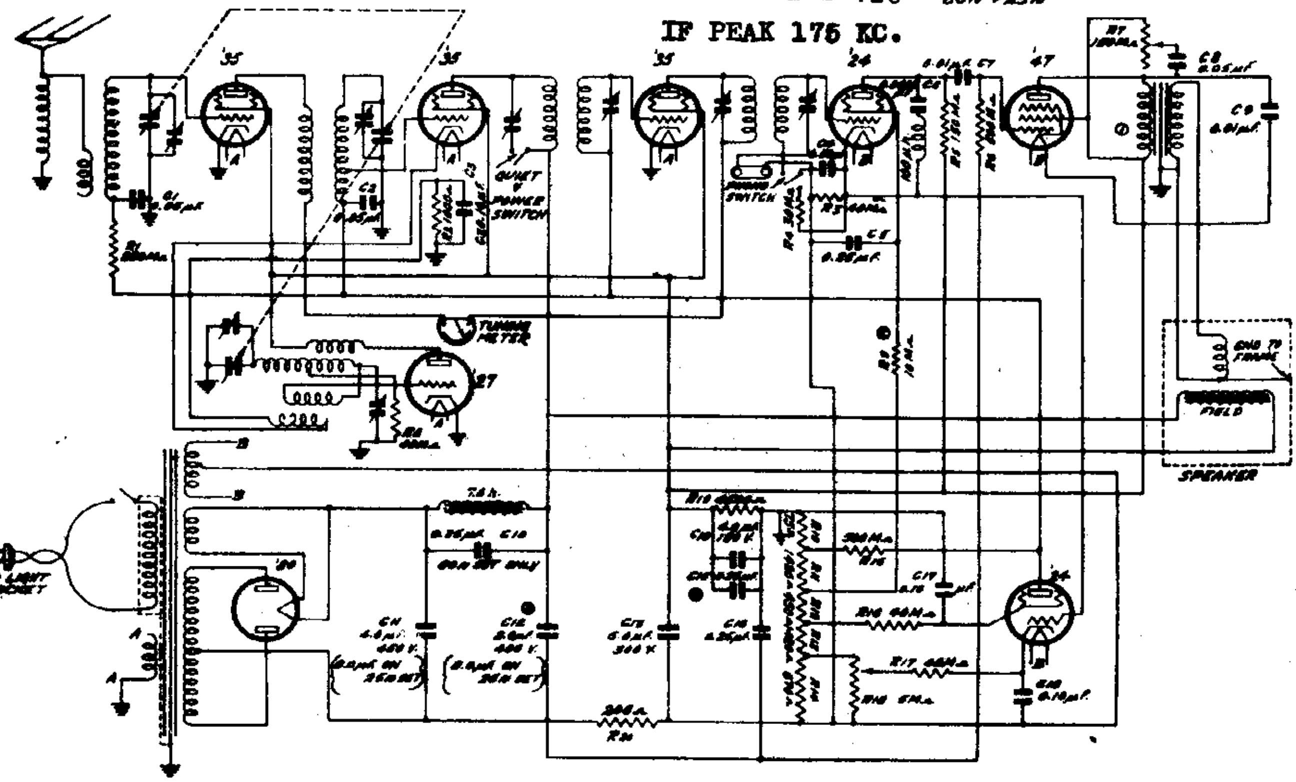
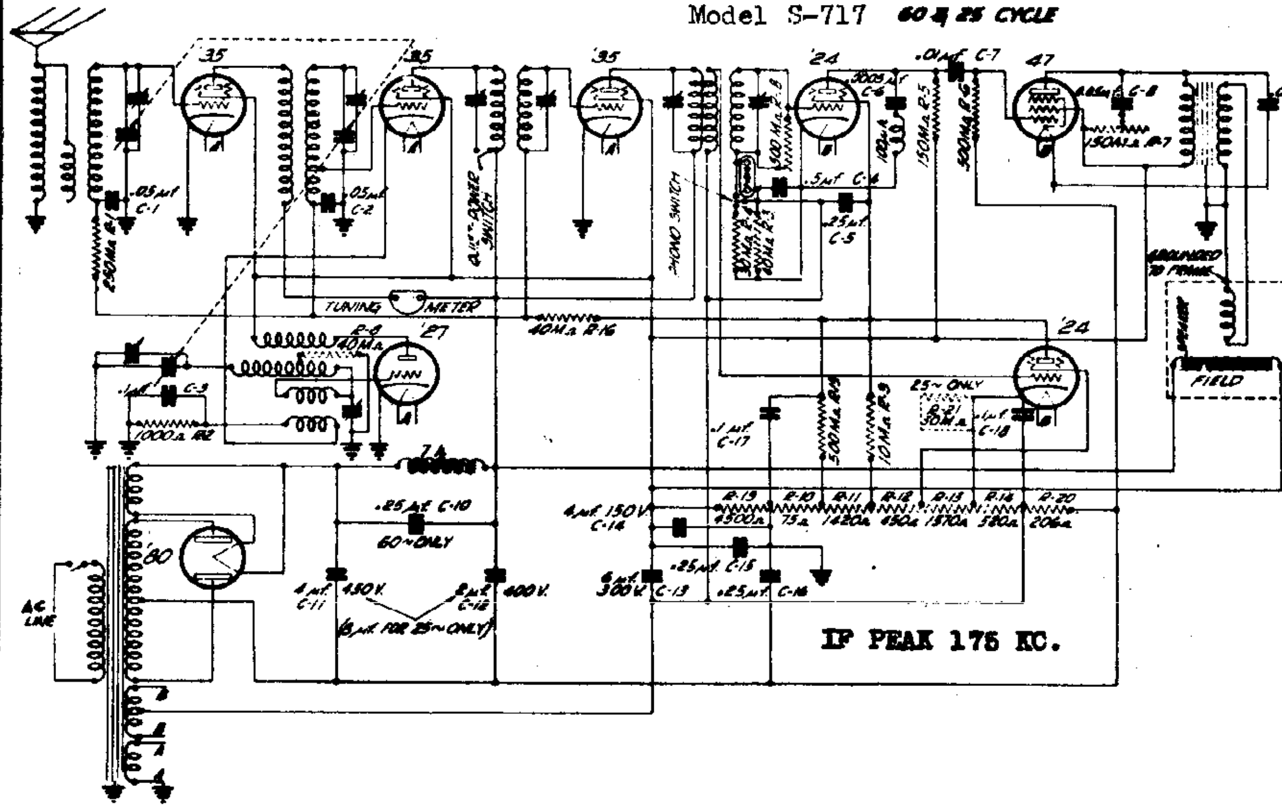
IF PEAK 175 KC.



Model S-717 60 & 25 CYCLE



WESTERN AUTO SUPPLY CO.

A modulated test oscillator and an output meter **MUST** be used when aligning this receiver to insure accurate alignment. It is important that the oscillator deliver a signal at exactly 175 K.C. in addition to frequencies in the broadcast band.

The adjustable condensers which tune the primaries and secondaries of the I.F. transformers are adjusted by inserting a screw driver through the holes in the chassis base directly below the I.F. transformer assemblies.

A trimmer condenser is mounted over each section in the gang and is adjusted by turning the screw located under the hole in the top of the gang shield.

The oscillator 600 K.C. tracking condenser is on the back of the chassis near the "QUIET-POWER" switch.

Make each adjustment in the order given below or the receiver may be thrown further out of alignment and it will then be a difficult task to align it properly.

The receiver and test oscillator must be well grounded and the output kept within the range of the output meter at all times.

All shields must be in place when making the adjustments.

INTERMEDIATE CIRCUITS.—Tune the test oscillator to exactly 175 K.C., and connect its output to the grid of the first detector tube after removing the clip on the tip of the tube. Connect the output meter across the secondary of the speaker coupling transformer and then adjust all four condensers which tune the intermediate transformers, for the greatest deflection on the output meter. Check the settings of all four condensers to make certain the maximum output has been obtained.

When the above instructions have been followed remove the test oscillator coupling and replace the grid clip on the tip of the first detector tube.

GANG CONDENSERS.—Turn the gang condenser plates all the way in and see that the dial pointer is on the first dial division point below 550 K.C.

Tune the test oscillator to 1,400 K.C., turn the dial to read 1,400 K.C., and then adjust each gang condenser trimmer for maximum output.

OSCILLATOR.—Tune the test oscillator to 600 K.C., and tune the receiver to the signal. Disconnect the output meter and then rotate the adjusting screw on the oscillator 600 K.C. tracking condenser. Rock the gang condenser back and forth across the signal at the same time, and listen closely until the maximum volume is obtained. The tracking condenser is then properly adjusted and remains fixed thereafter.

The gang condenser trimmers only must then be adjusted again at 1,400 K.C. for maximum output.

The receiver should be accurately aligned if the above instructions have been followed and no further adjustments need be made.

The blue lead on the filter block is common for condensers C4, C5, and C18, and the black lead is common for condensers C3, C15, C16, and C17. The second detector plate filter choke is also contained in the block and is connected by two yellow leads, C8, (white-red leads) and C10 (red leads) are connected as shown in Fig. 1 schematic wiring diagram.

Voltages at Sockets

The voltages shown in the chart were taken with a 1,000 ohm per volt voltmeter; voltage measurements taken with a voltmeter having a different resistance will, of course, differ from those shown.

Turn the volume control all the way on, connect the antenna and ground leads together and turn the gang condenser plates all the way out. Check the line voltage.

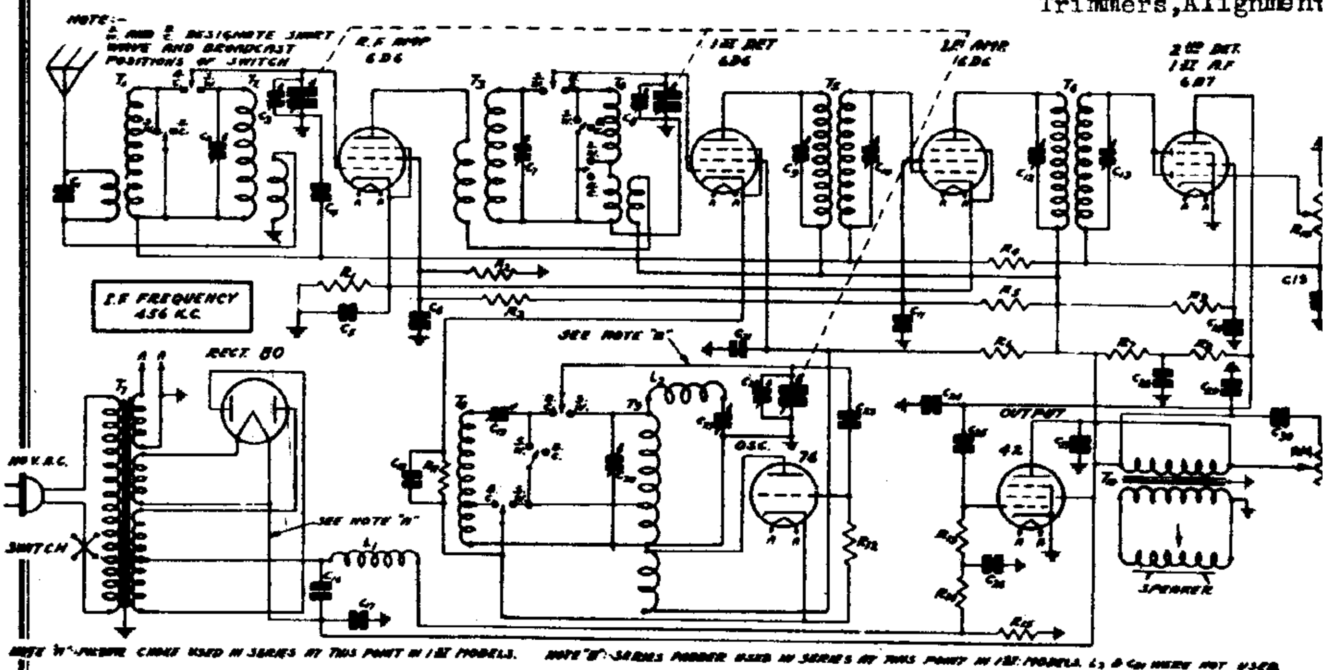

Fig. 1—Schematic Circuit Diagram

Condenser Alignment

Correct alignment is extremely important in connection with all wave receivers. The receivers are all properly aligned at the factory with precision instruments and re-alignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment. A signal generator that will provide an accurately calibrated signal of 456 K. C. and accurately calibrated signals over the broadcast and short wave bands, 530-1740 K. C. and 5.8-18.3 M. C., is required. An output indicating meter is also necessary. It will be practically impossible to align the receiver if unsatisfactory apparatus is used.

Use a non-metallic screw driver for the adjustments. The complete procedure is as follows:

Intermediate Frequency Adjustment

Set the signal generator for 456 K. C. Connect the antenna lead of the signal generator to the grid of the 1st detector through a .05 mfd. condenser. Turn the tuning condenser rotor until the plates are completely out. The ground lead from the signal generator goes to the ground lead of the receiver. The volume control should be at the maximum position. Attenuate the signal so that A. V. C. action is not obtained.

Then adjust the four I. F. trimmer condensers until maximum output is obtained. The adjusting screws for these condensers are reached from the top of the chassis and are in the round I. F. cans—See Fig. 2. The openings to the trimmer condensers are covered over by a small cover plate which is held in position by a screw. Loosen these screws until the cover plates can be swung around.

Broadcast Band Adjustment

The broadcast short wave switch should be in the broadcast position. Set the signal generator for 1740 K. C. Turn the rotor to the full open position. The antenna lead from the signal generator is in this instance connected to the antenna lead of the receiver. Attenuate the signal so that A. V. C. action is not obtained. Adjust the oscillator broadcast trimmer until maximum output is obtained. This trimmer is on the tuning condenser and its location is shown in Fig. 2.

Then set the signal generator for 1500 K. C. Turn the rotor until maximum output is obtained. Loosen the pointer

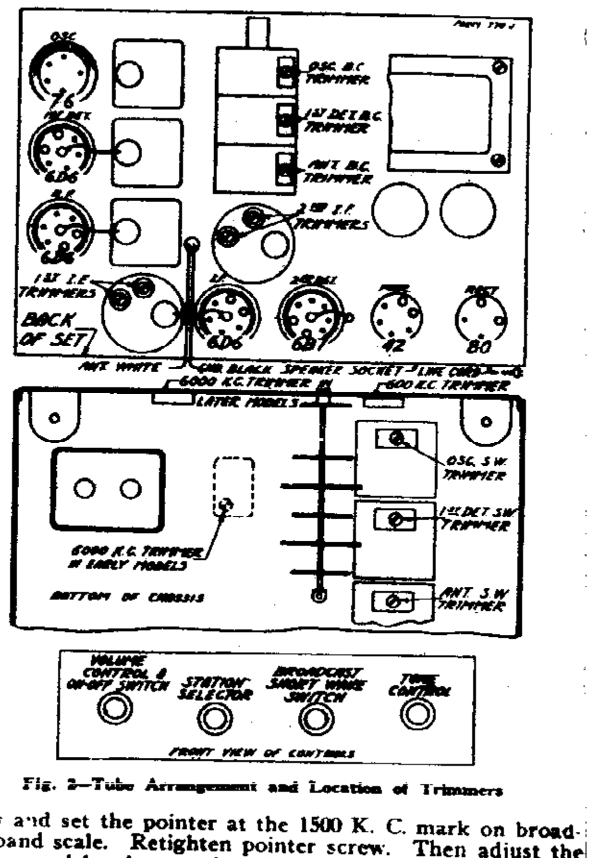

Fig. 2—Tube Arrangement and Location of Trimmers

screw and set the pointer at the 1500 K. C. mark on broadcast band scale. Retighten pointer screw. Then adjust the antenna and 1st detector broadcast trimmers until maximum output is obtained.

Next set the signal generator for 600 K. C. and adjust the 600 K. C. trimmer. The adjusting screw is reached through a hole in the front panel of the chassis as shown in Fig. 2. Turn the tuning condenser rotor until maximum output is obtained. Then turn the rotor slowly back and forth over

MODELS S-725, S-726
Alignment, Part 2
Voltage, Changes
Parts

WESTERN AUTO SUPPLY CO.

this setting at the same time adjusting the 600 K. C. trimmer screw until the highest output is obtained.

Short Wave Band Adjustment

CAUTION—After the broadcast band alignment as described above has been made, do not change the adjustment of any of the broadcast band trimmers.

Turn the broadcast short wave switch to the short wave position. Turn the rotor to the full open position. As explained above, the volume control should be at the maximum position and the signal should be attenuated to prevent A. V. C action. Set the signal generator for 18,300 K. C. Then adjust the oscillator short wave trimmer for maximum output. This trimmer is reached from under the chassis and its position is shown in Fig. 2.

Next set the signal generator for 15,000 K. C. Turn the rotor until the dial pointer is at the 15,000 K. C. mark on the short wave portion of the dial scale. Then adjust the antenna and 1st detector short wave trimmers until maximum output is obtained.

In aligning the short wave band of the receiver, it will be noted that the signal will be heard with the signal generator set at two points 912 K. C. apart. That is, if the receiver is tuned to 15,000 K. C. a signal will be heard when the signal generator is set at 15,000 K. C. and again at approximately 15,912 K. C. This is due to image reception or the fact that a 456 K. C. beat is obtained when the signal is 456 K. C. lower than the receiver oscillator and also when the signal is 456 K. C. higher than the receiver oscillator. Care should be taken to see that the receiver is tracked with the signal generator adjusted to the lower of the two frequencies at which a signal is heard, in order that the oscillator in the receiver will be 456 K.C. higher in frequency than the signal.

Next set the signal generator for 6000 K. C. and adjust the 6000 K. C. trimmer. In the first models of this receiver, this condenser was located at the point shown in Fig. 2 in dashed lines. In the later models it is reached through a hole in the front panel of the chassis as shown in the same illustration. Turn the tuning condenser rotor until maximum output is obtained. Then turn the rotor slowly back and forth over this setting, at the same time adjusting the 6000 K. C. trimmer screw until the highest output is obtained. In the early models this adjustment is broad while in the later models it is more critical.

Caution

The can of electrolytic condenser C16 is not at ground potential. Therefore in any work on the chassis, care should be taken not to touch this can and any other grounded point such as the other electrolytic condenser can.

Replacing Drive Cord

Remove chassis from cabinet.

Take off the pilot light assembly by lifting off the two sockets and spring clips.

Detach the large pointer by removing the screw at the center of the dial.

Loosen the dial assembly by taking out the two screws which secure the bottom of this assembly to the chassis.

Then lay the complete dial assembly face downward in front of the chassis. It is not necessary to remove the volume control and tone control collars which hold the indicator cords of these two controls in position.

Turn the drive drum until the opening in this drum is approximately vertical and with the hole at the top as shown in Fig. 3.

Remove the tension spring and the old drive cord.

See that the eyelet is in the hole in the drive drum as shown in Fig. 3. Insert one end of the drive cord from the outside through the hole in the eyelet in the drive drum.

Voltages at Sockets
LINE VOLTAGE — 115

(1) Cathode to ground
(2) Subject to variation
(3) Read with 1,000,000 ohm meter
(4) As read across R15

Tie the end of the cord which has been inserted in the hole to one end of the tension spring.

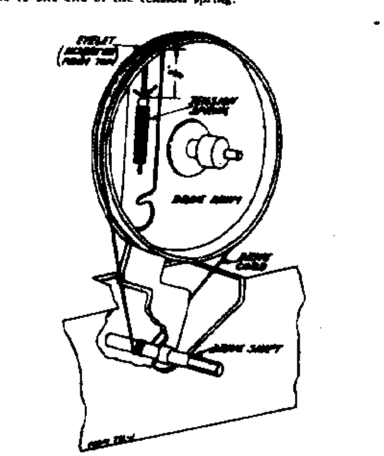

Fig. 3—Drive Cord Replacement

Wrap the cord in a clockwise direction (facing front of chassis) around the drive drum approximately one-half turn.

Then tilt the chassis up on its back panel and bring the cord mentioned in the previous paragraph down to the drive shaft. Wrap it two and one-half times around the drive shaft as shown in Fig. 3.

Then bring this cord up from the drive shaft and wrap it around the drive drum approximately one and one fifth turns in a clockwise direction until it is up to the hole in this drum as illustrated.

Insert the free end of the cord through the hole in the eyelet and tie it to the end of the tension spring. The end of the spring, when hanging free, should be approximately ⅜" from the flange of the drum as shown in Fig. 3. Cut off the surplus length of cord after it is knotted.

Then secure the other end of the tension spring over the spur on the drive drum.

Replace the dial assembly and pointer.

Replace the pilot light assembly after which the chassis may be reinstalled in the cabinet.

Changes in Early Models

There are two points at which the early models of this receiver differ from the present models. These points are indicated in Fig. 1 and described below.

Power Unit

In the early models a separate filter choke was used in series at the point indicated in note A in Fig. 1. The values of the two filter condensers C16 and C17 were less than as used at present. The values of the old and new condensers are shown in the parts list. A different power transformer was also used with the early filter system and this is likewise shown in the parts list.

The two power transformers are not interchangeable and care must be taken in ordering for replacement purposes to order the correct one. The original chassis can be identified by the separate filter choke.

Short Wave Oscillator

Referring to Fig. 1 it will be noted that there is a tracking coil L2 and a trimmer condenser C21 connected in series between the short wave oscillator coil and ground. In the first models of this receiver these two units, which are required for tracking the short wave oscillator, are not used. Instead a series padding condenser was used at the point in the circuit indicated by note B in Fig. 1.

At the time this change was made a change was also made in the oscillator assembly and care must be taken in ordering for replacement purposes to order the correct one. Early models with the original oscillator assembly have no spot of paint or a green spot of paint on the 80 socket rivet. Later models with the new oscillator assembly and new tracking system have a red spot of paint on the 80 socket rivet.

Twenty-five Cycle Receivers

The twenty-five cycle receiver differs from the sixty-cycle receiver only in the fact that a different power transformer is used. The correct power transformer is shown in the parts list.

The twenty-five cycle chassis can be operated satisfactorily from a sixty-cycle power supply. However, the reverse is not true, the sixty-cycle receiver cannot be operated from a twenty-five cycle power supply.

A 110-220 Volt, 40-60 cycle Power Transformer is also available for this model.

REPAIR PARTS LIST FOR 7 TUBE BROADCAST AND SHORT WAVE RECEIVER

When ordering parts be sure and give the part number. Also give the series number which will be found in the License Notice label. If there is a spot of paint on the chassis, give this color.

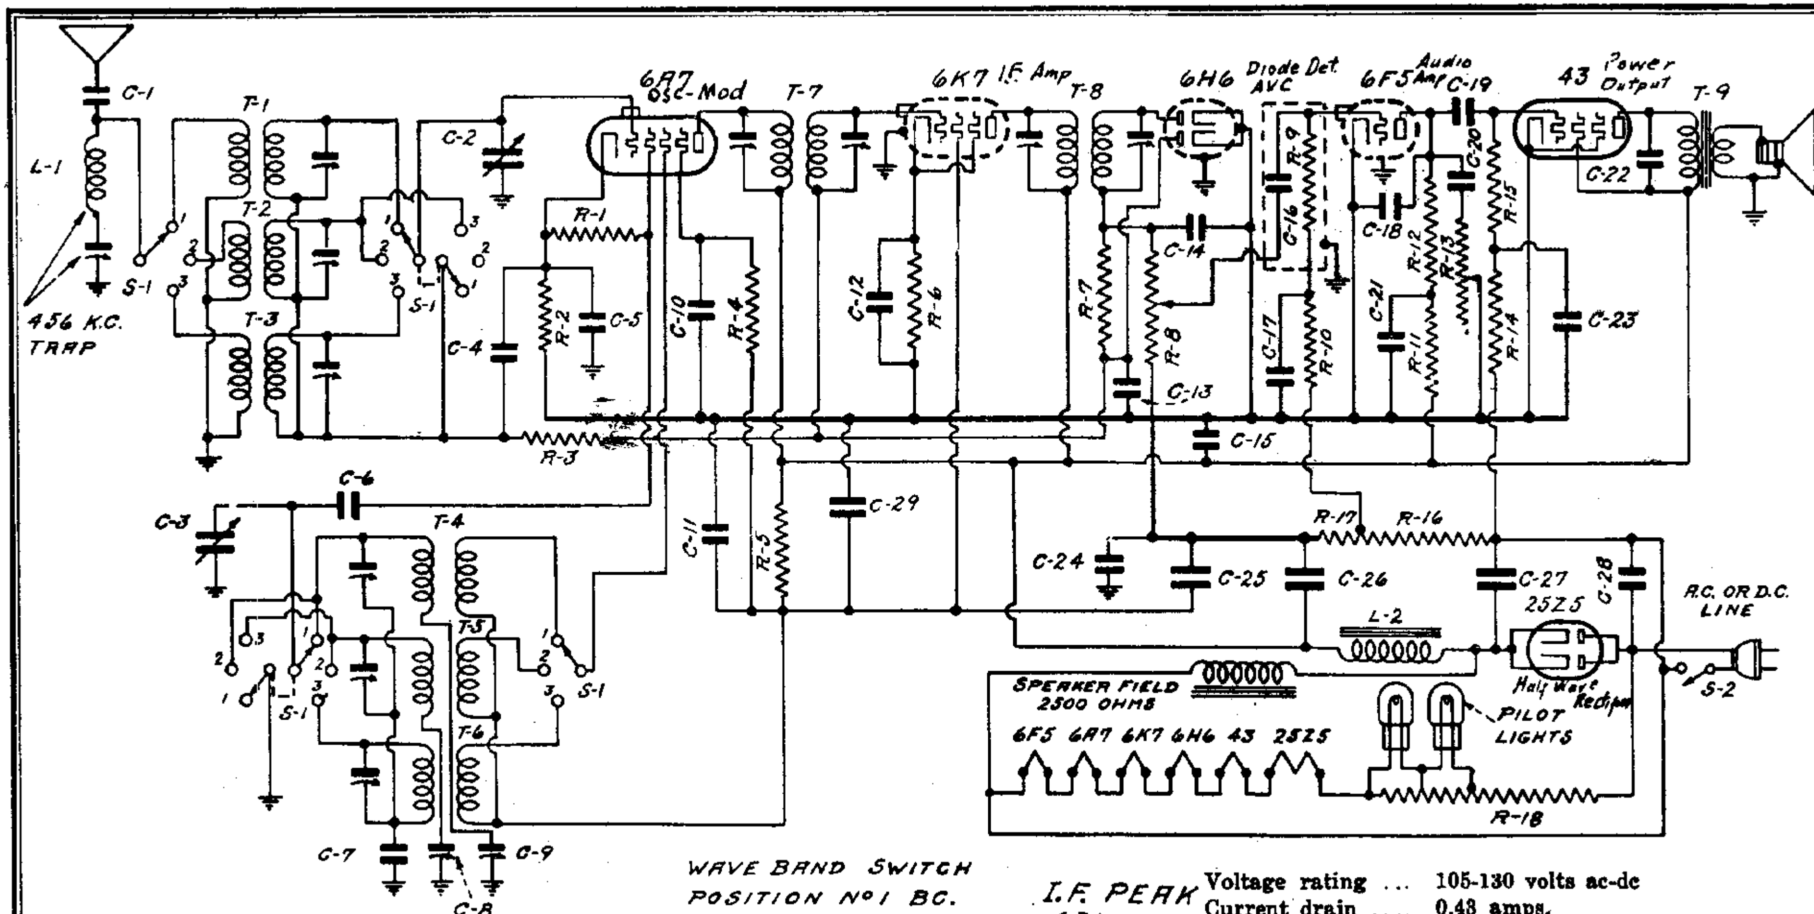
MODEL WR-101
Chassis U6F
Schematic, Voltage

WESTINGHOUSE ELEC. SUPPLY CO.



WAVE BAND SWITCH
POSITION No 1 BC.
POSITION No 2 POLICE
POSITION No 3 S.W.

I.F. PEAK 456 K.C.

Voltage rating ...	105-130 volts ac-dc
Current drain ...	0.48 amps.
Frequency ranges	540 to 1660 kc, 1580 to 4750 kc, 5.5 to 16 mc.

VOLTAGE ANALYSIS

Readings should be taken with a 1000 ohms-per-volt meter. Voltages listed below are from point indicated to the cathode of the 43 tube (B minus). Line voltage for these readings was 117.5 volts, 60 cycles, a.c.

Tube	Plate	Screen	Cathode	Osc. Plate	Fil.
6A7	99	43	1.1	80	6.3
6K7	99	80	1.8	—	6.3
6H6	—	—	0	—	6.3
6F5	50	—	0	—	6.3
43	87	99	0	—	24

Voltage across speaker field (black and yellow leads)—120
Voltage across filter choke—9.5

The 250 ohm bias resistor, R16 and R17 on schematic diagram, is located underneath the chassis deck near the volume control.
Voltage across the two outside terminals of this resistor—11.5
Voltage from cathode of 43 tube to central terminal of resistor—1.0

Fil. drop.res. 2LR-212 is a cyl. plug-in type and is located at chassis top bet. 6H6 & 25Z5 tubes. O.P. Transf. 2LT-221 (T9 on schematic) and filter choke 2CT-207A (L2 on schematic) are located in square can on chassis top to left of speaker.

MODEL WR-101
Chassis U6F
Alignment, Parts

WESTINGHOUSE ELEC. SUPPLY CO.

ADJUSTMENTS

An oscillator with frequencies of 456, 600, 1600, 1700, 4500 and 15,000 kc should be used. In addition, an output meter should be used across the voice coil or output transformer for observing maximum response.

I-f and Wave-trap Alignment

The i-f transformers are located on the top of the chassis. The four trimmers, two for each i-f transformer, are located at the tops of the cans. Set the wave-band switch to broadcast (extreme clockwise position) and rotate variable condenser to minimum capacity. Feed 456 kc to grid of the 6A8 tube and adjust the four i-f trimmers for maximum response. Then feed 456 kc through the antenna and adjust the wave-trap trimmer for *minimum response*. The trimmer is on the wave-trap, which is located on top of the chassis behind the speaker. This reduces telegraphic code interference.

Location of Coils

The antenna coils for the three bands are wound on one form and mounted on the top of the chassis to the right of the speaker. The three trimmers for these coils are mounted on the bakelite strip fastened to the coil form. The upper trimmer is for the short-wave coil, the central trimmer for the police coil and the lower trimmer for the broadcast coil.

The oscillator coils for the three bands are wound on one form and mounted underneath the chassis deck on the right-hand wall with the trimmers facing out. The trimmer screws are available through three holes in the chassis wall. The trimmer closest to front is for the broadcast oscillator coil, the central trimmer is for the police oscillator coil and the trimmer furthest from front is for the short-wave oscillator coil.

The adjusting screws for the dual padder are also available at the right-hand chassis wall. The screw closer to the front is for the broadcast band and the other is for the police band. The short-wave band has no adjustable padder.

Broadcast Alignment

Set the wave-band switch to broadcast position (extreme clockwise) and dial pointer to 600. Feed 600 kc through antenna lead and adjust broadcast padder (lower row on right wall, closest to front) for maximum response. Set pointer to 1600, feed 1600 kc and adjust the broadcast oscillator trimmer (top row on right wall, closest to front) for maximum response, and then the broadcast antenna trimmer (on antenna coil, lower trimmer). Return pointer to 600 and rock the variable condenser (rotate condenser back and forth through small arc) while adjusting the broadcast padder for maximum response. If a readjustment is necessary return to 1600 and realign the antenna and oscillator trimmers.

Police Alignment

Set the wave-band switch to police (central position), pointer to 1700 and feed 1700 kc through antenna lead. Adjust police band padder (furthest from front on right wall, lower row) for maximum response. Set pointer to 4500 and feed 4500 kc. Adjust police band oscillator trimmer (central trimmer on right wall, upper row) for maximum response. If two peaks are heard, select the one of minimum capacity (see General Instructions below). Then adjust police band antenna trimmer (central one on top) for maximum response, selecting the peak of maximum capacity. Again feed 1700 kc, with pointer at 1700, rock variable condenser and adjust police band padder for maximum response. Realign at 4500 if necessary.

Short-wave Alignment

Set wave-band switch to short-wave (counter-clockwise) position and pointer at 15 megacycles. Feed 15,000 kc through antenna. Adjust short-wave oscillator trimmer (furthest from front on right wall, top row) for maximum response. If two peaks are obtained, select the one of minimum capacity. Adjust the short-wave antenna trimmer (upper trimmer on antenna coil) for maximum response while rocking the variable condenser.

Check all three bands for dead spots or incorrect image responses.

PRICES ARE SUBJECT TO CHANGE WITHOUT NOTICE

General Instructions

The set's oscillator is higher in frequency than the signal on all three bands. Images, therefore, should be observed on the low-frequency side of the signals.

Always choose the minimum capacity peak on oscillator trimmers and maximum capacity peak on the antenna trimmers. The last motion in adjusting trimmers should always be a tightening one.

Never leave a trimmer with the outside plate so loose that there is no tension on the screw. Either bend the plate up or remove the screw entirely. Loose screws are a source of noise, frequency drift and microphonism.

In aligning antenna trimmers on the high-frequency signals there is usually a tendency for the oscillator to drift, due to interlocking. To compensate for this, always keep re-tuning the variable condenser.

WESTINGHOUSE ELEC. SUPPLY CO.

MODEL WR-208
Schematic
Voltage, Color Coding

The color coding of the i-f transformers is as follows:

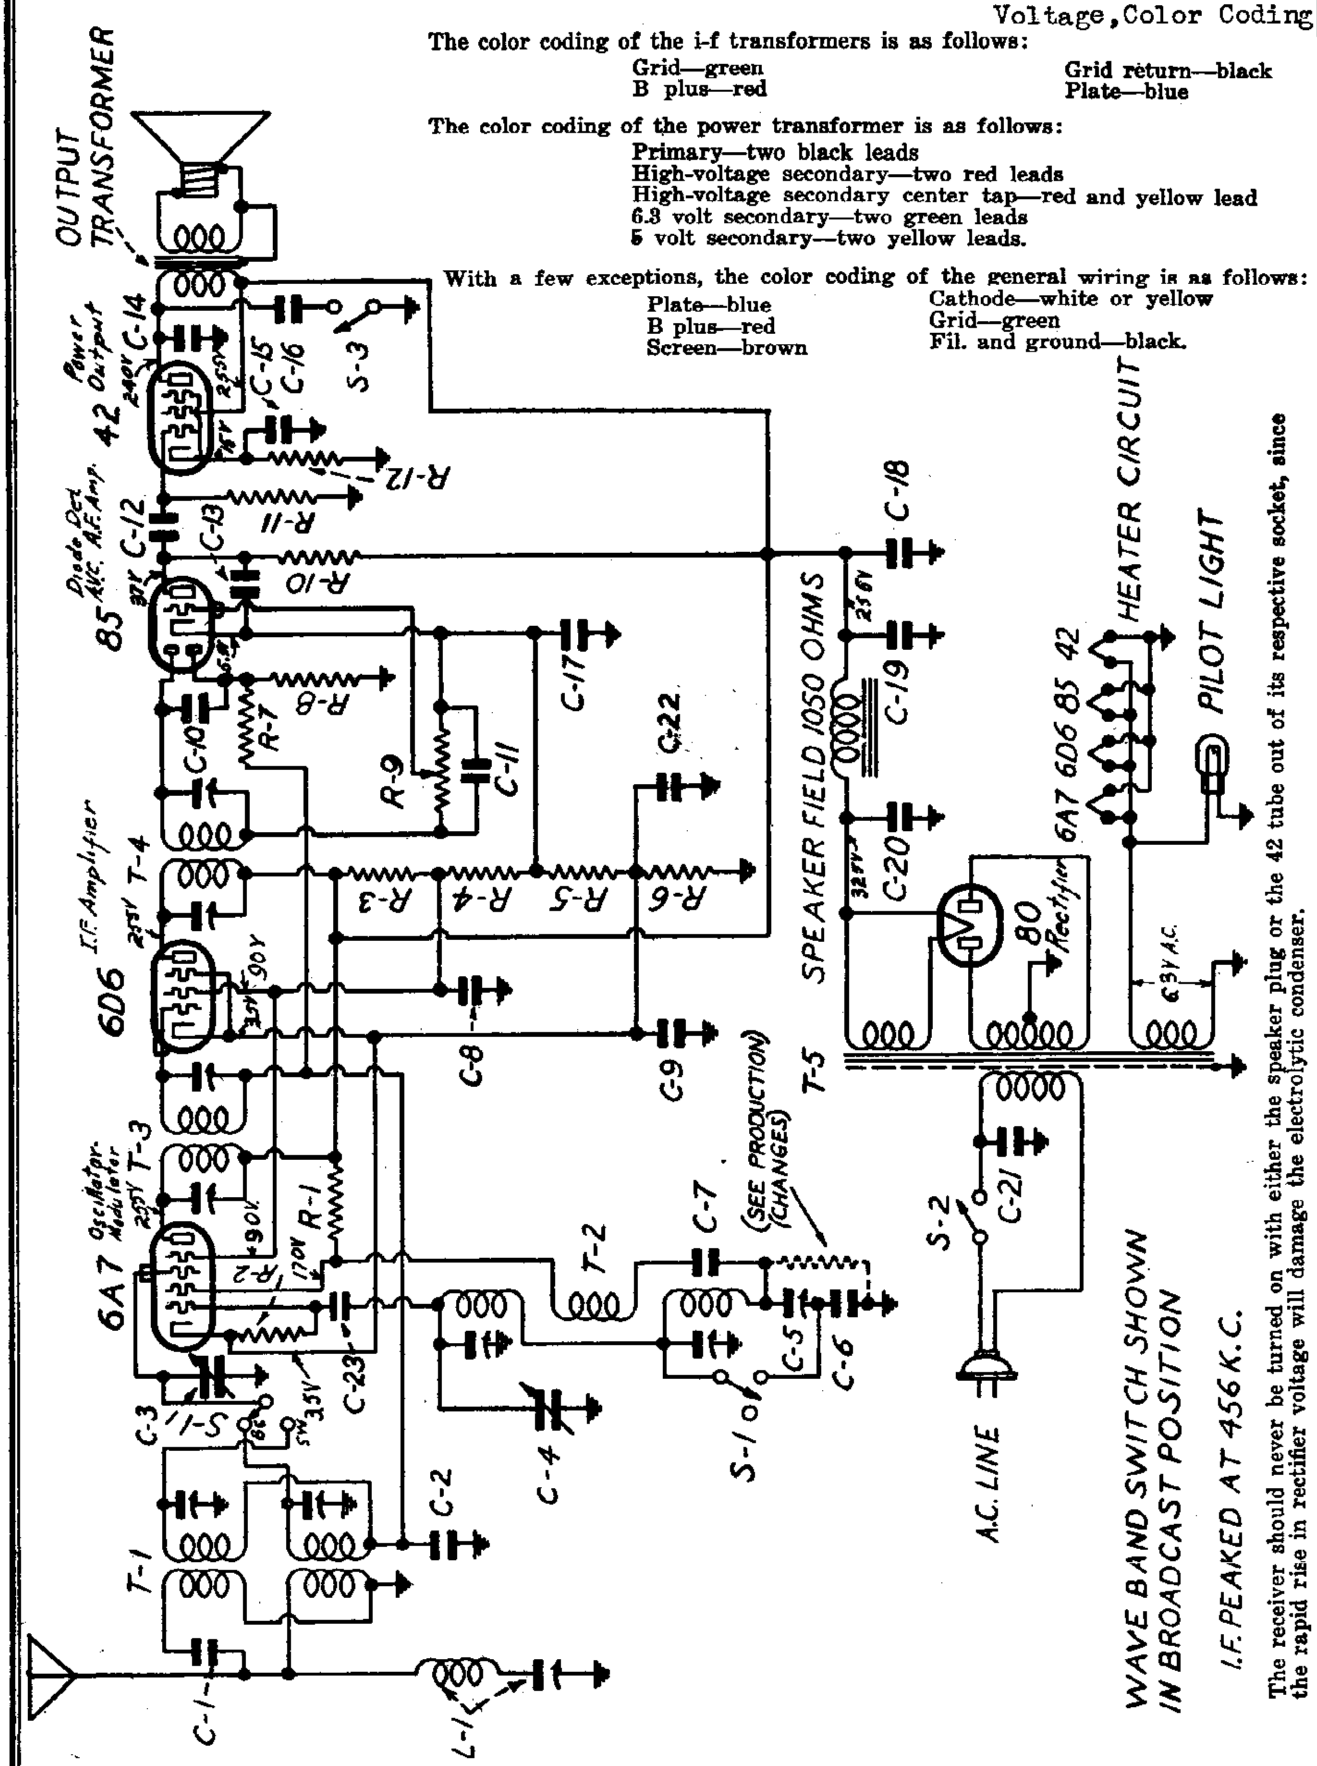
Grid—green
B plus—red
Grid return—black
Plate—blue

The color coding of the power transformer is as follows:

Primary—two black leads
High-voltage secondary—two red leads
High-voltage secondary center tap—red and yellow lead
6.3 volt secondary—two green leads
5 volt secondary—two yellow leads.

With a few exceptions, the color coding of the general wiring is as follows:

Plate—blue
B plus—red
Screen—brown
Cathode—white or yellow
Grid—green
Fil. and ground—black.



The receiver should never be turned on with either the speaker plug or the 42 tube out of its respective socket, since the rapid rise in rectifier voltage will damage the electrolytic condenser.

ADJUSTMENTS

An oscillator with frequencies of 456, 600, 1600 and 6000 kc should be used.
An output meter should be used across the voice coil or output transformer for observing maximum response.
If the circuit is at all disturbed, both the broadcast and short-wave bands must be realigned.

Location of Coils and Trimmer Adjustments

The two i-f transformers are located on top of the chassis deck. The second i-f is the one directly behind the variable condenser. The four trimmers, two for each transformer, are accessible through holes in the tops of the cans.

The 456 kc wave trap is located on top of the chassis deck between the 6A7 tube and the first i-f transformer.

The adjustable padding condenser for the broadcast band is mounted underneath the chassis (in the corner near the 6A7 tube) with the screw adjustment accessible through a hole in the top of the chassis.

The antenna coils for the broadcast and short-wave bands are wound on one form and mounted underneath the chassis deck directly behind the adjustable padding condenser. The trimmers for these coils are also accessible through holes in the top of the chassis. The trimmer nearest the front of the chassis is the short-wave antenna trimmer. The trimmer farthest from the front of the chassis is the broadcast antenna trimmer.

The oscillator coils for the broadcast and short-wave bands are wound on one form and mounted underneath the chassis deck near the variable condenser. The trimmers for these coils are accessible through holes in the top of the chassis. The trimmer nearest the front of the chassis is for the short-wave oscillator coil and the trimmer farthest from the front is for the broadcast oscillator coil.

I-f and Wave-trap Alignment

Rotate the wave-band switch to the broadcast position, clockwise. Set the variable condenser at the minimum capacity position and feed 456 kc to the grid cap of the 6A7 tube. Adjust the four i-f trimmers for maximum response. Feed 456 kc to the antenna lead and adjust the wave-trap trimmer (mounted on wave-trap) for *minimum response.*

Short-wave Alignment (Alignment of the short-wave band should precede broadcast alignment)

Use a 400 ohm dummy antenna (a 400 ohm resistor in series with the test oscillator antenna lead) in aligning the short-wave coils. Rotate the wave-band switch to the short-wave position (counter-clockwise) and set the dial pointer exactly at 6 megacycles. Feed 6000 kc and adjust the short-wave oscillator trimmer (closest to front beside the variable condenser) for maximum response and then adjust the antenna trimmer (left side of top of chassis, closest to front). Be very careful to choose the minimum capacity peak on the oscillator trimmer. (See General Instructions below.)

Broadcast Alignment

Use a standard dummy antenna in aligning the broadcast coils. (A .0002 condenser may be used as a substitute.) Rotate the wave-band switch to the broadcast position, clockwise. Set the dial pointer at 600 and feed 600 kc. Adjust the broadcast series padder (in corner near 6A7 tube) for maximum response. Move the dial pointer to 1600 and feed 1600 kc. Adjust the broadcast oscillator trimmer (farthest from front beside the variable condenser) for maximum response and then adjust the broadcast antenna trimmer (farthest from front at left side of chassis). Return pointer to 600, feed 600 kc and readjust the broadcast series padder, rocking the variable condenser (rotate the variable condenser shaft back and forth through a small arc) for maximum response.

GENERAL INSTRUCTIONS

The set's oscillator is higher in frequency than the signal, so images should be observed on the low frequency side of the signals.

Always choose the minimum capacity peak on oscillator trimmers and maximum capacity peaks on antenna trimmers. The last motion in adjusting trimmers should always be a tightening one, not a loosening one.

Never leave a trimmer with the outside plate so loose that there is no tension on the screw. Either bend the plate up or remove the screw entirely.

Always use as weak a test signal as possible during alignment.

PRODUCTION CHANGES

In early production:

a. Airplane dial was part number 2ND-34 and had a grey dial face. Later dial, part number 2ND-34B, has a black dial face.

b. C19 and C20 were each 12 mf, 450 volt electrolytics.

c. R2 was originally in position indicated by dotted lines. It was later placed across the oscillator grid and cathode of the 6A7 tube (as now shown in the schematic) and at the same time C23 was added and C22 omitted.

The adjustable padding condenser for the broadcast band is mounted underneath the chassis (in the corner near the wave-band switch) with the screw adjustment accessible through a hole in the top of the chassis. The short-wave band has a fixed padder which is a 1350 mmf molded mica condenser. (Note that this condenser is coded 1300 mmf.) When replacing this fixed padder be careful to use a condenser which has a capacity within 2% of 1350 mmf, otherwise the short-wave coils may not track.

WESTINGHOUSE RADIO MODEL WR-306

LINE-UP CAPACITOR ADJUSTMENTS

CAUTION: DO NOT INTERFERE WITH THE I.F. ALIGNMENT OF THIS RECEIVER EXCEPT WHEN IT HAS BEEN ABSOLUTELY DETERMINED THAT THIS IS THE CAUSE OF THE TROUBLE AND ONLY WHEN HIGH GRADE TESTING EQUIPMENT IS TO BE USED.

To align the circuits of this receiver it is essential to use a high grade modulated test oscillator, the output of which can be continuously varied with absence from overload when the individual circuits of the receiver are brought into alignment. A conventional output meter can be connected across the terminals of the speaker voice coil to indicate when the circuits are aligned. The sensitivity of the output meter must be sufficient to give satisfactory reading with a low input signal.

Before attempting to align the receiver, the service man should familiarize himself with the general layout of the chassis, the location of the tubes and various alignment condensers. Top and bottom views of the chassis are shown in figures #2, #3, and #4 and should be carefully studied before the actual work is started.

ADJUSTMENT OF I.F. (465 K.C.)

NOTE: BECAUSE OF THE VARIABLE SELECTIVITY INCORPORATED IN THIS RECEIVER, IT IS IMPORTANT THAT THE PROCEDURE OUTLINED BELOW BE FOLLOWED IN ORDER TO OBTAIN ACCURATE ALIGNMENT.

THE I.F. TRIMMERS ARE ADJUSTED ONLY WHEN THE VARIABLE SELECTOR COILS ARE PLACED IN A PARTICULAR MECHANICAL POSITION.

TO PROPERLY SET THE I.F. TRANSFORMERS, TURN THE FIDELITY CONTROL TO THE EXTREME RIGHT [illegible]. ADJUST THE PULLEY [illegible] OF THE TWO VARIABLE I.F. COILS IN A [illegible]R-CLOCKWISE DIRECTION [illegible]T THE STOPS. THIS IS [illegible] UP THE CORDS WHICH [illegible].

[illegible] DESIGNED THAT THE SENSITIVITY [illegible] VER CHANGES VERY LITTLE [illegible] SELECTIVITY TO MAXIMUM [illegible] TO ALIGN THE CIRCUITS [illegible]SSARY TO HAVE LESS [illegible]VIDUAL I.F. TRANSFORMER [illegible] PROVIDED BY THE MAXIMUM SELECTIVITY [illegible]NG.

[illegible] THIS LESSER COUPLING MERELY TURN [illegible] (INDICATED BY "W" IN FIGURE #3), [illegible] AS A STOP TO LIMIT SELECTIVITY, OUT ABOUT 1/4 INCH FROM ITS ORIGINAL SETTING. THIS ALLOWS A MOVEMENT OF THE VARIABLE COILS WHICH PUTS THE RECEIVER IN A VERY SELECTIVE BUT LESS SENSITIVE CONDITION. WITH THE CONTROL IN THIS POSITION ALIGN THE I.F. STAGES AS FOLLOWS:

1. Set volume control on full and connect output meter across voice coil of speaker.
2. Set test oscillator to 465 K.C. and adjust its output to produce a measurable reading on output meter when test signal is applied to the grid of the 2nd I.F. tube (6K7) thru a .5 mfd. blocking condensor.
3. Adjust trimmer #76 to maximum output, reducing output of test oscillator as required.
4. Apply test signal to grid of 1st I.F. tube (6K7) and adjust #63 and #65 to maximum output.
5. Apply test signal to grid of 1st detector (6A8) and adjust #54 and #56 to maximum output.
6. After the above I.F. adjustments have been made, replace the stop-screw to original position.

ADJUSTMENT OF PURPLE BAND

Note: During all of the subsequent adjustments, the selectivity control should be turned to the left or counter-clockwise direction.

1. Set wave-change switch to the purple band position.
2. Set test oscillator and dial indicator to 350 K.C. and apply test signal to antenna terminal of the chassis thru a .0002 mfd. series condenser and adjust #34, #26 and #8 to maximum output.
3. Set test oscillator and dial indicator to 130 K.C. and adjust #45 to maximum output.
4. Return to 350 K.C. setting with both test oscillator and dial indicator and repeat adjustment of #36, #26 and #8 for accuracy.

ADJUSTMENT OF BROADCAST BAND

1. Set wave-change switch to White or Broadcast Band position.
2. Set test oscillator and dial indicator to 1500 K.C. and adjust #37, #21 and #7 to maximum output.
3. Set test oscillator and dial indicator to 570 K.C. and adjust #44 to maximum output.
4. Return to 1500 K.C. setting and make readjustment of #37, #21 and #7.

ADJUSTMENT OF GREEN BAND

Note: In adjusting the Green and Red Bands, a .0002 mfd. condenser and a 400 ohms resistor connected in series should be inserted in the high side of the test oscillator leads. This condenser-resistor combination is the approximate equivalent of a short wave antenna.

1. Set wave-change switch to the Green Band position.
2. Set test oscillator and dial indicator to 5500 K.C. and adjust #35, #19 and #5 to maximum output.
3. Set test oscillator and dial indicator to 1900 K.C. and adjust #43 to maximum output.
4. Return to 5500 K.C. setting and make readjustment of #35, #19 and #6.

ADJUSTMENT OF RED BAND

1. Set wave-change switch to Red Band position.
2. Set test oscillator and dial indicator to 17000 K.C. and adjust #34, #18 and #5 to maximum output.
3. Set test oscillator and dial indicator to 6000 K.C. and adjust #42 to maximum output.
4. Return to 17000 K.C. setting and make readjustment of #34, #18 and #5.

Note: The adjustment of the two short-wave oscillator lag condensers (#42 and #43) is best made by the max-max. method. This is done as follows:

Tune the receiver with the left hand by means of the tuning knob and adjust the lag condenser in either direction and then without changing it, tune the receiver thru a maximum, noting reading of the output meter. Change the lag condenser further in the same direction, return receiver and note reading. If output drops with second adjustment, reverse direction of the adjustment of lag condenser. Continue this type of trial and error adjustment until no further improvement can be made when either the tuning control or the lag condenser are changed. While this procedure may appear difficult, facility can be easily acquired by practice and the operation requires only a few minutes.

IMPORTANT: WHILE TESTING OR MAKING REPAIRS ON THIS RECEIVER, THE CHASSIS SHOULD NOT BE TURNED UPSIDE DOWN OR ON ITS SIDE FOR ANY LONG PERIOD OF TIME WHILE THE SET IS TURNED ON AS THE CHEMICALS IN THE ELECTROLYTIC FILTER CONDENSER WILL COME OUT THRU THE AIR VENTS MAKING THE CONDENSER APPEAR TO BE DEFECTIVE. IF LEFT IN THIS POSITION TOO LO[illegible] MAY BE INJURED.

SERVICE PARTS LIST

Dia. #	Part #	Description of Parts	List Price
1	CG 9529	Variable condenser assembly	$ 4.25
2	RE 9529	300 ohms ¼ W. resistor	.10

GENERAL DESCRIPTION

This model is a ten tube, four band superheterodyne receiver designed for world wide reception including the U.S. Weather Band and employs the new all-metal tubes.

The circuit employs a high frequency amplifier using the new type 6K7 tube. This is followed by the first detector circuit employing a 6A8 tube and a separate oscillator (type 6C5). These tubes with their associated circuits (coils, variable condensers, trim condensers for R.F. and detector stages, and trim and lag condensers for the oscillators) comprise a complete assembly in compact form separately cushioned from the main chassis. This assembly is known as the "Precision Tuner". In addition the set includes a new and novel development of intermediate frequency circuits which allows the adjustment of the band width of the amplifier to be varied over a wide range. At one end of the range is the most selective condition which allows single channel reception even under the influence of powerful nearby stations. At the other end the transmission characteristic of the amplifier is so changed as to allow transmission without attenuation of frequencies up to 7000 cycles on either side of the carrier. As a matter of fact, the amplifier is overcoupled to such a degree that frequencies in the neighborhood of five thousand cycles on either side of the carrier are transmitted at greater efficiency than frequencies close to the carrier. This design is necessary since radio frequency circuits give rise to some side band attenuation, which must be compensated for in the I.F. amplifier. The net result is a smooth transmission curve over the entire band.

From the oscillator the energy passes thru a variable selector I.F. transformer and to a 6K7 amplifier tube. Then thru another variable selector I.F. transformer and to an additional 6K7 amplifier tube. From here further selection takes place in the 3rd I.F. transformer where the energy is passed on to the 2nd detector and A.V.C. diode (type 6H6). After detection there follows a first audio amplifier (type 6F5) and by means of an audio transformer the energy is sent to the power output stage comprising two 6F6 pentode in push-pull. A 5Z3 rectifier supplies the necessary direct current for the tubes.

REMOVING INDIVIDUAL COIL AND SWITCH SECTIONS OF "PRECISION TUNER"

If a component part located underneath the switch and coil assemblies of the "Precision Tuner" has to be replaced or a section of the unit has to be removed for inspection, each section can easily be removed separately. To do this proceed with care as follows:

1. Remove the three coil shields.
2. Remove the two self-tapping screws which fasten the mounting plate of the wave-change switch shaft to the chassis frame. Pull switch shaft straight out.
3. Unsolder the stator and rotor leads from the gang condenser.
4. The fastening screws for the switch sections are located on top of the "Precision Tuner" and are indicated by X, Y, and Z in Figure #3. Remove the corresponding screw.
5. Each individual section can then be pulled out straight.

Note: On the R.F. section, the plate lead from the 6K7 socket will have to be unsoldered from the switch terminal before the section can be removed.

On the oscillator section, the plate lead will have to be unsoldered from the 6C5 socket.

6. After repairs have been made resolder the plate leads mentioned above and replace the section being careful to observe that the slotted holes in the switch bracket line up with the round guide pins on the base plate of the "Precision Tuner". This is IMPORTANT as the switch shaft cannot be inserted if the switch brackets do not line up.
7. Replace the section fastening screw.
8. Resolder the stator and rotor leads on gang condenser.
9. Replace the switch shaft and the mounting fastening screws. When inserting the switch shaft, be careful that all the switch discs are in the same position. Otherwise the switch shaft will not slide in. NEVER force the shaft into the switch discs. If shaft does not slide in freely, examine the position of the slot in each switch disca.
10. Before replacing the coil shields, it might be adviseable to bend the shields slightly to assure that positive contact is made. To do this hold the shield with your two hands using the thumbs and first two fingers as shown in figure #1. Pull out the ends of the shield slightly and at the same time apply a little pressure on the sides of the shield as indicated by the arrows in the drawing. Then replace the shields and observe that they fit tightly. In addition to assuring positive contacts, this will also prevent the shields from rattling.

WILCOX-GAY CORP.

ALIGNMENT- MODELS 3JM6,A15,A16, 3JQ6,A17

APPARATUS:

Signal Generator having output frequencies of from 20 megacycles to 150 kilocycles.
Output Meter.
Small tools such as screwdriver, 1/4" wrench, etc.

GANGING OF INTERMEDIATE FREQUENCY AMPLIFIER:

The signal generator should be adjusted to 175 kilocycles and its output connected directly (no dummy antenna being used) to the grid of the first detector, which is the tube immediately to the righ of the variable condenser when facing chassis. With the volume control in its full-on position, the output of the signal generator should be so adjusted that a medium signal is indicated on the output meter not to exceed 50 volts across the output transformer. The last intermediate frequency transformer should now be adjusted and this adjustment is located on the right rear chassis skirt. After peaking this transformer, care being used to see that the output at no time goes to 50 volts across the primary of the output transformer, the first intermediate frequency transformer, which is that transformer on the right hand front side of chassis, should be trimmed, trimming first the secondary side and then the primary side, which adjustments are the left and right adjustments respectively as facing front of receiver. After ganging the three intermediate frequency adjustments in this manner, they should again be gone over and very carefully peaked.

GANGING OF OSCILLATOR AND PRESELECTOR CIRCUITS:

(Broadcast Band)

The signal generator and scale reading of the receiver should now be set at 1400 kilocycles. The wave change switch, which is th control on the left hand front chassis skirt of the receiver should be turned to its furthest counterclockwise position. The output of the signal generator should be connected to a standard dummy antenn to the frame and antenna lead of the receiver. The oscillator circuit should now be trimmed, which adjustment may be found above the rear gang of the variable condenser until the signal is peaked. The output of the signal generator should be regulated so that this voltage does not exceed 50 volts across the output transformer terminals The signal generator should now be adjusted to 600 kilocycles and the tuning control of the receiver varied in the vicinity at a scale reading of 600 kilocycles to check the reading of the receiver. In

the event this reading is off, the slotted plates of the oscillator condenser gang should be bent in or out until the scale reading is 600 kilocycles. Again adjusting the scale reading and signal generator to 1400 kilocycles, the oscillator adjustment should again be checked to compensate for any change the previous adjustment may have had and the two preselector circuits trimmed to resonance, which adjustments are the center and front adjustments of the variable condenser.

(Foreign Band)

The signal generator should now be adjusted to 15 megacycles and the wave change switch should be turned to its furthest clockwise position. By varying the tuning adjustment of the receiver back and forth in the vicinity of 15 megacycles as indicated on the red scale, the signal should be found in this immediate vicinity. There is no trimming adjustment for this band on the oscillator coil because it was the desire during design to extend the high frequency portion of the tuning range as far as possible. After again peaking in the above manner, the preselector on the froeign band should be adjusted, which adjustment is to be found at the center of the front chassis skirt and is the left adjustment of the two occupying this place. Intermediate points on this band should be checked at 10 and 6 megacycles respectively and any departure from ganging or alignment should be found negligible because after tracking is accomplished on the broadcast band the inductors are held to such a standard that tracking, after alignment at 15 megacycles is achieved, should be very nearly perfect.

(Police Band)

The signal generator should be adjusted to 4 megacycles and the wave change switch adjusted to its middle position. The set should now be tuned in the vicinity of 4 megacycles and the signal centered until peak output obtains. The preselector trimmer which is the right hand adjustment of the two in the center of the front chassis skirt, should be adjusted until a peaked condition of the signal is shown by the output meter.

ALIGNMENT - MODEL 3J4

GANGING OF THE I.F. AMPLIFIER:

The signal generator should be adjusted to 175 kilocycles and its output connected directly (no dummy antenna being used) to the grid of the first detector tube, which is the first tube on the right hand side of the chassis when facing front of chassis. With this connection made and the volume control turned on, the output of the signal generator should be adjusted so that some medium value of output is obtained not to exceed 50 volts across the primary of the output transformer. The last intermediate frequency transformer should now be trimmed to resonance which is accomplished by trimming the adjustment on the left hand rear chassis skirt of the receiver when facing front of chassis. This adjustment should be peaked, being careful to always keep the output of the set so that it is below the above mentioned 50 volts across the primary of the output transformer After peaking this adjustment, the secondary circuit of the first intermediate frequency transformer should be trimmed, which adjustment is the left hand adjustment on the first intermediate frequency transformer, which is that transformer on the rear right hand side of the chassis when facing front of chassis. After peaking this adjustment, the primary circuit of this transformer should be adjusted, which is the right hand adjustment on the transformer just referred to. After peaking the three intermediate frequency transformer adjustments in this manner, they should be again gone over and very carefully peaked.

GANGING OF OSCILLATOR AND PRESELECTOR CIRCUITS:

The frequency of the signal generator and the scale reading of the receiver should be adjusted to 1400 kilocycles. The output of the signal generator should now be adjusted for some medium value and the oscillator section of the variable condenser peaked, which adjustment is the rear adjustment on the variable condenser. While this peaking operation is progressing, the output reading should at no time exceed 50 volts. The two preselector circuits should now be adjusted, which adjustments are the center and front adjustments occurring on the variable condenser, for maximum amplitude, the same care being exercised in keeping the output voltage to a medium value as mentioned above.

GENERAL:

With this receiver, which is a battery receiver, care should be exercised in keeping all terminal voltages very close to specified values. The voltage to the tubes should now exceed two volts by more than 10%, for the tubes used in this receiver are particularly critical to this type of misuse.

ALIGNMENT

Every Zenith receiver is balanced, and the sensitivity measured on accurate crystal controlled signal generators before leaving the factory, and unless a part is changed, or the receiver otherwise altered, the adjustment should not be tampered with.

When alignment is thus required, an accurately calibrated service oscillator and output meter are essential.

The proper procedure is as follows:

MODEL 5M90

"A" Connect the service oscillator output leads to the control grid of the 6A7 tube, and to the chassis. If the oscillator output is a single shielded lead the shield should connect to the chassis.

Connect the output meter across the primary of the speaker transformer.

Set the service oscillator at 456 K.C., and adjust the trimmers on the I F transformers to the point giving the greatest reading on the output meter. These, as well as the following adjustments should be made using as small an output from the signal generator as possible so that the A.V.C. action will be least effective.

"B" Change the service oscillator connection from the grid of the 6A7 to the antenna wire, leaving the other lead attached to the chassis.

Set the service oscillator at 1600 K.C. and rotate the gang condenser until the plates are entirely out of mesh. Adjust the oscillator section trimmer until the 1600 K.C. signal is tuned in.

Change the service oscillator to 1400 K.C. Rotate the gang condenser until this signal is tuned in, and then adjust the ANTENNA trimmer on the gang condenser to the point given the greatest output reading.

"C" Set the service oscillator to 600 K.C., and rock the gang condenser slowly to and fro past the point where this signal is received, meanwhile adjusting the padder condenser for a setting which gives the greatest output reading.

"D" Repeat operation "B".

"E" Reset the service oscillator to 456 K.C., leaving it connected to antenna, and adjust the wave trap trimmer to the point giving the MINIMUM output reading.

MODELS 6-M-90, 6-M-91, 6-M-92

"A" Connect the service oscillator to the control grid of the 6A8 tube and the chassis.

Connect the output meter across the primary of the speaker transformer.

Set the service oscillator to 252.5 K.C., and adjust the trimmers on the I. F. transformers for the greatest output reading. These adjustments should be repeated several times using as weak an input signal as possible so as to obtain greater accuracy.

"B" Change the service oscillator lead from the grid of the 6A8 to the antenna connection. A male Delco Remy connector may be used in making a connection to the antenna lead.

Set the service oscillator at 1400 K.C.

Rotate the gang condenser one and one fourth turns from the minimum setting. At the proper position eight teeth on the tuning gear will be visible past the gear bracket.

Adjust the oscillator, R.F. and antenna trimmers in that order to the point giving the greatest output.

"C" Set the service oscillator at 600 K.C. and rotate the gang condenser to tune in this signal. Move the gang condenser to and fro past the signal meanwhile adjusting the oscillator padder condenser until the combination of adjustments giving the greatest reading of the output meter is obtained.

"D" Repeat operation "B."

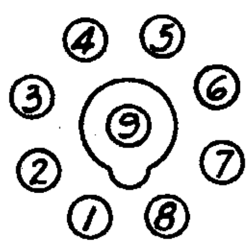
ALIGNMENT MODELS 5-S-29, 5-S-56, Chassis #5513, #5513-A

Alignment



BOTTOM VIEW OF SOCKET

1. Balance I.F. transformers at 252.5 K.C. with test oscillator connected to control grid of 6A8 and ground.
2. Turn band switch to C band. Connect test oscillator to antenna and ground leads. Set test oscillator at 15 Megacycles. Adjust oscillator trimmer on gang condenser for correct dial reading.
3. Adjust detector trimmer (located on top of chassis between front section of gang condenser and coil) for maximum output.
4. Turn band switch to A band. Adjust oscillator trimmer (located on right side underneath chassis) for correct dial reading at 1400 K.C. also adjust preselector and detector trimmers on gang for maximum output.
5. Adjust oscillator padder (next to oscillator section of gang on top of chassis) while rocking pointer back and forth past 600 K.C. to the combination giving greatest output.
6. Recheck 1400 K.C.
7. Repeat entire procedure.

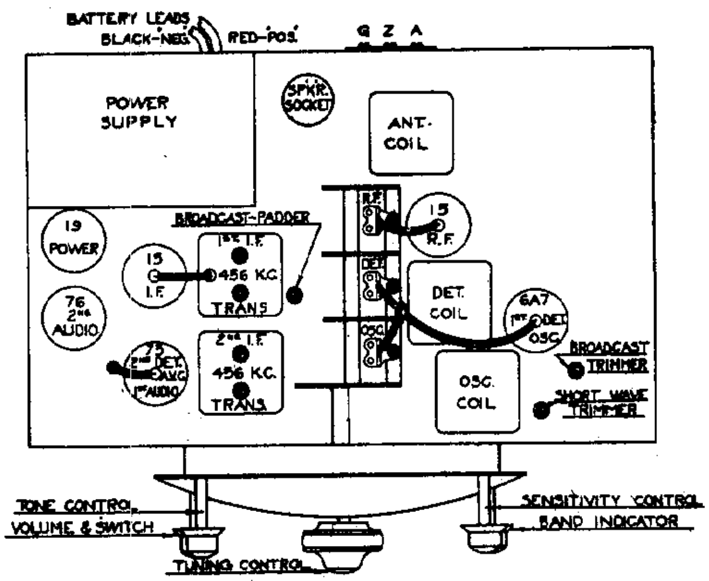
f—filament; k—cathode; g¹—control grid; g²—screen grid; g³—suppressor grid; p—plate.

All voltages measured from socket contacts to ground with 1000 ohm per volt D. C. meter. Antenna and ground disconnected.
Battery Voltage 6V.
Battery Drain 2.2 amperes.
Power Output 2 watts.



TUBE POSITION

CAUTION: Reversal of the battery polarity will damage the filter condensers. The storage battery must be connected as shown above.
NOTE: See bottom page 18 for details of antenna connector strip.

All voltages measured with 1000 ohms per volt D. C. meter.
Total current consumption 8.2 Amperes.
Sensitivity at one watt output 1Mv.
Maximum power output 9 watts at 6 volts.

Voltage at Battery 6V.
Voltage at Switch 5.8V.
Antenna disconnected.

Models 7-M-91S and 7-M-91D. (Chassis No. 5706)

The sensitivity switch should be in the clockwise or sensitive position during adjustment. The output meter may be connected across the voice coil connections at the speaker socket.

"A" Connect the service oscillator to the control grid of the 6A8 tube and the chassis.

Connect the output meter across the primary of the speaker transformer.

Set the service oscillator to 252.5 K.C., and adjust the trimmers on the I. F. transformers for the greatest output reading. These adjustments should be repeated several times using as weak an input signal as possible so as to obtain greater accuracy.

"B" Change the service oscillator lead from the grid of the 6A8 to the antenna connection. A male Delco Remy connector may be used in making a connection to the antenna lead.

Set the service oscillator at 1400 K.C.

Rotate the gang condenser one and one fourth turns from the minimum setting. At the proper position eight teeth on the tuning gear will be visible past the gear bracket.

Adjust the oscillator, R.F. and antenna trimmers in that order to the point giving the greatest output.

"C" Set the service oscillator at 600 K.C. and rotate the gang condenser to tune in this signal. Move the gang condenser to and fro past the signal meanwhile adjusting the oscillator padder condenser until the combination of adjustments giving the greatest reading of the output meter is obtained.

"D" Repeat operation "B."

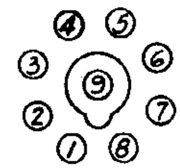
Line Voltage 115 Antenna and Ground Disconnected



BOTTOM VIEW
OF SOCKET

All voltages measured from point indicated to ground, using a 1000 ohm per volt D.C.meter (unless marked otherwise).

Alignment

The use of an accurately calibrated service oscillator is imperative in the alignment of modern superheterodynes. The alignment procedure is as follows:

(1) Connect service oscillator to grid of 6A8 and ground. Balance I.F. trimmers at 456 K.C.
(2) Connect service oscillator to antenna and ground binding posts and set at 6 megacycles. Adjust trimmer on gang for correct dial reading, (6 megacycles on Band B).
(3) Set service oscillator and pointer to 21 megacycles and adjust S.W. trimmer (through hole in top of chassis) for correct dial reading.
(4) Recheck 6 megacycle adjustment.
(5) Set service oscillator and pointer to 1700 K. C. (Band A) and adjust broadcast trimmer (through hole in top of chassis) for correct dial reading.
(6) Set service oscillator at 600 K.C. Adjust broadcast padder (through hole in top of chassis next to I.F.transformer), meanwhile rocking pointer to and fro past 600 K.C. on dial to combination giving greatest output.
(7) Readjust at 1700 K.C.

Note: These adjustments affect each other slightly and the entire procedure should be repeated to secure maximum results.

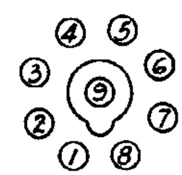
Line voltage 110. Antenna and Ground disconnected.



BOTTOM VIEW
OF SOCKET

All voltages measured from point indicated to ground, using a 1000 ohm per volt D.C.meter (unless marked otherwise).

Alignment

(1) Balance I.F. transformers at 252½ K.C. with test oscillator connected to control grid of 6A8 and ground.
(2) Turn band switch to "C" Band. Connect test oscillator to antenna and ground leads and set for 15 megacycles. Adjust oscillator trimmer on gang condenser to secure correct dial reading.
(3) Adjust detector trimmer (located on bracket on top of detector coil) for maximum output.
(4) Turn band switch to "A" Band. Adjust oscillator trimmer (through hole in top of chassis next to oscillator) for correct dial reading at 1400 K.C. Also adjust preselector and detector trimmers on gang for maximum output.
(5) Adjust oscillator padder (next to oscillator section of gang through hole in top of chassis) while rocking pointer back and forth past 600 K.C. to the combination giving greatest output.
(6) Recheck at 1400 K.C.
(7) Repeat entire procedure.

ZENITH RADIO CORP.

MODELS 91,92
Notes
MODELS 811,862,865
866,1162

Zenith 090,90,V-8

Chassis 2012-4J is used in Models 090,90 and V-8. This chassis is more or less similar to Chassis 2012 and 2012-J that was used in Models AH, CH, and RH, which are shown on the following pages in *Rider's Manuals: page 1-23 in the revised edition; *674-E, in the early edition, and page 2717 in the Rider-Combination Manual.* The circuit changes that were made in Chassis 2012 to make the Chassis 2012-4J are shown below and it is suggested that you make a notation in your Index about the similarity that exists between these two chassis.

The antenna circuit has been revised, as may be seen by comparing Fig. 1 with the schematic of Chassis 2012 on one of the pages mentioned above. Instead of a three-gang condenser (Part No. 22-116), a four-gang condenser is used with the fourth section tuning the antenna winding. (The part number of the four-gang condenser is 22-134.) The winding in the antenna circuit, which is tuned by the fourth section of the new condenser, has been added to the antenna coil assembly. Note that the condensers and resistors in this part of the circuit are the same as those shown in the schematic for the early chassis.

The padder condenser assembly (Part Nos. 22-120 and 22-82) has been replaced with a single variable condenser, Part No. 22-129. Also the 8-mf. filter condenser (Part No. 22-121) mounted at the side of the con-

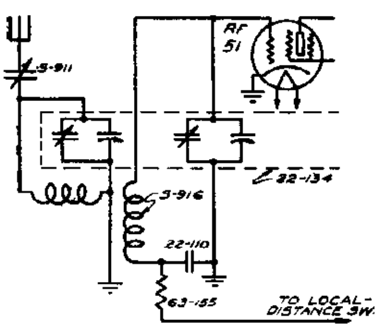

Fig. 1. Antenna circuit of Zenith Chassis 2012-4J shows new connections.

denser gang has been removed and mounted below the chassis. No mounting base is used, and it carries a new part number, 22-136.

Fig. 2 shows the voltage divider, the a.v.c. tube, and the new local-distance switch. Note that the lead marked "To Local-Distance Switch" in Fig. 1 is connected to that lead in Fig. 2 which carries an arrow in the plate circuit of the 24 tube. Note also that the condensers, Part No. 22-99, in the Chassis 2012 have been eliminated, and that the one in the plate circuit of the 24 tube has been replaced with one having a value of 0.03 mf., Part No. 22-111. The value of the resistor connected between the "Local-Distance Switch" and the lead to the tone control (the one at the right of Fig. 2) has a value of 4.5 megohms, Part No. 63-188. The 0.1-mf. condenser, connected between the movable arm of the

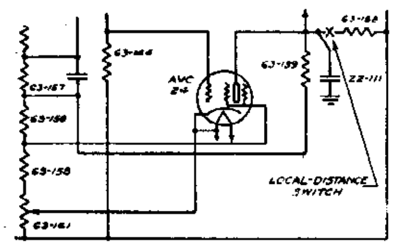

Fig. 2. A "Local-Distance" switch is now included in Zenith Chassis 4012-4J.

volume control and ground, has been eliminated. The part number of this condenser was 22-115.

In other respects the chassis 2012-4J is the same as chassis 2012.

Zenith ZE-12

This power ack, used with Models 39, 39-A, and 40-A, will be found on the following pages in *Rider's Manuals: 1-12 in the revised edition; *665 in the early edition, and 2698 in the Rider-Combination.* The values of some of the resistors and condensers were unavailable at the time of publication and are given below; this data was supplied by a serviceman.

The total resistance of the voltage divider is 7,250 ohms. The resistor designated as Part No. 22-42 is now a part of the voltage divider and a change should be made in your diagram, although the resistor is still connected between the center tap of the 7.5-volt winding and ground. Starting at the top of the diagram, the first section of the divider, *i.e.* down as far as the blue lead, is 1000 ohms. The next section, between the blue and red leads, is 3500 ohms. Between the red lead and ground, 1000 ohms. The section formerly designated as 22-42, is 1750 ohms.

The condenser in the yellow lead to the left of the choke is 2 mf. The one to the right of the choke in the green lead is 4 mf., as is also the one in the blue lead. The condenser in the red lead, shunting the 1000-ohm resistor, is 1 mf.

Zenith 811, 862, 865, 866, 1162

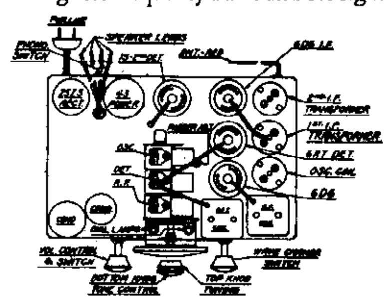
The model 811 (Chassis 5609) employs a 6-inch speaker, Part No. 49-93; models 862 and 1162 (Chassis 5610) use a 12-inch dynamic speaker, Part No. 49-94. The schematic shown on *Zenith page 6-5 in Rider's Volume VI* is used in both of these chassis. Below will be found a sketch showing the locations of the trimmers and the tube sockets.

Alignment:

Balance i-f. transformers at 252.5 kc. with signal generator connected to the grid of the 6A7 and the chassis ground.

Adjust wave-trap padder (located beneath the chassis at rear right side) for weakest signal with 252.5 kc. signal generator connected between antenna and ground.

Turn wave-band switch clockwise to the highest frequency band and set signal



Top view of the Zenith chassis 5609 and 5610, showing tubes and trimmers.

generator to 15 mc., still connected to the antenna and ground. Balance oscillator trimmer on gang condenser for correct dial reading at this frequency.

Turn wave-band switch counter-clockwise to standard broadcast position. Adjust broadcast oscillator trimmer (located beneath the chassis at the right center) for correct dial reading at 1400 kc. and adjust r-f. and 1st detector trimmers on gang condenser for loudest signal.

Set signal generator at 600 kc. Adjust oscillator broadcast padder through hole in top of chassis, simultaneously rocking the dial back and forth, for loudest signal.

Zenith 91, 92

The value of the center-tapped resistor, Part No. 63-210, was omitted from the list of parts shown in Rider's Manuals on pages 2-8, 674-N and 2714. The section connected to the junction of the speaker field and the choke is 2,800 ohms and the section connected to Part No. 63-167 is 10,000 ohms. Please make this addition to the schematic diagram of this set in your Volume II Manual.

BOTTOM VIEW OF SOCKET

Line Voltage 115 Antenna and Ground Disconnected
Voltages measured from point indicated to ground, using a 1000 ohm per volt meter, except heaters. (2-7)

Alignment

The bands are as follows:

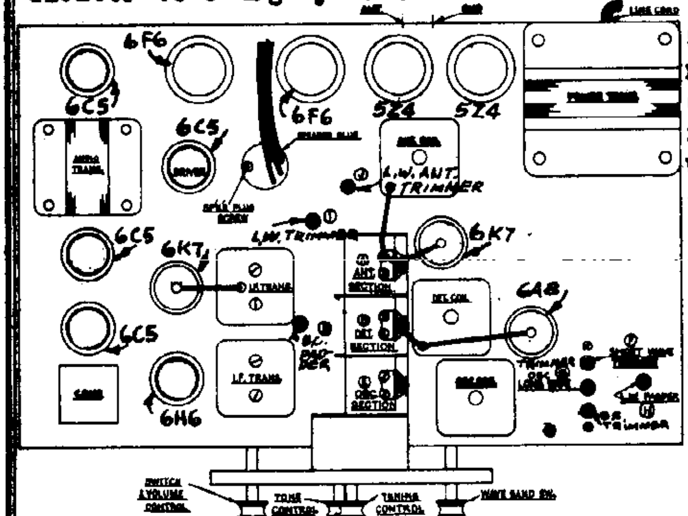
Band	Color	Kilocycles	Megacycles	Meters
A	Green	550-1,740	.55-1.74	545-172
B	"	2,000-7,000	2-7	150-42.8
C	Red	150-370	.15-.37	2,000-800
D	"	7,000-22,500	7-22.5	42.8-13.3

1. Connect service oscillator to grid of 6A8 detector, oscillator tube and peak I.F. trimmers (see diagram Page 3) at 456 K.C.

2. Connect service oscillator to antenna post and set to 1400 K.C. Adjust trimmer A, B and C to resonance with dial indicator to 1400 K.C.

3. Set service oscillator to 600 K.C. and adjust broadcast padder D for maximum gain while rocking dial slowly over 600 K.C.

4. Place band switch on band B (2-7M.C.) and set service oscillator and dial indicator to 6 megacycles.



5. Align D band (7-22.5 megacycles) next by setting service oscillator and dial indicator to 18 megacycles and rocking indicator slowly over that point while adjusting trimmer F to maximum output.

6. Set band switch to C band (long wave) and peak at 350 K.C. with trimmers G, I and J. Turn dial indicator and srvice oscillator to 150 K.C. and adjust long wave padder H while slowly rocking dial indicator.

7. Rebalance again at 6 megacycles and 1400 K.C. as in 2 and 4.

Line Voltage 115   Antenna and Ground Disconnected

Voltages measured from point indicated to ground, using a 1000 ohm per volt meter,except heaters(2 - 7)

Alignment

1. The diagram on page shows position of major components and aligning adjustments. It should be studied carefully before any attempt is made to adjust the various circuits.

2. Set service oscillator to 456 KC, and connect to the grid of the 6A8 tube. The grid cap should not be removed from the tube as this will remove bias. Tune the I.F. transformers for maximum output. Alignment should always be made with the service oscillator set to as low an output as will give a satisfactory indication on the output meter.

3. Connect the service oscillator to the antenna and ground post. With the band switch in the broadcast position, set the dial pointer to 1700 kilocycles, and adjust the oscillator trimmer on the gang condenser for a maximum output. Align the R.F. and detector condenser trimmers, also located on the gang condenser, for a maximum output.

4. Set the dial pointer to 600 kilocycles, and adjust the B.C. padder meanwhile rocking the gang condenser back and forth across 600 kilocycles until the padder setting for maximum output is obtained.. It may be necessary to go back and make a slight correction of the trimmer at 1700 kilocycles after the padder adjustment is completed.

5. Turn the band switch for the "B" band. Rock the gang back and forth across the 6 megacycle readings, meanwhile adjusting the oscillator trimmer on the gang condenser until maximum output is obtained. It will always be found that the dial reading for 6 megacycles is very close to this point. The service oscillator, of course, should be set at 6 megacycles.

6. Align "D" band (7-22.5 megacycles) next by setting service oscillator and dial indicator to 18 megacycles, and rocking indicator slowly over that point while adjusting the S.W. Trimmer to maximum output.

7. Set back to 1700 K.C. Readjust oscillator circuit this time using broadcast trimmer on chassis base.

8. Set band switch to "C" band (long wave) and peak at 350 K.C. with L.W.,R.F.-Det. and Oscillator trimmers. Turn dial indicator and service oscillator to 180 K.C., and adjust long wave padder while slowly rocking dial indicator.

9. Repeat operation #2.

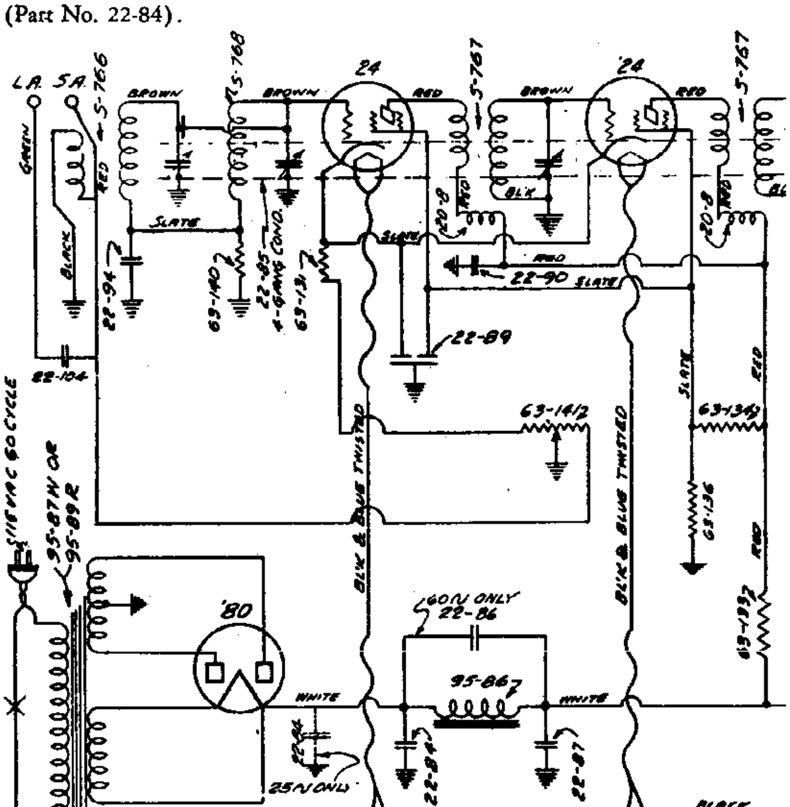
MODELS 430,440

Zenith A, B, C, D, Zenette

Several changes have been made in the improved chassis 2004, which is used in these models. These changes are shown in the accompanying schematic; only a portion of which is shown, as the remainder is the same as the early model.

If you will compare this with the original schematic (see *Zenith page 1-26 in the revised edition; *674-C in the early edition, and page* 2722 *in the Rider-Combination*), it will be seen that the green wire connecting the long antenna terminal to the center tap on the antenna coil, now goes to a condenser, Part No. 22-104, having a value of 0.0001 mf. The other side of this condenser is connected now to one side of the volume control, Part No. 63-141. The other side of the volume control is now connected to the 400-ohm resistor (Part No. 63-131) in the cathode circuit of the first 24, instead of to ground.

The 50,000-ohm resistor (Part No. 63-136) has been added in the screen grid circuits of the first two tubes. Also the 0.1-mf. condenser, across the choke in the power supply circuit, has been added in those receivers using 60-cycle supply. This condenser is omitted in 25-cycle sets and the condenser shown dotted is used instead; the value is 2 mf. (Part No. 22-84).



Partial schematic diagram of Zenith A, B, C, D Zenette showing changes in improved chassis 2004

Zenith Values

Some of the Zenith wiring diagrams in the early Rider Manuals do not show the electrical equivalents for certain parts numbers. While it is true that these receivers are quite old, we feel certain that this information will be found valuable.

Parts Number	Value		Parts Number	Value
22-21	.00025	mfd.	63-31	.35 ohm

Zenith 430, 440

Below will be found the voltage readings for these models, the schematic of which appears in *Rider's Volume III on Zenith page 3-7 and in the Rider-Combination Manual on page 2737.*

Tube	Position	Plate	Cath.	Screen	Suppr.	Plate Current
Z-58	1st R.F.	175	2.2	75	2.2	5.7
Z-58	1st Det.	190	4.5	75	4.5	2.3
Z-56	Osc.	100	0	—	—	3.5
Z-58	1st I.F.	200	2.2	75	2.2	5.5
Z-56	2nd Det.	110	10	—	—	0.3
Z-56	1st A.F.	170	80	—	—	0.8
Z-57	A.V.C.	—	-85	—	-85	—
Z-57	Q.A.V.C.	30	13	75	13	—
Z-59	Driver	190	20	190	190	13
Z-59	Power	195	-70	195	195	22
Z-80	Rect.	360	—	—	—	65

The filament voltage for all tubes, except the rectifier, is 2.5; that of the 80 is 5.0 volts.

Balance the i-f. stage at 175 kc. Condenser gang at 1500 kc. and oscillator padder at 600 kc.

Zenith 250, 260, 272

Below will be found the socket layout for these models, the schematic for which appears on the following pages in *Rider's Manuals: Zenith 3-6 and* 2734 *in the Rider-Combination Manual.*

Socket Voltages

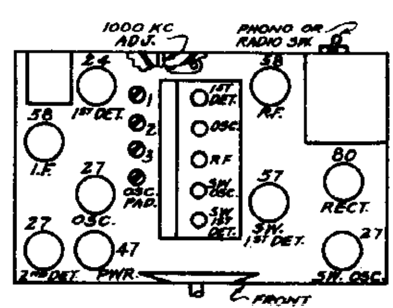
Tube	Position	Plate	Cathode	Screen	Suppressor	Plate MA.
58	R.F.	240	4	110	4	6.2
24	1st Det.	235	8	110	-	.5
57	S-W. 1st Det.	235	6	150	6	.5
27	S-W. Osc.	150	10	—	-	5.
27	Osc.	110	0	—	-	9.
58	I.F.	235	3	110	3	8.
27	2nd Det.	35	4	—	-	1.8
47	O.P.	215	—	230	-	28.
80	Rect.	110 each to ground				34. each

All controls maximum. Line—115 volts. Filament voltage of all tubes 2.4, with exception of 80, which is 5 volts.

Alignment Data:

Broadcast band. I-f. peak is 175 kc. Tuning condenser (three rear sections) 1500 kc. Oscillator padder 600 kc.

S-W. band. Set 1000 kc. adjustment shaft to the center of its tuning range and balance s-w. i-f. trimmers (1, 2, and 3) to 1000 kc. with s-w. oscillator tube removed. Insert tube and place s-w. tuning on scale by adjusting s-w. oscillator trimmer on condenser gang until a station on the 1.5 to 3.75-mc. band is resonated at its corresponding frequency on the dial.



Locations of trimmers and tubes of the Zenith Models 250, 260, and 272.

Circuit Diagram

CALIBRATION. Four sets of coils are used in Standard Model 10s, five sets in Marine Models. The escutcheon on the Wave Changing Switch gives the Megacycle coverage of each band and the Main Tuning Dial shows approximate dialings for frequencies within each band. The bands on the tuning dial are labelled the same as the Wave Changing Switch, so as to facilitate locating the proper scale. The 12-4.3 M.C. and 4.4-1.5 M.C. scales are above the center of the dial, the 20-12 M.C. and 1.6-.54 M.C. (Broadcast Band) below. The top edge of the dial has a standard 0-100 degree scale for use on extra bands and for accurate logging. For details of Band Spread dial calibration, see Band Spreader paragraph, below.

The Antenna Trimmer is to keep the r. f. stage resonant with the detector. Its position will vary somewhat for different dial settings and a careful operator will always check its adjustment on each signal. The right setting is the point at which maximum signal is heard. Two such points may be found if the Trimmer knob is rotated over the entire scale. They are identical,- use either.

When Regeneration is too far advanced (to right) the receiver will oscillate at the resonant Trimmer setting. This makes it difficult to determine the proper Trimmer setting, and a much simpler way to set it right is to proceed as follows. Turn Regeneration and Volume all the way on and set Wave Change Switch at some band other than broadcast, say the 4.4-1.5 M.C. Band. Set the tuning condenser at about 70 degrees on the top scale. Then turn the Trimmer rapidly over a wide arc. A "click" or "thump" should be heard in the speaker. Now place one hand on Regeneration Control and the other on the Trimmer. Keep turning the Trimmer rapidly back and forth across the "click" point, meanwhile gradually reducing Regeneration by turning this control slowly to the left. A point will be reached where the Trimmer will no longer cause a click but instead will bring in a light background hiss. This indicates sensitivity, and means that both Trimmer and Regeneration are at their proper settings. Now turn Main Tuning Dial until signals are heard, then check Trimmer setting on the signals. If a "squeal" is heard on the signal, there is too much regeneration. Always keep regeneration near the "hiss" point.

THE BAND SPREADER. The non-amateur operator will find the Band Spreader useful mainly as a vernier for tuning in short wave stations. For use in this way, set the Band Spread Dial with the needle vertical (at 50). An equal amount of adjustment to right and left will then be obtainable. Short wave stations can be located with Main Tuning Dial, then accurately centered with the Band Spreader.

To the amateur, we offer a receiver having an accurate calibration of the amateur bands. Note that on the dial the letters (A), (B), or (C) appear alongside the meter marking for the band. These letters refer to adjustments which can be made on the Band Spreader cam arm in the rear of the set. Remove the back of the receiver, and note the mechanical action of the Band Spreader. The Band Spread Dial drives a pivot that lifts the tuning condenser extension arm up and down. There are three threaded holes in the cam arm in which the pivot screw with its bakelite washer assembly may be fastened. The one nearest the dial shaft, or center of rotation is "A", the center hole is "B" and the outside one "C". All receivers are shipped with the pivot on "B", which is best for vernicr purposes and fits the 40 and 75 meter bands. The operator can easily change it if one of the other adjustments is desired.

HOW TO GET AN ABSOLUTELY ACCURATE SETTING ON THE BAND SPREADER. Suppose your Xtal is ground for 7050 K.C. (7.05 M.C.) With the pivot on adjustment "B", set the Band Spread Dial on the mark between 7.0 and 7.1 M.C. The Wave Change Switch, of course, should be on the 12-4.3 M.C. Band. Then, with the Main Tuning Dial, tune in the vicinity of 7 M.C. until your own transmitter frequency is picked up. This will give the proper "tank" setting to make the Band Spreader read accurately on this band. The same procedure would of course be followed for any frequency on this band or on the 20 or 75 meter phone bands. If the transmitter frequency does not happen to be an even figure for which there is a dial marking, the position of the Band Spread Dial can be closely estimated.

SPREADING THE WIDE BANDS,- 80 and 160 METERS. On adjustment "C" the Band Spreader covers a little more than half of each wide band. If the Band Spreader is adjusted to "O" on the transmitter

each side of the frequency on the 80 meter band, and 80 K.C. to each side on the 160 meter band. If the station's frequency happens to be at one edge of the band it may be more desirable to set the Band Spreader for the edge also instead of at "O". The wide bands are marked + and - K.C. to indicate the high and low frequency ends of the bands.

Atwater Kent 55

The early type of Model 55—*see A-K page* 3-21 *in Rider's Volume III and page* 159 *in the Rider-Combination Manual*—can be distinguished from the late type—*see A-K page* 3-23 *in Rider's Volume III and page* 161 *in the Rider-Combination Manual*—by the volume control. The first type has a single wire-wound volume contral of 6000 ohms, with the movable arm going to the screen grid of the 1st r-f. tube and the late type has a dual wire-wound and carbon volume control. The wire-wound unit of 6000 ohms has its movable arm connected to the screen grids of the r-f. tubes and the carbon unit of 10,000 ohms is connected in the antenna circuit.

Early or First Type:

This set has only one bleeder resistor, which is connected in series with the positive lead to the volume control. In *early production* of the first type (also known as the Early type) the bleeder is a 6000-ohm tubular resistor No. 15286A (colored purple over the entire resistor) or a 4000-ohm tubular resistor, Part No. 15286B (with a purple band about ¾ inch wide). In later production of the first type Model 55, the bleeder is a 4000-ohm wire-wound resistor, Part No. 16295, which supersedes No. 15286A. No. 15286B is superseded by wire-wound resistor No. 16330.

This set has only one bias resistor and in all cases it is 160 ohms, which value is critical. In early productions of the first type Model 55, the r-f. bias resistor was wound on the same fibre base with the filament-shunt resistor, the part number of the combined unit being 15274. If either section of this unit is found to be defective, remove the resistor and use a No. 16988, 160-ohm resistor as the r-f. bias, and a No. 17077 flexible 10-ohm resistor as the filament shunt. In later production of the first type of Model 55, the r-f. bias resistor is a separate unit and, when defective, should be replaced with a No. 16988 resistor.

Late or Second Type:

This set has two bleeder resistors, which are connected in series with the wire-wound section of the volume control. Bleeder No. 1 (4000 ohms) is in the positive lead to the volume control and bleeder No. 2 (850 ohms) is in the negative lead to the volume control. Bleeder resistor No. 1 is Part No. 16295.

Bleeder resistor No. 2 was made in two different styles. At first it was wound on the same fibre base with the r-f. bias resistor, the part number of the combined unit being 16868. If either section of this unit is defective, remove the resistor and install a No. 16988 as the r-f. bias and a No. 16340 as bleeder No. 2.

Later production of the second type Model 55 used a separate No. 16340 as the No. 2 bleeder.

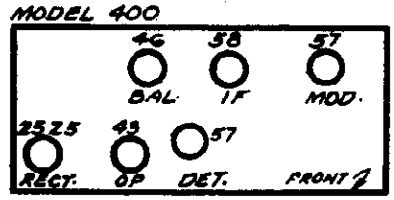
The early production of the second type Model 55 had a combined r-f. bias resistor and bleeder No. 2, the part number of the combined unit being 16868. If either section of the unit becomes defective, remove the unit and replace with a No. 16988 as bias resistor and a No. 16340 as bleeder No. 2.

Later production of the second type Model 55 used a separate No. 16988 as the r-f. resistor.

Majestic 400

The accompanying illustration shows the socket layout for the Majestic Model 400, the schematic diagram

MODEL 400



of which appears on *page* 3-42 *of Rider's Volume III and page* 1234 *of the Rider-Combination Manual.*

Philco Model G-Code 122

Run No. 1. A 25,000-ohm resistor, No. 71, Part No. 3656 has been added. One end is connected to the screen grid lead for the r-f., oscillator and i-f. tubes and the other end is grounded.

Run No. 2. Tuning condenser, No. 4, removed. Part No. 31-1274 added.

Run No. 7. Resistor No. 20 (1,500 ohms) replaced with Part No. 33-3048 (2,000 ohms).

G. E. A-66 and A-86

Please make a note in your *Index to Rider's Volume VI* that the General Electric receiver, Model A-66, uses the same chassis as Models A-64 and A-67. Also that Model A-86 uses the same chassis as Models A-82 and A-87.

G.E. A-70, A-75

On *G. E. page* 6-19 *of Rider's Volume VI* please change the value of the condenser, C-44, in the line between the switch S-6 and the resistor, R-4, in the cathode circuit of the 6A8, from 100 mmf. to 50 mmf.

In the list of replacement parts on *G.E. page* 6-23, delete "RC-235 Capacitor 100 mmf. (C-44)" and substitute for it "RC-210 Capacitor 50 mmf. (C-44) Mica Dielectric". In the stock number column you will find RC-091. Change the C-29 to C-28.

G. E. A-63

If a noisy Model A-63 is found, the trouble may be due to the field coil breaking down to ground. This trouble is not readily apparent, but it should be checked if you come across a very noisy receiver.

Silvertone 1822, 1831, 1824, 1830

A simple circuit change will correct noisy volume controls. Its effect is to remove the d-c. diode current from the volume control and in practically all cases, it will be found that the trouble will be corrected without changing the volume control. However, if the volume control is replaced, the circuit change should be made in addition to prevent noise difficulties.

Connect a 1-megohm resistor across the outer terminals of the tone control, as indicated in Fig. 1, the schematic, and Fig. 2, the wiring diagram.

Unsolder the two leads from the ungrounded outer terminal of the volume control and solder both these leads to one side of a 0.02-mf. condenser. Connect the other side of this condenser to the volume control terminal from which the two leads were removed.

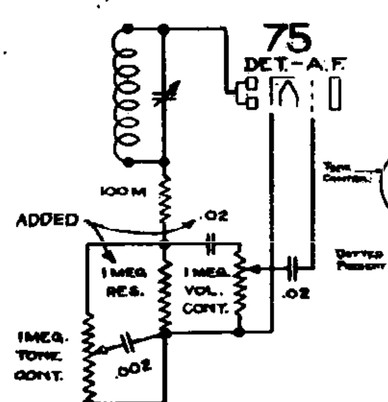


FIG. 1

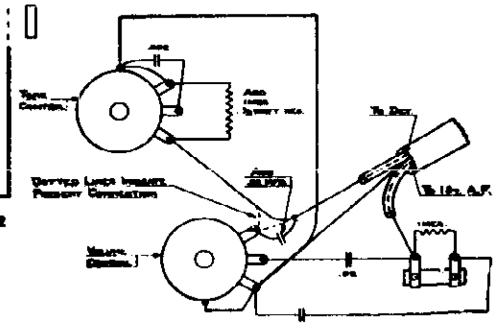

FIG. 2

By the addition of a 1-megohm resistor and a 0.02-mf. condenser, as shown in the diagrams above, noisy volume controls are quieted in these Silvertone sets.

Pilot 93

The Pilot model 93 is shown in Rider's Manual, page Pilot 5-5. Add to the schematic, the information that the i-f. peak is 115 kc. The tube placement is as follows, looking towards the rear of the chassis, with the tuning knob nearest to you: To the right of the 1st i-f. transformer, the 6A7. Between the two i-f. transformers, the 6D6. To the left of the 2nd i-f. unit, the 75 demodulator. Immediately to the left of the speaker transformer, the 25Z5 and on line, but to the rear of the volume control, is the 43 output tube. The i-f. transformers are accessible through the rear of the i-f. cans. The model 93 covers from 545 kc. to 1500 kc. and from 5750 kc. to 15,800 kc. The voltage table, which you should add to the page is as follows:

Tube	Plate	Cathode	Screen	Fil.
Osc.—1st Det	115	3	75	6.3
I-F Amp	115	2.5	75	6.3
2nd Det	50*	1.5	...	6.3
Output	95	15.	105	25.
Rect.	...	135.	...	25.

*Voltage measured through plate resistor.

All plate and screen voltages measured to cathode. All cathode voltages measured to chassis. Speaker field voltage is 110 volts.

The alignment trimmers are placed in various parts of the chassis. Broadcast band alignment trimmers for 1st detector is on side of first section of gang, nearest the front of the set. The pre-selector unit broadcast band trimmer is on the side of the middle gang and the oscillator trimmer for broadcast band is on side of third section. These trimmers are aligned at 1400 kc. The slide wire adjustment is the image suppressor trimmer, aligned at 160 kc. for MINIMUM response. Broadcast band trimmers aligned for maximum response. Short wave trimmer, aligned at 12,000 kc., is located on rear of chassis on line with the phonograph jack. The 600 kc. oscillator trimmer is located on the front of the chassis. To adjust image suppressor, tune the receiver and the test oscillator, feeding into the antenna and ground of receiver, 1630 kilocycles. Slide the wire in or out of the pre-selector circuit until response is MINIMUM. Then repeat alignment of the broadcast band at 1400 kc. for maximum signal.

•

Airline Model 62-153

This Montgomery-Ward receiver is the same as Models 62-124 and 62-129, found on page 5-5 of Rider's Manual, with the exception of the following:

A voltage regulator is incorporated on the chassis, this being mounted in the back left corner by means of a two-prong plug and a receptacle on the chassis. When no regulator unit is employed, the receptacle is covered with a piece of fibre, which is eyeletted in place to protect the jumper wire.

When these sets are shipped with a 3-volt dry "A" battery the regulator unit is in place on the chassis and the initial voltage adjustment has already been made. If the set was originally not equipped with a regulator and it is desired to change from a 2-volt battery to one of 3 volts, the regulator may be inserted by removing the fibre cover, pulling out the jumper wire and inserting the unit by matching up the two-prong plug with the receptacle and pushing down the unit until it rests firmly in the socket. The voltage regulator is connected internally in series with the plus A line.

In some of these sets considerable variation in the type 19 tubes has been experienced with the result that the tone quality has been poor when this tube was operated at a bias of 6 volts. This bias has been changed, therefore, to 4.5 volts, which has been found to be satisfactory in all cases. To effect this change, connect the white battery lead with the "C-6" marker to the —4.5 volt tap on the "C" battery. This lead and the green and yellow lead, with the "—4.5" volt marker, will then be connected to the same —4.5 volt tap on the battery.

•

Airline Models 62-149, 62-155, 62-160, 62-162

These Montgomery-Ward receivers are the same as those described on page 5-3 of Rider's Manuals (Models 62-120, 62-122, 62-126 and 62-128) with the same exceptions as those noted elsewhere for Airline Model 62-153.

•

Belmont 580

Starting with serial number 11501 the following changes have been made in the receiver, whose schematic diagram is shown on Belmont page 2-1 of Rider's Specialized Auto Radio Manual, Volume II:

The cathode and the suppressor grid of the 6D6 tube are now connected to R-3, R-5 and C-5 and so to the cathode of the 6A7 tube, instead of to C-1 and R-2. These last mentioned parts are now out of the circuit.

The value of R-6 has been changed to 19,000 ohms from 12,000 ohms and R-11 from 250,000 ohms to 500,000 ohms.

•

Philco 802

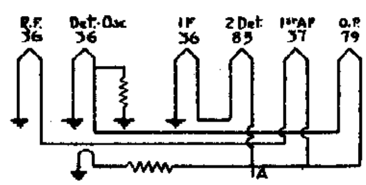
The alignment data for the Philco 802, the schematic of which will be found on Philco page 2-57 of Rider's Specialized Auto Radio Manual, Volume II, is the same as the alignment data for Model 800-Code 12?, which may be found on Philco page 2-56 of the same volume.

Run No. 2. Condenser, No. 52 (50 mmf.) removed and Part No. 30-1032 (250 mmf.) added. Filter choke, Part No. 32-1374 added, being connected in series between pilot lamp, No. 51, and resistor No. 53 and condenser No. 52.

•

Philco 12-Code 122

The original Model 12 was similar to the Model 8, shown on Philco page 3-5 and page 1599 in the Radiotron-Complete Manual, and was properly known as Model 12-Code 121. The later Model 12 is the Model 12-Code 122 and is similar to Model 9, except that it is for 12-volt operation. The tubes, circuit and base arrangement are the same, but the tube heater circuit is that shown in the accompanying illustration. Since 6.3-volt tubes are used,



Heater connections for Philco Model 112—Code 122

a series multiple connection must be used to operate them from a 12-volt battery.

The shunt resistor on the oscillator tube is Part No. 33-3002 and is 21 ohms. The speaker employed is the A-9 and is equipped with a 12-volt field. The Model EE dynamotor is used, supplying 40 milliamperes at 220 volts.

The Model 12 has been designed especially for bus and boat installations, where 12-volt battery systems are employed.

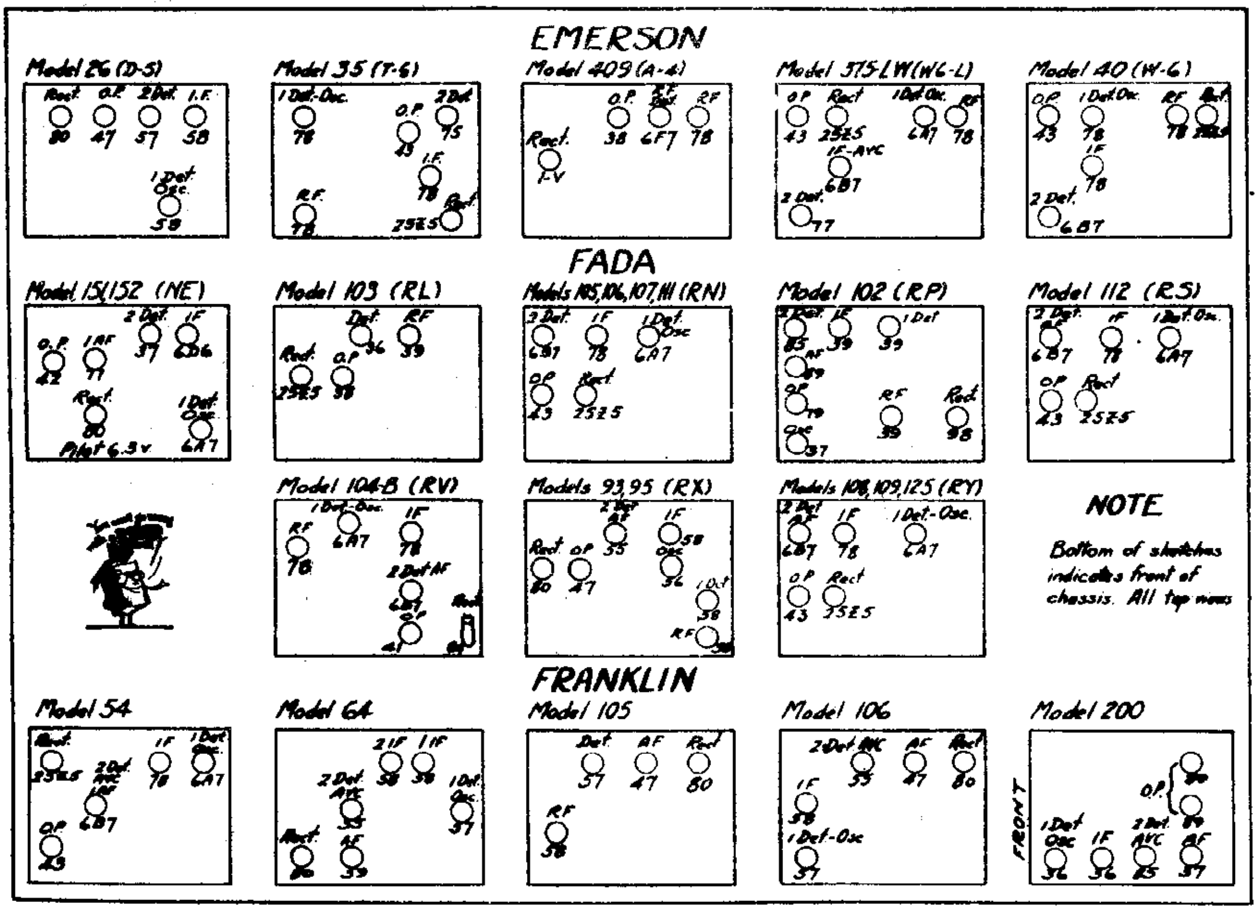
The alignment procedure for the Model 12-Code 122 will be found on Philco page 4-53 in Rider's Manual, Volume V.

•

Philco-Hupmobile H

Run No. 6. The first i-f. transformer, No. 17, replaced with a new type having the same part number. It may be identified by the green paint mark on the fibre. For schematic, see Philco page 2-19, Volume II, Rider's Auto Radio Manual.

•



Emerson, Fada and Franklin Layouts

Below will be found the pages in Rider's Manuals on which the schematic diagrams for the socket layouts given herewith will be found. It is suggested that these layouts be cut out and pasted on the respective pages.

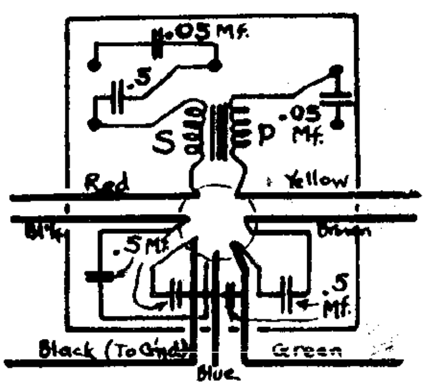
Radiola 66

The schematic diagram of the a-f. transformer and bypass condensers contains incorrect values of capacities. Kindly make the necessary changes from



Corrected values of condensers in Radiola Model 66 a-f. amplifier

the accompanying diagram in the condensers' values in the corresponding diagram in your Manuals, where it will be found on the following pages: 1-42, *499 and 1883 in the Radiotron-Complete.

Missing I-F. Peaks

Please add to page Franklin 3-1, the reference that the model 100 and the model 102 employ an i-f. peak of 175 kc.

On Galvin page 3-7 in Rider's Manual, add the data that the i-f. peak is 175 kc. This is the model 7T-47-A. Add the same data onto page Galvin 3-15, covering the model 61. Also add the same information onto Galvin page 3-13 and 3-14 in Rider's Manual, Volume III. This applies to the model 88.

●

Airline Model 62-165

This Montgomery-Ward receiver is the same as Models 62-132 and 62-137, described on page 5-8 of Rider's Manuals, with the following exception:

Part No. 98006, a three-section wire-wound resistor, has been replaced with Part No. 98006A, a resistor of the same type. The new resistor has the same resistance values, the only change being in the 6,000-ohm section (R-14), where a heavier and different wire is now used. This change was made because of breakage being encountered in this section in some of the early resistors. It is suggested that this section of the resistor be checked if this chassis is serviced. In the case of complete receivers in stock, it is NOT necessary to change this unit.

If in servicing, this section is found to be open, a complete new three-section unit or a separate 6,000-ohm, 1.5 watt, carbon resistor may be used for replacement. Should a separate unit be used, be sure NOT to use the end connection on the old three-section unit when making this repair, as the old 6,000-ohm section may be open intermittently. Unsolder all the wires which are connected to the end of the candohm resistor and resolder them to one end of the carbon replacement resistor.

●

Pilot 114 and 115

The intermediate frequency used in these receivers is 456 kc.

I-F Peaks

We suggest that you make note of the i-f peaks given in the accompanying table upon the correct pages in the Rider Manuals. These peak frequencies were not available when the schematic wiring diagrams were first published and we trust that you were not greatly inconvenienced.

Sparton 80, 83, 84, 85-X, 86-X

In some of the early receivers of this model, the resistor R-13, designated as 5,000 ohms, was 3,000 ohms. If this resistor burns out, check the condenser C-8, located in the plate-voltage supply lead to the r-f. tube. The early production used a 200-volt, .2-mfd. unit for C-8. If replacement is necessary, replace with a 600-volt unit. This receiver is shown on page Sparton 5-15 in Rider's Volume V.

●

Sparton 16-AW, 26-AW, 60, 28

The intermediate frequency of the converter used in these receivers is 900 kc. This data is omitted from the schematic shown on pages 2-10, 2-11 and 2-16 in the Sparton section in Rider's Volume II. The same frequency applies to the model 60 converter shown on page 2259 of the Rider-Radiotron Combination, page 2-39 in the revised Rider II, and on page 568-X-8 of the early Rider II. The model 28 employs 172.5 kc.

●

Silvertone 1806, 1823, 1829

Failure of the tuning meter to change its reading as a station is tuned in, together with failure of the AVC may be due to the following cause:

The lock washer under the screws that mount the No. 3 and No. 4 band short-wave coils to their trimmers may short to the stator plate of these trimmers. Although the likelihood is less, it is also possible for the lock washer to short to the movable plate of the trimmer, in which case the receiver will not operate.

If the tuning meter fails to function properly in these models (except 1806 which has no meter) or if the AVC fails to operate, examine the mounting of these coils to their condensers under the chassis. The trouble can be eliminated by loosening the screw, pushing the lock washer away from the condenser and then tightening the screw while holding the lock washer in this position. Service data covering these receivers appears on pages 5-35 and 5-36 in the Sears-Roebuck section in Rider's Volume V.

●

Philco Model 38, Code 123 Changes

In Run No. 7 a 0.1 mf. condenser (part No. 30-4122) was connected between the plus terminal of the 30 tube (1st A-F.) socket and ground. In Run No. 8 and thereafter, this becomes a 0.25 mf. tubular condenser (part No. 30-4146). This condenser acts as a by-pass and prevents oscillation. The schematic diagram of Model 38 will be found on page 4-22 of Rider's Manual.

Effective with run No. 9 a change in the volume control will be made. The value of the new volume control, which is Part No. 33-5094, is the same as before, i.e., 20,000 ohms; however, the lead from the antenna series condenser (40) will be connected to the arm of the control instead of the upper end, which now will be open. Also a by-pass condenser, Part No. 6287K (0.15 mf. bakelite block) will be added from the lower end of the volume control to ground. These changes produce quieter operation of the set.

Colonial Model 657

In later production runs, the pilot light circuit has been changed. See schematic diagram on Colonial page 5-40, Rider's Volume V. In place of the two 115-volt pilot lamps, a 50-ohm center-tapped resistor has been connected in the heater circuit between the 25Z5 and the 6A7. A 6.3-volt lamp (part No. R-2288) is connected across each half of this resistor. The sockets for these lamps with brackets are parts numbers R-10373-A and R-10363-F and are mounted on the variable condenser and volume control brackets respectively.

●

Colonial Models 651, 655, 657

In the sketches supplied by the manufacturer showing locations of the trimmers which will be found reproduced on Colonial pages 5-27, 5-35 and 5-40 for models 651, 655 and 657 respectively, the coil marked "Short Wave Antenna Coil" should in each case be marked "Broadcast Antenna Coil."

●

Midwest 16-34

Procedure for rebalancing the Midwest 16 tube, 1934 model is as follows: Peak the 1st, 2nd, and 3rd i-f. transformers at 450 kc. to maximum a-f. output. Do not measure the AVC voltage as is usually done. Trim the small AVC amplifier to maximum a-f. output.

Turn wave change switch to M position and dial to 12 mc. Adjust trimmers in oscillator and mixer section. (See *Midwest page 6-11 in Rider's Volume VI* for locations of trimmers.) Set switch to L position and adjust trimmers in r-f., mixer and oscillator sections at 4.5 mc. Turn dial to 1.6 mc. and adjust padder in oscillator section. Turn switch to A position and adjust trimmers in r-f., mixer, and oscillator sections at 1500 kc. Adjust A padder at 530 kc. Turn switch to E position and adjust trimmers in the r-f. oscillator and mixer sections to 370 kc. Adjust E oscillator padder to 160 kc. On H band no adjustment can be made, as this is done at the factory by spacing the turns.

The schematic diagram of this receiver will be found on *page 6-7, 6-8 of Rider's Volume VI.*

●

General Motors 251

The condenser, C-9, in the antenna circuit of the schematic diagram shown in *Rider's Volume II on page 2-9 in the revised edition and page 346-G in the early edition, and in the Rider-Combination page 1099,* should be marked C-7. This condenser has a value of 0.01 mf. Please make this change on the diagram in your Manual.

Wilcox-Gay 4G7, 4H11, 4J6, 4JA6, 4JB6, 4JC6 Alignment

The following alignment instructions apply to the above models *in toto,* with the exception of Models 4JA6 and 4JB6. When aligning either of these two models, disregard that part of the instructions pertaining to the No. 5 Long-Wave Band. Schematics and other data will be found on the following pages in *Rider's Volume VI* for the respective models: *4G7, 6-5; 4H11, 6-6; 4JA6 and 4JB6, 6-3; 4J6 and 4JC6, 6-4.*

I-F. Amplifier:

Set signal generator to 456 kc. and connect output to grid of first detector. Use minimum signal input consistent with proper indication. The first i-f. transformer is the one furthest to the left at the rear of the set. These two circuits should be tuned for maximum amplitude. After ganging the first transformer, the second one should be ganged, and then the third, which is the transformer in back of the variable condenser.

Ganging Oscillator and Preselector Circuits Broadcast Band:

Connect the output of the signal generator to the antenna and ground posts of the set through a dummy antenna. Set the signal generator at 1400 kc., the wave change switch to its fourth position and the tuning dial set so that No. 4 band reads 1400 kc. At this point the trimmer on the first section of the variable condenser should be adjusted. Then the two preselector trimmers on the second and rear sections of the variable condenser should be trimmed for maximum output. Change the signal generator and dial of the set to read 600 kc. and vary the reciprocal trimmer for the broadcast band, which is the left upper of the four trimmers on the front of the chassis, until the 600-kc. signal is indicated on the output meter. Tune the signal generator and the receiver again to 1400 kc. and retune the trimmer on the first section of the condenser for maximum amplitude at 1400 kc. Check the sensitivity at 1000 kc.

Police Band No. 3

Set wave band switch to No. 3 position, signal generator to 4 mc. Adjust upper trimming adjustment to the right of the wave change switch. Then adjust signal generator and receiver to 1.5 mc. and the left lower trimmer to the left of the wave change switch should be adjusted for maximum output. Reset to 4 mc. and recheck.

No. 2 Band:

Set wave change switch to the No. 2 position. Set signal generator to 10 mc. and the dial in the vicinity of this frequency. The center trimmer to the right of the wave change switch should be adjusted for maximum amplitude. Tune generator and set to 4 mc. and adjust the left lower trimmer on the left side of the wave change switch for maximum output.

No. 1 Band:

Set wave change switch to No. 1 position, signal generator to 20 mc. Adjust dial to vicinity of 20 mc. for maximum output and then vary the lower adjustment to the right of the wave change switch on the front of the chassis for maximum amplitude.

No. 5 Long Wave Band:

Adjust signal generator and receiver to 350 kc. and the wave change switch to No. 5 position. Adjust the left-hand trimmer of the three occurring immediately to the left of the variable condenser on the chassis top, until the signal is maximum. Afterwards the two adjustments immediately to the right of this adjustment should be trimmed for maximum amplitude. The generator and the dial should be set to 150 kc. and the adjustment furthest to the left above and to the left of the wave change switch should be adjusted for peak signal. Check again at 350 kc.

Tuning the Trap:

Set signal generator to 450 kc. and its output to antenna and ground. Its output should be a fairly high level. The trimming adjustment on the trap, which is the one immediately to the right of the first detector, should be trimmed for minimum response.

●

Packard Bell 45 M

To align this receiver proceed as follows: Have the variable condenser plates fully meshed. Set signal generator to 460 kc., the i-f. peak. Connect the output of the generator to the control grid of the 6A8 tube (top cap). Adjust trimmers on i-f. transformers for maximum gain. Tune the generator to 1700 kc. and the receiver to approximately the same frequency and adjust the trimmers of the oscillator and modulator condensers for maximum output. Be sure that the wave change switch is turned to the right. In case the receiver will not track, tune the generator to 1400 kc. and readjust for maximum output. The adjustments for 1000 and 600 kc. are made by bending the outside rotor plates of the gang condenser. Then turn the wave-change switch to the left and tune the signal generator to 18 mc. Adjust the trimmer condensers of the short-wave oscillator and modulator coils for maximum output. The adjustment at 6 mc. will have to be made by spacing turns of these two coils, but unless the receiver has been tampered with, it is unlikely that this adjustment will have to be made.

The schematic diagram for this receiver will be found on *page 6-4 of Rider's Volume VI.*

●

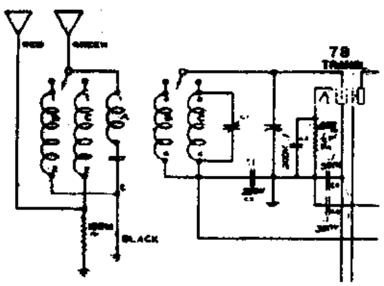
Packard Bell 35

The alignment of this receiver is as follows: Set signal generator to 460 kc., the i-f. peak, and the volume control full on. Set variable condenser with the plates fully meshed. Adjust the i-f. trimmers, directly beneath the variable condenser, for maximum output. Then tune the signal generator to 1700 kc. and adjust the trimmers on the variable condenser for maximum output. The adjustments at 1000 kc. and 600 kc. will have to be made by bending the outside rotor plates of the variable condensers for maximum signal.

The schematic will be found on *page 6-4 of Rider's Volume VI.*

Colonial 603

Changes have been made in the antenna circuit of this receiver, the schematic of which will be found on



Circuit change in Colonial 603

Colonial page 5-19 of Rider's Volume V. The new circuit is shown in the accompanying illustration. The rest of the wiring remains unchanged.

Colonial 656

In the schematic diagram of this circuit, appearing on *page 5-37 of Rider's Volume V*, the third section of the gang condenser was omitted in the antenna circuit, only the trimmer being shown. Please draw in on the above-mentioned schematic a variable condenser shunted across the trimmer, appearing in the extreme upper left-hand corner of the diagram.

The fixed condenser shunted across the 3000-ohm resistor in the cathode circuit of the 75 tube has a value of 0.1 mf. Please mark this in opposite this condenser.

The value of the resistor connected between the 500,000-ohm receiver in the grid circuit of the 42 tube and the junction of the speaker field and the 350-ohm resistor, has been changed from 4000 to 5000 ohms.

RCA D7-7

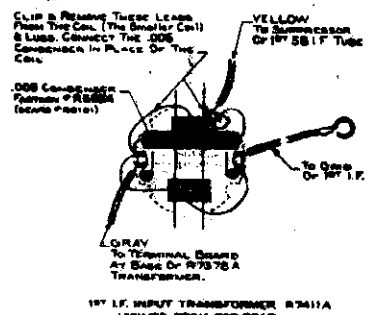
In some sets bearing the above model number, the value of the resistor, R-5, is 12,000 ohms. This ordinarily is 33,000 ohms. The resistor is connected between the screen grid of the 6K7 i-f. amplifier, and the ungrounded side of the 10-mf. condenser, C-22.

The usual value of the resistor, R-19, which is connected between the grounded heater terminal of the 6A8 tube and the same tube's oscillator grid, is 100,000 ohms. In some sets the value of R-19 is 56,000 ohms.

Sometimes heterodyning may be encountered on these sets due to excessive antenna capacitance. This may be corrected by reducing the size of the antenna or by inserting a 150-mmf. condenser in series with the antenna lead. This may be done in the receiver by removing the brown lead which goes from the antenna terminal to the wave trap inductance, L-1, and inserting the condenser between these two points. In some instances, interference in the form of "beats" may be remedied by tuning the antenna wave trap to that station. The wave trap will tune up to 700 kc.

Silvertone 1650

The selectivity of this set can be improved by disconnecting the two leads to the small choke coil in the 1st i-f. circuit and inserting in its stead a 0.005-mf. fixed condenser. (This choke coil is in parallel with the 20,000-ohm re-

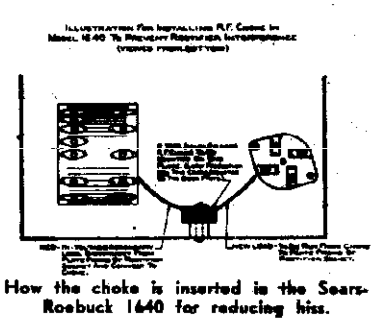


Substituting a condenser for the choke in the i-f. amplifier improves selectivity of Model 1650.

sistor in the input circuit of the 58 i-f. tube. *See Rider's Volume VI, Sears page 6-7.*) After this substitution, the i-f. stages must be re-aligned with an oscillator. This re-balancing is very important, as the effect of the change will be lost if it is not done. See accompanying sketch for locations of coil to be removed and condenser to be substituted.

Silvertone 1640

Reception can be often improved by the insertion of a choke (Part No. R-8301) in the *red* plate lead of the 283 rectifier. This will reduce the hiss or feedback. In some instances this tube may cause interference within the set, as well as other sets in the vicinity. If the use of one choke does not eliminate the trouble, a similar choke can be inserted



How the choke is inserted in the Sears-Roebuck 1640 for reducing hiss.

in the other plate lead of the 283. See accompanying illustration for installation of this choke. For schematic diagram, see *Rider's Volume III, Sears page 3-12 and page 2098 in Rider-Combination Manual.*

The undesirable effect of time lag (weak programs interrupted during bursts of static) can be greatly reduced by replacing the 0.1-mf. condenser, connected between the plate and cathode leads in the type 57 AVC tube, with one having a value of 0.01 mf. Making this change minimizes the time lag difficulty when tuning in distant stations in some localities without affecting the AVC action. The reduction of capacity lessens the charging time of the condenser and therefore the AVC recovery is practically instantaneous.

Silvertone 1855

The schematic diagram of this Sears-Roebuck receiver, appearing on *page 5-45 of Rider's Volume V,* should be changed according to the manufacturer.

There should be no choke coil across the upper 0.5-mf. condenser in the vibrator circuit.

The on-off switch should be in the other 32-volt line—not in the same line with the 2.5-amp. fuse.

The tap in the primary winding of the power transformer should go to the 32-volt line to the right of the on-off switch. In other words, the 0.5-mf. condenser should be across the 32-volt main.

The secondary of the power transformer should be tapped and connected to the junction of the two 0.5-mf. condensers that are shunted by the Globar resistor.

Silvertone 1822, 1831

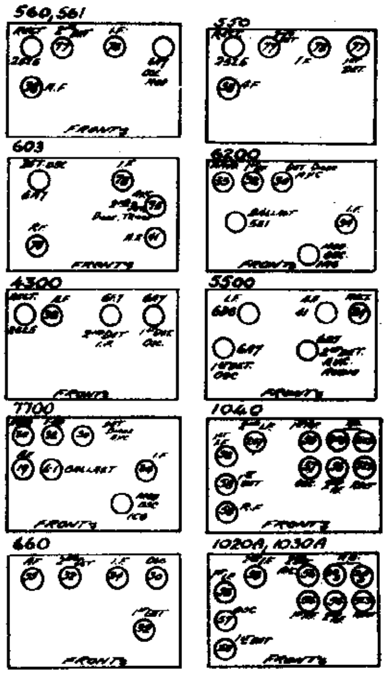
In some receivers carrying these model numbers a felt ring between the small speaker and the baffle was omitted, with a rattling of the speaker resulting. This is due to the fact that when the mounting screws of the speaker draw the speaker tightly against the baffle, the speaker frame may become slightly bent, throwing the cone off center. The felt ring acts as a cushion mounting to prevent this bending. Do not tighten the mounting screws any more than is necessary. If this felt ring is missing, one should be inserted, its part number being R9959.

Fada 25, 25-Z

The volume control used in this receiver is rated at 3,000 ohms. The schematic wiring diagram appears in the Rider Combination on page 915 and on page 1-15 in the Fada section and also on page *79 in the early editions of Rider's Volume I.

Sentinel Socket Layouts

Below will be found socket layouts for several Sentinel receivers. It is suggested that they be cut out and pasted



on the respective pages of the *Rider's Manuals* indicated. The schematic diagrams of the sets appears on the following pages: *560, page 3-3 and 2117 in the Rider-Combination; 550, page 5-9; 603, page 5-17; 6200, page 5-34; 4300, page 5-24; 5500, page 5-25; 7700, page 5-35; 1040, page 5-21; 660 Battery, page 5-19; and 1020-A, page 4-15.*

●

Erla Model 6200

The 0.02-mf. condenser, Part No. 9714, used to bypass the grid return of the first i-f. transformer was a 0.01-mf. condenser in early production. To eliminate any tendency of the i-f. amplifier to oscillate, the 0.01-mf. condenser has been changed to 0.02 mf. in later production. If receivers are encountered in which i-f. oscillation occurs, replace the 0.01-mf. condenser, if there is one, with one having a value of 0.02 mf.

The 10,000-ohm resistor, Part No. 6786, and the 0.005-mf. condenser, Part No. 1275, have been added to the plate circuit of the 33 output tube, where they are in series with the plate and ground. This addition improves the tone quality and decreases background noise. Excessive background noise and high-pitched tone in these sets can be rectified by adding these two components as indicated. Early production sets did not have this resistor and condenser.

The 4-mf. wet electrolytic condenser, Part No. 1291, connected between ground and the connection between the primary of the first i-f. transformer and the 10,000-ohm resistor in the No. 2 grid circuit of the 1A6 tube, has been added in late production sets to eliminate motorboating when the set is operated with low "B" battery voltages. If sets are encountered that motorboat when the "B" battery is low, install a 4-mf. condenser, as indicated.

The complete servicing data on this receiver will be published in Volume VI of Rider's Manual.

●

Erla Models 7700, 7732, 7741

In early production of these sets the value of the condenser in the grid return of the first i-f. transformer was .01 mf., Part No. 7860. To eliminate tendency of the i-f. amplifier to oscillate, this condenser has been changed to .02 mf., Part No. 9714. If any receivers are found having i-f. oscillations, change the .01 mf. condenser to one having a value of .02 mf.

To eliminate self modulation of the 1C6 tube the 50,000-ohm resistor, Part No. 6879, has been changed to 35,000-ohm resistor, Part No. 1618. Wherever self modulation occurs, try another 1C6 tube or replace the 50,000-ohm resistor with one having a value of 35,000 ohms.

●

Sentinel 108

The voltage and alignment data for Model 108 will be found herewith. The schematic diagram for this receiver appears on *Sentinel page 1-3 of the revised edition of Rider's Volume I; page *624-A of the early edition and on page 2107 of the Rider-Combination Manual.*

Type	Function	Filament	Plate	Grid	Screen	Plate MA
224	R-F.	2.4	250	4	75	2.15

280	Rect.	4.85				27 per plate

* Comparative readings; not true voltage applied.
** To take 245 bias reading, read between the electrolytic cans.

Alignment Data:

Set the signal generator to 175 kc. and connect the output to the grid of the 224, 1st detector, from which the grid cap has been removed. Trimmers of the i-f. transformers are accessible through the small holes in the top of the cans. Align the grid trimmer of the first i-f. coil, then the second i-f. coil.

Replace the grid cap on the 1st detector and connect the signal generator's output to the antenna and ground posts of the set, having tuned it to 1435 kc. Set the receiver's dial to this frequency also. Track the variable condensers by adjusting the trimmers in the following order: Oscillator, antenna and r-f. (The sections of the condenser are in this order, starting at the front of the set.) Then check the condensers at 1295 kc., by bending the end plate of the rotors. Check also at 880, 650, and 550 kc.

●

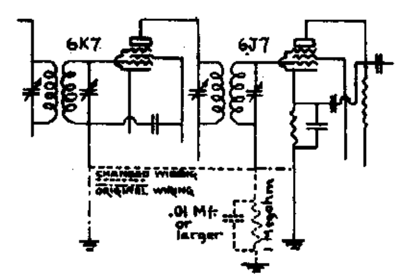
Erla Model 9100

Some of the early Model 9100 receivers had a tendency to motorboat on the broadcast band when the tone control was turned to the bass position. This has been rectified in later production by removing the 0.002-mf. condenser, Part No. 6590, and by passing the plate of each 30 a-f. tube with a 0.004-mf. condenser to the chassis base. Make this change if motorboating should be encountered in any Model 9100 receiver.

●

International 53, 553

The first production of these models, in which a 6J7 tube is used as the second detector, does not incorporate AVC. When operated in the vicinity of powerful broadcast stations, a tendency toward overloading may be found on strong signals. It is evidenced by blocking out of the signals as the volume control is advanced. This condition can be corrected by making the simple change shown in the accompanying illustration.



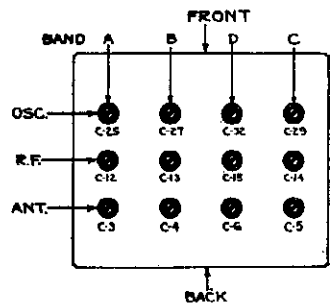
Partial schematic diagram of early Models 53, 553 showing changes to prevent blocking.

Originally the grid returns of the 6K7 and the 6J7 tubes go directly to ground. See schematic diagram in *Rider's Volume VI, page 6-8.* These should be removed from ground, tied together and returned to ground through a 1-megohm resistor shunted by a condenser of 0.01-mf. or larger. In making this change, be sure that the cathode of the 6J7 tube is connected as shown in the illustration and not left connected to the low end of the second i-f. transformer grid winding.

●

Stromberg-Carlson 68, 68-X

Since Volume V of Rider's Manual has gone to press, we have learned of the production of what is known as the Stromberg-Carlson 68-X. Basically, this receiver is the same as the model 68, which is shown in Rider's Volume V, pages 5-5 to 5-10, inclusive. However, the X models, which can be identified by an "X" following the serial number, incorporate certain changes. First, the secondary winding of the oscillator band A transformer contains a .00045-mfd. fixed condenser in shunt with the series trimmer, or in shunt with C-26.



VIEW OF BOTTOM OF CHASSIS SHOWING HOLES FOR ADJUSTING SHUNT ALIGNING CAPACITORS.

Second, a 10,000-ohm fixed resistor is inserted into the common lead joining the band B and band C secondary windings in the r-f. tube grid circuit. Third, a fixed condenser has been added between the common lead connecting the band A and band B secondaries of the r-f. input transformer, and ground. Fourth, the fixed condenser C-24, located between the common lead joining all of the oscillator primary windings and ground has been changed from .1 mfd. to .05 mfd. The location of the twelve shunt aligning condensers is shown in the accompanying illustration. The numbers correspond to the designating numbers shown upon the schematic and selector chassis wiring.

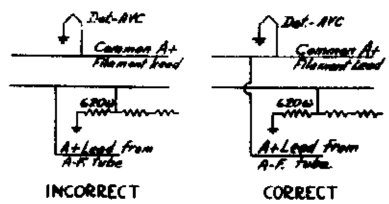
Sears-Roebuck 1857

A unique form of volume control is used in this receiver and we feel that it deserves mention. The schematic is shown upon pages 5-47 in the various issues of Rider's Manual Volume V. The output i-f. transformer is equipped with variable coupling between the primary and secondary windings. The variation in signal transfer between these two windings, as a consequence of the change in coupling, is the volume control. Incidently, the i-f. coupling unit, employed between the i-f. amplifier tube and the demodulator or second detector, is resistance-capacity coupling. Only the input and output i-f. coupling units are of the transformer variety.

Certain instructions pertaining to the increase of "high" audio response has been furnished by the manufacturer. Connect a 15-mmfd. condenser between the plate terminal of the input i-f. transformer primary and the grid terminal of the input i-f. transformer secondary. This condenser can be mounted inside the i-f. transformer shield can, atop of the Isolantite base. It will be necessary to re-peak the i-f. transformer at 175 kc.

Sentinel Model 7700, 7732, 7735, 7741

An error is acknowledged in the schematic of this receiver as shown upon page Sentinel 5-35 in Rider's Manual. The A plus lead is connected to the grid circuit instead of to the common filament lead. The diagram as shown and as correct appears below.



Correction in filament circuit of Sentinel 7700, 7732, etc.

Philco Model 16 (Codes 126, 127)

Starting January 10th the Shadowmeter shunt resistor, number 78, was changed from part No. 5310, which has a value of 5000 ohms, to part No. 7775, which has a value of 2500 ohms. This prevents the shadow from becoming too wide. Please note that this change will *not* be made in the model of 16 Code 125 receivers. However, it will be made in Model 500, Code 122 and Model 501, Code 122.

Philco Model 34

Starting with run No. 4, an r-f. choke, part No. 32-1514 is added, connected in the 135-volt B battery lead, between the points where diagram parts No. 37 and 45 join it. This prevents oscillation in the i-f. stage. For schematic see Rider's Volume V, Philco page 5-21.

Philco Model 144

Starting with run No. 3, the following change was made to improve stability:

The 0.25-mf. section of diagram part No. 26 bypass, which has been used as cathode bypass on the 6A7 tube, is now used as cathode bypass on the first 78 i-f. tube. A 0.25-mf. tubular condenser part (part No. 30-4146) is added, as bypass for the 6A7 cathode

The cathode bypass on the 78 first i-f. tube previous to this change was a 0.5-mf. tubular condenser (in Code 125); in code 121 it was a section of the diagram part No. 26 bypass block, as shown in the schematic on page Philco 5-41 in Rider's Volume V.

These changes also apply to Model 506, code 122, Radio Phonograph.

A change was also made in the shadowmeter circuit to improve its operation. Referring to the schematic, the upper end of the shadowmeter is no longer connected to the diagram part No. 65 resistor, but only to diagram part No. 33 second i-f. transformer primary and also to the primary of diagram part No. 28 first i-f. transformer. The lead from diagram part No. 52 now goes to lower end of shadowmeter only. A connection must then be made from the lower end of resistor No. 65 to the junction of diagram parts No. 52, 46 resistor and 42 condenser, to complete the circuit.

The shadowmeter used will now be part No. 45-2028 and an 8000-ohm resistor (part No. 33-1114) will be connected across it to prevent too wide a shadow.

Detrola "Roadmaster"

The i-f. peak of this receiver, shown on page Detrola 5-2 in Rider's Manual, Volume V, is 456 kc. Please make this addition to your manuals.

Sparton Model 35

The i-f. peak of this receiver is 172.5 kc. Please make a note of this on the schematic diagram, which will be found on page 3-5 of Rider's Volume III, and on page 2245 of the Radiotron-Complete edition.

Sparton Model 36

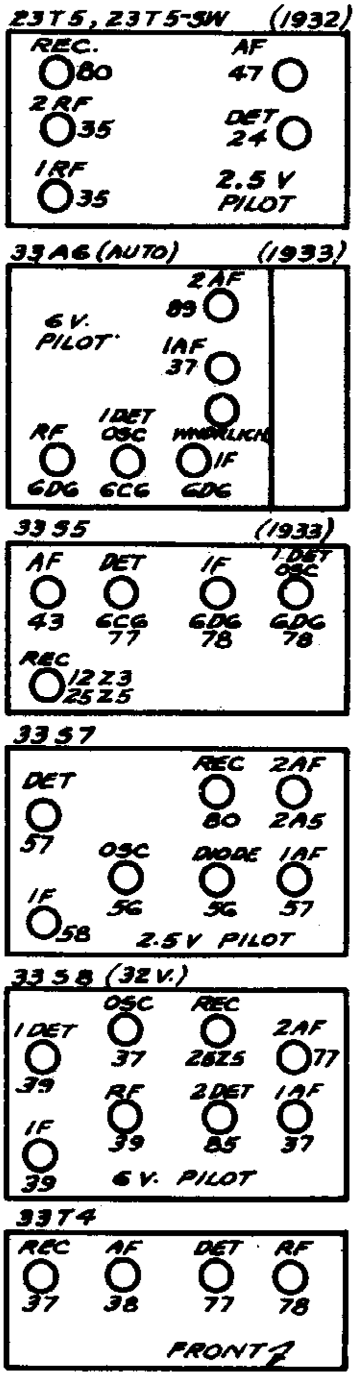
To protect the life of the vibrator in the Sparton model 36 auto radio receiver, add a 0.01 mfd condenser, rated at 1,600 volts, across the secondary winding of the power transformer in the eliminator unit.

Oscillation in Sparton 65, 66

In case the metal braid shielding on the control-grid lead to either of the type 78 tubes becomes pushed down on the leads, these receivers may oscillate or otherwise operate improperly. This shielding may be pushed down accidentally when removing or installing the tube packing or changing tubes. Therefore, always pull these shields up to their full length in case of oscillation in these models. Sparton models 65 and 66 are shown upon Sparton page 5-7, 5-8, and 5-9 in Rider's Volume V.

Audiola Socket Layouts

The accompanying illustrations show the socket layouts of six Audiola chassis, the schematics for which will



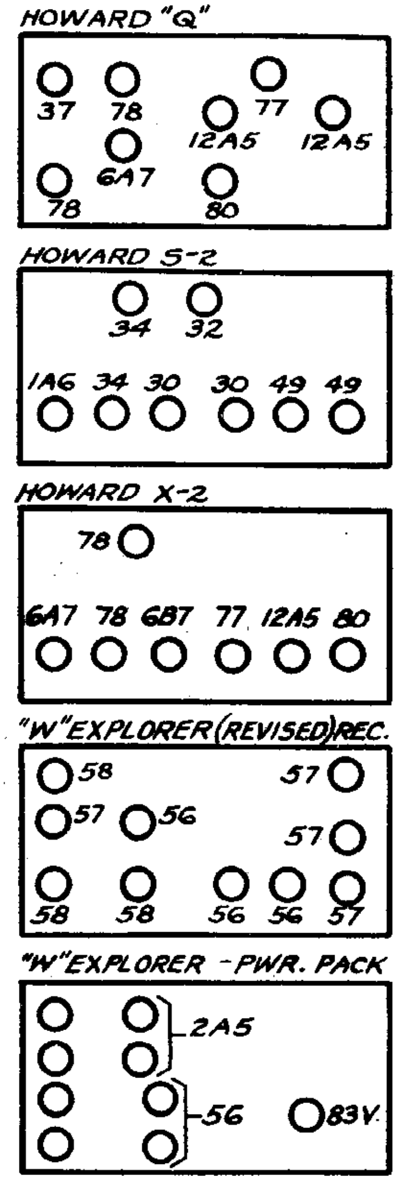
Audiola socket layouts.

be found on the pages in Rider's Manuals indicated opposite the model numbers below:

Model 23T5, 23T5-SW on Audiola *page* 3-6 *in Rider's Volume III and page* 346 *in the Rider-Combination Manual;* 33A6, *page* 4-5; 33S5 and 33S7, *page* 4-7; 33S8, *page* 4-4; and 33T4, *page* 4-7.

Howard Socket Layouts

Herewith will be found five socket layouts for Howard receivers, the sche-



matics of which appear on the following pages in Rider's Manuals:

Model	*Page*
"Q"	4-3
S-2	4-1
X-2	4-5
"W" Explorer (Revised)	6-13

The last layout—that of the power-pack of the "W" Explorer—applies to both the early and the revised models. See pages 5-6 and 6-13.

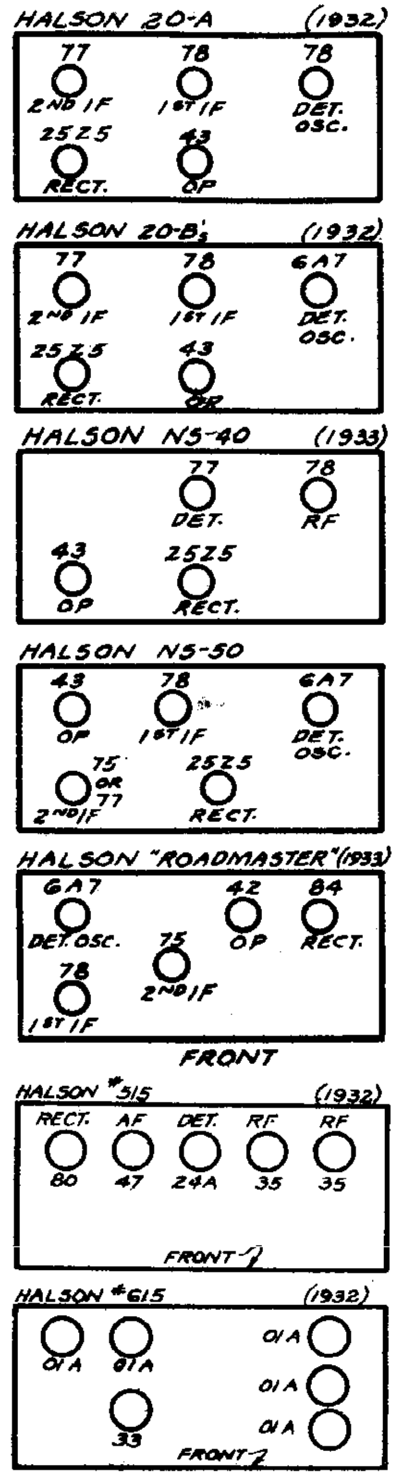
•

The schematics for the Halson receivers were run on the following pages: Model 515, 3-1 *in Rider's Volume III and* 1271 *in the Rider-Combination Manual;* Model 615, 3-3 *in Rider's Volume III and* 1273 *in the Rider-Combination.*

Halson Layouts

The accompanying socket layouts of Halson receivers are for those schematics that will be found on the following pages in *Rider's Manual, Volume IV:*

Model	Page
20-A	4—1
20-B	4—1
NS-40	4—3
NS-50	4—3
Roadmaster	4—5



Atwater Kent 60

The first or early type of Model 60 —*see A-K page 3-29 in Rider's Volume III and page 167 in the Rider-Combination Manual*—has a single volume control and the second or late type—*see A-K page 3-31 in Rider's Volume III and page 169 in the Rider Combination Manual*—has a dual volume control made up of combined wire-wound and carbon resistors.

First or Early Type:

When replacing the bleeder resistor, use No. 16295 wire-wound resistor, 4000 ohms. When replacing the first r-f. bias resistor, use No. 16253 wire-wound resistor, 1500 ohms and replace the r-f. bias resistor with No. 16988, 160 ohms.

Second or Late Type:

The bleeder resistor No. 1 was made in two types. The first type, No. 16905, consists of two 3000-ohm wire-wound resistors riveted together and connected in series. The second type, No. 17041, is a single 6000-ohm wire-wound resistor with a tap at the center. Use No. 17041 for servicing.

In early production of the second type Model 60, bleeder resistor No. 2 was wound on the same fibre base as the first r-f. bias resistor, the part number of the combined unit being No. 16872. If either section of this combined unit is defective, remove the unit and use a No. 16253 (1500 ohms) as r-f. bias, and a No. 15660 (1050 ohms) as bleeder No. 2. Later production of the second type Model 60 used a separate No. 15660 resistor as bleeder No. 2.

In early production of the second type Model 60, the first r-f. bias resistor was wound on the same fibre base as bleeder resistor No. 2, the number of the combined unit being No. 16872. If either section of this unit is defective, remove the unit and use a No. 16253 as a first r-f. bias resistor and a No. 15660 as bleeder No. 2. Later production of the second type Model 60 used a separate No. 16253 as first r-f. bias resistor.

Use a No. 16988 resistor (160 ohms) for replacement of the r-f. bias resistor.

•

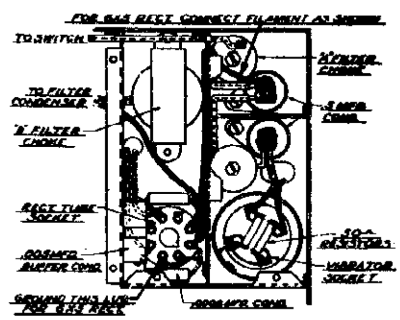
Motorola Golden Voice

We have been advised by the manufacturer that intermittent operation of their Motorola Golden Voice models, is due to low battery voltage delivered to the set from the car's battery. Check all connections between the car battery and the radio set to avoid undue voltage drop in the car wiring, as the OZ-4 rectifier tube will fail to start and fail to operate on a battery voltage of less than 5½ volts.

The OZ-4 tube requires 15 milliamperes or more of drain to produce ionization and proper rectification in this tube, and on battery voltages of less than 5½ volts the plate current drain of the receiver is insufficient to provide the 15 milliamperes starting current. Should the car wiring and the condition of the car battery indicate that at times the voltage may fall below 5½ volts, replace the OZ-4 rectifier tube with a 6X5 metal filament type rectifier.

With the exception of a few Golden Voice sets the filament contacts of the rectifier socket have been wired at the factory and the 6X5 rectifier may be plugged in the socket in place of the OZ-4. This will completely eliminate the difficulty due to low battery voltage.

On those Golden Voice sets not having the filament contacts of the rectifier socket wired, this wiring can be inserted by inverting the chassis and removing the cover from the hash compartment and connecting the filament contacts of the rectifier socket, as shown in the accompanying sketch. One contact to ground as indicated by



Connections when using a 6X5 in Motorola Golden Voice set

the heavy arrow at the bottom of the socket and the other contact to the .5 mfd. condenser as indicated by heavy arrow at the top of the sketch. When replacing cover be sure that all screws are tight.

•

Federal Model K

Below will be found the voltage data for this receiver, the schematic of which appears on the following pages in *Rider's Manuals: 1-21 in the revised edition; *284 in the early edition, and 987 in the Rider-Combination Manual.*

Tube	*Function*	*Plate to Frame*	*Scr. Grid to Cathode*	*Grid to Frame*
227	1st R.F.	120	7.5	—
224	2nd R.F.	110	1.5	60
227	Det.	65	0-1	—
227	1st A.F.	135	7.5	—
171A	P.P.O.P.	205	40	—

Emerson 108, 110

The changes listed below have been made in Chassis U5A, on models bearing serial numbers above 758,100. The schematic for models 108 and 110 appeared on *Emerson page 6-17 of Rider's Volume VI.*

Resistor, R-9, changed from 500,000 ohms, Part No. KR-56, to 50,000 ohms, Part No. KR-53. Resistor, R-11, changed from 500,000 ohms to 200,000 ohms, Part No. LR-61. Resistor, R-12, changed from 500,000 ohms to 100,000 ohms, Part No. KR-54. Condenser, C-13, changed from 0.01 mf., Part No. CCC-127, to 0.02 mf., 200 volts, Part No. FC-29. Condenser, C-14, from 0.1 mf. to 0.9 mf., 200 volts, Part No. BBC-131.

•

Sparton I-F. Peaks

The following receivers manufactured by Sparks Withington have an i-f. peak of 172.5 kc.:

Models 9-X, 13, 14-A, 15-X, 16-AW, 17, 25-X, 27-X, 28, 30-A, 33, 34, 35, 36, 111-X, 620-X, 750-A, 750-X, 870-A, 870-X.

The following Sparton models have an i-f. peak of 456 kc.: 71, 71-B, 81, 82, 333.

Model 60 has an i-f. peak of 900 kc.

Note: The s-w. converter in Model 16-AW operates on an intermediate frequency of 900 kc.

It is suggested that you write these i-f. peaks on the schematics for these models in your Rider Manuals.

•

Atwater Kent 55 and 60

If the first a-f. bleeder resistor is defective in either of these models, replace with a No. 15660 resistor (1050 ohms).

When either the yellow (No. 15544) or the maroon (No. 15545) second a-f. bias resistor requires replacing, do not use a new yellow or maroon resistor, but follow the procedure found below.

Remove both the yellow and maroon resistors and replace the yellow one with a white resistor (No. 16724), 40,000 ohms, 1 watt, and the maroon resistor with a black (No. 15592), 65,000 ohms, 1 watt.

These changes affect only the second a-f. bias resistors in Models 55, 55C, 60 and 60C.

•

Gorod I-F. Peaks

The i-f. peak of the receivers of this manufacturer, that are shown in *Volume VI of Rider's Manuals*, is 456 kc.

Grunow Chassis 5B

On *page 6–3 of Rider's Volume VI* the parts list showed that the same loud speaker was used for all four model numbers using this chassis. This has been changed. For models 501 and 550, the speaker parts are the same as those listed on the page in Volume VI, but in models 520 and 530, the output transformer part number is 34420 and that of the complete speaker is 34498.

•

Atwater Kent 317

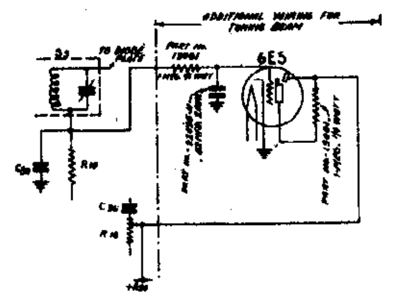
A couple of changes have been made in the early type of this model, the schematic of which was shown on *page 6–17 of Rider's Volume VI.* The value of R5 has been cut from 2 to 1 megohm (color, brown, black and green). The wattage rating is the same.

The other change is in the circuit of the 6H6 tube. Formerly both the plates P1 and P2 were connected. This connection is now opened. P1 now goes to the intersection of C8, R4 and R5. P2 is connected by the same green wire to the upper side of the secondary of the i-f. transformer, as it was before.

•

Pilot 243, C243, 245, C245

These numbers are used for models in which are incorporated the same chassis as were used in models 213 and 215, see *page 6–21 of Rider's Volume VI.* The change is the addition of a 6E5 tube connected in the circuit as shown in the accompanying partial schematic.



How the 6E5 tube is connected in the Pilot models mentioned in the text

To the left of the dot-dash line in the schematic are the points in the 213 or 215 circuit where the 6E5 is connected. On the right are the circuit elements used in conjunction with the tube.

To replace the tube in models 243 and 245, it is only necessary to remove the four corner bolts which hold the loud speaker. This gives access to the socket. On models C243 and C245, the 6E5 socket is held by a bracket, which can be removed when it becomes necessary to replace the tube.

Atwater Kent 856

Please note the following changes in the schematic on *A–K. page 6–45 in Rider's Volume VI.*

The resistance of R3 remains the same, but the wattage rating has been changed from one-half to one-third watt (color, brown, black and orange).

A condenser, designated as C15A, has been added. It is connected from the junction of the plate lead from the 6F5 (1st a-f. tube) with C–16, C–17, and R–13 to ground. It has a value of 120 mmf. (color, brown, red, and brown).

The connection between the plates, P1 and P2, of the 6H6, 2nd detector, has been opened. P2 now is connected to the junction of R5, the blue lead from the left-hand 0.05-mf. condenser in C9, and the black lead from point 9 on the antenna coil. The other plate goes to the same point as it did formerly on the i-f. transformer. (If you should happen to see a revised schematic of this receiver, note that the plate designations, P1 and P2, have been reversed. We use in the above explanation of the change, the designations as they appear in *Rider's Volume VI,* so that there will be no confusion.)

The value of R5 has been changed from 1 megohm to 0.5 megohm, same wattage rating (color, black and purple). The value of R6 has also been changed from 1 megohm to 0.5 megohm, 1/3 watt (color, green, black, and yellow).

•

Pilot X-43, X-45

The chassis which is used in these models has the same schematic as that shown on *page 6–2 of Rider's Volume VI.* The range of the X–45 (export model) is 1680–545 kc. and 3[illegible] 140 kc.

The following Long-wave Alignment data should be added on *Pilot page 6–2x*: Procedure in the X–45 is similar to the Broadcast section. Align at 375 kc. and adjust the padder at 160 kc.

Should it be necessary to remove the band switch assembly, it is advisable to realign the receiver after reinstalling.

•

Silvertone 1570, 1574

The paper form on which the windings of the output transformer were wound in these models, apparently contained some chemical that caused electrolysis in the layer of wire next to this form. This trouble has been eliminated by winding the coils on a bakelite form or else putting a layer of empire cloth between the form and the winding. Also the windings are now preheated and a sealing compound is used.

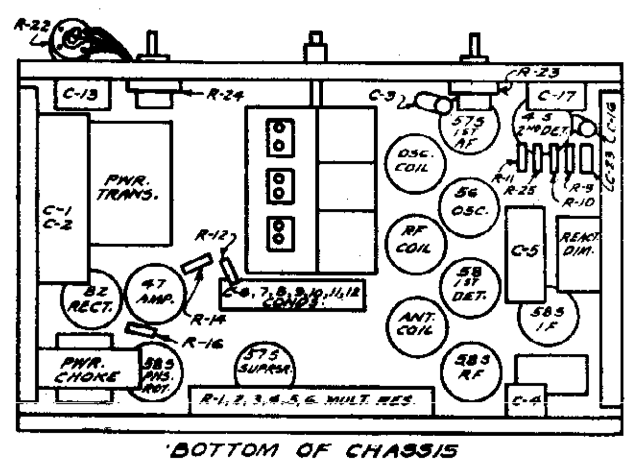
If any of these models come in to you for repair, it is suggested that you replace the old transformer with one of the new type, Part No. R-6790-A and R-4337-F.

•

Stewart-Warner 56

This model receiver employed the chassis 105 or 105-A, the schematic of which was published on *page 3-3 of Rider's Volume III and page 2349 of the Rider-Combination Manual.* The letter "A" after a Stewart-Warner chassis number means that the receiver is for use on 110 volts, 60 cycles a.c.

•



The lower view of the Majestic chassis 300 and 300-A. Note the locations of the various coils, which will give you the positions of the trimmers.

Majestic Chassis 300 and 300-A

Models 303, 304, and 307 contain these chassis and the service data on them appear on *pages 3-18, 3-19, and 3-20 in Rider's Volume III and on pages 1210, 1211, and 1212 in the Rider-Combination Manual.* Chassis 300 is equipped with twin speakers and chassis 300-A has a single speaker. The accompanying sketch shows the bottom view of the chassis with the various parts designated by the number shown on the schematic.

Wells-Gardner 7G and OD Series

If the double end pointer remains stationary when the tuning knob is turned, the following possibilities should be investigated and procedure followed:

First, be sure that the tuning condenser rotor has not reached the end of its travel. Also, see if the screw at the center of the large pointer is tight. Next inspect each pointer to be sure that it is not caught at some place.

If slippage continues, remove the chassis from the cabinet. Turn the knob to the point where the shaft seems to bind. See if the drive shaft set screw is tight, and if the idler and idler spring are in position—See Fig. 2.

Take off the two pointers, the large one by taking out the pointer screw and the small micrometer pointer by unscrewing it off of the shaft (turn it counter-clockwise to do this). Turn the

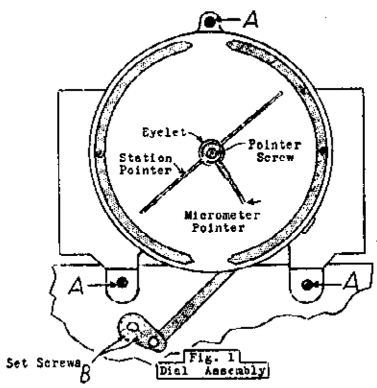


Fig. 1. Front view of the Wells-Gardner dial assembly.

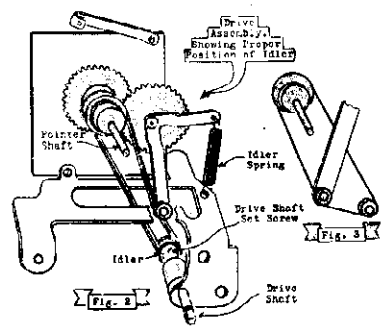
tuning knob and see if pointer shaft turns properly. Inspect the shaft to determine if it is at the center of the eyelet in the dial scale. If the shaft appears to be binding against the eyelet, loosen the three screws A, Fig. 1, which hold the dial assembly in position. Shift this assembly until the shaft is centered, tighten the screws and again see if the shaft turns properly when the tuning knob is rotated.

If the shaft continues to stick, remove the dial assembly by taking out the three screws A and the two set screws, B—See Fig. 1. Turn the tuning condenser rotor and see if the pointer shaft wobbles. If it does, straighten it by pressing the shaft to one side.

Also, in a few of the dial assemblies there is a burr at the back edge of the eyelet which can bite into the shaft. If this is the case, take a small round file and file down the burr. A penknife can be used if no file is available.

See if the pointer shaft and tuning condenser rotor turn the entire length of travel. If they do, put the dial assembly back into position to again determine if the drive turns properly. If the shaft and rotor do not turn the entire length of travel, inspect the gears for dirt, damaged teeth and any obstruction to the rotor.



Figs. 2 and 3. Rear views of the Wells-Gardner dial assembly.

In some cases the belt may slip because it is too long. The best way to correct this condition is to put on a new belt. It can also be corrected in many cases by putting the idler on the inside of the belt as shown in Fig. 3. This method should be followed only as a last resort and is not, in general, as satisfactory as changing the belt. If the idler is moved to the inside of the belt, the idler spring may not be under sufficient tension to keep the belt tight. To remedy this, take the spring off, cut off a piece and again put it back in place. Care should be taken when reducing the spring length not to make the belt too tight as this would cause the drive to turn hard.

After the above procedure has been followed, the drive should operate properly after reassembling. If it does not, it will be necessary to get in touch with the factory for further instructions. See *Rider's Volume VI, page 6-20* for further data on the 7G series.

G.E. A-64, A-67

In the schematic diagram for Models A-64 and A-67, on *G.E., page* 6-14 *of Rider's Volume VI,* you will find a connection between the low side of L-6 and the high side of L-8 (oscillator coils). This connection should be deleted. In the parts list for these models, note that the capacity for C-5 (Stock No. RC-210) is listed as 50 mf. This is incorrect; it should be 50 mmf., as is shown on the schematic diagram mentioned above. The parts list will be found on *G.E. page* 6-18.

The electrostatic shield of the 0.05-mf. condenser (C-23) that shunts the bleeder resistor R-7-8-9, sometimes makes contact with the high-voltage a-c. terminal of the 5Z4 rectifier tube socket. This causes a decided a-c. hum, which has none of the characteristics of the a-c. hums usually encountered.

This condenser, C-23, is mounted near the high-voltage terminal of the rectifier socket and vibration in shipment and operation, or pressure accidentally applied when the chassis is being serviced, may cause it to be moved against the terminal. This brings the electrostatic shield (the layer of foil just under the outer layer of wax paper) in contact with the terminal.

Dressing the condenser away from the terminal so as to assure permanent clearance, will eliminate the hum.

•

Philco 10

Run No. 3. A ground strap was added (Part No. 9481) from tuning condenser housing to receiver housing.

Run No. 8. The first and second i-f. transformers, Parts No. 16 and 25, were replaced with new types having the same part numbers. They can be identified by the red paint marks on the spools.

See Philco page 4-56, Rider's Volume IV.

•

Philco 10-Code 122

Run No. 2. Condenser Part No. 61 (50 mmf.) was removed and Part No. 30-1032 (250 mmf.) was added.

Run No. 3. The first i-f. transformer, Part No. 18, was replaced with a new type, having the same part number. This can be identified by the green paint marks on the fibre.

Run No. 4. Resistor, Part No. 23 (500 ohms) was removed and Part No. 6443 (700 ohms) was added.

For schematic diagram see Rider's Volume V, Philco page 5-5.

•

Philco-Pierce Arrow MT-3 and Philco-Reo RT-3

Run No. 1. An antenna choke, Part No. 32-1372, No. 75, has been added. It is connected in series with the antenna lead and the antenna transformer No. 1 and condenser No. 2.

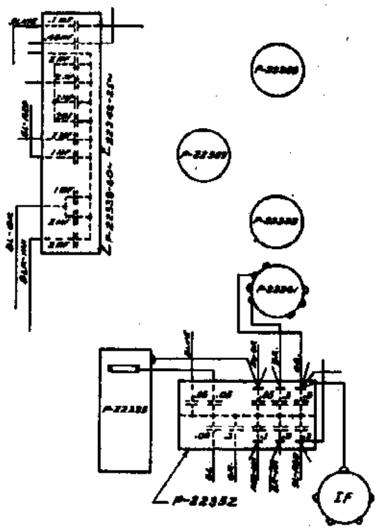
Run No. 3. Wire the white lead of the output transformer directly to the plate of the 42 tube socket instead of to the pin jack.

Run No. 4. Tone control, No. 56, removed. Part No. 30-4298 added. When using this new tone control, condenser No. 47 is also removed.

See Philco pages 6-99 and 6-102 in Rider's Manuals for data.

Stromberg-Carlson 29

The chassis wiring diagram of this model, which appears on *page 2-15 of Rider's revised Volume II; page 614-R of the early edition; and page 2401 of the Rider-Combination Manual,* is not clear in one or two places. So that no doubt will be in your mind when checking over two of the condenser banks,



Condenser banks of Stromberg Model 29

we are showing herewith enlarged drawings of the bank having eleven condensers, in the upper right-hand side of the diagram, and the nine-condenser bank that is shown in about the middle of the page. You can identify their positions on the wiring diagram by the apparatus in the vicinity and by the color and position of the leads. Notice that the top of the sketch shown here goes to the right-hand side of the diagram in your Manual.

Philco Model 144

Effective April 15, 1935 the center tap is removed from the filament winding on the power transformer. If a hum is experienced in reception, connect a 20-ohm, wire-wound resistor across the filament winding, with center tap of resistor grounded. This set is shown on page 5-41 in Rider's Manual Volume V.

•

"X" Models In The Sparton Line

Some of the Sparton model numbers conclude with the letter "X". The following data will no doubt be of value when seeking equivalent circuits in Rider's Manuals. In some instances, the "X" denotes a receiver intended for export sale and containing a special power transformer. In other cases, the letter "X" denotes some addition to the basic circuit.

Model 27-X is the model 18 chassis used in a model 27 cabinet. (Rider Manuals Sparton page 3-10, 3-11, 4-2, 4-3.)

Model 67-X is the same as the model 67 with a special power transformer and is intended for export. (Rider Manual Sparton 5-10, 5-11, 5-12.)

Model 73-BX is an export model.

Model 80-X is the same as the model 80, with a special power transformer and is intended for export. (Rider Manual Sparton 5-15, 5-16, 5-17, 5-18.)

Model 81-X is the same as the model 81, with the addition of a wave trap. (Rider Manual Sparton 4-16.)

Model 82-X is the same as model 82, with the addition of a wave trap. (Rider Manual Sparton page 4-17.)

•

Stromberg-Carlson 55, 56

The i-f. peak of these models, the schematic of which appears on *page 4-10 of Rider's Volume IV*, is 175 kc. Please make a notation of this on the above-mentioned schematic.

•

Bosch 239

Please make a note that Model 239 is similar electrically to the Bosch models 236 and 237, the servicing data on which are found on *page 3-11 in Rider's Volume III and on page 2531 in the Rider-Combination Manual.* This Model 239 was used in a table installation and the only difference between it and the other models mentioned is that the antenna and ground leads were braided together with the power supply cord in Model 239.

•

Howard Grand

Please make a notation that the power unit shown on *Howard page 6-16 of Rider's Volume VI* is for Series 2 of this model, as well as Series 1.

Packard Bell 34

If this set should need to be readjusted, the procedure is as follows: Set dial to about 1700 kc. and connect the output of a signal generator, set at the same frequency, to the antenna. Adjust the trimmer condensers of the r-f. and detector stages for maximum output. All adjustments at 1000 kc. and 600 kc. are made by bending the outside rotor plates of the variable condenser tuning the r-f. stage. The schematic diagram of this receiver will be found on *page 6-4 of Rider's Volume VI.*

•

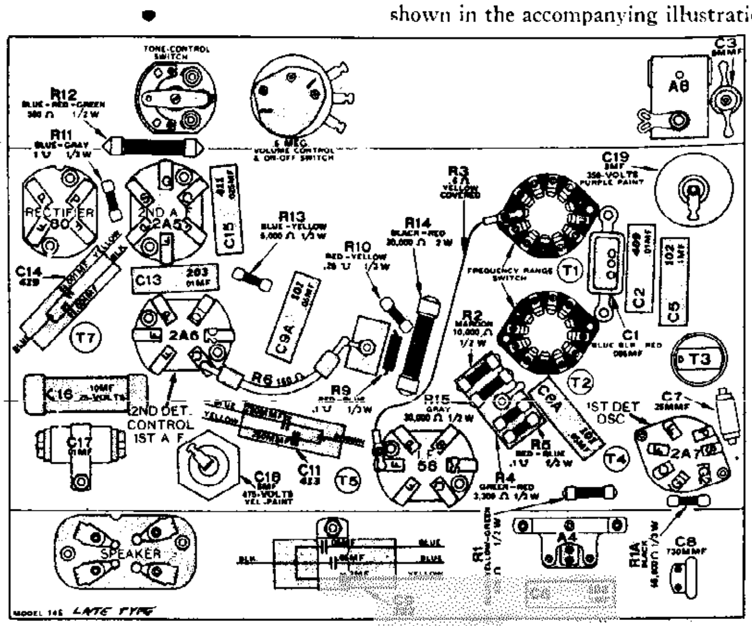
Crosley 815

We have received word from the manufacturer that no servicing data has ever been issued for the 815, but if you get one in the shop look up Model 8B3, on *page 6-10 in Volume VI of Rider's Manuals.* We are advised that the 8B3 is practically the same as the 815.

•

Atwater Kent 145, 325

The schematic diagram shown on *page 5-7 of Rider's Volume V* is for the early model but the note at the bottom of the diagram covers the changes that were made in the late model. The elimination of the condenser, C4, in the frequency-changing switch in the late models necessitated a rearrangement of the parts. The chassis layout for the late model is shown in the accompanying illustration.



The bottom view of the chassis used in A-K Models 145 and 325 of the late type

Wells-Gardner 7A Series Chassis

In a few receivers of this model, the tone control condenser C-9, 0.05 mf., 400 volts, has broken down. When this occurs the output plate voltage is applied across the tone control resistor and in many cases the resulting current burns the tone control. For this reason, if it is necessary to replace the condenser or the tone control resistor in this model; connect the side of the condenser which formerly went to ground to the +B end of the output transformer primary, as shown in Fig. 1.

This connects the tone control condenser and resistor across the primary of the output transformer. In this

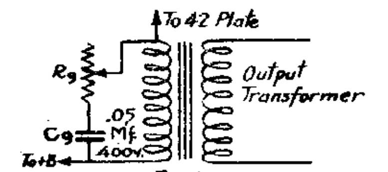


Fig. 1

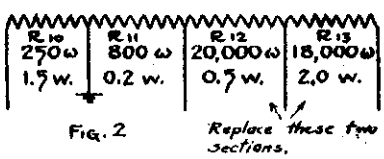

Fig. 2

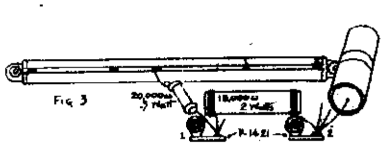
Fig. 1. New connections for tone-control circuit of Wells-Gardner 7A chassis.

Fig. 2. Resistor values of four-section unit.

method of connection, should the tone control condenser break down, no damage will be done to the resistor.

In case either the 18,000 or the 20,000-ohm section of the four section armoured wire-wound resistor becomes open, it is unnecessary to replace the entire resistor. A separate 18,000 ohms, 2 watt or 20,000 ohms, 0.5 watt carbon resistor may be used. DO NOT USE THE OLD LUGS OF THE WIRE WOUND RESISTOR TO MOUNT THE CARBON RESISTORS, AS THE OLD UNIT MAY HAVE AN INTERMITTENTLY OPEN CONNECTION. If one of these two sections, as mentioned, becomes open, it will be best to replace both of them. The values of the four sections of this unit are given in Fig. 2.

If the entire four-section unit is replaced, the old mounting holes and the old wiring connections are used. However, if the separate 18,000 and 20,000-ohm carbon resistors are used, they are mounted and connected as shown in



Method of mounting and replacing resistors in Wells-Gardner 7A Series chassis. See Fig. 2.

Fig. 3. Two single terminal mounting strips can be used for the wiring connections. The leads, which connected to terminals No. 1 and No. 2 on the old unit, are connected to the separate terminals marked No. 1 and No. 2 in the illustration.

P-98002A. 4 Section Resistor (2 wire wound, 2 carbon)
P-D-94183. 18,000-ohm, 2 watt resistor
P-B-94203. 20,000-ohm, 0.5 watt resistor

●

Silvertone 1904, 1906, 1908, 1911, 1914, 1938, 1954, 1964, 1984

Several changes have been made in the chassis used in the above models and they should be noted on the schematic, appearing on *Sears page 6-45 of Rider's Volume VI.*

The resistor, Rl, has been changed from 30,000 ohms to 40,000 ohms. R3 has been increased from 5000 to 20,000 ohms. R5 has been decreased from 50,000 ohms, 0.5 watt, to 25,000 ohms, 1 watt. This last change was made to correct motorboating that was sometimes experienced on the s-w. band "C," due to the 6A7 tube variations.

A tone control circuit has been added. One side of a 0.02-mf. condenser is connected to the lead coming from the grid of the 6F6 to the 200,000-ohm resistor, Rll, and the other side of this condenser is connected to one side of the 500,000-ohm tone control. The variable arm is grounded.

A condenser, 0.1 mf., 300 volts, has been shunted across the 8-mf. condenser, C20.

Metal glass tubes are used in the i-f., a.v.c., and output stages. These tubes are the same types as shown on the schematic in *Rider's Volume VI.*

Note the added model numbers above that should be included in your Volume VI index.

●

G.E. M-106 Changes

A change is recorded in the G.E. M-106 receiver. The type 76 tube originally used as the 2nd detector and AVC, has been replaced by a type 1-V tube. R-16 in the diagram, originally 1,000,000 ohms, now is 1,100,000 ohms. The G.E. M-106 is referred to in Rider's Manual Volume V, as the RCA 262, shown on page 5-103 in the RCA section.

●

RCA RAE-68

The RAE-68 receiver employs the model 82 Radiola 82 chassis with remote control and the automatic electric phonograph.

●

Sparton Chassis Similarities

It is possible that some Sparton models may come in for service and that you will not be able to identify the exact chassis because of some suffix letter which may appear in conjunction with the model number. Accordingly, it might be well if you added the following data to your Rider Manual Index:

Models 57-A and 57-B are basically the same as the model 57, shown on page Sparton 5-3, 5-4 and 5-5.

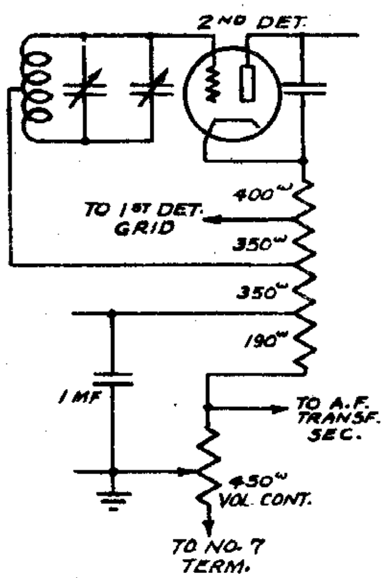
The model 81-A is basically the same as model 81, shown on page Sparton 4-18 in Rider's Manual.

The model 105 is basically the 104, shown on page 5-19 and 5-20 in Rider's Manual Volume V.

●

Radiola 62

The values of the tapped resistor strip and the volume control of the Radiola 62 were omitted from the manufacturer's schematic. These values are shown in the accompanying illustration. The part



Valves of resistor strip and volume control of Radiola 62

number of the tapped resistor is 5810 and that of the volume control is 5811.

The schematic for this receiver will be found on *RCA page 1-40 in the revised edition; page *497 in the early edition, and on page 1878 of the Rider-Combination Manual.*

●

Philco Model 32

Starting with Run No. 6, the part number of the volume control is changed from 33-5063 to 33-5004, and the waveband switch from 42-1017 to 42-1123. This makes the design and connection of these parts the same as in Model 89. See Rider's Manual, Volume V, page 5-17.

RCA R-10 DC

With the exception of the interlock, the R-10 DC is identical with the R-7 and R-9 DC chassis, shown on pages RCA 2-8, 2-9 and 2-10 in Rider's Manual, Volume II, pages 504-D-3 and 504-D4 in the early issues and on pages 1772, 1773 and 1774 in the Rider-RCA Combination Manual.

●

RCA RE-16

The RCA RE-16 receiver employs the standard R-7, R-9 AC Superette chassis already listed in Rider's Manual. To this chassis is added the phonograph motor, pickup and volume control. Service information other than those relating to replacement parts can be had by referring to the service notes covering the Superette and the Radiola 86 receivers.

In view of the absence of phonograph pickup connection to the Superette receiver, the pickup leads in the RE-16 are connected to terminals 1 and 2, the connecting link being removed. The ground connection upon the shielded lead is joined to terminal 4. The d-c. resistance of the pickup coil is 4.5 ohms. The pickup volume control is 60 ohms. The input transformer is tapped and the following values of d-c. resistance apply. Between terminals 1 and 2, 3.2 ohms; between terminals 2 and 3, 150 ohms, and between terminals 3 and 4, 4300 ohms. The connections of the pickup correspond with the data shown for the RE 16-A receiver, shown on pages RCA 4-19 and 4-20.

●

Crosley 5V2 and 5A3

The i-f. peak in these receivers is 181.5 kc. The alignment and servicing procedure for the 5V2 is the same as that for the 5V1, shown on pages Crosley 5-21 and 5-22 in Rider's Manual, Volume V. The circuit is substantially the same except for the addition of a 2,000-ohm resistor between the moving arm of switch 48 and the terminal which is a part of switch 48 and which connects to the low end of the input coil to the mixer portion of the 6A7. The voltage for the 5V2 is the same as that for the 5V1, shown in Rider's Manual.

●

Airline Model 62-166

The present production of these receivers differs from the early runs. In the early models the plate circuit of the 75 triode, contained only the plate coupling resistor of 150,000 ohms. In the later models a plate filter resistor of 50,000 ohms was added. In addition a .25-mfd. bypass condenser, which bypassed this plate filter resistor, was also added.

In the early models the capacity range of the trimmers used across the windings of the first i-f. transformer, was 150 to 300 mmfds.

●

Majestic 400

The receiver schematic appears upon page Majestic 3-42 and in the RCA-Rider Combination Manual on page 1234.

In some receivers the 250-ohm resistor R-3 and the 2000-ohm resistor R-11 were replaced by a 160-ohm and a 2500-ohm resistor respectively. The purpose of this was to make the G-57A-S modulator tube oscillate more readily. If a 250-ohm and a 2000-ohm resistor are used in the receiver, it may be necessary to try two or three different tubes in this stage, when replacement is being made, before a tube is found, which will oscillate readily over the entire frequency band. If trouble is experienced along this line, the changing of either one or both of the resistors mentioned should eliminate the difficulty.

Condenser C-17 will be found to have a value of .05 mfd, in a number of receivers; however, it should be replaced with a .1-mfd unit, as shown in the schematic.

Silvertone 1840, 1842 Oscillator Plate Resistor

In some instances, the 10,000-ohm wire-wound resistor in the oscillator plate circuit of the models 1840 and 1842 opens during operation. The cause of the breakdown is mechanical, rather than electrical. Apparently, the form on which the resistance wire is wound expands sufficiently during operation to break the wire. If this break occurs during operation, a small arc occurs at the point of open, making a burnt mark upon the resistor and creating the impression that the unit failed due to overload. As has been stated, such is not the case. At any rate, replacement should be made with a 10,000-ohm carbon resistor rated at 2. watts and bearing part No. R10465.

●

Montgomery-Ward Models 62-185, 62-187, 62-190, 62-196

In the early models 6D6 and 42 glass tubes were used. These have been replaced by the metal tubes, 6K7 and 6F6 respectively.

●

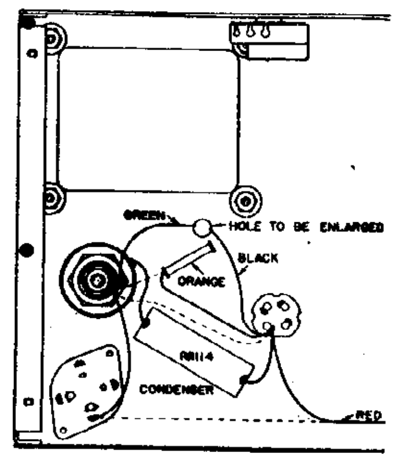
Silvertone 1720, 1725, 7065

Any trouble due to hum in these models can be eliminated by performing the following operations, the purpose being to add an additional section of filtering to the power supply.

Enlarge the hole in the chassis near the power transformer to about 0.25 inch diameter, as indicated in the illustration.

Remove the cover of the power transformer. To do this, it is first necessary to remove the four nuts on the under side of the chassis and then to unscrew the bolts that pass through the laminations. The tone control and switch will have to be dismounted in order to get at one of the transformer's nuts.

Mount a Part No. R10793B choke on top of the power transformer in place of the original transformer cover. Be sure to mount the choke so that its leads can come down through the enlarged hole in the chassis. Also be sure to tighten the bolts well, in order



Changes to be made in Silvertone Models 1720, etc.

to prevent hum. Then remount the transformer and choke assembly on the chassis and remount the tone control.

Make the wiring changes indicated in the illustration. The dotted lines represent the original wiring, which is to be changed and the solid lines show the new connections. Note that a new part, a 2-mf., 440-volt, dry electrolytic condenser, Part No. R11114, is added.

See page 4-22 of Rider's Manual for schematic diagram.

Sparton Models 61, 62

A 50-ohm, 2-watt resistor, Part No. B-6061-1, has been added in series with the plate lead of the 25Z5 that is drawn nearest the speaker field in the schematic diagram, shown on Sparton page 4-11 in Rider's Volume IV. This resistor protects the 25Z5 tube against voltage surges.

It is advisable to put this resistor in any Models 61 and 62 not so equipped that you may service.

Silvertone 1590, 1592

Several changes have been made in the chassis used in this model, the schematic of which appears on *page 3-8 in Rider's Volume III and page 2094 of the Rider-Combination Manual.*

The first detector has been changed from a 57 type to a 58, which improves the volume control action. The second i-f. transformer has been replaced with one whose secondary is tuned by a condenser mounted under the chassis. Some of the receivers have a hole in the chassis end plate to make this condenser accessible. In other sets, it is necessary to remove the end plate.

The cathode circuit of the 58 (first detector) has been changed. The cathode formerly went to ground through a 2000-ohm resistor. This resistor has been increased to 5000 ohms, and, in addition, a 0.1-mf. condenser has been inserted between the cathode and this resistor. Also a 5000-ohm resistor has been connected between the cathode and the junction of the 150-ohm and 50,000-ohm resistors. The 0.001-mf. condenser, which formerly was connected between the cathode of the oscillator tube and the oscillator coil, has its connections changed. One side still is connected to the 0.1-mf. condenser and the oscillator coil, but the other side goes directly to the junction of the cathode and suppressor of the 58 first detector tube.

The 20,000-ohm resistor connected between the screen of the first detector and the high-voltage supply (the filament of the 80 rectifier) has been changed to 30,000 ohms.

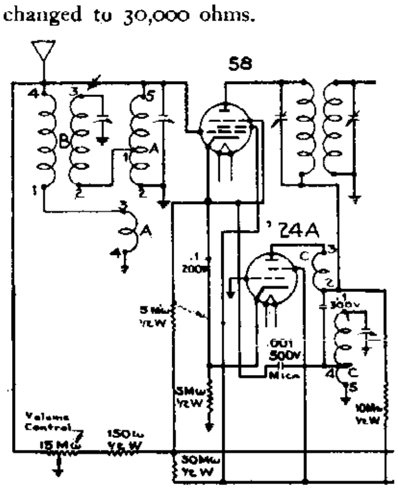


Fig. 1. The first detector and oscillator circuits of the revised Silvertone model 1590 and 1592.

In Fig. 1 is shown the first detector and oscillator circuits in which are located some of the changes mentioned above. Also note the numbering of the various coils, which correspond to the numbering on the schematics of the coils as shown in Fig. 2. In most cases

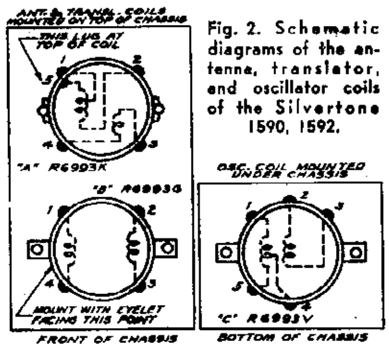

Fig. 2. Schematic diagrams of the antenna, translator, and oscillator coils of the Silvertone 1590, 1592.

it is clear in the schematic diagram (Fig. 1) where the various connections from the coils go, but where there is any doubt, the following notations may be of aid:

Coil "A":

Lug No. 2 is connected to the center terminal of the volume control.
Lug No. 5 is connected to the stator, middle variable tuning condenser unit, and the grid clip of the first detector.

Coil "B":

Lug No. 3 is connected to the stator, No. 1 (shaft end) of the variable tuning condenser unit.

Coil "C":

Lug No 5 is connected to the frame of the variable tuning condenser.

Silvertone 1584 and 1640

If any trouble is experienced with the 0.003-mf. condenser connected across the primary of the power transformer, breaking down, it has probably been due to a surge built across the transformer primary when the line switch is opened (set turned off).

To correct this difficulty, an 800-volt condenser is replacing the one of 600-volt rating used heretofore. This new condenser (Part No. R-6461, 800 V.) is connected between the line side of the on-off switch and the receiver chassis. Although these condensers may be marked 500 volts, they are really 800 volts and can be identified by the daub of yellow paint.

Westinghouse WR-21

Intermittent oscillator operation in this model may be due to a high resistance ground return in the oscillator coil. The coil is grounded through a spade terminal, this being one of the two spade terminals mounting the coil in its aluminum can. The can is riveted to a strap which in turn is screwed to the chassis. Apparently the oxide film on the aluminum causes the high resistance contact and the consequent intermittent operation. The repair can be made by drilling another hole in the can bringing out a ground wire. The schematic for this receiver will be found on *page 5-2 in Rider's Volume V.*

Kolster K-60

In the resistance test data appearing on *page 2-4 of Rider's Volume II and on page 1455 of the Rider-Combination Manual,* the resistance from the plate of the 47 tube to chassis is given as 850 ohms. This reading should be 7300 ohms. Please make this correction in your Manual. Thanks.

G.E. A-70, A-75

In the earlier models of the A-70 and A-75's it will be noted that the diode plate lead (green rubber covered) is soldered to one of the lugs of the second i-f. transformer. If for any reason it is necessary to remove or replace this transformer or wire, it is important that the wire be dressed as far as possible toward the front of the chassis to obtain full sensitivity. Sets carrying later serial numbers have this lead tied to the center tap of the coil inside the can. However, it is still necessary to keep it toward the front of the chassis to prevent a feed-back between the plate dropping resistor between the first and second i-f transformers, and the lead itself.

For schematic, see *G. E. page 6-19, Rider's Volume VI.*

Crosley 161 and 8B1

We are advised by the manufacturer that only a comparatively few of this model were made and that it is practically the same as Crosley Model 160, the servicing data on which will be found on *page 3-32 of Rider's Volume III and on page 756 of the Rider-Combination Manual.*

Model 8B1 is practically the same as Model 143. See *page 4-7 of Rider's Volume IV* for servicing data.
